The cardium genus, as laid down by Linnaeus, is far from exceptional. It is adopted by the belw continental writers, under the title of Cardium butardi, Carys, Conus cerdiformes, and other significant appellations, alluding to the heart-shaped appearance which the shells exhibit, in a greater or less degree, when viewed sideways. These shells are of a somewhat cordiform shape, with the valves denticated or folded at the margin; beaks contiguous; hinge with two oblique teeth in each valve near the beak, locking into each other; lateral teeth remote, and fitting also into each other.

Mactra. Animal a tethys. Shell bivalve, unequilateral; valves equal; middle tooth of the hinge complicated, with a small hollow on each side, and lateral remote teeth inserted into each other.

Twenty-seven species of this genus are described by Linnaeus and Gmelin. Lamarck proposes to divide the Linnaean mactra into two genera, mactra and tarnaria; both shells are unequilateral, and gaping at the ends, but the constitution and situation of the teeth are very different, as we see elucidated most completely by comparing the mactra flutum of Linnaeus with the mactra lustra of the same author.

Donax. Animal a tethys. Shell bivalve, with the margin in general crenulated, the anterior end very obtuse; hinge with two teeth, a solitary one somewhat remote (the latter rarely double, triple, or none). Linnaeus.

This genus, in the Linnaean system, contains nineteen species. The donax of the modern continental naturalists is rather differently defined; they describe it as a transverse shell, with the sides unequilateral, a little gaping at both ends, and having two mucronular impressions in the inside of the shell; two teeth pointing towards the beaks in one valve, and a single bird tooth displaced in a similar manner in the other; and the ligament of the hinge on the outside. This character agrees with the Donax rugosus of Gmelin. Another genus is established under the name of petricola, the character of which is exemplified in the Linnaean Donax irus, and Venus vulgicida of Chemitz. The shells of this new genus are unequilateral, a little gaping at both sides, and having two mucronular impressions in the inside of the shell; two teeth pointing towards the beaks in one valve, and a single bird tooth in the other; with the ligament of the hinge on the outside.

Chama. Animal a tethys. Shell bivalve, anterior margin with two crenulate lips; hinge with three teeth, all which are approximate, the lateral ones divergent at the tip; "valva et anis difficilce." Linnaeus.

There are divided by Linnaeus into two sections; * pu- bentes, and * impubes, the last of which is subdivided into three families: † subcordata, ‡ orbiculata, and † ‡ ‡ ovalia, foro roman fabuganulae. The total number of species described in the "Gmelinian System," amounts to one hundred and forty-five. It is chiefly in the descriptions of the shells of this genus that Linnaeus has adopted terms which we do not feel at liberty to render into common language for the perusal of the general reader.

Many of the shells of this genus were arranged by writers previous to the time of Linnaeus under the title of chama. The animal is described as a tethys differing from that of the cardium, chiefly, in having the foot of the animal when protruded lamina-formed, instead of hooked, and as a mol luscan animal, taking a variety of forms when the creature moves. It should however be observed that we are yet very imperfectly acquainted with the animals inhabiting this extensive tribe of shells.

Spondylus. Animal a tethys. Shell with unequal valves, hard, and rigid; hinge with two recurved teeth, and a small hollow between.

The Linnaean spondylus are few in number, in the last edition of the "Systema Naturae," comprehending no more than four species. The spondylus have been by some called thorny oysters. Rumphius, Argovius, Siba, and Davilia, rank them as oysters; while Linnaeus, Guatier, Linnaeus, Mutschchen, and da Costa consider them as a distinct genus, under the name of spondylus. The spondylus are either ear-like or furnished with ears; the valves uneven, thick, and rude or uncouth, and forming in their general exterior an intermediate natural family between the oyster and the scallop. Lamarck, and other late French writers, divide the Linnaean spondylus into two genera, spondylus and plicatula. One essential distinction between these shells consists in the spondylus having ears, and the plicatula being without: but this is not the only difference. A striking character is drawn from the structure and appearance of the beak of the lower valve, which projects beyond the beak of the upper one, and in spondylus exhibits a plain triangular flat face, divided by a furrow: while in the genus plicatula the beak has no such characteristic face or flat surface, and the edges are rounded or folded. These new genera are well exemplified in the two Linnaean shells, spondylus gaedareus, and spondylus plicatula.

Chama. Animal a tethys. Shell bivalve, rather coarse hinge with a calous gibbosity, obliquely inserted into an oblique hollow; anterior hinge closed (valva clausa abique nymphia, Linnaeus.)

In da Costa's "Scheme of Shells," the Linnaean chama are divided into two genera, tridens or bracconum, and chama or papyrii. The tridenc are shells of equal valves, and dissimilar sides, in hinge and appearance like the heart cockles, but on the longest side from the beak to the extreme margin the two valves are open, leaving a large ovate or heart-shaped gap, the lips of which are very broad, and turn upon the edges. The chama gibbs of Linnaeus is of this family, and is the largest and heaviest shell at present known, weighing from six to seven hundred pounds. The chama,
The genus tridacna is retained by the latest French writers, with some amendment in the definition of the character. They describe it as an equilateral and subtransverse shell, with two compressed teeth in the hinge, and the lumen at the posterior slope gaping. The shape of these authors are adherent to other bodies, and have the valves unequal, and the lumen of each marked with two mucroniform impressions; and the hinge confining of a single thick obliqued tooth. Hippopos, cardita, and iofascia, are also new genera formed of the Limncean chame; the last is an excellent genus, founded on the peculiar structure of the chama cor of Limneus: this shell is heart-shaped, with the valve unequal at the sides; the beaks diverging somewhat spirally and remote; in one valve under the beak a flat tooth, locking horizontally between two in the opposite valve, and a single dilatant tooth in the anterior part, below the ligament.

Aeca. Animal a tethys. Shell bivalve, equiva!se; hinge with numerous sharp teeth alternately inserted between each other. This genus is divided into two principal families, these having the margin entire, and those with the margin crenated; and both families are again subdivided into two sections, the first distinguished by having the beaks recurved, the other inflected; the species described altogether amount to forty-two.

This genus derives its name of area, ark, or Noah's ark, shell, from the similitude which most of the species bear when the valves are closed to a boat, or hull of a ship, "concha rhomboidalis navicularum expressimus." Lillier places some of these shells among the multarticulate cockles, and the rest with the mussels, under the title of many-throated mussels. Woodward ranks them among his "polygyrini formae oblongae." Argenville as a family of heart-cockles, and Davila and Guiliéron as a distinct genus: the first under the title of area, the latter as "concha rhomboidalis." These writers were succeeded by Linnaeus, who considered these shells as a distinct genus, and called them arca.

The principal alteration in the Limneean classification of the genus area proposed by late writers, is to retain only such shells under the title of area as are unequalateral, with the beaks remote; and have the line of the hinge simple and straight throughout, with numerous teeth placed parallel to each other, and fitting or locking between those on the opposite valve. Admitting this as the character of the area, and it exactly corresponds with the area neoe, and most others, the little fibrous ark; area nucleus of Limneus, with its analogous species, is excluded. To comprehend the latter, a new genus is recently established by the French writers under the name of nuculine, or nucula, the character of which is remarkably decisive: it is described as a triangular or oblong shell, with the sides unequal; the hinge confining of an angulated, or broken line befit with numerous teeth, which are transverse and parallel, and a single oblique tooth placed under the beak, and out of the range of parallel teeth before mentioned. The beaks also, shielded of being remote in an area nuculina, are placed close together, and turn backwards.

These are divided into three families, * valves radiated and eared, as in the scallop; ** rough, or rough, as in the oyster, * * * hinge with a perpendicular furrowed line, as in the species perna and ifrigonum. The scallops are again subdivided into three sections, namely, those with the valves univalve, and the ears equal; those with the ears unequal, and having one of them generally dilated with the formes within; and those with the valves gibbons on one side. The two other families are not subdivided.

The difference between the oyster and the pechen tribe is so obviously implied by the habit of nature on the respective shells which compose them, that few writers on this subject have paused silent over the impropriety of placing them together. If, however, we examine a number of the other shells included by Linnaeus in the extenuate genus ostrea, many will be found, which though less distinct in the first view, equally deserving of being considered generally distinct, as well as the two tribes before-mentioned. The form of the shell is sufficient to guide us in an arrangement possibly of shells; but when the peculiar structure of the animal confirms the propriety of classifying new genera, no doubt can remain that such amendment was requisite. With respect to the ostrea, the animals of several of its natural families are unknown; some of the oyster and pechen tribe are, on the contrary, well acertained, and these are proved to be very distinct.

As Linnaeus considers these animals the same, and describes them as a tethys, it may not be improper to speak more fully on this subject. The scallop differs from the oyster in being endowed with a higher locomotive power: the animal is different in having the branchiae coriellated, or fringed; in being furnished with a kind of foot, which it protrudes from the shell near the auricle of the hinge; and in throwing out a byillus like the pinna and the mufles, by which it affixes itself to other bodies. Aritistic, and other ancient writers, attribute to the scallop the power of moving from place to place, a fact pretty correctly ascertained by the observations of the moderns. Argenville describes the process of its movements both in the water and out; he relates, that when wet dry, by a sudden and violent closing of its valves, sufficed by the foot, it has the power of springing four or five inches at a jerk, repeating this motion in order to regain its element. In the water, it is affected by this writer, the scallop has the power of rising and subsisting itself near the surface, turning about in various directions, and on any alarm suddenly closing the valves and sinking to the bottom. The oyster has the branchial simple, and not fringed, and is unfrustrated either with a foot, or with byillus; and its powers of motion consist in turning either the flat or convex side upwards or downwards, and even to effect this, the animal takes advantage of the force of the ebbing or flowing of the water to assist it. Vide Dr. Pultney's Cat. — Lilier on Scallop, in Phil. Trans. &c.

Before the time of Linnaeus, most writers considered the scallops and oysters as distinct. Guiliéron describes the scallops as a peculiar family, and divides them into two genera, or those with equal, and those with unequal valves; the first of which he calls pedunc, the latter concha pedunculata; and the scallops with unequal or single ears, he calls pedunculata. The oyster is ranked as a distinct family by most authors. De Costa observes that the "head or exint character of the scallop family is a trigonal frame, and an elastic cartilage for its hinge in the very centre of the top of the shell." "The oysters have unequal valves, though there are some species that have equal valves, but none are eared. The hinge of this family has not any teeth, but consists of one large inarticulate gutter, running the length of the top of the shell, in both shells alike, and is covered and filled with a strong cartilage." We should add, that in the
the scheme of classification by the writer, the spindle-
fish forms an intermediate genus between the ptilodons
and oysters.

In Lamarck's arrangement, the two genera, buitmus, oretes,
and pecon, ptilodons, are retained; but four other genera are
constituted, under the names of malacites, gunas, lirides, and
praelum, into which the Linnaean oretes are distributed. Lari-
troclae forms another genus under the name of grypus, the
trocha of living and fossil species of Linnaeus, a shell found only in a fossil
state. We are not exclusively indebted, however, to Lari-
troclae for the establishment of this genus. Vide "Donov.
Tour South Wales and Monmouthshire," in which the
course of an immense stratum of these antediluvian shells
is particularly described, with remarks on the genus oretes
and grypus.

ANOMIA. Animal, a ciliated flag-shaped body, with
bristles or fringe affixed to the upper valve; arms two,
linear, longer than the body, convoluted, projecting, alternate
on the valve, and ciliated each side, the fringe affixed
to each valve. Shell inequivalve, one of the valves flattened;
the other gibbous at the base with the shell produced, and
generally curved over the hinge; one of the valves often
perforated near the base; hinge with a linear prominent
carapace, and a lateral tooth placed within, but in the flat
valve on the very margin. Two bony rays for the base of the
valve.

Many of the Linnaean species of anomia are found in
送料 only, and rarely afford an opportunity of inspecting
their internal structure; neither is it reasonable to
imagine we shall ever become acquainted with the animals
by which they were inhabited. Our observations on these
points must be confined to the recent kind, only, which, so
far as they have been attentively examined, are found to
comprehend shells extremely dissimilar in structure, and to
be inhabited by animals differing in many essential particu-
larities. It is remarked by Dr. Pultney, that the animal of
the anomia is different from that of any other shellfish, and is
not reducible to any of those in a molluscan state hitherto
known. Hence, probably, the name Linnaeus imputed
comports anomia, "quasi irregularis dlimus a larga diferens.
" The animal of the anomia cepa is figured by Mur-
ray, in his "Considerations," vol. 2, p. 23; and that of another species, by Forkell, in his "Icones Animal-
orum," pl. 430. B, under the name of anomia tridentata.
The dissimilarity of these two renders it highly probable,
that in the different shells which come under the appellation
of this genus, the inhabitant animal is various. Linnaeus
describes that of the anomia tridentis as extending from
its body a tongue-like process fringed with fine hairs,
and furnished with two extensive ciliated arms, by which
it is enabled to open and shut the shell. In the anomia triden-
tata, the animal is furnished with two flat, wedge-shaped,
trilobated arms, placed opposite to each other; these it pro-
trudes out of the shell when it moves, and these are the organs
by means of which it moves in the sea. Some other kinds of
anomia are inhabited by animals which, it is supposed from
the structure of the shell, cannot open the valves so freely
as those, and are furnished with processes of a different
nature, which they protrude through the aperture or per-
forations at the base; and other kinds again, instead of
arms, have only a ligament passing through the perforations
of the shell, by means of which it is firmly fixed to other
bodies.

Columna is the first writer who speaks of shells of this
kind; he describes some few of the Shy tribe (the only
species known in his time) under the title of "Conchæ
radiores anomia." Hence the term anomia was afterwards
employed by other writers, and has since become the usual
name for this family of shells. Lithes figures some of the fossil
kinds in his "Appendix de Conchis" to his "Histoire de
Mollusques." Woodward forms an arrange-
ment of them under the name of anomia, ranking
them with the shells of unequal valves, in a chapter,
both valves convex, and one of them broken, and thence he
divides them into three families, the smooth, striated, and faceted. Gaspé-
tiery figures some few of the recent kinds as a new genus
under the title of terebrata. Argenville places some of the
anomia among his heart cockles. Davila treats them as a
genus of his biotters; Da Costa as a genus of bivalves
with unequal exils valves. The bank of the large or under valve
greatly produced, and rising or curving over the base of the
smaller or upper valve, which is pierced through like a
tube: the hinge is in articulation to the teeth, and they have
always a remarkable interior structure. These are the
terebra of some late writers, and comprehend only part of the
Linnaean anomia.

Thosc shells of the recent kinds among the anomia of
Linnaeus, which are most dissimilar in structure, are the spe-
cies terebrata, planeta, and epiphippium; each of which
stands at the head of a natural family, and offers characters
which may be adopted with facility as distinctions of innum-
ber genera. We are persuaded the genera formed by the subdi-
sion of the Linnaean anomia might be extended with much
propriety to a great number of shells, but we are unwilling to
reproduce them without the most absolute necessity. With
respect to the fossil kind of Linnaeus anomia, some may be
referred to the genera above mentioned, others are in no
manner applicable to them, and for the arrangement of such
it is requisite to form new genera. Lamarck proposes one
coloe, derived from the characters of the anomia tere-
brata of Linnaeus, and his genus cratera of the Lin-
naean anomia. Certain genera may be confounded as in a great
measure pertaining to the fossil shells only. These genera
are laid down with pertinacity; but Lamarck we are perfused
might have proceeded further. We consider Linnaeus
often times blamable for intermixing the recent and
fossil shells promiscuously together, and may embrace
ourselves excused sometimes at least for abstaining from
his example. Lamarck too differently; he approves this
method, and having ventured from the boundaries of the
present into the labyrinths of the antediluvian creation,
makes us expect a greater number of new genera
might have been established, those at present formed being
altogether inadequate to the reception of those numerous
remains of the terraque which are admitted among the
anomia of the Linnaean conchologist.

But to return to the recent anomia,—What, we would
inquire, might possibly induce Linnaeus to place that singular
bivalve, called from its transparency by the English col-
ever "the Chine glass window" among the anomia?
Or what signification can be more remote than the effe-
tial character of his anomia epiphippium et terebrata?—In the
first, which is to be found in his Systema under the name
of anomia planeta, both valves are of an equal size and
form; in epiphippium the valves are unequal, one being flat,
and in the other, as in the volva; in epiphippium the flat
valve is perforated with a round hole in the disk
near the hinge through which aavigent polices, and by
this means affixed to flows and other bodies; the A.
placenta has no such perforation. In A. teretabula there
is a perforation; but instead of being situated in the
flatter valve appears at the base of the straight tube as it
appears in the calcareous stone, which is elongated.
Near the hinge in one valve of A. placenta are two longitudinal lamell-
CONCHOLOGY.

Lamelliform processes, which approach near the beaks, and then diverge obliquely to as to resemble the letter V, and upon the valve opposite two corresponding processes longitudinally cleft, in which, when the shell is closed, two lamelliform teeth reposed. An internal structure of longitudinal processes occurs in the species terebratula, but very different from the preceding, and no such internal structure occurs in the anoma eclipsum. These characters denote fully evidently that they are not only essentially different in the conformation of their shell, but that they are inhabited by animals distinct from each other.

Mytilus. Animal an ascidia? Shell bivalve, rough, usually affixed by a beard or by filzus of fiky filaments: hinge in general without teeth, and except in a few species with a subulate excavated, longitudinal line, Linn.

The Linnean mytilus are by no means inconsiderable in number, and as they comprehend many shells very distinct in appearance, and some essential particulars, are necessarily distributed into several sections, or families, such as *paralitios, those affixed by claws, exemplified in mytilus crista galli; **planis, &c, flat, or compressed into a flattened form, and lightly armed, as in mytilus margariferus; or ***ventriculifur, ventricose, as in mytilus edulis. The older writers appear to be perfectly agreed as to the mytilus genus, but the moderns think it necessary to divide them into two or more genera. Lamarck separates them into mytilus (monk), *protomylus (monile), and *anodonta (anodonte). In defining the mytilus he notices in particular the unequalled, or claw-like termination of the shell at the narrowest end as a peculiar character. We do not perceive the absolute utility of his fectus genus, monile, though we think it admissible, but we perfectly agree in the adoption of the latter anodonta. This last mentioned genus consists of what are vulgarly called the river, or fresh water muscles, shells which we have always conceived it improper to refer to the same genus as the marine mytilus. In the colour of the valves, and form and situation of the beaks, the most obvious dissimilitude prevails, and a distinction still more evident resulting from the different conformation of the animal occurs in the inside of the shell, which exhibits three impressions of muscles or ligaments by means of which the animal is attached to the shells, while the shells of the common muscle, and its congeneres, have only one such impression.

Pinna. Animal limax. Shell sub-bivalve, fragile, erect, grasping, and furnished with a byfus, or beard; hinge without teeth, the valves uniting into one. Linn.

This genus is well defined; the shells of which it consists are wedge-shaped, or of a somewhat triangular form, widening from a pointed or narrow top to a very broad end. The hinge is inarticulate, the two valves being united in that by part, and thus forming, what Linnaeus truly terms it, a sub-bivalve, for it is not strictly of two valves, being thus connected. The pinnae are known by different writers under the various appellations of sea-hams, sea-wings, and pinnae marine, or by other fiky worms of the sea, which falt they obtain from the quantity of fine firon brown byfus, which the animals produce, and by means of which they affix themselves to the rocks; the byfus consists of fine fiky fibres of a brown colour, and which is easily woven into fluff or small articles of drefs. Among the ancient Romans this kind of fik was held in considerable esteem: it is even said that there are still manufactories of it at Naples, Messina, and Palermo.

Eighteen species of this genus are described in the last edition of the Systema Naturae.

Argonauta. Animal sepia, or clio. Shell univalve, spiral, involute, membranaceous, and unilocular, or consisting of a single cell. Linn.

The principal species in this genus of shells is the Linnean argonauta argo, the celebrated nautilus of Piny, lib. ix. 29, the animal supposed to have taught men the use of sails, and art of navigation in the early ages of society. The ancient knew this species by the name of nautilus, as appears sufficiently obvious from many passages to be found in their writings. Linneus, however, in conformity with Rumphius, applies the name of nautilis to a chambered shell of a very different kind, (sic Nautilus), and retains the nautilis of the ancients, under the title of argonauta, with the essential character above-mentioned.

In the Gmelinian edition of the Systema Naturae, the number of species described under the genus argonauta amount to five, argo, vitreus, cymbium, cornu, and arctica. But the minute observer of nature disposed to descend to the investigation of the microscopical kinds of shells will be able to add considerably to this number; a work published in Germany in 1728, the united labours of our friend L. A. Fichelt, and C. A. Moll, entitled "Systema Microsca" is a minutie examination of genera Argonauta et Nautilus ad naturam picta et descripta," contains in particular, a number of new species in this curious genus, and a few others are known to us which we have reason to apprehend have not been noticed by any other writers. By the accession of these latter species the genus becomes materially enlarged; but we have, at the same time, to observe that the whole of the Linnean shells, described under this generic title, are not strictly admissible among the argonauta, and that the removal of these will occasion a slight reduction of the species already mentioned. That very rare shell known among collectors by the name of glaftus nautilus, the argonauta vitreus of Gmelin, is separated by Lamarck from argonauta, and constituted a new genus under the name of carinaria. In the Linnean system it would be difficult to refer it with certainty to any genus. Linneus was himself in doubt where to place it, and at length referred it to the limpet tribe, under the name of patella crilata, but it cannot surely belong to this genus. In the last edition of the Systema Naturae, we see it transfused from thence to the argonauta with more propriety, but we are still perused it cannot claim a place in this genus, though it is more closely allied to it than any other of the Linnean genera; it is certainly of a new genus as Lamarck describes it. The principal distinction between these two genera, the argonauta and carinaria, is very striking; in the true argonauta, (or nautilus of the ancients) the spiral involutions turn into the opening of the shell, whereas in carinaria, the spire is situated at the summit of the shell and the mouth is entire. This character we think alone sufficiently decisive in defining the essential characters of the two genera. The carinaria is further distinguished by the shell being conic, and flatter at the sides, the spiral whorl very small, the back furnished with a single denticulated keel, and the mouth, or aperture of the shell, of an oval-oblong form, narrower near the angle of the keel. The argonauta shell, instead of being conic, is somewhat boat-shaped, and has from this very circumstance been named cymbium, both by Gauliciri and Tofin; and the dorsal carination which is single and denticulated in carinaria, is uniformly double and tuberculated in argonauta.

In conclusion of our remarks on this genus, it will be proper to observe that the glaftus nautilus, or carinaria vitrea, is one of the most choice and uncommon of the tellaceous tribe;
it is not, however, unique, for we know of three specimens, one of which is in the cabinet of Mr. Jennings in England, and the two others in the Museum of Natural History in Paris, one of which was obtained from Lyonet's cabinet. A large fossil shell of the argonauta genus, a singular species, and the only one we are acquainted with, occurs in the London Museum.

**Nautilus.** Shell univalve, divided into several departments, communicating with each other by an aperture or siphunculus.

The Linnean nautilus consists of two principal families, the one which are spiral and rounded, and such as are elongated and straight. Of the spiral kinds there are two distinct sections, the one of which have the whorls contiguous, the other the whorls separated; the nautilus of a straight form are comprehended in one section only.

Under the general title of nautilus, Linnaeus includes the three genera of modern naturalists, nautilus, spirula, and orthoceras, with some others which may hereafter, on accurate investigation, be found genetically distinct likewise.

The nautilus is a spiral rounded shell, having the last whorl very large, and enveloping the others, which are numerous, and divided internally into many chambers by transverse partitions, the dull of which is perforated by a siphunculus or tube. This character is drawn from the nautilus pomphilus of Linnaeus, a shell admitted by the latest authorities as an amplification of the nautilus genus; of the modern school only we would observe, for it has been previously shewn, under the genus argonauta, that it is not the nautilus of the ancients. The character of the new genus spirula, is derived from the nautilus spirula of Linnaeus, (erroneously readed spirula in Gmel. Syll.) or what we call the ram's horn. This shell is truly of the lituus or crozier family, being of a spiral structure with the whorls separated, and the last chamber at the aperture elongated into a spiral cylindrical form. Linnaeus describes only the spiral termination of the shell, which being of a concomerated or chambered structure, and perforated with a siphunculus; induced that naturalist to place it with the nautilis, notwithstanding the striking dissimilarity of the disposition of the spiral involutions. This shell, when perfect, affords an essential character which at once removes it from the genus nautilus, in which Linnaeus places it; namely the last or cylindrical chamber, which is alone sufficient to distinguish it. We may easily presume that no blame attaches to Linnaeus in this particular respect, for it is pretty certain that naturalist never saw the perfect shell. In collections we have at various times seen some thousands of the spiral terminations, (for it is a very common West Indian shell,) fearfully one of which has retained the lighted vigil of this chamber, though all appear readily broken, and different from a natural termination or aperture. This chamber of the shell is extremely thin and brittle, inasmuch that the slightest agitation of the waves will destroy it, and as those shells inhabit the deep waters, and are collected by the curious only from the **rejeâmentions** of the sea cast upon the beach in storms, it is natural to conclude that it is rarely found complete. It was not till of late years that the true form of the perfect shell appears to have been ascertained. The orthoceras is the orthoceras of Gaultier and Brynuius revived. This shell is straight or arched, and a little conic, with distinct chambers formed by transverse simple divisions perforated by a tube, which is sometimes placed centrally and sometimes laterally. We are of opinion this amendment would be improved by forming two genera of the orthoceras, one containing the straight and the other the arched kinds; and indeed we conceive fill further that those, with the siphunculus placed on one side, should form a distinct genus from those having the siphunculus in the centre. The Linnean character of the nautilus confounds all these distinctions; they are all nautilus of that writer.

Among the fossil genera remains of the antediluvian world, are many singular spiral shells, allied to, or of the same genera with the foregoing, and others which, though spiral and concamerated, cannot possibly be reduced to these tribes; such as the ammonites, the orbilutes of Lamarck, hélices of Guettard, facultes of Faujas, and the belenmites, or "thunder-bolts," of most authors. See article Fossils.

**Conus.** Animal a limax. Shell univalve, convoluted, and tuberated; aperture or opening affuse, longitudinal, linear, toothlike, with the base eftive; pillar smooth.

This genus is divided into five distinct families. **Truncatilis, having the spire nearly truncated.** **Pyriformes, with the base rotundate and sub-cylindric;** the cylinder half as long again as the spire. **Elongati, with the base rotundate, cylinder twice the length of the spire.** **Ventricosar, in the middle, and narrow at each end.** **Ventricosar, emits a tinkling sound, when thrown on its back upon a board or table.** The total number of species included in this genus, in the last edition of the Systema Naturae, amounts to seventy-one. Many of the conus, or cone tribe, are beautiful shells, and bear a high price on account of their rarity; the cedo nullis of Lyonet, valued at one hundred guineas, is of this genus. We have no species of this genus upon the English coasts. Some very curious kinds have been discovered in a fossil state in England, chiefly in the chalk cliffs of Hampshire.

**Cypræa.** Animal a limax. Shell univalve, involuted, subovate, obfute, and smooth; aperture affuse at each end, linear, dentate at both sides and longitudinal.

Linnaeus forms several distinct families of the cypræa genus, one of which is distinguished by being obtuse, and without any manifect spire; such, for example, as the species caput serpen tinus and tigris, the last of which is well known by the name of tiger cowry; another kind is perforated, or furnished with umbilicus, as in cypræa ziczac; and a third is margined like the common Well India cowry, vulgarly called "blackmoor's teeth," cypræa moneta of Linnaeus. In the young state, the cyprææ have much the appearance of a volute, and are entirely delinute of the thick denticulated lip or margin, so obvious in the adult shells. Writers have been even to far misled by this specious appearance, as to describe the young of several kinds for shells of the volute genus. The voluta junonis of Pennant's British Zoology, is clearly nothing more than the young of the common English cowry, cypræa pediculus, which that writer mistakes for a perfect shell.

**Bulla.** Animal a limax. Shell univalve, convoluted, and unarmed with teeth; aperture somewhat straightened, oblong, longitudinal, and very entire at the base; pillar lip oblique and smooth.

The arrangement of the bulla family is very confused in the works of the old writers. Littor makes them a genus of the cowry, and calls it concha veneris bali umbilicata. Grew and Bonnani place it with the fusæ; Argenville and Davila with the cochlea globofæ; and Gaultier as a genus between the paper nautilus (argonauta) and the cowries. The term bulla implying the bubble-like form, or swollen appearance of the shell, was applied by Rumphius to the bulla ampulla, from whom it was adopted by Kitin, and afterwards by Linnaeus as a generic appellation. The shells...
CONCHOLOGY.

included by this last-mentioned writer under the name of bulla, are more than commonly anomalous in habit and form; few instances can be adduced of greater dissimilarity than is observable between the bulla ovum, fuscus, terebellum, and virginica. The species ovum has the habit of a cowry, the fuscus that of a murex, the terebellum that of a cone, or a baccinum, and the virginica of a turbinated helix. The bulla adactyla, and other bulla cylindrica likewise offer characteristic differences, which may, without any impropriety, constitute generical distinctions.

According to Linnaeus, the animal of the bulla is a limax; but if it be such, as Dr. Pultney observes, in any particular species examined by that author, it does not hold throughout the whole genus; nor even in those which were primarily and eminently distinguished by the name of bulla. In some species the animal appears more to resemble an ascidia. The animal of bulla aperta forms a new genus in Lamarck's arrangement, under the title of bullae. The animal of bulla lignaria is furnished with miliary organs, consisting of three teflaccous bodies placed within the flomach or gizzard, by the help of which it is enabled to break small shells and hard substances. This instrument was first discovered by Pancesius in the bulla aperta, in which we ourselves observed it. An account of this in the gizzard of the bulla lignaria, by Mr. G. Humphreys, is inserted in the Linnaean Transactions. These latter mentioned teflaccous bodies were first introduced among conchologists as a new genus of shells by M. Gioe'ni, a Sicilian naturalist, after whom it was named gioenia, by Bruguiere. Retzius also describes it, but under the name of tricha. An account of the discovery of this important error, was published by Draparnaud, in the Bulletin des Sciences, n. 35.

VOLUTA. Animal a limax. Shell single-celled and spiral; aperture without a beak, somewhat effuse; pillar folded or plaited, and generally without lips or perforations. This extensive genus is diversified by Linnaeus into the following principal families. * Aperture or opening entire. ** Somewhat cylindrical and emarginate. *** Obovate, effuse, and emarginate. **** Fulfiform. ***** Ventricose; spheropapillary at the tip. The whole includes one hundred and forty-two species.

Linnaeus has deservedly incurred some blame for having too often transfused long established names from objects to which they were before assigned, and imposed them on others without any apparent or sufficient reason, which were never underlaid among his predecessors by those terms. An instance of this kind of innovation occurs to us at present. The term voluta, derived "a volendo forte revolutione spirali" was always applied to the cone tribe, and is very expressive of the peculiar rolled, or involuted structure of those shells; Linnaeus deprived them of that name, called them cones, and gave the title of voluta to the shells of which we are about to treat. The voluta genus, furthermore, as now laid down, is highly objectionable. Linnaeus, in the establishment of this new genus, has been less attentive to the natural families of shells than could have been wished, and has, by that means, brought promiscuously together shells which scarcely agree in any one individual respect, except in having plats or folds upon the pillar.

This error does not rest, however, entirely with Linnaeus, for he was not the original projector of the genus; he only adopted it, and gave it the name it now bears, when he might with more propriety have expunged it, or diversified the shells contained into other genera. In Lister's work, section ii. b. ii. a, we find a class of shells entitled, "buccina columelce dentata," in which that author arranges the buccina and other shells which have the pillar plaited. Linnaeus, by the adoption of this genus, under the title of voluta, comprehends a number of shells possessing very distinct generic characters, and which had been distinguished by his predecessors under the various names of oliva, rhombus, cylindricus, turbacillus, mitra, mafica, and others applicable either to their figure, or to the essential characteristics of their respective natural families. It is a singular corroboration of the accuracy of the ideas entertained by those writers, that the animals inhabiting the shells above-mentioned, have been recently ascertained to be as dissimilar in structure as the shells. Linnaeus considered the animal of all the volutes as a limax or frag; but from the investigation of Adanson and Argenville, and since the time of Müller, Poli, Lamarck, and many others, it appears that no opinion was ever more unfounded; the animal of each family being differently formed, and adapted to the peculiar shape or structure of the shell.

Da Costa, in his "Elements of Conchology," abolishes the Linnaean voluta genus altogether, but the shells are not restored to his method to their proper or natural families; his definitions want precision, and his scheme is confused and uncoath. But notwithstanding, the scheme of classification laid down by Da Costa was never acceded to by conchologists, and certainly never will now; from the circumference of its being the only elementary work in the English language (Barbot's Gen. Verml. excepted) it has answered one useful purpose, that of directing the general collector to dispose their shells into particular families, in a more comprehensive manner than could have been accomplished by attending to the Linnaean arrangement. Thus, in the Linnaean volute, the families are distinguished by the title of papal cows, Peruvian cows, mitra, olives, mitochondes, oysters, and other trivial apppellations, by which they are known even to this day among English collectors. As Da Costa derived his principal distinctions of these families from writers who flourished before Linnaeus, so also it has happened with the French conchologists; they disapprove of the Linnaean arrangement, but retain most of the original families described by those earlier writers, and thus we see at the present time the genera olive, turbinelle, mitra, harpe, &c, recalled and adopted with some improvements, by the best informed conchologists of that country.

BUCCINUM. Animal a limax. Shell univalve, spiral, gibbous; aperture ovate, terminating, in a short canal, leaning to the right, with a rectate beak, or tip; inner lip expanded.

The buccina are separated into secions, in the following order: * amputation, &c, inflated, rounded, thin, and sub-dichlamnous, and brittle. ** Cassidea, candaia, &c,; tail short, exerted, and reflected; lip unarmed outwardly. *** Cassidea, unguiculata, &c, lip acutated on the outside of the posterior part, otherwise retaining the left division. **** Cassidea, &c, pillar lip dilated and thickened. ***** Detrita, &c, pillar lip appearing as it worn flat. ******* Laviegata, &c, smooth, not enumerated in the former divisions.

Linnaeus has occasioned strange confusion in his classification of the shells which he denominated buccinum; in the indefinite latitude which his character of this genus admits, he embraces shells varying in size, whether they are bivalve or univalve. He has thus rendered the classification of this genus of shells highly objectionable. Linnaeus has, however, this advantage, that he has confounded altogether in this most copious genus, it is not sufficient that these be kept apart by being referred to different families, they should certainly constitute distinct genera.
The French have long distinguished these different shells, by the appellations of tumén, casque, harpe, pourpre, &c.; the English collector will better conceive, perhaps, what is meant by the trivial distinctions of tumis, partridges, harps, and whelks. In Lamark's arrangement, they assume a more classic form, and are defined generically, under the title of delum, harpa, cassis, terebra, purpura, bucium, and naria, as will be more accurately explained hereafter.

**Strombus.** Animal a limax. Shell univalve and spiral; lip of the aperture often much dilated, and produced into a groove leaning to the left.

Previous to the time of Linæus, the term *strombi* was applied to shells of a different description from those at present understood by that name. Under the title of *strombi*, the Greeks originally designated all kinds of turbinated shells. Among the older writers, the term *strombi* was indiscriminately employed as synonymous with turbo, trocirus, and sometimes with *murex*. *Strombi* was then a term indefinite, but rather applicable to the flender kinds, muriæ, or *rombi*

Linæus was the first who limited the application of the word *strombus* to those univalve shells, which have the canal or gutter directed to the left, and the lip expanded. He was not, however, the first to establish the genus. Lifer describes the shells of this family which have the lip entire, under the title of *purpura* seu *buccina* bilingua, and classifies them in the twelfth section of his fourth book. Ruppinus, and after him Maucliren, make a distinct genus of them, under the title of *alaia*, and by the same name alatus, they are pretty generally known to this day, it being well known that Solander intended to have established such a genus under this name. Davila ranks these winged alata among his muriæ, but independently, and as a distinct genus, consisting of simple or entire winged shells; placing immediately after them another genus, comprehending those which have the expanded lip digitated, or elongated into prong-like processes. Linæus rejects this arrangement of Davila, including in his genus *strombus*, the whole of those winged or alated shells; not in a promiscuous manner, but in sections or families, as *Digitatis*, libio in lacinis linearis ex:cut. *Lobati*, *Amphiatus*. The French writers to this time, on the contrary, follow the example of Davila, and form two distinct genera of these shells under the title of *strombus*, and *ptercera*, and to these another has been lately added after our countryman Lifer, under the name of *rotellaria*.

On this arrangement, the genus *strombus* is described as being a ventricose shell, terminated at the base by a short canal, flowing off or truncated: the right margin or lip dilating or expanding with age into a simple or entire wing-like lobe, and having a sinus beneath, distinct from the slope of the base, or in the Linæan language, the beak. This genus is sufficiently explained by the shell called among English collectors the "pugilist's fist," *strombus pugilis* of Linæus. The genus *ptercera*, has the shell ventricose, terminated below by a long canal; the right margin, or lip expanding with age into a digitated wing, and having a sinus near the base. The Linæan *strombus lambis* is of this genus. The generic character of *rotellaria* is drawn from the *strombus* satus of Linæus, described by Lifer, t. 854, l. 11.; and Martini, t. 159, f. 1500. The shell is full-form, terminated beneath by a canal, ending in a subdued or pointed beak; right margin entire or dentated more or less dilated into a wing-like process with age, and having a sinus contiguous to the canal or gutter.

We may hereby add, that the young shells of the *strombus* genus do not possess the striking peculiarity of the ample dilated lip before-mentioned, and that in consequence, such shells have been sometimes referred to very different genera, an error committed by some of the best among the early writers.

**Murex.** Animal a limax. Shell inequivalve, spiral, rough, with membranaceous futures; aperture ending in an entire canal; either straight, or somewhat ascending.

The Linæan genus *murex* is very extensive; in the latest edition of the *Systema Naturæ* a hundred and sixty three species are described under the following sections: *Spinolus*, *spinous*, with the tail (or beak) produced. *Frounolus*, futures expanding into crisped foliations; tail (or beak) abbreviated (vulgarily called *purpura*). *Varicolus*, futures rounded, protuberant, and thick. *Ecaudatus*, without tail (or beak) and somewhat spinous. *Caudigerus*, tail (or beak) subulate, clofled, straight and elongated; unarmed with spines. *Turriti*, tapering, subulate, with the tail very short.

The muriæ of the elder writers consist for the most part of such shells of the wheel or *bacina* kind as exhibited any considerable degree of asperity or ruggedness on the exterior surface; the Greeks having employed the word *murex* to express the roughness of rude stones or wall. Many of the Linæan muriæ are of that kind described by his predecessors under the name of *purpura*, the animals of which are spoken of by the ancients as being furnished with a tongue-like process, by means of which they are enabled to perforate other shells, and derive subsistence from the included animal. The English call the muriæ rocks, and the French in imitation, *rouche*.

Three genera of shells formed of the Linæan muriæ by the continental writers, claim particular attention; these are *falcioria*, *pleurotoma*, and a genus, retained under the name of *murex*. The first of these consists of such shells as the *murex* *tulipa* of Linæus are of a somewhat fulliform, or spindle shape; smooth or without roughness, and having upon the pillar two or three very oblique folds or pates. *Pleurotoma* is also of a spindly form, with the aperture terminating below in a long gutter or canal, and has the lip eleft or cut off in a slope near the summit. The third or *murex* genus is of an oval or oblong form, canaliculated at the base, and having the outside of the shell constantly belet with prominent longitudinal ridges, and for the most part with tuberculations, spines, or fringes. We cannot refrain observing that this, and perhaps some further amendments in the Linæan muriæ, were requisite to reduce them to lucid order; it will not we think admit of any doubt that the two first genera before mentioned, ought not to be arranged in the same genus with the muriæ, admitting the Linæan character of that genus as it stands in the *Systema Naturæ*. Linæus, it is true, included shells of both these families among the muriæ, but surely without sufficient attention to the generic character he had himself proposed for the murex tribe.

**Trocillus.** Animal a limax. Shell univalve, spiral, and subconic; aperture somewhat angular, or rounded; upper sfle transverse and contracted; pillar placed obliquely.

The trochi Linæus divides into three families: *umbilicati*, &c.; umbilicis, erect, and with the pillar perforated; as in the species niloticus and *peripherius*. *Imperforati*, &c.; erect, with the umbilicus clofled; as in *labio*. *Turriti*, &c. turritis, with the pillar exserted; shell falling on one side when placed on the base.

This is a long established genus of shells, having been adopted by the principal conchological writers a considerable time.
time before the Systema Naturae of Linnaeus appeared. Notwithstanding this, we perceive no small degree of difficulty arising in a general arrangement of shells from too strict an adherence to this genus as the character is proposed by Linnaeus. We do not object to the trochus genus altogether; it is an excellent genus in itself, so far as relates to the greater number of the conic species, which may be readily distinguished by their outline, but we cannot, it must be acknowledged, so easily reconcile our ideas to the propriety of including with these the turrited or tapering trochi of this writer; such as, for example, in the species telecopium, and others in that family. Furthermore, it may be added that some amendment in the distribution of these shells is rendered the more necessary for the sake of perspicuity in the arrangement of a number of new species not strictly according even with the former, and which have been discovered since the time of Linnaeus.

Lamarck, and after him Latreille, constitute a new genus of the turrited kinds of the Linnean trochi, under the title of pyramidalis, and which they define generally, as being a turrited shell, with the opening entire, and semiova; pillar projecting, raised, with three transverse folds, and perforated at the base. This genus is fully illustrated by the Linnean trochus dilabratus.

The new genus pyramidalis was certainly necessary; but besides this, the continental naturalists above mentioned, have indicated some other genera from the Linnean trochi, as polarium, and monodonta. The Linnean trochus perspicuus elucidates the character of the first of these three genera, which consists in being of a depressed conic form, with an umbilical opening in the base, crenulated along the inner margin of the spiral volutions, and the opening or aperture almost quadrangular. This is the shell known among English collectors by the name of staircase trochi, from a fancied resemblance of the internal view of the umbilical opening to a well, or spiral staircase. The shells are comprehended by Linnaeus in his first family of trochi; but we should rather incline to admit them as a genus distinct from that tribe, the depressed contour of the shell, and singular structure of the umbilical opening, forming an excellent general distinction. The Linnean trochus labio, and its analogous species, being of an oval or conoid shape, with the opening roundish and entire, but furnished with a projecting tooth, are the description of shells of which the genus monodonta consists.

Turbo. Animal a limax. Shell univalve, spiral, and foliol; aperture contracted, orbicular, and entire.

The shells of this genus are divided into five families; * neritoides, &c. having the pillar-margin of the aperture flat, or dilated and imperforate; ** foliis, foliis and imperforate; *** foliis, foliis and umbilicated, or perforated; **** cancellati, cancellati; ***** turriti proprii. (Negr.)

Turbo. Animal a limax. Shell univalve, spiral, and foliol; aperture contracted, orbicular, and entire.

The shells of this genus are divided into five families; * neritoides, &c. having the pillar-margin of the aperture flat, or dilated and imperforate; ** foliis, foliis and imperforate; *** foliis, foliis and umbilicated, or perforated; **** cancellati, cancellati; ***** turriti proprii. (Negr.)

The shell genus, as it stands in the Linnean Systema, is much too diffuse, and comprehends shells to very remote from each other in various essential circumstanc...
CONCHOLOGY.

mack, Latreille, and various other writers, and which we
cannot hesitate to admit as highly necessary. The distinc-
tions between these two genera are sufficiently characteristic.
Stomatia has the shell of an oval form, and ear-shaped,
with the spire prominent; the aperture ample, entire, and
longer than its breadth; disk imperforate, or without ori-
fice. Haliotis shell flat, ear-shaped, with the spire very
low, not almost lateral; aperture very ample, and longer
than its breadth, and entire; and the disk pierced with ori-
fices disposed in a line parallel with the left margin.

Lamarck, in his "Animal Architecture," places the halo-
ities, or ear-case, among the turbinate shells, between
the nerita and trochus; the same mode of arrangement is
observed in his work "De Animalibus Angulis," where he
says it is "spiral at the clavicle, in the three manner as other
larger shells, and is therefore placed erroneously by some
among the simple shells. Guénée ranks them among finalis,
with less or flattened spire; Adhemuz, in the first
family of spirals shells; Da Costa immediately after the
patella, his first genus of simple shells, and Lamarck be-
tween the tellaceae, which follows the helices and urteas,
and the vermiculaceae sculptura.

Some writers admit it as a collateral character of the
baliotis, that the inside is always of the finest pearl, and
pearls are often produced in these shells. The perfora-
tions vary in number in different species. It has been
observed, that the animal always closes one of those holes
towards the spire, whenever he opens another towards the
head as he grows bigger, and by that means that the num-
ber of openings is invariably the same in different individuals
of the same species. Shells of this genus are very rarely
discovered in the fossil; we much question if any of those de-
scribed by writers are truly of this genus.

Patella. Animalia limax. Shell univalve, sub-conic,
and without spire. Linn.

These are the limpets, and are known from their res-
semblance to a little plate, or patella, and are more or less
conic without, and concave within. Some have the apex or
top entire; others perforated: the chambered limpets are
distinguish by a peculiar kind of projecting process, or
lip within; most have the margins entire, but some have an
indent or fissure in that part; and again others are so com-
pletely spiral or wreathed in their exterior appearance that
they resemble rather the trochi, or top shells, than the lim-
pet. Linnaeus, in order to comprise shells so very dissimilar
in appearance under one genus, found it necessary to con-
tinue no less than five distinct sections or families for their re-
ception. Thence he arranges in the following order.
* Labiata, &c. furnished with an internal lip; shell en-
tire.
** Dentata, &c. with the margin angulated, and
-toothed.
*** Mucronata, &c. with the pointed tip recurved.
**** Integerima, &c. very entire, and not pointed at
the tip.
***** Perforata, &c. with the crown perforated.

Lamarck, as being one of the latest writers on this sub-
ject, defers particular attention; he divides the Linnaean
patella into six distinct genera, which he calls patella, filu-
rella, emarginula, conchoplas, crepidula, and calyptra.

The shells retained under the old name of patella (pa-
telle) are defined generally as being univalve, without
spire, oval, or fusiform, shield-form, or bonnet-shaped,
concave and simple beneath, with the summit entire, and
margin without fissure, as exemplified in patella telludinaria,
in the fourth Linnaean family. Fissurella (fissurelle) has the
shell shield-form, without any kind of spire, concave be-

mest, and at the summit an oval or oblong aperture. The
fissurellae correspond with the fifth of the Linnaean families
perforata, and with the genus formed by Da Costa under
the name of pierced limpets or mufita, in his "Elements of
Conchology." The little slit limpet, patella filula of Linnaeus, very clearly illustrates the genus emarginula (emarginul), of Lamarck; the genus is distinguished by the
shell being of a conic form, concave beneath, and hav-
ing the posterior margin cleft. The conchoplas has the
shell univalve, oval, convex above with the summit oblique-
ly inclined upon the left margin; the cavity within simple,
and two teeth and a finitude at the base of the right
margin. This genus is exemplified in the conchoplas per-
vulna of Pavanze, and buccinum lepas of Bruguiere.

Some other writers admit it as a family of the limpets which they
distingiuish simply by having the beam produced and some-
what twisted or crooked. The crepidula (crepilula) of
Lamarck is of an oval, or oblong form, with the summit
inclined upon the margin, and a partial simple diaphragm or
division in the cavity. The Linnaean patella porcelain is of
this genus. The calyptrae (calypticae) is of the chambered
kind, appearing in the first of the Linnaean families, and is
sufficiently explained by the Linnaean patella equilateral.
The shells of this kind are of a conoid form with the sum-
imt vertical, entire, and pointed, and the cavity furnished
with a thin plate, or tongue-like process in the centre,
which is either detached or connected to one side of the
shell, and runs in a spiral direction.

Dentalium. Animalia terellæ. Shell univalve, tubular,
slightly curved, with the cavity open at both ends, and
undivided. Linn.

The simplicity and precision of the generic character of
dentalium merits commendation, and, although some later
writers on the continent seem too fastidious to admit it, we
deem it unexceptionable. The shells of this kind are known
in England by the name of tooth shell. (Donov. Brit. Shells.) We have few species, and those are principally of
the minuter kinds, in this country. Gmelin enumerates al-
together twenty-one species of this genus, some of which are
found only in a fossil state.

Serpula. Animalia terellæ. Shell univalve, tubular,
and adhering. Often separated internally by divisions at
uncertain distances.

By the introduction of a few particular shells the Lin-
naean serpulae are rendered altogether incongruous. The
genuss, as now retained, is extremely vague; and which,
indeed, is necessary in order to comprise the whole of the
species described by Linnaeus under this general head. No-
thing absolutely certain is established for its character, ex-
cept its being an univalve shell, a circumstance common to
the greater part of the shell tribe, and its being tubular with-
out a regular spire, which is not less applicable to the dentala,
the teredins, and if, like Linnaeus, we admit the genus to
be really of the tellaceae tribe, the situation also.

What then remains to fix the character of a serpula? that it ad-
ters to other bodies, but even this is not always the case;
and beyond this we are again left in doubt, its character
being confusedly indefinite and local, "timp illa-
mis integris paullim intercepit," Linn. There are some-
times internal divisions at uncertain distances in these
shells, but what we can infer from these in constitut-
ging a generic character: these divisions are in the first place
concealed within the shells when entire, and are only to be
discovered by destroying them! and can this be considered
as a character well calculated to afford a generical cireteion?
Nor is this all, these internal divisions are by no means
constant; they are not as in the nautilus and other regularly
formed
formed chambered shells placed at equal intervals, neither are they pierced by a siphunculus, or pipe-like receptacle communicating from chamber to chamber for the reception of the linear body of the animal inhabitant; the creature must remain in the single chamber or enclose, having no means of extending itself into the rest of the shell. And besides this, the concamérations above-mentioned do not seem constant to any particular species, but depend on the age of the shell, and appear to be formed progressively at various intervals as the animal from various causes or its increase of growth finds it necessary to form a larger dwelling. In this case the deserted chamber left occupied being no longer useful is closed up, to render its new habitation more compact. We now advert only to particular shells; there are many species which do not exhibit such a concamérated structure.

One of the first writers upon this subject, after the time of Linnaeus, was Da Coila, who in his "Elements of Conchology" takes occasion to notice the manifest impropriety of uniting in the same genus the shell known by the Linnaean student under the name of ferpula penis, and the simple vermiculi.

He proposes to obviate the difficulty by constituting two genera, the vermiculi, or tubular worm shells, which have no fixed or regular form, as the common vermiculi, (ferpula vermicularis, Linn.) and penicilli, or those worm-shells which, in the whole, or any especial or particular part, have a determinate regular shape or structure. Of this last genus, he observes there are few species; the watering pot (ferpula plius, Linn.) from the East Indies is the chief kind, and when perfect is much valued. The propriety of dividing these families of shells is well conceived, but the distinctions are not happily defined than might be expected. The suggestion, however, of this writer has been improved upon by the later French naturalists. The genus arboefor or penicillus of Lamarck is the penicilli of Da Coila; and yet, in truth, we should add, that though the genus was laid down by Da Coila, we may trace it to Argenville, who had previously, say, even before the time of Linnaeus, described the watering-pot shell under the title of pennisculus marinus. The genus arboefor, or penicillus, as defined by Lamarck, is a good one, and the same may be truly said of the filanaria of Davila, a genus exemplified in the Linnaean ferpula anguina, which is distinguished by having a longitudinal sub-articulated opening or cleft, extending throughout the whole length of the shell. The concamérated ferpula, we have seen, are not to be regarded as generically different from the rest.

The vermiculi of Gualtieri include the Linnaean turbo scalaris, a rare spiral shell, better known in England by the name ofwentletrap, and which is esteemed of considerable value on account of its rarity. This writer places it with the vermiculi, because, as he observes, the spires of the shell are not produced from or supported by a peduncle, as is constantly the case in turbinated shells, but poise, on the contrary, the true character of the spiral worm shells; and there is certainly much truth in the ideas of Gualtieri, though we do not at the same time perceive the absolute necessity of removing it to this genus, and we shou'd anxiously and most fervently avoid any needless innovation. Lastly, we shall mention that the author of the "Tellacca Britannica" proposes as an amendment in the ferpula, to divide them into two distinct genera; the ferpula he retains under the old Linnaean character, "shell univalve, tubular, adhering, or affixed to other bodies; in some species divided into cells." The other he calls vermiculam, and defines "shell univalve, shape various; not attached, or adhering to other bodies." This we believe must in candour be admitted as more vague and indefinite than even the Linnaean distinction, and by the laxity of expression may as well apply to the whole tribe of univalve shells, the adherent ferpula excepted, as to the particular family called vermiculam. But though we disapprove of the character assigned, we perfectly agree with the ingenious author as to the propriety of separating the adhering kinds of ferpula from those species which constantly occur detached.

**Teredo.** Animal a terebella, furnished with two calcareous, hemispherical valves, or maxille, truncated before, and two others of a lanceolate form; shell tapering, flexuous, and penetrating wood.

The animal inhabiting this shell is a terebella of a particular kind; the body being of a soft and gelatinous nature, but having the head provided with an instrument of a calcareous substance, which performs the office of an augur, and enables the worm to penetrate the hardest oak. The most destructive of the animals of this genus is the teredo navalis, which penetrates the bottoms of ships. It was originally imported from India into Europe about seventy years ago. Sell us, in the year 1753, published a treatise on this subject under the title of "Historia Naturalis Teredinis, seu Xylophagi marini Tubulo-conchoidis." It was afterwards described and figured by several writers, and among others by Bailler, in the Philosophical Transactions, vol. xxxi. It is now too well known by the name of **shipworm.** See Donov. Brit. Shells.

Three species only of this singular genus have been yet discovered, and which are named navalis, urticula, and clava. Pavanoe and Guettard divide these shells into two genera, teredo (taret) and filuliana; the shell of teredo is distinguished as being tubular, cylindric, and open at both ends, lower orifice furnished with two lozenge-shaped valves, and the upper with two spatulate operculas. Filuliana is a genus composed of a single species, teredo clava, Gmel.: the shell is tubular, elevated at one end, open at the flender extremity, and containing in the cavity two non-adherent valves. This last is called by Pavanoe, filuliana cornicula, and filuliana gregata by Guettard.

**Sabella.** Animal a nereis, with ringent mouth, and two thicker tentacula behind the head: shell tubular, composed of plates of sand, broken shells, and vegetable substances, united to a membrane by a glutinous cement. The fabela, according to Linnaeus, is inhabited by an animal of the nereis kind. Some of these animals were known among the old writers under the name of sea scolopendus. Since the time of Linnaeus, the number of species has been greatly augmented by the discoveries of Faisas, Fabricius, Müller, and others, and the nature of those animals become better understood; in consequence of which, they have been discovered to be the habitations not only of the nereis, but also of the amphitrite and terebella genera. We speak of the marine kinds: with respect to several of the supposed species of fabela found in fresh water, it is accurately determined they are not of this race of animals, but the larvae of ephemere, phryganea, and other insects, which contrive cylindrical cells of extraneous matter, in which they reside while they remain in that state in the water. Some naturalists, in order to avoid confusing these larvae with the true fabela, have cautiously omitted the whole; and we indeed suspect, that although they may continue to be retained by the Linnaean student among the shell tribe, they will be expunged, or many of the species at least, by future sistematics. The Gmelian system comprehends 25 species.
Species of shell, the fresh-water kinds, described by Schroetter, included.

The marine shellfish shells are composed chiefly of sand and the fragments of shells; those of the supposed shellfish found in fresh-water, either of small fragments of vegetables, or the broken shells of tectaceous vermes, those of the helix tribe especially.

Having presented the reader with a detailed view of the Linnaean system of conchology, we shall next proceed as before to speak of the other principal writers on the subject, as nearly in chronological order as circumstances will permit.

The third volume of the extensive and costly work of Seba, "Descriphtio Thuefani Rerum Naturalium," was produced at Amsterdam in 1758. This part treats on marine subjects generally, as crustaceans and tectaceous animals, corals, &c.; and contains besides plates in other departments, sixty-one elucidatory of conchology. As a book of reference to the more striking and well-known kinds of shells, the work of Seba possesses merit; it has been observed, and with much truth, that this valuable publication might however have been rendered less expensive by the omission of a number of figures, which conflict merely of repetitions, and also the specimens of art abundantly introduced, such as the fanciful decorations on the shells of the nautilus, and the examples of "shell work," on which a profusion of engraving is unnecessarily expended.

In the "History of Cornwall," Dr. Borlase presents us with a plate of shells containing about thirty species; the descriptive matter is slight, and is principally copied from some of the oldest writers on the subject. This was published in folio in London, A.D. 1758.

The magnificent work of Francois Michael Regenfus, "Choix de coquillages et de crustacées," appeared at Copenhagen, under the patronage of the king of Denmark, in the same year as the preceding. The work comprises twelve coloured plates in imperial folio, and each plate comprehends twelve shells. The descriptions, which are written both in the French and Danish language, are the joint labours of prof. Franz Kratzenhnen and Dr. Alcatus. It has been lamented that the talents of this artist were not employed on subjects better deserving of elucidation, as those which are figured by Regenfus fall daily under the notice of the most humble collectors. A second volume was begun, and considerable progress made in it before the year 1779; but as the artist is no more, the undertaking is in all probability relinquished. Twelve plates designed for the second volume are possessed by sir Joseph Banks, and which include shells of greater rarity than those inserted in the first volume.

We have already adverted to the "Claf's Conchylorum" of Carolo Augusto de Bergen, published at Nuremberg in 1760. This little treatise contains a compendious view of the principal systems of conchology which had then appeared, under the heads of "Methodi Universales," and "Methodi Particulares," with concise prelatory structures on each. These remarks of Bergen have evidently furnished later writers with many useful criticisms on the several works that fall within the compass of his view, and may, upon the whole, be thought far preferable to many more elaborate observations that have since appeared on the same subject.

The "Amusement Microcopique" of Ledermuller relates to minute shells, and contains many figures. The first part was published at Nuremberg in 1764, and in 1766 and 1768 two other parts of the same work.

Davila's "Catalogue Systematique et Raifonné des Conchylidés de fon Cabinet" was printed at Paris, in 1767, in three volumes octavo, preparatory to the dispersion of his collection in the following year. The first volume treats entirely of shells, and contains twenty-two plates of the rarer specimens in his cabinet, many of which are scarce even at this day. This work affords much interesting information, though it is to be considered only as a file catalogue. The same year a similar production, "Catalogue Systematique des Coquillages de Arnold Leers, de Rotterdam," appeared at Amsterdam, as an announcement of the sale of his valuable collection. This was written by Mr. F. C. Meinheer, German envoy at the Hague, and contains a sheet of shells.

The work of Geoffroy, "Traité des Coquilles, tant fluviales que Terrestres, que se trouvent en Environs de Paris," was printed in 1767, and forms a valuable acquisition in this department of science. Three plates engraved by Duchoef, contain figures of forty-six shells described by Geoffroy.

A curious and interesting paper by Hering, occurs in the Mem. de l'Acad. des Sciences, for 1768, entitled, "Éclaircissements sur l'Organisation jufqu'ici inconnue d'une Quantité considérable de Productions Animales, principalement de Coquilles des Animaux," with eight illustrative plates, three of which relate to shells. In the same year the "Memoire sur le Coquillage appelé Dette en Provence" of A. D. Fourgeroux de Bondaroy, was inserted in Mem. Etrang. de l'Acad. Roy. de Sc. together with a plate elucidatory of the subject, which is the Linnaean mythus lithophagus.

Cotte's observations on the physiology, &c. of the shell, occur in the "Journal de Scavans" for 1770, and in the "Journal de Physique des Dépôts des Yeux, et de l'Eléphant" of Knorr, completed in 1773, consist of six parts, and altogether contain 975 figures of shells. The author was a painter at Nuremberg, and his publication commenced in 1763; but not living to finish the undertaking, the last part was brought forward by his executors. Knorr had collected materials for another tectaceal work, his "Delicais Nature fechez," which was afterwards prepared for public view under the direction of Müller and De la Blaquière.

Another conchological work, of still greater extent, "Neues Systematisches Conchylcien-cabinet," was in a progressive course of publication at Nuremberg, about the same period. The first part appeared in 1769, another in 1771, and a third in 1777. These constitute the first three volumes, which were all its author, Martin, lived to complete. Seven volumes have been since added by F. H. Chemnitz. The body of the work is written in the German language; the embellishments consist of 366 plates, and exhibit a number of figures on each plate. It is highly probable this work will never be extended beyond its present limits; Chemnitz being dead, and his collection of shells, which was very copious, having been dispersed within the last four years by public sale. The catalogue of sale bears date Feb. 7, 1803, it was drawn up by H. S. Holten, in a small duodecimo, entitled, "Enumeratio Systematica Conchylorum J. H. Chemnitzii," &c.

Schröter is the author of many treatises on the subject of shellfish, and which appear to be little known. He has in particular distinguished himself by his observations on the river shells of Thuringia; the source from whence Gmelin has obtained many of the new-species described in his edition of the Systema; the labels of this writer are very numerous. See his "Die geschichte der Pluonconchiden, mit vorzüglichlicher rückicht auf diejenigen welche in den Thüringischen
which wasser leben," 1779. This was preceded by a small publication on the land shells found chiefly in the neighbourhood of Thiangfladt, "Verfich einer Systematischen abhandlung über die Erdkonchylen um Thiangfladt." A later production of this writer's is the "Einleitungen in die Conchylen kenntniss nach Linnee," published in three volumes octavo, 1783-1786, and which to the German scholar forms a valuable introduction to the study of conchology.

The "Zoologie fundamenta" of Martinus Thane Brunnich, was published in 1772, and relates in a partial degree to shells.

In the "Verrnimus terestrium et fluviatilium Hiloria" of Müller, we are presented with an arrangement of land and river teleoconous animals divided according to the characters of the animals themselves instead of their shells. The first volume was begun in 1773, and the second in the year following. The teleological productions of Denmark are described in the "Zoologia Danica" of this author.

The "Viaggia in Dalmazia," or travels in Dalmatia, by Albert Furti published at Venice in 1724, contains a few figures elucidatory of those shells which he found in the Porto di Buri.

The "Elements of Conchology," by Da Coa, was published in 1756. This work presents us with a new arrangement of shells, and besides contains some judicious observations on the classification of Linneus, and some other writers; which latter, in our opinion, deserve more attention than his system of shells. The "Elements" of this writer is one of the most inferior of this author's works. His "British Conchology," published in 1758, is more valuable, though it does not take a sufficiently extensive view of the British teleoconae. Da Coa had intended to publish a second edition of these with considerable improvements; the collection of materials, and the MS., for which are in the possession of Mr. Donovan, and have been in part incorporated into his "Natural History of British Shells." The great force of Da Coa appears to be in the antennial race of shells, and other extraneous fossils, and in the more useful departments of mineralogy, or what he denominated native fossil. Upon these subjects alone, no less than ten volumes of unpublished manuscripts are preserved at this time in the extensive collection of original MS., &c. formed by Mr. Donovan, which are intended to be placed in the library of his museum.

Among the few teleological works noticed by Da Coa, in the introduction to his "Elements," he speaks of "a new and anonymous conchology, began to be published in this metropolis, in 1779, in folio, illustrated with copper plates," "it was intended (he observes) to be a general natural history of shells, and to include figures of all the known species, common as well as rare, beautiful or otherwise, and some copies were designed to be accurately coloured for the use of the curious. This anonymous production was, to our knowledge, written by Da Coa, and was the joint undertaking of himself and Mr. George Humphrey, by the latter of whom most of the shells were furnished that are described in this work. The numbers of this work that were published comprehended the first three families of its system, limpet, sea ear, and terebra.

The publication of Ignaz Edler von Born, the celebrated mineralogist entitled "Index Rerum Naturalium Mafeli Conchae Vindobonensis" presented the public in 1788 with the description of the shells preserved in the museum of the empress queen at Vienna; and was undertaken at the express command of her imperial majesty. "Two years after the baron published his "Telea Conchae Vindobonensis," as a splendid illustration of his former work; this contains about two hundred coloured figures delineated in eighteen folio engravings.

The early editions of the "British Zoology," as it is entitled by Mr. Pennant, though in reality it embraces only an inconsiderable portion of the zoological productions of Britain, include none of the tellaceous tribe: these were added in a fourth volume published in 1778. This volume contains an enumeration of 163 species of shells with concise descriptions, and 56 plates exhibiting figures of nearly all that are described. Mr. Maton oberves in his comments on this work that "most of the plates are valuable for reference, but some of them are executed less carefully than could have been wished. In the descriptive part (says the doctor) the author has transmitted pretty chiefly the specific characters, given by Linneus, whenever they could be had, but there are several species of which the former is to be looked upon as the first definer. It is very remarkable, however, that he should have wholly omitted which had been noticed by Lithé and Petiver, and others which are unquestionably natives of our island." The number of British species of tellaeae known to us at present amount altogether to several hundreds more than Mr. Pennant was acquainted with, and it is our knowledge of these which renders his catalogue of little moment.

But we ought in candour to allow that considering the very low ebb of natural science in this country at the period Mr. Pennant wrote, his work is a respectable performance; we mean with regard to the number of species contained. The defractive matter certainly betrays great want of information, as well as Science: many of the synonyms are misapplied, and the names erroneous.

The "Observation fur les moules" in the "Journal de Physique," 1779, is from the pen of a lady, Madoonde Collot, and relates to the reproduction of mussels. Desquesne treats upon the locomotive faculty of oyters in the same volume of this journal "Sur la Faculte locomotive des huieres," p. 241. tom. 28.

In 1780 the "Pataf Gramslandica," of Otto Fabricius was printed at Leipzig. This work contains the description of fifty-seven species of shells found in Greenland, among which are a number not previously observed by writers. Fabricius pays considerable attention to the structure and habits of the animal as well as the shell.

The "Zoophyllum Gramsianum," a description of the rich museum of L. T. Grouvino senator at Leyden was published in 1781. There are in this work a scientific description of 789 species of shells, and among the plates, two appropriated to the illustration of the rarer kinds.

Molina's "Saggio sulla flora naturale del Chilli," or natural history of Chili, comprehends descriptions of the shells observed by this writer in that part of South America. The work was printed in octavo, at Bologna in 1782.

A small octavo tract was published at Naples in 1784 entitled "Dificerzione di una nuova famiglia, e di un nuovo genere di Tellacce, trovati nel littorale di Catania, con qualche osservazione sopra una specie di olliche," by M. Gioeni. The supposed new genus of shells which occurred to the notice of Gioeni on the shores of Catania was no other than the land teleoconous faunace found in the gizzard of bulla liguria, a similar organ to which we have ourselves found in the gizzard of bulla aperta. Some years passed before this misconception was detected; it had been really considered a shell by profilo Ratti from whom it obtained the name of tellaeae Gioeni; and it is arranged also in the system of Brugniere under the name of gioeni scula.
C O N C H O L O G Y.

ficula. M. Draparnaud claims the merit of having first ascertained the real nature of this teledacous sublance, an account of which he inserted in the Nouv. Journ. de Physique. We should add that the same article is deficient and illustrated with figures in the second volume of the Linnean Society by Mr. G. Humphrey, associate.

A variety of new and very curious experiments by the indefatigable Spallanzani on the reproduction of the head of the common flea is recorded in two memoirs, the first of which was published in 1782, the other in 1784. See "Rifultati de Esperienze sopra la Reproduzione della Testa delle Lucane Terrestri," Mem. della Soc. Ital. t. 1. Part. 2. pag. 556.

The splendid work on shells by Martyn entitled the "Universal Conchology," was begun in the year 1781, and was continued to be published at uncertain intervals till 100 plates appeared, when its progress was finally impeded. This work commenced with the non-descript shells collected in the different voyages of the English circumnavigators in the South Seas; many of which are still esteemed valuable, while others, as may be imagined from our more habitual intercourse at this time with the southern hemisphere, are become common. As a scientific work, this performance will be found altogether defective, and it is besides too barren of general particulars, to render the subject pleasing to the common reader. Much greater praise is due to the plates, which are the productions of Grozier, and many other artists, and are for the most part well executed; it may be indeed added, that they are the representations of objects in themselves so beautiful as to afford the artist every facility in the display of talent. A number of the original specimens are in the cabinets of Mr. Wood, apothecary, Mrs. Forster, and others in London.

A small quarto treatise embellished with three plates, the joint labour of Mr. W. Boys, and Mr. O. Walker, appeared in London in 1784. The work treats only of microscopic shells, and the references of its authors were confined to the sandy shores of Sandwich as the title indicates. "Tellurica minuta rariare superum detecta in arenâ littoris Sandwichiae." It is dedicated to the late duchess of Portland.

In the Philosophical Transactions for 1786 is "an account of some minute shells, either not duly observed, or totally unnoticed by authors." This is illustrated with three plates and is the production of the rev. Mr. Lightfoot, the learned author of the "Flora Scotica," to whom the world is so highly indebted for his indescribable inquiries respecting the British fungi and conifers.

In 1786, C. L. Kämmerer described the collection of the hereditary prince of Schwarzburg-Rudolstadt. This catalogue is in the German language, and is embellished with twelve plates; it bears the title of "Die Conchlien in Cabinet der Herrn. Erb.—Prinzen von Schwartzburg-Rudolstadt. An appendix, with four additional plates, was published at Leipsic in 1791, under the title of "Nachtrag zu der Conchlien un Fürstlichen Cabinet zu Rudolstadt."

The "Journal de Physique" for 1787, contains a description accompanied with figures of chiton squamosus by Lefèbvre des Hayes.

In the Travels of the Russian Academy, for the year 1795, we find a memoir of teledacous, entitled "Marina variis, nova, et rarioris," by Pallas. The subject treated of are fornpila piriformis, large carola, pholos teredula, chiton amiculatus, and helix coriacea. This author had previously distinguished himself by his critical writings on conchology, both in his "Spicilegia Zoologica," which appeared in 1780, and his "Miscellanea Zoologica," published some years before.

Retzius in the same year printed his "Nova Teledacorum Genera," a work in quarto, in which many alterations and improvements on the Linnean system of conchology are projected. It was previously the subject of an inaugural dissertation at Lund. Retzius was likewise the author of a description of Venus Iphithyphora, published in the Memoirs of the French Academy for 1786.

Cordier's work of "Remarkable Runs and Romantic Prospects of North Britain," appeared on upwards of a hundred folio, and besides the views comprises some plates of natural history, among which are a few of the more remarkable species found on the coast of Scotland, grouped with a variety of other marine productions. Antiquity is however the leading feature of this work. Only part of this production appeared in 1788; some additions have been made to it since that time.

In the year 1789, Bruguier, the well known traveller in the eal, commenced the teledacous part of the grand work, carried on in France, under the title of "Encyclopédie Méthodique," but unfortunately for the cause of science, this fluky naturalist lived only to complete the first volume, which does not go beyond the letter C. of the article veras (worms). The prefatory matter to this volume contains the method of an arrangement he intended to pursue, founded principally upon that of Linnaeus, with such additions and deviations only, as he conceived to be required by the discoveries of other naturalists since the publication of the Linnean Systema. This is the principal, though not the only production, on the subject of conchology, Bruguier submitted to the world.

A pleasing variety of beautiful and curious species of teledacous tribes, chiefly the extra-European kind, have been introduced, at various times, to the notice of the English reader, through the medium of that well known periodical undertaking the "Naturalis Miscellany," of Dr. Shaw. We are not a little surprised indeed to observe, that the greater number of univalve shells in this work are reverenced in the plates, and are therefore likely to mislead the incautious observer into a persuasion, that they are in reality heterostrous. This work commenced in 1790, and still continues in a progressive course of publication.

The "Zoologia Adriatica," of Abbé Oliver, printed in 1791, contains an account of the shells found in the gulf of Venice, with a series of engravings, to illustrate some of the more remarkable species. In the "Ann. de Chimie," for the same year, M. Vaucqualin treats of the respiratory process in the helix pomatia, and proves in the course of his observations, that the venes require vital air for the excitement of their pulmonary system as well as other animals. The species above mentioned (according to this author) will replire azotic and carbonic acid gas, as long as any oxygen remains combined with either. The "Observations sur la génération des Buecins d'Éau douce," by M. Ribaucourt, inserted in the "Journ. d'Hist. Nat." for the same year, tend to prove that all the species of that tribe are viviparous. The bulk we have to mention in this year are the papers of M. Cuvier, the celebrated comparative anatomist. These relate to the anatomy of the Linnean patella vulgaris, and unguis; and the bala apera, and are to be found in the "Annales du Musée Normand." The first volume of "Teledacographia et Zoophytographia parva et microscopica," by Am. Soldani, is dated 1789; a second volume appeared in 1795. The microscopic subjects, described by this writer, are principally shells discovered.
CONCHOLGY.

discovered by himself at Porto-Ferrara; the island del Giglio; on the shores of Calabugnello, la Follonica, &c.

No less than 1,8 plates embellish this work, in which the shells are represented both of their natural size and magnified.

A number of minute, or microscopic, shells, discovered by the late Mr. Adams, on the coast of Pembroke, are described by that ingenious collector in the third and fifth volume of the Transactions of the Linnean Society, in which will also be found two plates, containing figures of the shells described.

Among the "Observations sur les Coquilles," inserted in "the Journ. d'Hift. Nat." for 1792, and in the "Pro-
drome d'une nouvelle Classification des Coquilles," Mem. Soc. d'Hift. Nat. An. 7, the curious reader will find much more information matter relative to the tectaceal systems of Linnæus, and Bruguiere, and also a sketch of that proposed by their author, M. Lamarck. These were the prelude to his more important undertaking "Système des Animaux fans Vertebres," in which we meet with a new arrangement of tectaceal more comprehensive and satisfactory than has perhaps hitherto appeared upon this interesting subject.

The "Téfasea Microcoepica attentu ex Gen-
eribus Argonauta et Nautilus ad Naturum picta et descrinpt," published at Vienna in 1798, is the joint produc-
tion of L.A. Fichtell and J. P. C. Moll. It treats prin-
cipally on the minute shells of the argonauta and muninis genera, and contains, besides the deformations in the Latin and German languages, accurate figures of a great number of species, among which many that escaped the observa-
tions of Plancius, and every other writer.

Mr. Hutchinson's new and enlarged edition of the "History

of Dorsetshire," includes a catalogue of the birds, shells, and more rare plants of that county, by Dr. Pul-
ney. The tectaceal part of this catalogue is that which interests us in the present detail. Dr. Pulney be-
flowed considerable attention on this department; his re-
marks on the Linnean genera, which the limits of his views permitted him to notice, are judicious; the species he describes are, however, lets numerous than might be expected, nor can we refrain adding, with due respect to the memory of that zealous and well informed naturalist, that all the shells described as species, are not defined in a clear and sat-
 satisfactory manner. As a local catalogue we admit its gen-
eral utility with this exception.

The above mentioned catalogue was printed in 1799, and in the Philosophical Transactions for the same year, ap-
peared Mr. Hatchett's "Experiments on Shell and Bone," in which that accurate chemist relates the particulars of his discoveries resulting from analysis of the component parts of tectaceus and crustaceus substances, in the first of which he de-
tected the presence of phosphate of lime, and he found the other to contain only of the carbonate of lime mixed with glistening matter. The publication of Donovan's "Na-
tural History of British Shells," commenced early in 1799.

This work was designed to include all the species hitherto discovered in Great Britain, systematically arranged in the Linnean manner, with scientific and general observations on each. Five volumes have since appeared in a progressive course of publication, comprising altogether 180 plates, with many coloured figures. The writer of this article does not feel at liberty to comment further on a work which he has himself submitted with deference to public opinion.

It is allowed by Dr. Maton and Mr. Rickett, in their re-
view of tectaceal writings, infested in the Linnean Transac-
tions, "that the author has given several new spe-
cies, and that he has rectified many errors of preceding writers."

The fifth or last volume of Mr. Drwayer's "Bibliotheca

Hist. Nat. Bruskenia," was published in 1827. This is an account of the books on the subject of natural history, in the valuable library of Sir Joseph Banks, and although only a catalogue, will be found to contain much gen-
eral information. In the "Elenchus S. Clionum," we are

prefixed with a methodical arrangement of the principa-
l tectaceal subjects treated of by different writers, nec-
ated in the other part of the catalogue; and which, in many respects, may prove more acceptable as a mode of reference than a catalogue confining merely of the titles of the books and names of the authors.

A paper describing the hinges of some British shells of the bivalve tribe, by Mr. W. Wood, is inserted in the

sixth volume of the Linnean Transactions. The attempt

is ingenious, but on a very confined scale, and it presup-
poles, without the flighty countenance of fact, that among the many writers who had previously noticed shells, or even
written pretentiously on them, no one had hitherto paid atten-
tion to their hinges. The paper is illustrated by fix plates of outlines.

In 1823, the "Tectaceae Britannica" of Mr. G. Mont-
agnu, was published in two quarto volumes. The number of shells described in this work is considerable, as it com-
prehends an account of the microscopic kinds, in addition to those of a larger size. It is embellished with sixteen coloured plates.

"The Historical Account of Tectaceal Writers," to

which, in the course of our foregoing observations, we have had frequent occasion to advert, appeared in the sixth volume of the Linnean Transactions, published in 1824, and is the joint production of Dr. W. G. Maton, and the Rev. Thomas Rackett.

The "Tableau Methodique des Mollusques," by La-
turcle, published in the twenty-fourth volume of the "Nou-
veau Dictionnaire d'Histoire Naturelle," printed at Paris in 1824, affords us an arrangement of shells, founded on that of Lamarck, with some additions that may render it more applicable to general use.

The rise, progress, and general traits of the history of

this science may be more readily collected, we apprehend, in the course of the foregoing review of the different works that have appeared on the subject, than from any other mode that might be devised; and, under this idea, we have adhered as nearly as possible to the chronological order of arrangement, this being the most likely to facilitate the purpose intended. From the perusal of this, the reader will at once perceive which are the most considerable and valuable works on the subject, as well as obtain a general knowledge of a number of treatises, tracts, and memoirs, on particu-
lar articles connected with tectacology, which, being dif-
pered through a variety of miscellaneous and voluminous publications, might, without such reference, escape at-
tention. The leading features, or design, of the respective performances, are likewise detailed, and the embellishments which accompany them pointed out; and, in fact, every other particular deemed likely to assist the student in his choice of the best books in forming a tectaceal li-

brary.

In resuming this subject, as we propose under the ar-
ticle TECTACEOLOGY, we shall be prepared to offer some further, and more general remarks on this topic, and in particular to submit our own ideas as to an enlarged and improved arrangement for the classification of tectaceous shells.
bodies, founded on the leading principles of the best authors, with such amendments as we conceive necessary. D.

Miscellaneous Additions relative to Conchology.

The following instructions for collecting, cleaning, and preparing shells, may not be unacceptable.

The teleosts, like all other animals, have their particular results; some inhabit only the deep parts of the sea, and are what the old writers distinguished by the name of pelagian shells; others are as constantly found in shallow water, in bays, or those parts of the sea which are contiguous to the entrance of rivers: it has also been observed, that many fine and rare shells are sometimes found in the straits between islands, and in shallow near the coast, of four or five fathom water. Some species also are found on rocky, and others on sandy shores. The best shells are those taken alive out of the sea, from whence they may be obtained by means of a trawling-net, such as the fishermen employ, if the depths are not too great; they are also brought up by the cable in weighing anchor, the log-line in foundling, and various other means. Sometimes valuable marine shells are found sticking to the bottoms of ships, or the sides of rocks.

After a storm, good shells may be picked up on the sea beach or flake, as the violent agitation of the water in a tempest separates them from their native beds, and often calls them ashore. But such as have lain exposed for some time to the heat of the sun, or beaten by the waves, are of little value, as their colours will be found faded, and the shells worn and broken; those only are worth selecting from the sea-shore, which have the animal alive within, or which have been recently thrown up.

River shells are, in general, of an obscure colour, and remarkably thin and brittle, in utmost that some have imagined it a peculiar character, by means of which they may be distinguished from the marine or terrestrial kinds. This is not, however, an absolute criterion, for many of the latter are as thin as the river shells, as we observe, for example, in the argonaut, or paper nautilus, some pinnae, and many other sea shells, and in numbers of the shells of the terrestrial kind.

Terrestrial, or land shells, though few in comparison with the former, are oftentimes very beautiful, and not less esteemed than the marine kinds. Those are found most commonly crawling, like the snail tribe, on various sorts of plants, and in warm countries especially abundant.

Many shells possess such a smooth, and highly polished surface, and are so beautiful in colour when they are filled up, that art cannot improve their appearance, such as for instance, the cyprea or cowry, and the voluta or varole, with many others. It is the commonly received opinion, that the animal, inhabiting all naturally polished shells whatever, are capable of not only adding to the extent and growth of their shells, but that they are able, from time to time, as occasion may require, to add a fresh polished covering to the whole shell. Should this opinion be unfounded, they can at least extend their organs to such a length, as to clean away all impurities from their shells, as we learn from many cows and tortoises, or any extraneous bodies, adhering to any part of them.

Other shells are covered with an epidermis or membrane, intended with no doubt by nature to defend them from accident, and aid their growth. The structure of this epidermis varies very much, being in some laminted, in others fibrous or brush-like, or pilous, and velvetty. The epidermis prevents the leprous, and other similar shells, or marine worms, from fixing their habitations on them; it is worthy of remark, that most shells, with a leprous surface, are covered with an epidermis. Many others, when taken out of the sea, are limy, and encrusted with lime, coraline, and other extraneous matter.

Immediately after gathering or collecting the shells, and these especially taken from the sea, the first process necessary, is to destroy and extract the animal inhabitant, without injuring the shell, and then to prepare the shell, that it may not be damaged by the action of the marine salts, with which they are saturated. As shells are of a calcareous nature, all acids should be as much avoided as possible, both in killing the animal, and preparing the shell; it is usual to boil them in water for this purpose, but as boiling may injure the shells, it will be most advisable to dip them into boiling water, which will be sufficient to kill the animal, after which, let them remain for two or three minutes to cool, and then put them into cold water, in which they may lie till they are taken out to be cleaned. The animal, by being killed in this manner, becomes condensed, and somewhat solid, and may be picked out by any sharp instrument.

Shells encrusted with extraneous matter should be allowed to steep for some time in warm water, both for the sake of melting these substances, and to extract as much as possible the marine salts. They may be suffered to remain in water two or three minutes without any injury. After this brush them well, observing only that the brush must not be too hard. If that proves insufficient to clean them, rub or brush them again with tripoli or emery, or put them into weak acid for the space of a minute and then dip them into cold water, which process may be repeated as often as will be necessary to remove the extraneous matter. Strong soap may also be used with a rag of woollen or linen cloth to rub them, or a key of pearlash and when cleaned finish them with a soft brush and fine emery.

Scientific collectors endeavour to preserve one at least of every shell with the epidermis on, to exhibit its natural appearance, together with the uncoated specimens.

The epidermis may sometimes be so thick that it will be necessary to take it off before the shell can be pointed. For this purpose pour a quantity of the spirits of nitre, or nitrous acid, into water, in the proportion of about one-fifth or one-tenth part of the former; put this into a shallow basin or saucer, and place the shell or shells therein, in such a manner that the corrosive fluid may act only on the coat, without injuring the orifice or mouth, which in some cases may be coated with beeswax; change the situation of the shell every two or three minutes, that all the parts may be equally uncoated; wipe off the bubbles as occasion may require with a feather, first dipped in water, when you perceive the enamel in any part free from the coat, take it out, and wash off the aquafortis, and after this proceed rub them with fine emery powder. If instead of a thick epidermis it is only a pellicle, it is sufficient to steep it in hot water, and then pick it off; or steep the shell in vinegar till it peels off freely, or is corroded away. The epidermis of some shells is so coarse and thick as to require the corrosive quality of acids diluted, or even of aquafortis; emery with strong brushes is then substituted, or flesh-flour, and pumice stone, or the exterior coat may be ground off with a grindstone, or files of various dimensions. If the matter is too obtuse to be cleared off by this means, pour some spirit of nitre into a cup or other vessel, upon the part
part of the shell that may be susceptible of injury with soft wax, as carefully as possible, and put it into the liquor in the vessel; remove it every minute into cold water, but observe never to first it into the same water more than once, and wash it every time before you return it into the corrosive liquor. If the shell is warped, irregular, or armed with points, examine it with a common magnifier; and if you perceive on the more prominent parts through the wax any appearance of the polished surface, cover them with wax, and let the shell remain a few minutes longer in the spirit, take it out and wash it again; after which, polish the shell with fine emery, and pulp a camel’s-hair pencil with gum arabic over them to brighten the colours; the white of egg is sometimes used, but it is very apt to turn yellow in time, though at first it appears glairing; and varnish communicates a disagreeable smell.

Some shells have naturally a slight polish; those may be rubbed by the hand with chamois leathers, which will give them a bright glossy appearance; avoid when possible the use of emery powder, as it is apt to detriment the beautiful workings on the shells; it cannot however be often left out of use.

It is desirable as far as can be to point out the impressions which are often practised on those who are not well acquainted with shells, and are therefore not aware that any individual shell may be made to assume a very different appearance by having the first or second exterior coat of the shell removed by acids, or any other means. Thus, for example, we see that though the outer surface of the common cowry, or tile shell, is of a pale colour, with dark spots; when that is cleared off, it is of a fine violet colour: the sea ears are clouded with brown, green, and white; but when that coat is rubbed away it appears of a beautiful pearl colour. Thus also the nautilus shell is externally of a pale brown or ochreous hue, variegated with streaks of cheetah, but on the exterior coating being taken off, the whole shell will be found of that luscious known by the familiar name of mother of pearl. The same circumstance is observed of the true mother of pearl shell, the exterior coat of which is blackish; many of the trochis, or top shells, and an infinite variety of other shells of different genera are of the same description. Among these shells which alter their appearance most, we must not omit the volute, called by us the purple or violet tip, and by the French epaule; it has a brown epidermis which, being taken off, discovers the ground colour to be a dull yellow. When this is worked down to beneath the crust or surface, it is of a pure white, with the tip of a fine violet. We shall lovingly mention the common murex: the exterior coat of which is dull blueish black, that beneath purple, and the inner one white: sometimes we have seen muscles in the hands of dealers, and in scientific collections, of a fine purple colour, variegated with large distinct spots of white or brown, so dexterously managed as to have all the appearance of a shell in a natural state, though in reality such shells are the work of art, and no other than the common edible musles. For this purpose those of the largest size are usually selected, which, being first ascended down to the brightest purple surface, are afterwards fretted or rubbed with a file, in particular parts, till the white or inner coating is seen through the purple. The spots may be managed however with more certainty, by covering the whole surface with a thin coat of wax, then ferapring off the wax in such parts as it is designed should exhibit spots, and hastily suffuring the shell to remain in spirit of salts diluted, or nitrous acid, till the outside is corroded in those parts down to the white or inner coat of the shell. After washing the shell, and clearing off the wax, the spots thus formed may be flained of any colour, according to the fancy of the operator. A preparation of the oxyd of iron, or manganese, are most commonly employed, as these produce a brown colour of different tints, and form an indestructible film. The Dutch, who are great amateurs in conchology, paint shells with a variety of colours, and to that ingenuity, as to render it difficult to detect the imitation. Neither are they less expert in joining broken shells, cementing and filling up holes pierced by marine worms, or fractures, and filling the mouths and tips in such a manner as to entirely alter their appearance.

Fossil shells should be noticed here if any instructions were necessary for their preservation; but these in general constitute the most durable part of a collection, being either chalky, casts in flint or stone, or replacements of party matter, with perhaps only some light fragments of the shell adhering, and that very rarely. They are dug out of chalk-pits, lime-flour, or other flint-quantities, and coal-pits, &c. Vide "Donovan's Instructions for collecting and preserving Subjects of Nat. Hist." from which the above particulars are chiefly extracted.

CONCHUCOS, in Geography, a jurisdiction of South America, in the vice-royalty of Peru, subject to the archbishop of Lima, which commences 40 leagues N. N. E. of Lima, and extends along the centre of the Cordilleras. Its air, therefore, is different according to the height of the situation of its several parts, the mildness of which produce all kinds of grains and fruits, and the others, where cold checks their fertility, afford pasture for all kinds of cattle. This jurisdiction abounds with looms: the principal occupation of the Indians being woolen manufactures of various kinds, which constitute the greatest part of its commerce with other provinces.

CONCIATOR, in the Glass Art, is for the crystal glads what the founder is at the green glads houses. He is the perfon that weighs and proportions the salt on ashes and sand, and works them with a strong fire, till they run into lumps, and become white; and if the metal be too hard, and conquitently brittle, he adds fat, or ashes; and if too soft, sand; still mixing them to a fit temper, which is only known by the working.

CONCILIO—Quaera corum rege et Concilio. See Queerta.

CONCINNA, DANIEL, in Biography, an Italian Dominican, born in the Venetian territory about the year 1696. He was highly distinguished for his pupit talents, which attached to him numerous admirers in Italy, and even in Rome itself. As a writer he was esteemed, on account of the support which he gave to the inftitutions of the Papal church. He was author of numerous publications in the Latin and Italian languages, on historical, moral, and critical subjects, among which are "Defenso Concili Trientini, et Apoll. Cons. Eccle. Rom. in causa Papauratis Monatli. &c.," "Utra Contractu trini Differuntissimus Hitt. Theol. demonstrat.," &c. "De Spectaculis Theatrabus Christiano Exequisu, tum Laico, tum Clerico, vetatis, &c.," "Theologiae Chiristiana, dogm atico-moralis," in 12 vols. 4to. "The logical, Moral, and Critical Differenlates, relative to the Logic of Probabilities, with Supplementary Observations." "A Defence of Revealed Religion, &c." He died at Venice in the year 1756. Nov. Hist. Diet.

CONCINNOUS Intervals, in Music, are such as are apt and of use in harmony, as the V. 4th. III. 5th, 6th, IV. and 5th. in contradistinction to such as are inconceivable, as the intervals deficient or redundant by a comma. See Comma-Redundant, Fifth, Fourth, &c.
CONCINO CONCINI, MARSHAL D'ANCRE, in Biography, was a native of Tuscany, and, with his wife, Leonora Galgai, accompanied Mary de Medicis, queen of Henry IV. into France, in 1660. He was made gentleman of the bed-chamber, governor of Normandy, and marshal of France, in 1615. As he was raised by the influence which he attained over the mind of the queen, he held the reins of government during the minority of Louis XIII., and behaved so haughtily a manner to the young king, that he was induced to order his arrest, and, in case of resistance, the person sent on the business was commanded to kill him. The captain of the guard demanded his favor as he was passing the drawbridge of the Louvre, and upon his refusing to comply, he shot him dead, April 24, 1617. His body, after it had been buried, was taken up and given to the populace, who treated it with every indignity. His wife was afterwards condemned, by a decree of the parliament, to be hanged and burnt. Moreri.

CONCIOLO, an Italian painter, who flourished in the commencement of the thirteenth century. Upon a picture at Subiaco, in the Ecclesiastical State, representing the consecration of a church, the artist has thus signed his name, Conciolus pinxit, 1219. This is one amongst the many proofs, with which the churches and convents of Italy abound, to shew that however low the state of the arts in Europe, previous to Cimabue and Giotto, the intervention of Greek painters was by no means necessary to their establishment. Lanzi. Storia Pittorica.

CONCIONATORES, in Antiquity, common-councilmen, freemen, called to the hall or assembly, as most worthy. Thus, "quodam tempore cum convenienent concionatores apud London, &c." Hist. Elen. apud Gale, c. 49.

CONCLAMATTO, a shout raised by those present at burning the dead, before they set fire to the funeral pile. See Sicut. The word was also applied to the signal given to the Roman soldiers to decamp, whence the expression "conclamare vasa," and "conclamari arma," was a signal for battle. It was likewise used for a practice of calling to a person deceased three times by his name, and when no reply was returned, they thus expressed his decease, "conclamatum est." Whence the same term was afterwards applied to the ejection of the Roman empire.

CONCLAMATO, among the Greeks, Romans, and several other nations, was a spontaneous cry or shout, which all the soldiers of an army made when they understood or heard the third signal for combat.

CONCLAVE, an assembly or meeting of all the cardinals that are at Rome, shut up for the election of a pope; whence it derives its name. See Cardinal.

The conclave had its rise in the year 1270, and on this occasion: Clement IV. being dead at Viterbo, in 1268, the cardinals were nearly three years old, viz. from the 29th of November 1269, to the 1st of September 1271, without being able to agree on the election of a successor; in effect, things were carried to such a pass that they were upon the point of breaking up, without coming to any conclusion at all.

The cardinals, being apprized of their design, by the advice of St. Bonaventure, then at Viterbo, shut the gates of their city, and locked up the cardinals in the pontifical palace adjoining to the cathedral, till they were brought to a better understanding.

Hence arose the custom, which has since prevailed, of shutting up the cardinals in a single palace, till they have elected the pope.

Such was the origin of the conclave, as related by Onuph. Panvinio, Cimabue, and Papebroch.

Pavilion informs us, that John of Toledo, cardinal bishop of Paffo, seeing the cardinals daily praying the Holy Ghost to inspire them with the spirit of concord and union, and yet difcord continuing to reign among them, said pleasantly, "Let us uncover the room, else the Holy Ghost will never get at us." When this facetious remark was reported to the magistrates of Viterbo, they immediately ordered the roof of the room in which the cardinals were assembled, to be taken off, hoping that this new inconvenience would oblige them to hold the election; but their obstinacy prevailed against all inconveniences, till the magistrates betook themselves of daily affronting their subordinates; and this had the desired effect. For being thus reduced to the alternative of starving or agreeing, they left the election by compromise to fix of their number; and then Gregory X. was elected.

Conclave is also used for the place wherein the election of the pope is performed; which is now at St. Peter's in the Vatican; though Gregory X. and Clement V. appointed it should always be held in the place where the last pope should die. But if he should die in a borough or village, where the electors could not conveniently meet, the election was to take place in the episcopal city, or in the nearest to it, if that city were under an interdict.

While the affair is in hand, if it be in winter, the walls and windows are all mured up, excepting only a single pane, to give a little light; in summer the windows are not closed; but the great door of the hall is secured with four locks and four bolts; an aperture being, however, left, through which to supply the imprisoned prelates with victuals.

If the election takes place at Rome, the door of the conclave, and all the avenues to it are to be carefully guarded by the city guards, by the Roman nobility, by the ambassadors of princes, and by the bishops and conservators of the city. If the election is to be made out of Rome, the same duty is incumbent upon the temporal lords and magistrates of the place; and it is a duty common to them all to see that nothing be carried into the conclave, or out of it, that has the least tendency to retard or prevent a lawful election.

In the hall, which is very ample, there are cells or flails erected for as many cardinals as are to be present at the election; the cells being only separated by deal boards, and the room having no outlet, except to the privy.

The cells are marked with letters of the alphabet, and are distributed to the cardinals by lot: each cardinal puts his arms on the cell that falls to his share.

No one shall be allowed to go into the common room or conclave, nor out of it, but in case of sickness, or on some other urgent occasion.

After the assembly has continued three days, they are only allowed one dish for a meal; and after fifteen days more, only bread, wine, and water, though this rule is not very strictly regarded.

Each cardinal is allowed two conclavists, or servants to attend him, and to be shut up with him.

The election is begun ten days after the pope's decease, and decided by a majority of two parts in three of the cardinals present, who vote by ballot; and if, upon the fourth, no one of the candidates has two-thirds of the votes, the balloting must, after a fazed interval, be repeated. And this continues to be reiterated, if they should remain shut up for years, till one of them attains the fore-mentioned superiority. Cardinals who arrive before the election is finished, are included with the rest.

These regulations were principally established by Gregory X. in 1-74. But as this conclusion of Gregory X.
was thought by the cardinals to be too rigorous, they prevailed upon Clement VI. in the year 1351, not long before his death, to mitigate it. Clement allowed them to have each two servants, clerks, or laymen; to have curtains round their beds, and one dish of fish or fish at dinner, and another at supper, besides bread, wine, fruit, and sweetmeats, so long as they continued in the conclave.

Matthew Paris says, the word conclave actually signified the pope's wardrobe.

It is a popular proverb in Italy, _chi entra papa, e scappa cardinal_; he who enters pope, comes out cardinal; q. d. he who according to common report will be elected pope, ordinarily is not.

We have various accounts, both by papist and popish writers, of the intrigues that have been practised in the conclave, during contested elections. What is said to have passed upon the decease of Alexander VII. is no tale invented by papists, but related by grave Roman catholics, viz. that on the day following, cardinal Sforza, going into the conclave, asked another cardinal, his intimate friend, what he thought would be the issue? He returned this frank answer: "Signior cardinal, if the French make the pope, he will be cardinal Farnese; if the Spaniards, cardinal Rospigliosi; if he is made by the people of Rome, he will be cardinal Barberini; if the Holy Ghost appoints him, cardinal Odescalchi will be the man; if the devil has a hand in it, he must be your eminence, or myself." Upon this, Sforza replied with a laugh, "then Rospigliosi will be the man," and he was accordingly chosen by the name of Clement IX. In the year 1724, upon the death of Innocent XIII, the following farcical distinction was made between the candidates for the papal throne:

"Il Ciolo vuol Orfini
Le popolo Corfini
Le Donne Ottoboni
Il Diavolo Alberoni."

_Le S. "Heaven is for Orfini,
The people for Corfini,
The ladies for Ottoboni,
The devil for Alberoni._

But Orfini was chosen by the name of Benedict XIII.

**CONCLUSION.**

**Keyser's Trav. vol. ii. p. 109.**

**CONCLUSION.** In _Law_, is a man by his own act upon record hath charged himself with a duty or other thing, or confessed any matter whereby he shali be concluded: as if a sheriff returns that he hath taken the body upon a capias, and hath not the body in court, at the day of the return of the writ; by the return, the sheriff is concluded from plea of escape, &c. Terms de Ley, 152, &c. In another sense the word conclusion signifies the end of any plea, replication, &c. and a plea to the writ, is to conclude to the writ; a plea in bar, to conclude to the action, &c. Conclusion of plea in bar shall be, et loco paratus est verificare—of other pleas et de loco ponit se super prationem. Kitche. 219, 220. See _Plea._

**CONCLUSION of deeds,** mentions the execution and date of the deed, or the time of its being given or executed, either expressly, or by reference to some day and year before-mentioned. Not but a deed is good, although it mention no date, or hath a false date; or even if it hath an impossible date, as the 50th of February; provided the real day of its being dated or given, that is delivered, can be proved.

**CONCLUSION.** In _Logic_, the last part of an argument; or the consequent drawn from something either assumed or proved before.

The conclusion of an argument contains two parts: the consequent, which is the matter of it; and the consequence, which is its form, and which, of a simple absolute proposition, renders the conclusion relative to the premises whence it is drawn.

The question and conclusion, say the schoolmen, are the same ideas, only confidered in different views, or relations: in the question they are considered as doubtful; in the conclusion as void of doubt.

**CONCLUSION.** In _Oratory_, consists of two parts: the recapitulation, or enumeration, and the _Passions._ See _also Peroration._

**CONCLUSIONS D'UNE procedure militaire,** Fr. See the article _JUDGE ADVOCATE._

**CONCOBAR,** in _Ancient Geography_, a town of Asia, in Upper Media, towards the S.W. of Ecbatana.

**CONCOCTION,** in the _Animal Economy_, a term used by the older writers to denote the processes which the food undergoes in the stomatch, and by which it is converted into chyme and chyle. The process is now more usually termed _Diggestion,_ which see.

**CONCOCTION,** in the _Pathology_ of Hippocrates and Galen, and their numerous followers, was also employed to signify certain changes in the fluids in the course of acute diseases, from a supposed analogy between the changes, and those which the aliment undergo in the stomatch during digestion. The process of concoction may be particularly illustrated in the case of a common phlegmon, or boil: the progress of which is marked, according to Galen, by four distinct stages. The first, or _incipient stage_, in which these fluids are beginning to collect, is considered as the stage of crude and unchanged humours: in the second, or stage of _increa_ , in consequence of the progress of concoction, heat is diffused through the part, and the pain, tension, and tumour are increased: when the humours are completely concocted, and converted into _pus_, the stage of the phlegmon is laid to be _stationary_, or the disease to be in its vigour: and the fourth stage is that, in which the tension and tumour become less, and which is termed the _decline_ of the ewelling. A similar progress is observable in almost all inflammatory diseases.

Thus in catarrh, afflicting the mucous membrane of the nose, the discharge in the commencement is thin and watery, and, in the language of the humoral pathology, _crude_; by degrees a thicker and more opaque matter is discharged, which, at length (becoming completely concocted), assumes a very thick and purulent appearance, which betokens the decline of the disease. Such also is the progress of change in the fluids excreted in inflammations of the lungs and bronchiae, discharged from the eyes in ophthalmia, &c. By an analogy somewhat remote, this doctrine was transferred to febrile complaints, where no local inflammation, or depositary of morbid concocting matter, existed. In an idiopathic fever, as syphusus or typhus, the alvine excrements, the urine, and the discharge from the skin, were referred to, as evidence of the process of concoction; and the varieties of the appearance of these discharges are described by Hippocrates, and his commentator Galen, as denoting the states of crudity and of concoction, and hence as affording a prognosis of the future progress and event of the disease. The alvine excrement is laid to be well concocted, when it is, as in health, soft and connected, and is discharged with the usual regularity. When it is not in this state, but liquid and watery, partly liquid, partly
partly solid, &c, it is considered as not concocted, and therefore indicating the unhealthy condition of the bowels, through which it had passed. And thus, with respect to the urine, when it is extremely thin and alkaline, it is said to be crude; and when it is slightly tinged with yellow, it is considered as having undergone a small degree of concoction, which is still more complete, if it soon depairs a moderate sediment. But the signs of concoction in the urine were said to be different in the young and the old, and different also in different dis- eases. Thus in bilious and summer fevers, a light cloud suspended in the urine was deemed the sign of concoction; in inflammatory fevers, a white sediment. See Galen, de Tot. Morb. Tempor. et de Cirrhis, lib. i.

CONCOLIN, in Geography, a town of France, in the department of the Ille; 43 leagues N.E. of Grenoble.

CONCOMITANT, in Theology, something that accom- panies, or goes along with, another.

Concomitant grace, is that which God affords us during the course of our actions to enable us to perform them; and as the Roman schoolmen say, to render them meritorious.

Concomitant necessity. See Necessity.

Concord, Form of, in Ecclesiastical History, a stand- ard-book among the Lutherans, composed at Torgau, in 1576, and thence called the Book of Torgau, and reviewed at Berg, by six Lutheran doctors of Germany, the principal of whom was James Andrea. This book contains in two parts, a synoptical history of the subscription of which was a condition of communion, and a formal and very severe condemnation of all who differed from the compilers of it, particularly with respect to the majesty and omnipotence of Christ's body, and the real manifestation of his flesh and blood in the eucharist. It was first imposed on the Saxons by Augu- gustus, and occasioned great opposition and disturbance, both among the Lutherans and Reformers.

Several of the most eminent churches of the Lutheran communion rejected it so firmly and reluctantly, that no arguments nor inter- ries could engage them to admit it as a rule of faith, or even as a mean of instruction. Accordingly, it was rejected for various reasons, by the churches of Hesse, Pom- erania, Nuremberg, Holstein, Silesia, Denmark, Brunswick, and others. Among the Reformed, or Calvinists, the Swiss doctors, at the head of whom was Hofmianus, the Bel- gian divines, those of the Palatinate, together with the prin- cipalities of Anhalt and Bade, declared war against it. This form of concord, however, was patronized in a special manner by Julius, duke of Brunswick, to whom, in a great measure, it owed its existence; and who employed his authority and influence in encouraging those by whom it was composed, and in commanding all the ecclesiastics, within his dominions, to receive and subscribe it as a rule of faith. But soon after it was published, this zealous prince changed his mind, suffered it to be publicly expounded by the divines of his university of Helmuid, and to be excluded from the number of creeds and confessions that were received by his subjects. Various means were used to obviate his objections; and particularly in the year 1583, a convocation of divines from Saxony, Brandenburg, Brunswick, and the Palatinate, was held at Quedlinburg for this purpose. But Julius perilled in his opposition, and professed that the form of concord should be examined, and its authority disallowed by a general assembly or synod of the Lutheran church.

In the year 1614, John Sigismund, elector of Branden- burg, following the example of the landgrave of Hesse, renounced Lutheranism, and, under certain restrictions, embraced the communion of the Reformed churches. This event occasioned a dispute, which was agitated with violence, and which occasioned the form of concord to be suppressed in the territories of Brandenburg, and the subjects of that electorate to be prohibited, by a solemn edict, from studying or defending it in the country of Walfenburg. Towards the close of the 17th century, viz. in the year 1675, a new contentious of faith was drawn up by the Helvetic divines, under the denomination of the "form of concord or of agreement," and which was reissued, the "Confession of Faith;" but the introduction of it occasioned contentions and tumults in several places. It maintained, however, its credit and authority in the church of Geneva, until the year 1728, when, without being abrogated by any positive act, it fell into disuse. In several other parts of Switzerland, it was still imposed as a rule of faith, particularly in 1718, by the magistrates of Bern, who published an order, by which all preachers and pastors, particularly those of the university and church of Lausanne, who were suspected of entertaining any erroneous opinions, were obliged to declare their adherence to this formulary. Many pastors and candidates for holy orders refused the omen that was demanded by the magistrates, and some of them were punished for this refusal. In consequence of these warm contending and previous complaints letters were addressed by George I. king of England, as also by the king of Prussia, in the year 1723, to the Swiss cantons, in order to procure the abrogation of this form, or confession, which was considered as an obstacle to the union of the Reformed and Lutheran churches. Mo- lembach. See Necessity.

Concord, a town of America in the state of Vermont and county of Essex, lying on the Connecticut river, opposite to a point of the 15 mile falls.
Concord, or usually that for in •« and t from the spot where the first opposition was made to the British troops, on the 19th of April 1775. The grand court has been held here, when contagious diseases have prevailed in the capital. N. lat. 4° 25'. Concord, a small river of Massachusetts, formed of two branches, which unite near the centre of the town of Concord, whence it takes its course in a N.E. and N. direction through Bedford and Billerica, and empties itself into Merrimack river at Tewfickbury. This river is remarkable for the abundance of fish that swim in its current. At low water mark it is from 100 to 200 feet wide, and from 6 to 12 feet deep. During floods it is nearly a mile in breadth: and when viewed from the town of Concord, exhibits a fine appearance.

Concord, a township of Delaware county in the State of Pennsylvania.

Concord, a settlement in Georgia, on the E. bank of the Mississippi, about a mile from the fourth line of Tennessee, 128 miles N. from the mouth of Yazoo river, and 218 below the Ohio. N. lat. 35° 55'. W. long. 91° 25'.

Concord, in Grammar, that part of syntax, or construction, whereby the words of a sentence agree among themselves, i.e. whereby nouns are put in the same cafe, number, gender, &c. and verbs in the same number and person, with nouns and pronouns. The rules of concord are generally the same in all languages, as being of the nature of what is use almost everywhere, for the better distinguishing of discourse.

Thus, the distinction of the two numbers singular and plural obliges us to make the adjective agree with the substantive in number, that is, to put the one either in this or that number, according as the other is for the substantive being the thing confusedly, though directly, marked by the adjective; if the substantive word mark several, there are several subjects of the form marked by the adjective, and of consequence this should be in the plural; as bonînes doûti, &c.

Again, the distinction of masculine, and feminine, renders it necessary to put the substantive and adjective in the same degree.

And verbs should have concord or agreement with nouns and pronouns in number and person.

If any thing occur apparently contrary to these rules, it is by a figure; i.e. something is implied, or the ideas are considered more than the words themselves. See Syntax.

Concord, Order of, in Heraldry, was instituted by Christian Ernelt, Margrave of Brandenburgh, on his return from Spain, in the year 1666, to distinguish the part he had taken in restoring peace and union to many European princes. The badge of the order is a gold crown of eight points enamelled white, surmounted by an ecclesiastical crown; in the centre of the cross a medal thereon, two olive branches paling fatterwise through two crowns; around the medal the motto concordamus. On the reverse the founder's cypher with the date of the institution. This badge is worn pendant from an orange ribbon.

Concord, in Law, is the agreement between parties who intend the levying a fine of lands to one another, how and in what manner it shall pass. This is usually an acknowledgment from the deforciants (or those who keep the other out of possifion) that the lands in question are the right of the complainant. And from this acknowledgment or recognition of right, the party levying the fine is called the cognisant, and he to whom it is levied the cognisant.
of numbers; we know what it is pleases us, though we do not know why: we know, o. gr., that the ratio of 1:2 constitutes concord, and 6:7 discord; but on what original grounds agreeable or disagreeable ideas are connected with those relations, and the proper influence of the one on the other, are above our reach.

By experiment we know, that the following ratios of the lengths of strings are all concord; viz. 2:1, 3:2, 4:3, 5:4, 6:5, 7:5; that is, take any string for a fundamental, which shall be represented by the number 1, and the following divisors thereof will be all concord with the whole; viz. 2:1 1.5:1 3:2 2:1.

So that the distinguishing character between concords and discords must be looked for in the numbers, expressing the intervals of sound, and not in the intervals themselves, but as expressing the number of vibrations. Now, unisons are in the first degree of concord, or they have the most perfect likeness or agreement in tone; and therefore have something in them accessory to that agreement which is found, less or more, in every concord: the nearer two sounds come to an equality of tone, the flower are the beats, and the more agreement they have; therefore, it is not in the equality or inequality of the numbers that this agreement lies.

Further, if we consider the number of vibrations made in any given time by two strings of equal tone; on the principle laid down, they are equal: and therefore the vibrations of the two strings coincide, or commence together as frequently as possible, i.e., they coincide at every vibration; in the frequency of which coincidence, or united mixture of the motions of the two strings, and of the undulations of the air which they occasion, it is, that the difference of concord and discord must be sought. Now, the nearer the vibrations of two strings approach to a coincidence as frequent as possible, the nearer they should approach that condition, and consequently the agreement of unisons which is confirmed by experience.

For if we take the natural series 1, 2, 3, 4, 5, 6, and compare each number to the next, as expressing the number of vibrations in the same time of two strings, whose lengths are reciprocally as those numbers; the rule will be found exact, for 1:2 is best, then 2:3; after 6 the union is unfavourable; the coincidences being too rare: though there are other ratios that are agreeable, besides those found in that continued order, viz. 3:5, and 5:8, which, with the preceding five, are all the concordant intervals within, or less than an octave, or 1:2; that is, whose acutest term is greater than half the fundamental.

On this principle, 2:3 will be preferable to 4:5; because those being equal in the number of vibrations of the acuter term, there is an advantage on the side of the fundamental in the ratio 2:3, where the coincidence is made at every third vibration of the fundamental, and every fifth of the acuter term, but the ratio 4:5 is less perfect than 2:3; because, though the vibrations of each fundamental that go to one coincidence are equal; yet in the ratio 4:5 the coincidence is at every sixth of the acuter term, and only at every eighth in the other case.

Thus, we have a rule for judging of the preference of concords, from the coincidence of their vibrations: agreeable to which rule, they are disposed into the order of the following table; to which the names of the concords in practice, the ratio of their vibrations, the lengths of the strings, and the number of coincidences in the same, are expressed.

</table>

Though this order be settled by reason, yet it is confirmed by the ear. On this foundation, concords must still be the more perfect, as they have the greatest number of coincidences, with regard to the number of vibrations in both the strings; and where the coincidences are equal, the preference will fall on that interval, whose acutest term has fewest vibrations to each coincidence: which rule, however, is in some cases contrary to experience; and yet it is the only rule hitherto discovered.

Indeed, Kircher, after father Merleau, gives us another standard for settling the comparative perfection of intervals with regard to the agreement of their extremes in tone: and it is this.

The perception of concordance, say they, is nothing but the comparing two or more different motions which in the same time affect the auditory nerve: now we cannot make a certain judgment of any concordance, till the air is as often struck in the same time by two strings, as there are units in each member expressing the ratio of that concord; o. gr. we cannot perceive a fifth, till two vibrations of the one string, and three of the other, are accomplished together; which strings are in length as 5 to 2: the rule then is, that those concords are the most simple and agreeable, which are generated in the least time; and those, on the contrary, the most compound and harsh, which are generated in the longest time.

For instance, let 1, 2, 3, be the lengths of 3 strings, 1:2 is an octave; 2:3 a fifth; and 1:3 an octave and fifth compounded, or a twelfth. The vibrations of strings being reciprocally as their lengths, the string 2 will necessarily vibrate once, while the string 1 vibrate twice, and then exits an octave; but the twelfth does not yet exist, because the string 3 has not vibrated once, nor the string 1 twice, which is necessary to form a twelfth.

Again, for generating a fifth, the string 2 must vibrate thrice, and the string 3 twice; in which time, the string 1 will have vibrated 6 times; and thus the octave will be thrice produced, while the twelfth is only produced twice; the string 2 uniting its vibrations sooner with the string 1, than with the string 3; and they being sooner consonant than the string 1 or 2 with that 3. Whence, that author observes, many of the mysteries of harmony, relating to the performance of harmonious intervals, and their generation, are easily deduced.

But this rule, upon examining it by other instances, Mr. Malcolm has shown defective, as it does not answer in all positions of the intervals with respect to each other; but a certain order, in which they are to be taken, being required: and there being no rule, with respect to the order, that will make this standard answer to experience in every case; so that at last we are left to determine the degrees of concord by experience and the ear.

Not but that the degrees of concord depend much on the more or less frequent uniting the vibrations, and the ear's being
being more or less uniformly moved, as above; for that this mixture or union in motion is the true principle, or, at least, the chief ingredient in concord, is very evident: but because there seems to be something farther in the proportion of the two motions necessary to be known, in order to fix a catholic rule for determining all the degrees of concord, agreeable to sense and experience.

The result of the whole doctrine is summed up in this definition.—Concord is the result of a frequent union, or coincidence of the vibrations of two harmonious bodies, and, by consequence, of the undulating motions of the air, which, being caused by those vibrations, are like and proportionable to them; which coincidence, the more frequent it is, with regard to the number of vibrations of both bodies, performed in the same time, esteris parallelius, the more perfect is that concord: till the rarity of the coincidence, in respect of one or both the motions, produces discord.

See some of the remarkable phenomena of sounds accounted for from this theory, under the word Unison; &c. also Interval, &c.

Mr. Carre, in the Memoirs of the Royal Academy of Sciences, lays down a new general proposition, to determine the proportion which cylinders which have, in order to form the concords or consonances of music. And it is this—that the solid cylinders, whose sounds yield those concords, are in a triplicate and inverse ratio of that of the numbers which express the same concords.

Suppose, e. gr. two cylinders, the diameters of whose bases and lengths are as 3 to 2: it is evident their solidities will be in the ratio of 27 to 8, which is the triplicate ratio of 3 to 2: we say then, that the sounds of those two cylinders will produce a fifth, which is expressed by those numbers; and that the biggest and longest will yield the grave sound, and the smallest the acute one. And the like of others.

Concords are divided into simple, or original, and compound.

A simple, or original concord, is that whose extremes are at a distance less than the sum of any two other concords.

On the contrary, a compound concord is equal to two or more concords.

Other musical writers state the division thus: an octave 1: 2, and all the inferior concords above expressed, are all simple and original concords: and all greater than an octave, are called compound concords; as being composed of, and equal to the sum of one or more octaves, and some simple concords less than an octave; and are usually, in practice, denominated from that simple concord.

As to the composition and relations of the original concords, by applying to them the rules of the addition and subtraction of intervals, they will be divided into simple and compound, according to the first and more general notion; as in the following table:

<table>
<thead>
<tr>
<th>Simple Concord</th>
<th>Compound Concord</th>

</table>

The octave is not only the first concord in point of perfection, the agreement of whose extremes is greatest and the nearest to unison; infomuch that, when founded together, it is impossible to perceive two different sounds; but it is also the greatest interval of the seven original concords; and, as such, it contains all the lesser, which derive their sweetness from it, as they arise more or less directly out of it; and which decrease gradually, from the octave to the lesser sixth, which has but a small degree of concord.

A remarkable circumstance is the manner wherein these minor concords are found in the octave, which shews their mutual dependences.

For, by taking both an harmonical and arithmetical mean between the extremes of the octave, and then both an harmonical and arithmetical mean between each extreme, and the most distant of the two means last found; viz. between the lesser extreme and the first arithmetical mean, and between the greater extreme and the first harmonical mean; we have all the lesser concords.

Thus, if between 360 and 180, the extremes of octave, we take an arithmetical mean, it is 270; and an harmonical mean is 240; then, between 360 the greater extreme, and 240 the harmonical mean, take an arithmetical mean, it is 300; and an harmonical mean is 288. Again, between 180 the lesser extreme of the octave, and 270 the first arithmetical mean, it is 225, and an harmonical one 216.

Thus, we have a series of all the concords, both ascending towards acutenesses from a common fundamental 360; and descending towards gravity from a common acute term 180: which series has this property, that taking the two extremes, and any other two at equal distances, the four will be in geometrical proportion.

The octave, by immediate division, resolves itself into a fourth and fifth; the fifth, again, by immediate division, produces the two thirds; the two thirds are therefore found by division; though not by immediate division; and the name is true of the two thirds. Thus all the original concords arise out of the division of the octave; the fifths and fourths immediately and directly, the thirds and sixths mediately.

From the perfection of the octave arises this remarkable property, that it may be doubled, tripled, &c. and yet will preserve a concord, i.e. the sums of two or more octaves are concords; though the more compound will be gradually less agreeable: but it is not so with any other concord less than octave; the doubles, &c. of which are all discords.

Again, whatever sound is concord to one extreme of the octave, is concord to the other also; and if we add any other simple concord to an octave, it agrees to both its extremes; to the nearest extreme it is a simple concord, and to the farther a compound one.

Another thing observable in this system of concords is, that the greatest number of vibrations of the fundamenta cannot exceed five; or that there is no concord where the fundamental makes more than five vibrations, to one coincidence with the acute term. It may be added, that this progress of the concords may be carried on to greater degrees of composition, even in infinitum; but fill the more compound, the less agreeable.

So a single octave is better than a double one, and that than a triple one; and so of sixths, and other concords.

Three or four octaves form the extremes of all the intermediate sounds; what will afford all the variety of pleasure the harmony of sounds is capable of affording, or at least that we can receive; for we can hardly rate any sound beyond that compass, either by voice or instrument, that shall not offend the ear.

The phenomena attending simultaneous sounds have been considered by Euler, and treated of in his clear and peripatetic...
CONCORD.

On testing a simple musical sound, our ear is struck with a series of vibrations equally distant from each other, the frequency and number of which, in a given space of time, contribute the difference which subsists between low notes and high; so that, the smaller the number of vibrations or strokes produced in a given time, by a second, the lower we estimate that note; and the greater the number of such vibrations, the higher is the note. The perception of a simple musical sound may, therefore, be compared to a series of dots equidistant from each other, as . . . . . . .

If the intervals between these dots be greater or smaller, the sound produced will be lower or higher. It cannot be doubted, that the perception of a simple sound is somewhat familiar, or analogous, to the sight of such a series of dots equidistant from each other: we are enabled thus to refer to the eye, what the ear perceives on hearing sound. In the distance between the dots were not equal, or if these dots were scattered about confusedly, they would be a representation of a confused noise, inconsistent with harmony. This being laid down, let us consider what effect two sounds emitted at once, will produce on the ear. First, it is evident, that if two sounds are equal, or if each performs the same number of vibrations in the same time, the ear will be affected in the same manner as by a single note; and, in music, these two notes are said to be in unison, which is the simplest union or combination of two sounds: we mean by the term the blending of two or more sounds heard at once. But if two sounds differ in respect of low and high, we shall perceive a mixture of two series of pulsations, in each of which the intervals are equal among themselves, but greater in the one than in the other; the greater intervals corresponding to the lower note, and the smaller to the higher. This mixture, or this combination of two notes, may be represented to the eye by two series of dots, arranged on two lines, A B, and C D;

```
A 1 2 3 4 5 6 7 8 9 10 11
B 12
C 1 2 3 4 5 6 7 8 9 10 11 12
D
```

and in order to form a just idea of these two series, we must have a clear perception of the order which subsists among them, or, in other words, of the relation between the intervals of the one line and of the other. Having numbered and marked the dots of each line, and placed No. 1 under No. 1; those marked with the figure 2, will not exactly correspond, and still less those marked 3; but we find No. 11 exactly over No. 12; from which we discover that the higher note makes twelve vibrations, and the other only 11. If we had not affixed the figures, the eye would hardly have perceived this order; it is the same with the ear, which would with much difficulty have traced it in the two notes, which are represented by two rows of dots. But in the following figure,

```
1
2
3
4
5
6
7
8
9
10
11
12
```
you discover at the first glance, that the upper line contains twelve as many dots as the under, or that the interval8 in the under are twice as great as those of the upper. Th9 is undoubtedly next to unison, the simplest of all cases, in which you can at once discover the order which subsists between these two series of dots; and the same thing holds with respect to the two notes represented by these two lines of dots: the number of vibrations contained in the one, will be precisely the double of the vibrations contained in the other, and the ear will easily perceive the pleasing relation of these two sounds; whereas, in the preceding case, it was extremely difficult, if not impossible, to discriminate. When the ear readily discovers the relation subsisting between two notes, their combination is denominated consonance; and if it be very difficult, or even impossible, to catch this relation, the combination is termed dissonance. The simplest consonance, then, is that in which the high note produces precisely twice as many vibrations as the low note. This consonance, in the language of music, is called octave; every one knows what it means; and two notes which differ precisely in octave, harmonize perfectly, and possess such a complete resemblance, that musicians mark them by the same letters.” Euler’s Letters, vol. i.

Let the series of equal parts contained in the parallel right lines 01, 02, 03, &c., figure a, Music-Plates, represent the series of equal times between the successive pulses of air that beat on the ear, when the single sounds 01, 02, 03, &c. are heard respectively; then, when any two of these sounds are heard together, the combination of the two corresponding lines, will rightly represent the two series of equal times, if the magnitude of the equal parts in one line be to the magnitude of those in the other, in the ratio of the single vibrations of the sounds; or, the whole lines being supposed equal, if the number of aliquot parts in each be severally the same, as the least numbers of the vibrations of each sound, made in the same time. And the points which divide the separate lines, will subdivide the combined lines into smaller portions, as in fig. b, where 04 represents a third series, or cycle of times, in which the pulses of the sounds 02 and 03 interchangeably succeed each other in beating upon the ear; in like manner 04 and 05 will represent the cycles respectively produced, by the union of the sounds 03 and 04, in the first case, and 03 and 05 in the second case, &c. See Cycles.

According to Dr. Smith, (Harmonics, p. 15.) such a mixture of pulses, succeeding one another in a given cycle of times, terminated at both ends by e incident pulses, and sufficiently repeated, is the physical cause that excites the sensation of a given consonance or concord; especially when considered as distinct from any other consonance, whose single vibrations having a different ratio from that of the former, will constitute a different cycle, and excite a different sensation. And although the absolute times may be different, yet if the ratio is the same, the consonances are similar, and may be looked upon as the same in this respect, that their cycles have the same form; the times in both having the same order, and the same proportions. And that this form of the cycles serves to excite the sensation of a particular concord, is evident, from considering, that if the agreeable sensation of consonances, according to the received principle in harmonics, be the result of the frequent coincidences of their pulses, and consequently be more or less agreeable, according as the coincidences are more or less frequent; all the consonances in tempered systems, whose vibrations are incommensurable, ought to be the greekest discords in nature; it being impossible for their pulses to coincide more than once in an infinite time. For as no two numbers, how large soever, can express the ratio of such vibrations, so no multiple of one vibration can ever be equal to any multiple of the other. And yet experience shews that
that such confonances are much more agreeable than perfect discords, whose pulses coincide very often.

We may, indeed, says Dr. Smith (p. 99.) approach as near as we please, and certainly much nearer than the lente can dilullh, towards the exact magnitude of an incommensurable ratio, by the ratios of whole numbers; but as these will grow larger and larger without bounds, so will the time between the successive coincidences, or the length of the approximating cycle of the pulsus by which it is meant the time of either of the incomensurable vibrations, multiplied by the heterologous term of the approximating ratio. Let any man tell us then where we may stop, and which of those cycles it is, whose repetition excites the determine fenation of the confonance.

The like difficulty occurs in approaching gradually even to a commensurable ratio of the vibrations of any perfect confonance. For, if either of its vibrations be pretty much altered at once, and then be made to approach by degrees to its former length, the terms of the several approximating ratios will grow larger and larger without bounds, and in regular order, except when ratios occur whole terms are reducible; and the cycles of their pulses will accordingly be longer and longer, and their coincidences fewer without limit, those interruptions excepted; and yet the confonance will grow better and better by regular degrees, till it arrives at perfection, as is certain by experience. For instance, the ratio 10 to 21, 300 to 221, 3000 to 2101, &c. approach nearer and nearer to 3 to 2. and the Viths, whose vibrations are in those ratios, grow more and more harmonious, though the cycles of their pulses grow longer and longer to infinity.

It seems indispensible, that coincident pulses are not necessarily to such harmony as the ear judges to be perfect. For if any long period of imperfect unisons, intercepted between two beats, be lengthened greatly and indefinitely, as in tuning an instrument, any given part of it, as long as any musical note, will approach indefinitely near to perfect unisons; certainly nearer than the ear can dilullh, as being often doubtful of their perfection. And yet throughout that part (supposed to be small in comparison to the whole period) the pulses of one found divide the intervals of the pulses of the other very nearly in a given ratio, of any determined magnitude, between infinitely great and infinitely small, in proportion to the distance of that part from the periodical point or point of coincidence. Nevertheless, the ear cannot distinguish any difference in the harmony of such different parts, as is evident by often repeating the same confonance, which can hardly begin confluently in the same place of the long period, and this argument applies to all other confonances besides unisons.

Dr. Robinson supports this train of argument, by a reference to the well known fact, that if two musical instruments, as two organ pipes, tuned so exactly in unison that their pulses may be supposed to begin and end at the same instants, making the most perfect coincidence of pulses, be placed at a given distance from each other, and sounding the confonance will be perfectly the same, in whatever part of the room or space round the sounding pipes the ear of an auditor may be placed; while, owing to the time taken up by found in travelling through a given space, it is evident that the supposed coincidence of the pulses in the sounds cannot so affect or reach an ear unless it be placed exactly at equal distances from each of the sounds; whereas, by placing himself exactly in the middle of the right line joining two union sounds, and gradually approaching one of the sounds, every possible diludation or deviation of the pulses from coincidence will prevail, in their action upon one of the ears of an observer, while in most cases the other ear will be very differently affected, owing to its relative distances from the sounding bodies being different. And hence, as Dr. Robinson concludes, — a musical found is the termination of a certain form of the aerial undulation which agitates the auditory organ. The perception of harmonious found is the sensation produced by another definite form of the agitation; this is the composition of two other agitation; but it is the compound agitation only that affects the ear, and it is its form or kind which determines the sensation, making it pleasant or unpleasant, or in other words, a concord or a discord.

On the supposition that nature has appointed no certain limits between concords and discords, Dr. Smith (Harmon. p. 15.) inquires into the order of simplicity of the confonances between different founds, perfectly adjusted according to their ratios, on the principle, that one confonance may be considered as more or less simple than another, according as the cycle of times belonging to it is more or less simple than the cycle belonging to the other, or, as the sum of the least terms expressing the ratio of the single vibrations is smaller than the like sum in the other confonance; and that, when several such sums are the same, those confonances are Simpson to the same order as the lesser terms of their ratios are smaller, and he divises the confonances in a table, differing little, except in arrangement of the columns, from the following:

<table>

</table>

The first and second columns of this table can scarcely need any explanation; the third contains the concords, major and minor, expressd as in the second column of the general table of concords, which follows in this article: the blanks in this column denote the discords, such as are marked with a *, being composed of primes larger than 5, as 7, 11, 13, &c., and have no existence in music, except in the false notes of
of the Trumpet, Horn, &c.; see those articles: the others, or their octaves, will be found in the table of Discords: see that article.

On the other hand, Dr. Robison and other writers have maintained, and we think fairly, that nature has not left the concord without other distinctions than those of the expressions and uncertain preference given to them by musicians, but in addition to the almost universal delight which concords afford to every description of auditors, that the phenomena of flow and audible beats, accompanying each concord, when slightly tempered either in excess or defect, sufficiently distinguish each from all other musical intervals, comprised properly under the denomination of discords, or imperfect concords; and we cannot but agree with Dr. R., in thinking, that the study of the principles of harmonics would be greatly facilitated by considering the concords as the elements or fundamental intervals of melody fixed by nature, and that we should proceed to supply the other steps wanting in the scale, from their differences or combinations, rather than by affuming the tones and hemitones (which are discords that the most refined ear cannot accurately distinguish) to be the elements for composing the practical intervals of music; which it is not meant to contend, that they cannot accurately do in theory, but that concords of the truth or exact magnitude of which ordinary ears can at once judge with sufficient exactness (while the curious can attain them in practice, by help of the beats, to any defined degree of accuracy) are better adapted to the purposes of harmonical computations and reafonings, and will admit of a more direct and perhaps also of some new applications in practice.

For illustrating this subject, we beg to allow to mention an experiment by Dr. Robison, made with a wheel monochord, perhaps improperly so named, because it had two strings, which, by means of a refined revolving wheel, could be made to yield clear and even sounds for any required space of time: one of the strings giving constantly the same sound, while the length of the other, after being accurately tuned in unison therewith, admitted of being shortened in any required degree, without altering its tension.

Beginning with the unison (but which was not exactly the order in the Doctor's experiment), the moveable bridge, which determined the length of the variable string, was slowly and gradually moved forwards: at first a very slow, and by degrees a quicker, beating of the imperfect unison was heard, which increased in rapidity until the beats could no longer be counted, and at length they became a violent rushing flutter, which degenerated into a disagreeable jar. Still advancing the bridge, vile discordant noises resulted from the sound of the two strings, until the variable string had been shortened nearly \( \frac{1}{2} \), or when a little more than \( \frac{1}{2} \) of the string continued to sound: when a very rapid angry flutter commenced, that became rather less rapid and offensive as the point \( \frac{1}{2} \) was approached, and again increased after that, until the discordant jar prevailed again; and this continued, until the \( \frac{2}{3} \) of the string was approached. When a similar flutter commenced, decreased, and again increased as this point was passed by the bridge; the jar beginning again, and accompanying the motion of the bridge, until it almost arrived at \( \frac{2}{3} \) of the string's length, when a flutter and rapid beat commenced, decreasing in frequency, until at \( \frac{2}{3} \), or when the minor third \( (\frac{3}{2}) \) was sounded, they ceased entirely, and the result was a concord rather agreeable than otherwise, but strongly marked by a mournful melancholy in the expression; which, being sufficiently noticed, the bridge was again advanced, and produced the same beating, flow at first, then quicker, and at length fluttering, until the like grating dissonance succeeded as before. This continued, until near the point marked \( \frac{4}{3} \), when the beating again commenced, having a peculiar frightful expression as they decreased in quickness, owing to the advance of the bridge, to the point of the major third \( (111) \), where the beats ceased, and the pungent and envenoming and gay character of this concord was experienced by the hearers, who noticed an angry and wrathful expression to accompany the succeeding beats as the string shortened, but which gave place gradually to the same flutter and jar as before.

When little more than \( \frac{4}{3} \) of the string's length continued to sound, the flutterings and rapid beats were again heard, and the latter decreased and ceased entirely, at the point marking the fourth \( (\frac{4}{3}) \) which was noticed as a soft and agreeable concord. To this first flow, and then rapid, beats succeeded, and rapid flutterings, and a jarring noise. Near \( \frac{5}{3} \) of the string the fluttering commenced again, and decreased until about into one could be counted in a second of time as the false IV was passed, after which they increased again in rapidity as the bridge advanced, and an indistinct and jarring noise succeeded, which soon again became a flutter that decreased until at \( \frac{5}{3} \) of the string about eight of the angry flutterers could be counted in a second, corresponding to the false fifth; after which they increased in rapidity, and the jarring noise was again heard.

The bridge being progressively moved, the flutterings began, beats succeeded, and passed into a gentle and not unpleasant undulation which ceased entirely at \( \frac{5}{3} \) of the string, when the fifth (V) with the cheerful sweetness which characterizes it, was heard in the accordance of the two sounds, neither of which could be separately distinguished: after which the flow and rapid beats, and fluttering, and jar succeeded as before. Some time before the bridge reached the mark for \( \frac{6}{3} \) of the string the flutter and beats began again, and at that point the minor fifth \( (\frac{6}{3}) \) a confluence in a slight degree pleasant was heard of a mournful character, without any beating, but which were heard to recommence and increase as the bridge advanced; and the jarring dissonance continued, until little more than \( \frac{6}{3} \) of the variable string was left sounding, when flutters and beats succeeded, and such ceased when the true major fifth \( (61) \) was heard, the character of which it was found difficult to express, otherwise than as being greatly inferior to the V in sweetness, and to the III in gravity, but passing in a lower degree both of these qualities: shifting the bridge forwards, beats, flutters, and discordant noises succeeded, attended with two perceptible changes to flutters, in its progress towards the \( \frac{5}{3} \) of the string; which was not reached without the violent flutters, rapid and slower beats, so often before described; but when the beats ceased the true octave \( (\frac{8}{3}) \) was heard, the treble note being with difficulty distinguished from the bas or fundamental afforded by the other string, and not at all if the notes were duly portioned in loudness. After this, if the bridge was still further advanced, beats, flutters, &c. succeeded as before, answering to the octaves of the sounds already described, as the bridge advanced to make half of the lengths of the former strings, respectively.

The doctor concludes his account of this very interesting experiment by remarking, that he has perhaps been rash in allusing certain moral or sentimental characters to certain concords; because he had few instances of persons who gave them different denominations, but these were very contradictory to his, but always expressed some sentiment allied to those above assigned. A person capable of a little determining reflection was never met with by the doctor, who did not acknowledge a manifest sentimental distinction among the different
different concords, which could not be confounded. Speaking in another place on this subject, the doctor remarks, that he had made numberless trials of the different concords with persons altogether ignorant of music; none of all thus examined had much pleasure from an octave; all without exception, were delighted with a fifth, and with a major third, and many of them preferred the latter. All of them agreed in calling the pleasure from the fifth a sweetness, and that from the major third a cheerfulness or fineness, or by names of similar import. The greater part preferred even the major sixth to the fourth, and some felt no pleasure at all from the fourth. Few had much pleasure from the minor third or minor sixth. Care was in the above instances taken to find these concords without any preparation, merely as founds, not as making part of any musical passage, circumstances which have great effect on the mind. When the minor third and sixth were heard as making part of the minor mode, all were delighted with them, and called them sweet and mournful. In like manner the chord never failed to give pleasure. Dr. Smith (Harmonics, p. 21.) seemed to think that the concords within the octave would be found to affect the ear with smoother and pleasanter sensations in the following order: viz. VIII, 5, 4, VI, III, 3, 6, the last being the least harmonious; but this conclusion he seems to have formed from the numerical simplicity of their ratios as expressed in his Table above, rather than from a series of experiments on their effects: but it is plain that this cannot express the order of harmoniousness, because four discordant will be found to intervene among the seven concords above, two of which also include the primes 7 and 11, which excludes them from our scale of music.

It will appear from the above, that each of the seven concords has a natural foundation and place in the scale of melody, but perhaps they will not all be found equally fit to be considered as elements in composing the scale. Reflecting which, it may be right here to observe, that no general and strictly accurate method of notation, for composing or viewing the relations of musical intervals, can have less than three terms (for logarithms are only an approximation to the ratios, depending on the number of places of figures used) whether these are the musical integers, 2, 3, and 5; the intervals T, 7, and 4, &c, or any other (Phil. Mag. xxiv. 105, and xxv. 140). The comparative perfection of the harmony of the VIII, V, and 4, the facility with which they are to be tuned by the ear, and the simplicity of their ratios 2, 3, and 2, might seem to point them out as the most eligible, for concordant elements of the scale, but considerable experience in these kinds of calculations and inquiries has led us to prefer the three smallest concords, or 4, 3, and 4 for this purpose; (see Common Chords) because subtration of the ratios is thereby most avoided, at the same time that the larger concords can by inspection be formed, out of these, in most instances. The following Table has been calculated and arranged with considerable care and trouble, and it will, we hope, prove useful to our musical readers in saving much of their time when pursuing these curious and useful speculations.

### A TABLE of the Relations which the several Concordts bear to the Key-Note, within the Comps of Seven Octaves.

</table>

The titles of the columns are placed at the bottom of the foregoing Table, because it is intended to be read from the bottom upwards, agreeably to the practice of musicians, who read their notes upwards. Column 1 contains the number of finger-key intervals or half-notes: it will be found of use in rough calculations respecting musical intervals; thus, suppose a VI were to be added to a 6, and it was required to know on what note the sum would fall, we have 9 + 8 = 17, which answers in the Table to the 11th, and which happens to be exactly their sum, as is evident by comparing column 7, fuppofe again, that it was required to know the interval answering to three III, we have in this case 4 x 3 = 12; this in the Table answers to the VIII, but it is evident from col. 7, that this is only an approximate value, because this is 4 + III + 3 instead of 3 III, the difference being an enharmonic diesis, or the Tierce wolf of earl Stanhope.

Column 2 contains the marks of the intervals, the major intervals being denominated by Roman, and the minor intervals by Arabic characters, or numbers. Column 3 shows the notes of the gamut, distinguishing the seven different octaves, the first or lowest by Roman capitals, the next by Italic small letters, the third by the same, the fourth by the same double accented, the fifth by three accents, and the sixth and seventh octaves by small figures or indices, to express the number of accents.

Column 4 contains the ratios of the several notes, in their lowest terms. Column 5 contains the common or Briggs's logarithms to eight places of figures, the last being separated by a comma, in order to agree with the common Tables;
Concord. Table}, which have only seven places: whenever this number only is wanted, the seventh figure must be increased an unit, in every case where the eighth figure in the table exceeds 5.

Column 6 shows the ratios, expressed in their component primes, for the convenience of decomposing the fame into tunable intervals, as explained in our article Comma; thus, the second fraction, or $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}$ may be divided or expressed by $\frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}$, which shows it to be equivalent to $6 \times 8 + 6$, as in column 7. The fraction answering to the $\frac{1}{4}$, or $\frac{1}{2} \times \frac{1}{2}$ may be thus stated, viz., $\frac{1}{2} \times \frac{1}{2}$, or $\frac{1}{2} \times \frac{1}{2}$, the left term being negative, because the ratio or fraction expressing it is found reversed.

Column 7 contains several different values of each interval in colors, all expressed in tunable intervals, or chords; the first, in each case, is expressed in the concordant elements, or smallest concords 4, 3, and 3; the next expression in each line has one or more VIIth vii. in its composition; we have next given those tunable intervals, which are found to express each interval by two terms only; and have then added two others, (being all that our room would admit) of the various expressions in tunable intervals, which can be had for any concord in col. 2, especially if negative signs are admitted, as we have done in the lowest octave of our table. Matter for curious reflection will present itself to the musical student, who attentively considers the last column of our table, such as 11, that the octave is the only concord which admits of being added to itself, without producing a discord; 3rdly, that the complement of every concord to an octave (or to 2, 3, 4, &c. octaves,) is a concord; 4thly, that all the simple combinations by one, by two, or by three, of our concordant elements 4, 3, and 3, produce concords; 5thly, after these simple combinations are made, no farther ones can be made, except the addition of an equal number of each of the concordant elements (as $4 \times 3 + 3 \times 4 + 2 \times 3 + 3 \times 4$ &c.) without producing discords &c. If the difference between any two concords be wanted, as between the XVII and the X, such is readily obtained from column 7th thus; $4 \times 3 + 3 \times 3 + 3 \times 4 - 2 \times 3 - 3$ is equal to $4 \times 3 + 3 \times 3$, or the octave. The sum also of any concords, as a VI and a 6th, is thus obtained; $4 \times 3 + 3 \times 3 + 3 \times 4$, which answers to the 11th, as before observed, when explaining the uses of column 1.

It may be of use here to mention, that the differences between each adjoining concord, in each several octave in column 7, will be found to be $3^2$, $3 - 3$ (or the minor femtene, $3^2$), $4 - 3$ (or the major femtene $4^2$) $3 + 3$, or $V - 4$ (or the major femtene $4^2$), $4 - 3$ (or the major femtene $4^2$), $3 - 3$, and $3^3$; and this, whether we begin at the top or at the bottom of the octave, which shews that nature has distributed these fix concords, in a surprisingly uniform manner, between the union and the octave. The intervals which will, in addition to those above, be found by deducting every concord within the octave from each other, are, $4 - 3$ (or the minor tone $4^2$) and $4 \times 3 + 3$ (or the comma deficient tritone or harp fourth $4^2$).

It has been remarked by Mr. I. Holdin, that the number 6 combined with itself, or with every less integer, produces in every instance a concord, thus $6^2$, $6 \times 5$, $6 \times 4$, $6 \times 3$, and $6 \times 2$, express the union, $9^2$, $6 \times 8$, $6 \times 7$, $6 \times 6$, $6 \times 5$, and $6 \times 4$, express the concord, or Concordia, in Mythology, was personified by the Romans, and worshipped as a deity under this appellation. Concord is commonly represented on coins as a graceful female, holding a cup in her right hand, and in her VOl. IX.
his. The work is in four volumes folio, printed at Rome in 1621.

Of all the helps towards understanding the Hebrew Scriptures, says Dr. Geddes (Prospectus, p. 71) a good concordance is undoubtedly the most useful. But we yet want a good concordance; and the man who should devote five or six years to the compiling of one from Buxtorf, Calado, Noldus, Taylor, Kircher, Montfaucon, and Trompou, would do a flagitious service to biblical studies. Buxtorf's method of arrangement, with very little improvement, should be strictly followed; the errors of orthography rectified from the authority of manuscripts and other sources of emendation; and the various acceptions of the same word in the ancient versions exactly noted and methodically distinguished. Such a work would be worth all the commentaries that have ever been made.

We have several very copious concordances in English; as Newman's, &c. But the last and best esteemed is that in 4to. by Alex. Cronin.

CONCORDANT Elements. In Myers, are the fourth (ad') the major third (III) and the minor third (g'). See Concord. Dr. Smith considers the major tone (7) the minor tone (1) and the hemitone (6) as elements; Harmonics, p. 13.

CONCORDANT Verbs, such as have several words in common; but which, by the addition of other words, convey an opposite, at least, a different meaning. Such are these,

\[
\begin{align*}
\text{Et} & \quad \text{Consil} \\
\text{Lur} & \quad \text{in} \\
\text{Venus} & \quad \text{nutritur} \\
\text{Somnia} & \quad \text{servat} \\
\text{Oligia} & \quad \text{ogulat}
\end{align*}
\]

CONCORDAT, in the Canon Law, denotes a covenant, or agreement concerning some beneficiary matter, as a resignation, permutation, promotion, or the like.

The council of Trent, s. vi. de reform., cap. 4. speaking of concordats made without the authority and approbation of the pope, calls them concordatia, quae tantum host obli-
gant autore, non juraecum. And the congregation of cardinals, who have explained this decree, declares also, that a concordat cannot be valid so as to bind successors, unless confirmed by the pope.

The concordat is also used, absolutely, among the French, for an agreement concluded at Bologna in 1516, between pope Leo X. and Francis I. of France, for regulating the manner of nominating to benefices. The concordat leaves in lieu of the pragmatic function, which has been abrogated; or, rather, it is the pragmatic function restored and reformed. The king went in person to the parliament to offer the concordat to be registered, and letters patent were made out, requiring all the judges and courts of justice to observe this act, and see it executed. The parliament, after deliberating a month upon this important matter, concluded not to register the concordat, but to observe still the pragmatic function, unless the former edict was received and established in as great an assembly as that was, which published the latter in the reign of Charles VII. And when, by violence and force, they were obliged to publish the concordat, they joined to the publication a solemn protest and an appeal from the pope to the next general council, into which measures the university and the clergy entered with the greatest alacrity and zeal. But royal and papal deposition at length prevailed. The chancellor De Prat, who was principally concerned in promoting the concordat, has been generally regarded as an enemy to the liberties of the Gallican church. The illusory and learned Hainault has defended his memory against this accusation, and justified the concordat as an equitable contract, and as a measure attended with fewer inconveniences, than the pragmatic

function. He observes, that by the king's being invested by the concordat with the privilege of nominating to the bishoprics and vacant benefices of the first class, many corruptions and abuses were prevented, which arose from thefinancial practices that prevailed almost everywhere, while, according to the pragmatic function, every church chose its bishop, and every monastic its abbot. He observes moreover, that this nomination was the natural right of the crown, as the most considerable part of the great benefices had been created by the kings of France; and he particularly insists on this consideration, that the right which Christian communities have to choose their leaders, cannot be exercised by such large bodies without much confusion and many inconveniences; and that the subject, by entangling their sovereign with the government of the state, invexed him, by his faults, with an authority over the church, which is a part of the state, and its nobility branch. The most specious objection that was made to the concordat was this: that, in return for the nomination to the vacant benefices, the king granted to the popes the annates or first fruits, which had too long been complained of as an intolerable grievance. There is, however, no mention of this equivalent in the concordat. And it was by a papal bull that succeeded this compact, that the pontiffs claimed the payment of the first fruits, of which they had put themselves in possession in the year 1316, and which had been refused by the pragmatic function.

As the concordat gave to the kings of France the absolute right of succeeding to all the great, or what are called the confessional benefices, of the Gallican church; it was a very important edict. Since the establishment of the pragmatic function and of the concordat, the clergy of France in general (before the late Revolution) manifested levy respect to the decrees of the papal court than the clergy of any other Catholic country. In all the disputes which their sovereign has had with the pope, they have almost constantly taken part with the former. Their independence on the court of Rome seems to have been principally founded on this act.

The concordat between the pope and the republic of Venice resembles the former. There is also a German concordat, made between the emperor Frederic III. and the princes of Germany, in 1448, relating to beneficiary matters, confirmed by pope Nicholas V.

CONCORDAT, as it is now used in France, is a term that applies exclusively to an agreement or convention exchanged between the pope, Pius VII., and the French government, the 23rd Fructidor, an. 9. or September the 10th, 1801. In this agreement the Roman Catholic religion is acknowledged to be that of the majority of the French people; and the better to consolidate the restoration of its worship, which had been almost totally neglected since the year 1792, the pope engages not to disturb the proprietors or purchaser of estates, which, before the French revolution of 1789, belonged to the church; and he acknowledges in the first article of the French government the same rights and prerogatives which the ancient government possessed. By virtue of the said concordat, the whole territory of European France is divided into ten archbishoprics; viz., Paris, containing eight bishoprics, Mantes fevrau, Belfort five, Lyons four, Aix four, Toulon five, Bourdeaux three, Bourges three, Tours seven, and Rouen four; and fifty bishoprics; viz., Troyes, Amiens, Soissons, Arras, Cambrai, Verfailles, Meaux, Orleans, Namur, Tournay, Aix la Chapelle, Troyes, Gand, Liege, Mayence, Aulnay, Metz, Strasbourg, Nancy, Dijon, Mende, Gresorer, Valkcan, Cambery, Nice, Avignon, Ajaccio, Digne, Cahors, Montpellier, Careafon,
Concordat. Agen, Bajme, Poitiers, La Rochelle, Angouleme, Clermont, Saint Flour, Limoges, Le Mans, Angers, Nantes, Kennes, Vannes, Saint Brieux, Quimper, Coutances, Bayeux, Sizy, and Evreux. The nomination to the sees rests with the French government; the pope only confirms each nomination by his canonical institution, according to the forms anciently established with regard to the Gallican church, whose privileges and immunities continue in full force. The bishops, before they enter upon their functions, shall take before the first confab, in person, the oath of fidelity which was in use before the change of government, expressed in the following terms: "I swear and promise to God, upon the holy evangelists, to preserve obedience and fidelity to the government established by the constitution of the French republic. I also promise to have no correspondence, nor to affit at any council or cabal, either within the country or out of it, that shall be contrary to the caufe of the public tranquility; and if in my diocese, or elsewhere, I shall learn of any plot or machination prejudicial to the state, I shall inform the government of it." The clergy of the second order shall take the same oath before the civil authorities appointed by the government. The following prayer shall be recited at the end of divine service in all the Catholic churches of France:

Domine, fulvam fac rem publicam! Domine, fac tus fac confules!

The bishops shall make a new division of parishes in their dioceses, subject to the consent of the government: the bishops shall name the curés, subject to the approbation of the government. The bishops may, however, have a chapter in their cathedral, and a feminary in their diocefe, but the government is not engaged to endow them. All the metropolitan, cathedral, parochial, and other churches, undisposed of, shall be placed at the disposal of the bishops. The government engages to secure a suitable provision for the bishops and curés, whose diocefe and parishes shall be marked out by the new division. The allowance of the archbishops shall be 15,000 livres annually, and that of the bishops 10,000. Bishops may add to their titles the qualification of "citoynen," or "monfieur." No man can be named a bishop but a Frenchman, aged at least 35 years, having an attestation of his morals delivered by a bishop, and after an examination of his doctrine by a bishop and two priests; nor shall bishops quit their fees without the permission of the first confab. Bishops are required to visit every year a part of their diocefe, and the whole every five years. No clergyman shall be ordained as priest, who is not 25 years of age, and possessed of 300 livres annual revenue. The curés shall reside in their parishes; and priests, who do not regularly belong to any diocefe, shall not officiate. The clergy in general shall wear black clothes; and the bishops violet coloured frockings. There shall be a liturgy and a catechism for the French church. The names of the days shall be as in the ancient calendar; and Sunday shall be the day of rest for the public functionaries; nor shall any other holidays, except Sundays, be kept without the consent of the government. The bells shall only be rung for divine service. The same temple shall be consecrated only to one form of worship. The nuptial benedictions shall be only given by the clergy to those who have been married by the civil officers.

With regard to the Protestant religion, no person shall exercise the ministerial functions but a Frenchman; nor shall the Protestant churches and their ministers have any connection with any foreign power. The ministers and their communities shall pray for the prosperity of the French republic, and the confabs. No doctrine, nor alteration of doctrine, shall be published or taught, without being first authorized by the government. The maintenance of the ministers shall be provided for, wherever the property and oblations of the communities fall short. The articles for the liberty of foundations, in the organic laws of the Catholic worship, shall be common to the Protestant churches. There shall be two seminaries, one in the city of Toulouse, for the instruction of ministers of the confession of Augsburg; and the other at Geneva for the reformed churches. The professors are to be named by the first confab, and no minister to be appointed without a certificate of his having studied in the seminary of his religion. The regulations of the seminaries are to be settled by the government. The reformed churches of France shall have pastors, local consistorys, and synods. Their clergy shall be a corporation for every 400 souls of the same commune. Five consistorial churches shall form the district of a synod. The number of ministers or pastors in the same consistorial church cannot be increased without the authority of government; nor can the pastors resign without altering their motives to government, which shall approve or reject them. The title of election shall be presented to the first confab for his approbation. Each synod shall consist of a pastor and a notable of each church. The synods shall superintend the celebration of worship and conduct of ecclesiastical affairs, and all their decisions shall be submitted for the approbation of government. The synods cannot assemble until they shall have received the permission of government; nor shall any synodal assembly last more than six days.

The churches of the confession of Augsburg shall have pastors, local consistorys, inspensions, and general consistorys. The pastors and consistorial churches shall be subject to the regulations prescribed for the reformed pastors and churches. The churches of this confession shall be subordinate to the inspensions. Five consistorial churches shall form an inspension, which is to assemble only by permission of government. Each inspension to elect an inspector, and two laymen of such choice to be confirmed by the first confab. There are to be three general consistorys; one at Strasburg, for the Protestants of Augsburg, of the departments of the Upper and Lower Rhine; a second at Mentz, for those of the departments of the Sarte and Mont-Tonnere; and the third at Cologne, for those of the departments of the Rhine, Moselle, and Roer.

Concordat Militaire, Fr., an agreement entered into by officers of the same corps, to establish a fund or provision for one of them that quitted it. This agreement, however, was only tolerated in particular cases and circumstances, to which the chiefs seemed to consent, without either openly, or with their signatures, giving their approbation to the same.

Concordia, in Antiquity Geography, a town of Italy, with the title of colony; placed by Ptolemy in the country of the Carpi, but by Piny in that of the Veneti, between Pons Lignacum and Titalagum. Eutropius and the Itinerary of Antonine place it in Venetia. It took the name of Julia, because a colony had been sent thither by Julius Caesar.—Allo, a town of Spain, placed by Ptolemy in Lusitania, supposed to have been the present Tamar.—Allo, a town and Roman fortress of Gaul, in Germany Prima, between Broconum and Noviomagus, according to the Itinerary of Antonine.

Concordia, in Geography, a town of Italy, in the duchy of Mirandola, on the Sesia; 6 miles W. of Mirandola; between which cities there is a fine canal, which facilitates the communication of both.—Allo, a town of Italy, in the country of Triul; which, though in ruins, is the lee of a bishop, who resides at Porto Creton.
CONCOTS, a town of France, in the department of the Lot; 3 leagues S. S.E. of Cahors.

CONCOU, in Botany, a name given by the people of Guinea to an herb which is in great esteem with them for killing that troublesome sort of worm called the Guinea-worm, which breeds in their flesh. They bruise the leaves, and mixing them with oil, apply them in form of a cataplasm. The leaves of this shrub somewhat resemble those of the cargon, but they are thicker and flatter, and are not so full of veins. They are broaded within one third of the base, and from thence they go tapering to each end. They are placed on long footstalks of a fine green throughout. Phil. Trans. No. 232.

CONCOURS, in Geography, a town of France, in the department of the Aveiron, and district of Rhodex; 7 miles N. N. E. of Rhodex.

CONCOURSE, or CONCURRENCE, the reciprocal action of divers persons or things co operating toward the same effect or end.

The schoolmen distinguish two kinds of concurrence; viz. immediate, which consists in giving a power or faculty to act; and immediate, which is a contemporary influence of one cause along with another, to produce an effect. Thus, the grandchild concurs mediate to the production of a grandchild, as he originally gives the power of generating to the father; but the father concurs immediately with the mother to the production of the same child. With respect to the agency of God, some divines maintain both these kinds of concurrence; others deny the latter. See Cause.

Concourse, Point of. See Focus.

CONQUE, Fr. A piece of artillery, of which the bore is wider towards the muzzle than towards the breech. It is also the name of a shell, which the ancients made use of in their armies instead of a trumpet.

CONCRESSAUT, or CONCRASSAUT, in Geography, a town of France, in the department of the Cher, on the Saudre, almost ruined by the civil wars; 25 miles N. of Bourges.

CONCRETE, in the School Philosophy, an assemblage, or Compound.

Concrete, Physical, or a Concrete body, may denote any mixed body, or body composed of different principles; and consequently, all sensible bodies whatever, as all bodies arise from a coalition of divers elements, or at least of divers principles, matter, and form.

But, in this sense, concrete is only used for those compounds wherein the ingredients still retain their distinct natures, nor are wholly converted into any new common nature.

Authors distinguish natural concretes and artificial ones: antimony is a natural concrete, and soap a fictitious concrete.

Concrete Juice. See Juices.

Concrete, Logical, or a Concrete word, called also paronym, is that which has a compound signification, as denoting both the subject and some quality or accident of the subject, which gives it its denomination.

Such, e. g., are man, learned, cubite; for man signifies as much as having human nature; learned, as much as having learning, &c. Hence, the word concrete is chiefly used to express the union of qualities or quantities with the bodies or subjects, without any separation, even in idea. The opposite term, whereby things are separated in thought, is abstract.

Concrete properly signifies a subject accompanied with its form or quality; as pious, hard, cubite: abstract, on the contrary, expresses the form and quality without the subject, as piety, hardness, cubitaten.

Concrete Numbers, are those which are applied to express or denote any particular subject: as two men, three pounds, two thirds of a shilling, &c.

Whereas, if nothing be connected with a number, it is taken abradically or universally: thus, three signifies only an aggregate of three units; let those units be men, pounds, &c.

Concrete, the act whereby soft bodies are rendered hard; or an insensible motion of the particles of a fluid or soft body, whereby they come to a confluence.

The word is used indifferently for induration, concretion, coagulation, and concretion.

Concrete is also used for the coalition of several little particles into a sensible mass, called a Concrete; by virtue of which union, the body acquires this or that figure, and these or those properties.

Concrete, in Surgery, from concretio, the adhesion or growing together of parts. This term also denotes the impacting or cohering of substances together, so as to form a mass; as in the fangous concretion, the biliours or biliary concretion, the calculous concretion, &c. The coalescence of parts which ought to be separate, as of the fingers and eyelids, might be rather called agglutination or cohere.

Membranes and other parts may adhere together, either from natural or accidental causes; but the most frequent cause of external concretions is an ulceration or abrasion of the skin, so that two surfaces lying in contact shall unite by inflammation and reparation, or granulation. In all such cases, where an operation is practicable and necessary, the surgeon must separate the united parts with a seapal, and keep them alunde during the cure. See Stone and Calculus.

Concupination sometimes expresses a criminal or prohibited commerce between two sexes; in which sense it comprehends adultery, incest, and simple fornication.

Promiscuous concupiscence is productive of a great variety of evils, and tends not only to the corruption, but to the ultimate destruction, both of individuals and of society. It is not only ineffectual to promote love, and the tender affections, either between persons themselves, or towards their offspring, but it contributes towards exciting and maintaining endless jealousies and quarrels among mankind. The great and radical mischief attending unrestrained promiscuous concupiscence in a state of society, consists in its tendency to diminish marriages, and thus to defeat the several beneficial purposes resulting from this institution. (See Marriage.) It discourages marriage by weakening the force of a very urgent motive and temptation to it, arising from the intention of the original former of mankind, and the constitution of human nature. "The male part of the species," says Dr. Paley, "will not undertake the incumbrance, expense, and restraint of married life, if they can gratify their passions at a cheaper price; and they will undertake any thing rather than not gratify them."

A just idea may be formed of the magnitude of this mischief, by attending to the importance and variety of the uses to which marriage is subservient; and by duly considering that the malignity and moral quality of each crime are not to be estimated by the particular effect of one offence, or of one person's offending, but by the general tendency and consequence of crimes of the same nature. The libertine may not be conscious that those irregularities hinder his own marriage; from which, as he may allege, he is deterred by different considerations; nor may he perceive, or be disposed to acknowledge, that his indulgences hinder the marriage of others;
others; but it behoves him to reflect, what would be the consequences of universal licentiousness in this respect, and what should prevent its becoming universal, if it be innocent or allowable in him. Moreover, fornication supports prostitution; and prostitution entails on its victims almost certain misery, occasioned by the indulgence, disfigure, and infamy, to which these wretched outcasts of society, who infest populous cities, are subject; the whole aggregate of which is a great consequence of fornication, and to the increase and continuance of which, every act and influence of fornication contribute. Besides, fornication promotes habits of ungodly lewdness, which introduce the more aggravated crimes of seduction, adultery, violation, &c.; to which we may add, in this connection, that the criminal commerce of the sexes depraves the mind and moral character more than any sanguinary fact of whatever; these indulgences prepare an easy admission for every other crime: in low life, they are usually the first stage in men's progress to the most deplorable vilenesses; and, in high life, to that lamented disfigurement of principle which manifests itself in a profligacy of public conduct, and a contempt of the obligations of religion and moral probity. Habits of libertinism also incapacitate and indispose the mind for all intellectual, moral, and religious pleasures, which would very much contribute to counterbalance the calamities of human life.

It deserves further to be considered, that fornication perpetuates a disease, which may be accounted one of the severest maladies of human nature; and the effects of which are said to contaminate the constitution of even distant generations. This dreadful malady, the feverous scourge, says Dr. Robertson, (Hist. of America, vol. ii. p. 87), with which, in this life, offended Heaven chastises the indulgence of criminal defiles, seems to have been peculiar to the Americans; and he adds, that by communicating it to their conquerors, they have not only simply revenged their own wrongs, but by adding this calamity to those which formerly embittered human life, they have, perhaps, more than counterbalanced all the benefits which Europe has derived from the discovery of the New World.

Dr. Hartley, in his “Observations on Man,” (p. 413), remarks, that the shameful, loathsome, and often fatal disease, which peculiarly attends the vice of lewdness, may be considered as a most unquestionable evidence of the Divine Will. This disease, with all its consequences, would for various moral purposes, could it be brought under the restraints of lawful marriage; but must ever continue, whilst licentiousness continues. Without this check, however, the licentiousness which has always been observed to follow improvements in arts and politeness, and to attend upon bodies politic in their declension, and which the corruption of the Christian religion in some, and the disbelief of it in others, have, in a manner, authorized, would have brought on utter disfigurement in this western part of the world, such as would have been inconsistent with the very existence of regular government. Nay, it may be, that this will still be the case, and that we are hastening to our period, through the great wretchedness of the world in this respect particularly, though our lives, as a body politic, be somewhat prolonged by this correction.

If we appeal to the Christian scriptures on the subject of this article, it is certain that these sacred writings condemn fornication absolutely and peremptorily, and that they class this crime with murders, thefts, false witnesses, and blasphemies. Besides, the aggravated sin of idolatry is represented by adultery and fornication in the prophetical writings. Although the scriptures give no sanction to those statutes which have been imposed upon the world under the name of Christianity, as the censures of the clergy, the practice of perpetual virginity, the "prohibito concubitiis cum gravida," yet, with a just regard to the condition and interest of all human species, as they have professedly been the frame of one man with one woman, an adequate gratification for the propensities of their nature, and have refrained them to that gratification. The avowed separation, and in some countries the licencing, taxing, and regulating of public brothels (see Bawdy houses), have appeared like a fiction of fornication, and have contributed, with other concurring causes, so far to vitiate the public opinion, that there is no practice, the immorality of which is so little thought of or acknowledged, although there are few in which it can be more easily and more satisfactorily evinced. The legislators who have patronized receptacles of prostitution ought to have foreseen this effect, and also to have considered, that whatever facilitates fornication, diminishes marriage. As to the usual apology for this relaxed discipline, the danger of greater enormities if access to prostitutes were too freely watched and prohibited, "it will be time enough," says Dr. Paley, "to look to that, when the laws and magistrates have done their utmost." After all, these fears are without foundation in experience. The men are in all respects the most virtuous, in countries where the women are the most chaste.

In its more refrained senses, cohabitation is used for a man's and a woman's cohabiting together in the way of marriage without having passed the ceremony thereof.

This species of cohabitation is, without doubt, distinguished from vagrant concubinage, and by reason of its resemblance to marriage, may be thought to participate of the sanctity and innocence of that state. In modern phrase, it is denominated "the keeping of mistresses," under the favoured circumstance of mutual fidelity. For this practice the following kind of apology has been sometimes alleged:

"That the marriage rite being different in different countries, and in the same country among different sects, and with some, fearlessly any thing; and, moreover, not being preferred or even mentioned in scripture, can be regarded only as a form or ceremony of human invention; and that, consequently, if a man and woman betroth and confine themselves to each other, their intercourse must be the same, as if they were legally married; for the addition or omission of that which is a mere form and ceremony can make no difference in the light of God, or in the actual nature of right and wrong."

To this species of reasoning, archdeacon Paley has replied:

1. If the situation of the parties be the same thing in marriage, why do they not marry? 2. If the man choose to have it in his power to dismiss the woman at his pleasure, or to retain her in a state of humiliation and dependence inconsistent with the rights which marriage would confer upon her, it is not the same thing. 3. It is not at any rate the same thing with respect to the children. Moreover, as to the marriage rite being a mere form, and that also variable, the same may be said of signing and sealing of bonds, wills, deeds of conveyance, and the like, which yet make a great difference in the rights and obligations of the parties concerned in them. And with respect to the rite not being appointed in scripture, the scriptures forbid fornication, that is, cohabitation without marriage; leaving to the interpretation of the point to pronounce what is, or what makes, a marriage; in like manner as they forbid theft, that is, the taking away of another's property, leaving it to the municipal law to fix what makes the thing property, or what it is, which also,
as well as marriage, depends on arbitrary and mutable forms. Independently of the injunctions of scripture, the plain account of the scriptural seems to be this; it is immoral, because it is precarious, that man and woman should cohabit, without undertaking certain irrevocable obligations, and mutually conferring certain civil rights: if, therefore, the law has annexed these rights and obligations to certain forms so that they cannot be secured or undertaken by any other means, which is the case in this instance (for whatever the parties may promise to each other, nothing but the marriage ceremony can make their promise irrevocable), it becomes in the same degree immoral, that men and women should cohabit without the interposition of these forms. Paley’s Principles of Moral and Political Philosophy, vol. 1. b. 3. c. 2.

Concubinage was anciently tolerated: the Roman law calls it an allowed custom, liberty confectu. When this expression occurs in the constitutions of the Christian emperors, it signifies what we now call a “marriage in conscience.”

The concubinage tolerated among the Romans in the time of the republic, and of the heathen emperors, was that between persons not capable of contracting marriage together: nor did they even refuse to let inheritances descend to children which sprang from such a tolerated cohabitation.

Concubinage between such persons who looked on as a kind of marriage, and even allowed it several privileges: but then this concubinage was confined to a single person, and was of perpetual obligation, as much as marriage itself. Hottomans observes, that the Roman laws had allowed of concubinage long before Julius Caesar made that law whereby every one was allowed to marry as many wives as he pleased. The emperor Valentinian, Socrates tells us, allowed every man two.

Concubinage is also used for marriage performed with less solemnity than the formal marriage; or a marriage with a woman of inferior condition, and to whom the husband does not convey his rank, or quality.

Cujas observes, that the ancient laws allowed a man to espouse, under the title of concubine, certain persons, such as were esteemed unequal to him. On account of the want of some qualities requisite to sustain the full honour of marriage. He adds, that though concubinage was beneath marriage, both as to dignity, and civil effects; yet was a concubine a reputable title, very different from that of mis-treff among us.

The commerce was esteemed so lawful, that the concubine might be accused of adultery in the same manner as a wife.

This kind of concubinage is still in use in some countries, particularly in Germany, under the title of a half-marriage, morgengalic marriage, or marriage with the left hand; alluding to the manner of its being contracted, viz., by the man’s giving the woman his left hand instead of the right.

This is a real marriage, though without solemnity: the parties are both bound for ever; though the woman be thus excluded from the common rights of a wife, for want of quality or fortune.

The children of concubines were not reputed either legitimate or bastard, but natural children, and were capable only of donations.

They were deemed to retain the low rank of the mother; and were on this ground unqualified for inheriting the effects of the father.

Concubinage, in a Legal Sense, is used as an exception against her that sufh for dower, alleging thereby, that she was not a wife lawfully married to the party, in whose lands she seeks to be endowed, but his concubine. Brit. c. 107. Bract. lib. iv. tract. 6. cap. 8.

Concubine, a woman whom a person takes to cohabit with him, in the manner, and under the character, of a wife, without being authorized thereto by a legal marriage.

Concubine is also used for a real, legitimate, and only wife, distinguished by no other circumstances but a disparity of birth or condition between her and the husband. Du-Cange observes, that one may gather from several passages in the epistles of the popes, that they anciently allowed of such concubines. The fourteenth canon of the first council of Toledo declares, that he, who with a faithful wife keeps a concubine, is excommunicated; but that if the concubine served him as a wife, so that he had only one woman, under the title of concubine, he should not be received from communion, that she who had legitimate wives under the title of concubines.

In effect, the Roman laws did not allow a man to espouse whom he pleased; there was required a kind of parity, or proportion, between the conditions of the contracting parties; but a woman of inferior condition, who could not be espoused as a wife, might be kept as a concubine; and the laws allowed of it, provided the man had no other wife.

It is certain the patriarchs had a great number of wives, and that these did not all hold the same rank; some being subaltern to the principal wife, which was what we call concubines, or half-wives. The Romans prohibited a plurality of concubines, and only had regard to the children springing from a single concubine, because the might become legitimate wives. Solomon had 700 wives and 300 concubines; the emperor of China has sometimes two or three thousand concubines in his palace. Q. Curtius observes, that Darius was followed in his army by 365 concubines, all in the equipage of queens; and Diodorus Siculus says, that he maintained as many as the days of the year. Artaxersxes had by his concubines 115 children. The concubines were introduced to the Persian king, each in her turn; whence some have concluded, that the ancient Persian year consisted of 365 days, since several of the Persian monarchs had this number of concubines, who went to their kings in constant course.

Concupiscence, among divines, an irregular desire, appetite, or lust after carnal things, inherent in human nature.

The dominion or prevalence of concupiscence, according to T. Miletbranche, is what we call original sin.

The origin of concupiscence he ascribes to those impressions made on the brain of our first parents at their fall; which are still transmitted and continued on those of their children; for as animals produce their like, and with like images in the brain (whence the same sympathies and antipathies in the same kind; and whence the same conduct on the same occasions); so our first parents, after their fall, received such deep traces in the brain, by the impression of sensitive objects, that they might well be supposed to communicate them to their children.

The schoolmen use the term concupiscent appetite for the desire we have of enjoying any good; in opposition to irissible appetite, whereby we effect what is evil.

Concurrence. See Concours.

Concurring, or Concurrent Figures, in Geometry, such as, being laid upon one another, do exactly correspond to, and cover one another, and consequently must
must be equal among themselves. Thus, triangles having two sides and the contained angle equal each to each, appear to be equal to one another in all respects. See Con-

**CONCUSSION.**

**CONCUSSION crimen repetundarum, in Jurisprudence,** is the abuse of power by some person entailed with a public commissio or employment; by extorting money from those under his power or command. This crime is taken notice of in the heads of the Digell, or Code — al legem Judic. - and is remedied in the same, but with respect to the crime itself.

**Concussion, in Surgery, from concussio, a shaking together.** This term is most applied to a violent commotion of the body, and especially of the brain; but a concussion of the nervous system in general, or of the spinal marrow in particular, may produce the same train of symptoms in a partial degree, as a commotion of the brain does in the whole body. A concussion of the brain may be occasioned not only by blows on the head, but also by violence inflicted upon other parts of the body. It is frequently occasioned by a fall upon the thighs when stretched out straight, or upon the breech; it is also observed in cases of contusion of the face, and fractured bones, occasioned by a fall from a considerable height, in gunshot wounds attended with a splintering of the bones, and, in general, in every case of external violence attended with considerable commotion of the whole body. However, from whatever cause it may arise, it always requires surgical treatment.

When there are symptoms attending a fracture of the brain occur also in concussion; but in a compressed state of the brain they are more permanent. See Concussion.

There is no discharge of blood from the eyes, nose, or ears, which frequently happens in concussion; and instead of that apopleptic stertor in breathing which accompanies concussion, the patient seems to be in a sound and natural sleep. The pulse is irregular and slow in concussion, and grows stronger and fuller by bleeding; but in concussion it is weaker, being soft and equal, and sinks by bleeding. There are besides, convulsions in concussions, which are not observed in a state of concussion. The symptoms arising from concussion come on immediately after the injury is received. In the violent degrees of these, the patient remains quite insensible; the pupils are much dilated, and do not contract though the eyes be exposed to the strongest light.

In more violent accidents, especially when the patient is rendered insensible, it is extremely difficult to distinguish between concussion and depression; for symptoms which have been supposed to arise entirely from concussion, have, after death, been found to be owing to extravasation or undiscovered fracture; and extravasation has been blamed, when, on dissection, the leat morbid appearance could be discovered.

The symptoms consequent upon concussion of the brain are various, in proportion to the different degrees of the violence inflicted. In its lightest degree, it produces stupor and inclination to sleep, dulness of the intellectual and corporeal faculties, insensibility, or paralysis of some particular part. In the second degree, the patient lies without sensation and motion in a state of profound coma, from which he cannot be roused. But at the same time he is generally restless, tosses about, speaks much in his sleep, sometimes looks up, flares wildly, raves, is affected with convulsions, and generally his pulse betokens irritation. In the third degree, death supervenes, either immediately, or as the symptoms increase in violence.

These symptoms, however, are not always of the same nature and origin, and therefore require different methods of treatment. Thus the blood-vessels of the brain may be weakened in consequence of the violence inflicted; the blood may be preternaturally accumulated in them, and dilate them, to which sometimes also a congestion in the head contributes. Sometimes, also, the external violence acts upon the subflance of the brain itself and the whole nervous system, either by the irradiation or by the depression of parts of it, which it induces: in the first of these cases symptoms of delirium, delirious fits, want of sleep, or convulsions, are observed, and in the second the patient is thrown into a state similar to syncope.

Before the external violence has been inflicted, it may happen that the patient may have been in a state of great anxiety and fear, and he may have been greatly terrified by the danger whilst it was full impending, in which cases the consequences of these violent emotions of the mind, may be mistaken for effects of a concussion of the brain. The patient is in a very different state when the injury has been inflicted whilst he was intoxicated, or in anger, or when his stomach was full. Not unfrequently also some of the symptoms proceed from lesions of other parts of the body more remote from the head, or from collateral causes, especially from inflammatory, and bilious complaints in the vixera; which frequently produce not only a determination towards the head, but also various other symptoms indicative of irritation.

All these symptoms the surgeon must take into mature consideration, in order to be able to form a proper judgment concerning the state of the patient in whom he discovers symptoms of concussion of the brain. These symptoms are commonly of a fourfold nature; that is, they are symptoms indicative of compression of the brain, and arise from the congestions in the vessels; or they are symptoms of dulness and insensibility of the concussed nervous system; or they are symptoms of irritation in the nervous system; or finally, they are consequences of preternatural irritating causes in the abdominal vixera. Commonly the symptoms belonging to each of these four different heads are combined; but frequently those of one class are more violent than those of the rest, and to this circumstance the surgeon must especially attend in regulating his method of treatment.

With respect to the cure, much also depends upon making the proper distinction between the symptoms of concussion and those of extravasation. In many cases this may easily be done: for the symptoms of concussion come on immediately after the violence has been inflicted, whilst those of extravasation generally supervene within a longer or shorter time after. This criterion is however not always to be depended upon, nor discoverable in every case; for when the patient was alone at the time when the accident happened, and is now deprived of his senses, the surgeon cannot.
Concussion.

Whether the symptoms followed the accident immediately.

If the symptoms abate after the use of antiphlogistic remedies, such as blood-letting, evacuations, glisters, washing with cold water, &c., they ought to be continued but in the contrary case, they are to be relinquished and an opposite method of treatment adopted. The effects of blood-letting alone sometimes form an important criterion; for in cases of concussion of the brain it frequently lowers the pulse to a great degree, may, even aggravates the symptoms; whilst in extravasations, even though it be frequently repeated, it produces a far less decisive effect upon the pulse, and frequently alleviates the symptoms.

Amongst the various remedies that have been recommended in concussions of the brain, blood-letting is most generally employed; but it ought to be moderated. Topical abstraction of blood from the head has sometimes been found useful. Purgatives are always very serviceable, but in general it is necessary to administer them in large and repeated doses. Still more beneficial are emetics, and amongst these tartar emetic and vitriolated zinc commonly prove the most efficacious; though, on account of the insensibility of the patient, they must usually be administered in very large doses, in order to produce their effect. Many recommend also stimulating glisters, and various other stimulating remedies; such as the volatile alkalies, blisters applied to the head, and it is affirmed that some have even administered wine internally with the bell effects. Cold fomentations are here particularly useful, as they are adapted to all cases, as are likewise all the remedies usually employed in syncope. Where there are symptoms of irritation, spasms, and convulsions, antispasmodic remedies are frequently found to produce great benefit; and in these cases Dover's powder is particularly recommended. Before using it, the warm bath, and when the patient is plethoric, blood-letting is prefcribed. This remedy must be continued as long as the symptoms remain, and it must be repeated when they return. Also a mixture of three parts of Vin. Antimoni and one part Tinct. Theb. given in doses of ten drops every four hours, is found very useful. The use of laudanum alone has sometimes removed the symptoms of concussion.

Notwithstanding that all the above mentioned remedies and recommended by authentic experience, yet as they are so opposite to each other in their properties, it cannot possibly be advisable to prescribe them all together, or any single one in all cases; and the surgeon has therefore in every single case to choose those remedies that are particularly adapted to remove the most urgent symptoms of the case. Thus, when the symptoms of preternatural repletion of the vesicles of the brain are urgent, he must employ blood-letting, cold fomentations, evacuations, and glisters; to the latter of which it has been particularly recommended to add powder of squills: when the urgent symptoms are those of debility bordering on syncope, he may use volatile alkalies, wine, epiphatics, cold fomentations, emetics, and other tonic remedies; when the spasm, and symptoms are the most prominent, Dover's powder, Tinct. Antimoni, and laudanum; when the symptoms of bilious excitements prevail, emetics and purgatives.

As there is always reason at first to suspect an accumulation of blood, and to apprehend inflammation, it will almost always be advisable first to draw blood, unless it should be contraindicated by any peculiar symptoms. Stimulants and tonics will produce more benefit after the symptoms have continued for some time, than if administered at the beginning. If after the first or second blood letting, the pulse sinks whilst the other symptoms remain the same, or are even aggravated, it ought not to be perfused in, but a contrary mode of practice is to be attempted. We may expect advantage from blood-letting, purgatives, and emetics, when the pulse is full, hard, and quick; from antispasmodics, when it is small and hard; and from stimulant and tonic remedies, when it is small and soft. Neutral salts, gentle purgatives, and blood-letting, may be employed when the patient is strong, vigorous, plethoric, and fluid; stimulant antispasmodics, when he is weakly, very irritable, pale, and cold.

Finally, we must also attend to the state in which the patient has been before the injury: should he have received it whilst in a state of intoxication, cooling evacuations, and blood letting are necessary; if he has received it whilst his stomach was full, or whilst in a paroxysm of anger, emetics and antispasmodics are indicated; if whilst under the influence of great fear or apprehension, tonic and antispasmodic remedies will be proper. Moreover, the head of the patient must be carefully guarded against all motion and concussion during the course of the cure.

Should the patient recover under the use of the above-mentioned remedies, he must still for some time after carefully avoid all commotion of the head, and whatever tends to accelerate the circulation, as anger, wine, violent bodily exercise; it is also proper to continue still for some time, to wash or bathe the head in cold water; and sometimes to take tonic remedies, such as Peruvian bark, acid of vitriol, &c. When the patient, though in other respects recovered, still continues to labour under debility or paralysis of particular parts, these complaints may sometimes be removed by the continued use of internal and external tonics and stimulants, especially volatile alkali, emetics, blisters, electricity, &c. But when the symptoms increase in spite of the most careful treatment, the surgeon is authorized, especially when the diagnosis is doubtful, to suppurate an extravasation, and in the last instance he may be forced to amputate the part that has been injured. And supposing even that the surgeon has drawn a false conclusion, the operation of the trepan, skillfully performed, will do no harm, may, may even in some instances be productive of benefit, in consequence of the discharge of blood which it occasions.

On this important subject Mr. Abernethy's observations deserve particular attention. He is of opinion that the effects of concussion have not been justly described by authors, nor the symptoms related by them those which usually occur. In his Surgical Essays, he, therefore,-selects two cases out of many others, in order to shew what really are the common consequences of this injury named concussion.

"The whole train of symptoms following a concussion of the brain," says he, "may, I think, be properly divided into three stages. The first is, that state of insensibility and derangement of the bodily powers which immediately succeeds the accident. While it lasts, the patient fearfully feels any injury that may be inflicted on him. His breathing is difficult, but, in general, without tertor; his pulse intermitting, and his extremities cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which I consider as the second stage of concussion. In this, the pulse and respiration become better, and though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The feeling of the patient is now so far restored that he is sensible if his skin be pinched; but he lies stupid, and inattentive to slight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to his chief suffering at the time, as pain in the head,
CON

head, &c. otherwise, he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate; but as the former abates, the latter seldom fails to increase; and this constitutes the third stage, which is the most important of the series of effects proceeding from concussion.

"These several stages vary considerably in their degree and duration; but more or less of each will be found to take place in every instance where the brain has been violently shaken. Whether they bear any certain proportion to each other or not, I do not know. Indeed this will depend upon such a variety of circumstances in the constitution, the injury, and the after-treatment, that it must be difficult to determine.

"With regard to the treatment of concussion, it would appear, that in the first stage very little can be done; and perhaps, what little is done, had better be omitted, as the brain and nerves are probably insensible to any stimulants that can be employed. From a loofe, and, I think, fallacious analogy between the insensibility in fasting, and that which occurs in concussion, the more powerful stimulants, such as wine, brandy, and volatile alkali, are commonly had recourse to, as soon as the patient can he got to swallow. The same reasoning which led to the employment of these remedies in the first stage, in order to recall sensibility, has given a kind of sanction to their repetition in the second, with a view to continue and increase it.

"But here the practice becomes more pernicious, and less defensible. The circumstance of the brain having so far recovered its powers, as to carry on the animal functions in a degree sufficient to maintain life, is surely a strong argument that it will continue to do so, without the aid of means which probably tend to exchange parts already weakened by the violent action they induce.

"And it seems probable that these stimulating liquors will aggravate that inflammation which nullifies or later endures. The access of it, in the cases which I have related, is sufficiently evident; and its cure is to be effected by the common methods. The great benefit of evacuations was, in those cases, very evident."

After some further remarks in opposition to the cordial plan of treatment, and the relation of a fatal case of simple concussion, in which that system would have been manifestly hurtful, Mr. Abernethy adverters to the very desirable object of pointing out the marks by which we may distinguish between compresion and concussion of the brain; for these, he apprehends, may in general be distinguished.

"As far as my observation goes," says he, "the insensibility is much less in concussion, especially after a short time has elapsed. Patients in this case, though they seem reluctant to answer questions, yet complain much if their heads are moved; and in those infirmities where it was judged necessary to inspect the bone, I have generally found they made great complaint during the operation. The pupils also are usually more contracted than in compresion of the brain; the muscles of the limbs retain their natural state of tone, and respiration is performed with little or no flectors, though the pulse generally intermits in a very considerable degree. In the lighter cases of concussion, the sicknes of the patient is often very great.

"But, in cases of compresion of the brain, circumstances very much the reverse of those just related take place; the sensibility is much diminished in proportion to the degree of the injury; from this cause also the pupils are dilated, and the limbs relaxed; the respiration is attended with flectors; and the pulse is subject to much less intermission."

COND, CON, or CONN, in Sea Language, signifies to guide or conduct a ship in her right course.

He that conds her, stands aloft with a compass before him, and gives the word of direction to the man at the helm, how he is to steer. See Steering.

If the ship go before the wind, or, as they call it, between the sheets, the word is either furlboard, or part the helm; according as the conder would have the helm put to the right or left side of the ship, upon which the ship always goes the contrary way.

If he says, below a midship, he would have the ship go right before the wind, or directly between her two sheets.

If the ship fail by wind, or on a quarter wind, the word is, aloof; keep your helm, fall not off, over no more, keep her to, touch the wind; have a case of the lee-latch; all which expressions are of the same import, and imply that the steersman should keep the ship near the wind.

On the contrary, it would have her fail more large, or more before the wind, the word is, cast the helm, no nearer, bear up.

If he cries boldly, it means, keep her from going in and out, or making yaws (as they call it), however the fail, whether large or before a wind; and when he would have her go joll as she does, he cries keep her thus; thus. &c.

CONDA, or Kond, signifies forrest, and often occurs as a termination of words in the south part of India, in this sense, as cotta and cote, which have the same significations, do in the north.

CONDABORA, in Ancient Geography, a town of Spain, placed by Ptolemy in Cilicia.

CONDALUS, in Antiquity, a kind of ring usually worn by slaves.

CONDAMINE, Charles-Marie de la, in Biography, a celebrated traveller, was born at Paris in the year 1701. In early life he distinguished himself as a military man; but quitting the profession of arms for the purpose of indulging a laudable curiosity, and a thirst for natural science, he diligently surveyed all the countries bordering on the coasts of the Mediterranean, and travelled into various parts of Leffer Asia, Egypt, and Turkey. He was elected a member of the Academy of Sciences, and proposed a voyage to the equator, in order to measure a degree of the mediter.

In 1736 he went, with other mathematicians, to Peru for this purpose, and exhibited the greatest affability and skill in accomplishing the work. On his return he descand the celebrated river of the Amazons; in this enterprise he
he suffered many hardships, which were, however, more than 
conquered by the indomitable, regions so remote, and so 
profuse of the wonders of nature, afforded him. Here he 
condensed the number of vibrations made by the same pendulum, which he had used at Paris, at Quito, and other 
places, and he found out that for 100,000 vibrations at Paris, 98,770 
were made by the same pendulum at the tide of the 
Amazons, 98,720 at Quito, and 98,720 on Pinch'ica. He 
published in the year 1745 an account of his travels, under 
the title of "Relación Abreviada d'un Voyage fait dans l'Inter 
deur de l'Amerique Meridionale," and in 1751, a 
"Journal du Voyage fait par Ordre du Roi à l'Equestre, 
avec un Supplemen, en deux Parties." Condamine, after 
a short residence at home, went to Italy, where he was 
honoured with the particular notice of the pope, who granted 
him a dispensation to marry his own niece. In 1752 he published 
some remarks on what he had seen in his tour through 
Italy. He then visited England, and, among other inter 
esting objects, he became warmly attached to the new prac 
tice of inoculation for the small-pox. On his return he 
published in two volumes "Memoires et Lettres sur l'Ino 
culation." About this period he was elected member of the 
French Academy of Belles Letters; he likewise received the 
same honour from several foreign learned societies, as 
those of London, Peterburgh, Berlin, and Bologna. He 
died in February 1774, in consequence of an operation for 
the hernia. "The acquisitions of M. de la Condamine," 
says one of his biographers, "were more extensive than pro 
founds; and he polished rather an ardour for making re 
searches on a variety of subjects, than patience completely 
also the article Bouguer.

CONDADORE, in Geography, a town of Hindoosfan, 
in the country of Golconda; 15 leagues E. of Adoni. N. 
latitude 15° 49'. E. longitude 76°.

CONDAPILLY, a town of Hindoosfan, and capital of 
a circle of the same name, near the bay of Bengal; 142 
miles S.E. of Hydrabad. N. latitude 16° 40'. E. longitude 80° 
45'.

CONDAPILLS, a circle of Hindoosfan, bounded on the 
N.E. by the circle of Ehlire, on the S.E. by the bay of 
Bengal, on the S.W. by the river Kíñnah, which divides 
it from Guantoor, and on the N.W. by the country of Gol 
conda; about 80 miles long and 25 broad.

CONDATCHY, a bay of Ceylon in the Eáil Indies, 
living on the west side of the island, six miles south from 
Arippo, and about 12 miles from Mannar. N. latitude 8° 45'. 
E. longitude 80°.

In this bay all the boats are collected for the 
pearl-fishery. The bay forms nearly a half-moon; the 
beach which surrounds it is an extensive sandy waiae, with 
only a few miserable huts scattered along the shore between 
the bay and the woods which skirt the beach. Such is the 
appearance which this bay presents at most seasons of the 
year; but during the fishery the scene is entirely reversed. 
At that time the bay is crowded with small vessels, and the 
beach presents an astonishing multitude of people from every 
quarter of India. The principal bank for the fishery is op 
posite to Condatchy, and lies out at sea about 20 miles. 
See Pearl-Fishery.

CONDATÉ, in Ancient Geography, an appellation, prob 
ably of Celtic origin, bearing relation to the idea of 
Coenat, and giving name to several towns, such as follow.

CONDAS, or REDONES, Remes, a town of Aramécia, 
the capital of the Redones, according to Ptolemy.—Allo, 
Monteau, a town of Gaul, between Meloduim and 
Ageidium, which afterwards bore the name of Monals 
riolium.—Allo, Combe, a place of Gaul between Noviomagas 
and Darocass.—Allo, Coas, a town of Gaul, between 
Nemurrum and Brivodurum.—Allo, Goynag, a town of 
Gaul, between Medionam Santonum and Vefnu na, according to 
the tab e of Peutinger.—Allo, a place of the Isle of Albion, 
between Manuicum or Manchelota and Dova or Chelet hit in,
Antonine’s Itinerary : generally placed at Congleton; but 
Mr. Horsey Lath made it very probable that it was some 
place near Northwicb.

CONDATEN-PERRIERES, in Geography, a town of 
France, in the department of the Tarn; 10 miles N. of 
Murat.

CONDATOMAGUS, in Ancient Geography, a place 
of Gaul, marked in the Peutingterian table between Sego 
dunum and Lutetia.

CONDAVIR, in Geography, a fortified place of 
Hindoosfan, and a principal port in the circuit of Guantoor; 
strongly situated on a mountain, eight coffes to the west of 
Guantoor, and ten from the bank of the Kíñnah. Not far 
from Condavir is Colose, a diamond mine on the southern 
bank of the Kíñnah. Condavir is distant S.E. from 
Hydrabad 143 miles; from Madras 276 miles; from Nagpaur, 
S. 385 miles; and N.E. from Seringapatam 414 miles.

CONDE, LEWIS I. De Bourbon, in Biography, was 
the son of Charles of Bourbon, duke of Vendome, and born 
in 1570. He distinguished himself when very young at the 
battle of St. Quintin, and behaved with great gallantry till 
the death of Henry II, when he became a leader of the 
Huguenots. He was accused of having been the principal 
conspirator of the conspiracy of Amboife, but, in the pre 
fence of the king, he vindicated his honour with all the 
intrepidity natural to him, and offered to maintain his 
independence in single combat against his accuser. He was let 
free, but engaging in another plot, he was condemned by 
his judges to have his head struck off on a scaffold before 
the king’s apartment. To the sudden death of the fore 
man he was indebted for his freedom a second time; he 
now openly put himself at the head of the Huguenots, and 
was admitted, with Admiral Coligny, to share their full 
confidence. After many and very important successes, he was wounded and taken prisoner in the battle of 
Dreux in 1562. At the battle of Jarnac 1569, he en 
countered the enemy with his arm in a scarf, and as he 
marched to the attack, the horse of his brother-in-law 
reared and broke his leg; superior however to this painful 
accident, he thus addressed his followers: "Nobility of 
France, know, that the prince of Condé, with an arm in a 
scarf, and broken leg, fears not to give battle, since you 
attend him." The village of Jarnac has been rendered me 
orable by the courage and constancy with which the 
Huguenots disputed the day; but their leader Condé, ex 
thuasted with fatigue, was surrounded and taken prisoner. 
Thrice to whom he had yielded his sword, had placed him at 
the foot of a tree, when Montegueau, captain of the duke 
of Anjou’s guards, shot him dead, in cold blood, in re 
venge of a private quarrel. This savage, and truly infa 
mous deed has affixed an indelible stain on the character of 
the duke of Anjou who was supposéd to have authorised it. 
The body of Condé, thrown upon an al, was carried to the 
castle of Jarnac, and after being exposed to the view of the 
victorious army, was delivered to the duke of Longueville, 
his brother-in-law, who caused it to be interred with thos 
e of his ancestors at Vendome. In his person, the prince of 
Condé was ungraceful and diminutive, yet his wit and vivi 
city rendered him a great favourite with the ladies. His 
amours gave occasion to the conclusion that he engaged in 
the cause of the Huguenots more as a party-man, than as a 
religious. This trait in his character was a foil to quali 
...
ties the most splendid, and to virtue the most heroic. Of high and determined courage, he was formed to shine in camps as well as courts, and though his income was narrow, he displayed a magnificence of temper worthy his birth and station. Nouv. Hist. Dict. Hist. de France.

Condé, Lewis II., de Bourbon, was born at Paris, Sept. 7, 1621. He was styled Duke d'Engignié, and is known in history, under the appellation of the great Condé. He succeeded to the rank of prince by his father's death in 1646. In his infancy he was of an extremely delicate constitution, and was sent into the country for the sake of pure air. At a proper age the prince took upon himself the task of governor, and selected, as his amiable, in this important business, M. de la Bouillé, a private gentleman, upon whom he could depend for the most exact attention to the orders given him. Two jouts were likewise assigned to him as preceptors, who, with some officers of high rank and eminent probity and discretion, formed the household of the young prince. With these attendants he went to Bourges, where he frequented the college of jouts, and became distinguished in every branch of learning. His inclination was evidently turned towards the military art, and at the age of eighteen he made a campaign under Marshal de la Meilh rage, that laid the foundation of that renown by which he was afterwards distinguished as the greatest general of his age. In the year 1643, he was entrusted with the command of the army opposed to the Spaniards who had invaded France; by a signal victory which he at that time gained, he was looked upon as the guardian genius of his country. So much confidence did he display on this occasion, that on the night preceding the battle, after he had made all the proper dispositions, he slept so soundly that it was necessary to awaken him when it was time to begin the attack. He then formed the project of besieging Thionville, and proposed the scheme to the council of regency, who unwillingly consented to it. The duke, contrary to expectation, carried it into execution with so much skill that the town soon surrendered. After this he was engaged in many combats in Germany, in one of which he threw his general's staff into the enemy's trenches, and led on a regiment, sword in hand, to recover it. The victories of the duke d'Engignié, and his great and growing reputation rendered him an object of jealousy to Cardinal Mazarin, who did everything in his power to thwart his ambitious projects. The treachery of the cardinal, and the artifices of the leaders of the country party, excited cabals and troubles, but the duke d'Engignié, who, by the death of his father, had succeeded to the title of the prince of Condé, was cared for by both parties. As he at length took part with the court, though he felt it was an ungrateful task, and he protected the minilor without feeling for him the least esteem.

The royal family left Paris privately, and went to St. Germain, upon which the parliament sent deputies to learn from the queen the cause of her departure; but Mazarin dismissed them contemptuously and without an answer. Exasperated at this, the people made a common caufe, and resolved to defend themselves against the power of the court. With about 8000 men, the prince of Condé formed a design of reducing above 500,000 entrenched behind walls. He had neither money nor magazines; nevertheless he triumphed over Paris, and this success added not a little to the glory he had already attained. During the siege he constantly deposed the troops of the malcontents; he prevailed on the army that marched to their assistance under Turenne, to abandon their general; he stopped the progress of the duke de Longueville, who had caused an insurrection in Normandy, and got the start of the Spaniards who were advancing to give him battle. Peace was at length concluded, but Condé alone acquired glory by this war; and after the treaty was signed, the prince traversed the streets in his coach alone. All perquisites of any rank paid their compliments to him, and he received a vote of thanks from the parliament. The people, however, were uneasy at the king's absence, and Condé at length brought the royal family to Paris amidst the acclamations of the public; for this he was not recompened in the manner which he had anticipated; he accordingly united with the malcontents, was arrested in 1650, and detained a year in prison. Soon after his liberation, he broke out into open revolt, and a civil war followed which was attended with various successes. Condé exhibited great prowess, and sustained his military reputation through the whole of this unhappy warfare, though he was engaged in the service of the Spaniards, the inconstant foes of his country, whom he had formerly obtained so much glory in refiling. At the peace of the Pyrenees in 1659, the re-establishment of the prince of Condé was made a condition. In 1668, he contributed very materially to the conquest of Franche-Comté. He took part in the invasion of Holland in the year 1672, and received a wound at the famous passage of the Rhine. He fought the bloody battle of Senef against the prince of Orange, in which he had three horses killed under him, and was anxious to lead to a fourth attack, but as an officer of three years, "No one but the prince of Condé was desirous of fighting any longer." After the death of his great rival Turenne in 1675, Condé was sent to check the progress of the imperial army, in Alsace, and displayed so much caution in this business, as he had before exhibited ardour and insubordination. By his confusmate prudence and judgment he forced the enemy to cross the Rhine, and then, full of glory, he resigned the military profession, and retired to Chantilly, where he spent the remainder of his days cultivating and patronizing letters and the fine arts, to which he had been always attached. During the last two years of his life his faculties had so much declined, that feebly a trait was left of the great Condé. He died in 1686 at Fontainebleau, leaving behind him two sons, by his wife, the niece of cardinal Richelieu. Nouv. Hist. Dict. Hist. de France.

Conde', in Geography, a small town of France, in the department of the Aisne, and chief place of a canton in the district of Chateau-Thierry, 9 miles S.E. from Chateau-Thierry. The place contains 508 and the canton 9613 inhabitants. The territory includes 253533575 square miles, 77 communities. Also, a fortified town of France, in the department of the North, on the confluence of the Haine and Scheldt, 9 miles N.E. from Valenciennes, known at present by the name of Nord Libre, which it took under the republican government of France. After a blockade of nearly four months, it surrendered to the Austrians on the 11th of July 1790, but was soon evacuated. It is the chief place of a canton in the district of Donay, and contains 5078 inhabitants. The territorial extent comprehends 253533575 square miles, 77 communities, and 13,021 inhabitants. Before the revolution of 1789, Conde' was a principality from which the princes of Condé derived their title. There are in France several other small towns of the name of Conde', which signifies confluence, from the Latin confluent, circumducunt, and means a place built on the spot where two rivers meet. See Condé.

Conde', a town of France, in the department of Calvados, on the river Nive, or Nireu, chief place of a canton in the district of Vire, 24 miles S. from Caen, and 150 W. from Paris. The place contains 5039.
and the canton 10,681 inhabitants. The territory includes 12,351 kilometres, and 12 communes. The inhabitants carry on a considerable trade in cloth, leather, and cutlery.

Conde for Imm, or Conde in Eveux, a town of France, in the department of the Eure; 12 miles S.W. of Evreux.

Conde, a town of France, in the department of the Orne, and district of Bellefle; 10 miles E. of Bellefle.

Conde, a cape or promontory of North America, in the province of Yucatan; 100 miles W. of Merida. N. lat. 20° 50'. W. long. 95° 37'.

Condemnation, the act of passing, or pronouncing sentence, or giving judgment against a man; whereby he is subjected to fine, penalty, punishment, or death.

Condemnation to the galley. See Galley.

Condemnation of prizes taken from the enemy. See Prize.

Condensation (from condenfate, and condenate from the Latin condensata), denotes the contraction of a given quantity of matter into a smaller space, and in this sense only the word condensation ought to be used; however, in common language, the infilling, the thickening, or hardening of certain compound substances, in consequence of the escape of some of their component ingredients, is frequently expressed by the same term; thus the juices of fruit, of plants, of meats, &c. are often said to be condensed over the fire. Condensation and condensation (though sometimes used the one for the other) differ in this, viz., that the former denotes a diminution of bulk, occasioned by the application of external force; whereas the latter expresses the same effect, when produced without that external application, as it is the case with moist bodies in cooling. But the word condensation has been more commonly used for denoting the conversion of vapour into water, or of vapours in general into liquids.

The particulars which might be noticed with respect to condensation are, the quantity and rate of contraction in different bodies, the causes which produce it, and the limits of that contraction. These particulars, however, will, with more propriety, be stated under the articles Expansion, Thermometer, and Pyrometer, which see.

Notwithstanding the above-mentioned definition, it is to be remarked, that in every case of condensation, or of the contraction of a body into a narrower space, the effect is produced by the escape of something; and in bodies, which seem to be the simplest in nature, the contraction which they undergo in cooling, is occasioned by the escape of the caloric, which the present state of phæophysial knowledge reckons amongst the elementary substances. But the reverse of this proposition is not always true; viz., bodies are not always contracted in their dimensions when the caloric escapes from them; and such has been found to be the case with water, with iron, and with some other substances, in certain temperatures. This will be rendered more evident in the sequel.

Most bodies are susceptible of three successive states of existence; namely, the solid, the liquid, and the elastic or vaporous; and all these are effected by the introduction of different doses of caloric. During every one of those states, a different degree of condensation is produced by the intermediate gradations of temperature; viz., such as are not quite sufficient to induce a different state of existence in the body concerned. Thus, a quantity of the vapour of water, which, at the temperature of 242° (Fahrenheit's thermometer), and under the mean gravity of the atmosphere, occupies the space of 3500 cubic inches; if it be gradually cooled until the temperature becomes equal to about 212°, its bulk will be contracted so as to occupy half the space it did before, viz., about 1800 cubic inches. If the temperature be lowered below 212°, the vapour will be condensed into liquid water, which will occupy the space of not more than a single cubic inch. If the cooling be continued, the water will be condensed in its bulk, but not very regularly (that is, the decrements of bulk will not be exactly proportional to the decrements of heat); until the temperature approaches to about 32°. Below that degree, the water, instead of contracting its bulk, is expanded by further cooling; viz. by a further abstraction of caloric. This is a very remarkable property of water, upon which some interesting phenomena of nature are depending. The water, though expanding below the temperature of 27°, still continues fluid as far as about the temperature of 32°; but below this last mentioned point, by farther cooling it becomes a solid; namely, ice; and in this state water occupies a greater space than it did in a liquid state. (See Congelation.) Similar irregularities have been observed in the condensations of several other bodies, both solid and fluid; and it is to be wished that experiments capable of determining the laws of condensation were inculcated with all those bodies which are at all susceptible of the trial.

The causes of condensation are by no means thoroughly understood. It may seem, at first sight, sufficient to say, that since caloric is an elementary substance, which is combined in various proportions with every other known body, the separation of part of that element from the other bodies, naturally enables the particles of the latter to come closer to one another in virtue of their mutual attraction. But that this cannot be the sole cause of the condensation in its whole extent, is easily pointed out by the following queries.

1. Are the particles of bodies dissolved, that they may be capable of approaching, or of receding from each other? 2dly. Why the degrees, or quantities, of condensation are not always proportionate to the degrees of caloric that are abstrafted from bodies? And, 3dly. Why clouds, fogs, mists, &c. which confit of the vapour of water suspended in the atmosphere) are not always condensed into liquid water below the temperature of 212°; which is actually the case in the atmosphere?

It has for a long time been an opinion prevalent amongst philosophers, that the particles of bodies do not actually touch one another; for otherwise it seemed impossible to comprehend how a body could be expanded and condensed. But the least consideration will easily suggest a variety of dispositions of the particles, which, whilst they actually touch one another, will readily admit of the dilatation and condensation of the aggregate. Conceive, for instance (as professor Prevost of Geneva judiciously observes), the particles to be elongated, and united at their extremities like the legs of a pair of compasses, and they may then, with regard to this point of union, as a centre, and produce condensations and dilatations of the whole apparent mass of the body. A sponge likewise will dilate in water without interrupting the continuity of its parts. One may also conceive the particles of bodies arranged in the form of rings; that is, many of them to be in absolute contact, one with the next, and this with the following, &c. so as to form circular or oval rings. With this disposition of particles, the dilatation and condensation of the aggregate is nothing more than an alteration of the form of those rings; viz. they become more like circles when the body is expanded, and more oblong when the body is condensed; it having been demonstrated by mathematicians, that the circle comprehends an ampler space than any other figure of the same periphery. Though the general disposition of the particles of a body is not known, yet a variety...
riety of phenomena clearly indicate that they are not confoundedly placed; but that some arrangement, probably a peculiar one, for the particles of each different body, actually takes place; and to this peculiar arrangement some of the effects of dilatation and condensation, at least the irregularities of those alterations, must undoubted be attributed. Thus the particles of water crystallize in freezing; that is, they displace themselves with a peculiar regularity, somewhat resembling the filaments of a feather. These filaments of water form angles of about 60 degrees with a larger filament, which is, as it were, the item of the feather; and to this crystallization the enlargement of the bulk of water in freezing is with propriety attributed. Such is the force with which the particles of water endeavour to arrange themselves in that particular order, and of course to enlarge the bulk of the aggregate, that several astonishing effects are produced by their united efforts. Pieces of timber, stones, and other bodies, are buried by the freezing of inclosed water. Even iron mortars—hulls, such as are used in war, filled with water, and accurately flopped, have been buried by the freezing, and the consequent enlargement of the inclosed water.

Since the enlargement of the bulk of water commences at about the temperature of 45°, which is 10 degrees above the point of melting ice, commonly called the freezing point, which is 32°, it is evident that the particles of water begin to arrange themselves in a particular order long before the freezing takes place. And, by following the analogy, it may be supposed, that in every state of existence the particles of bodies have, more or less, a tendency to arrange themselves in a certain order; to which tendency the irregularities in the constitution of bodies are probably to be attributed.

The above-mentioned particulars, respecting the condensation of water, must in great measure be understood to belong to a great variety of bodies; for all those which have been subjected to deceptive experiments have been found to contract or to enlarge their bulk with irregularity, in some part at least, if not throughout, the whole scale of heat.

The condensation of vapour in the atmosphere, which is not always accompanied with a proportionate degree of temperature, forms another difficulty, which the present state of philosophical knowledge is not entirely capable of explaining. We shall, however, briefly state certain facts and certain considerations, which ought to be kept in view by those who are willing to investigate this intricate and interesting subject. The conversion of water into vapour is attended with an increase of its capacity for containing heat, or caloric, and likewise with an increase of its capacity for containing electric fluid; so that if a quantity of water, held in an open and inflated vessel, be suffered to evaporate, the vapour will deprive the vessel of part of its heat, and of part of its electric fluid: consequently, the vessel will be cooled and electrified negatively. Now that which philosophers wish to ascertain is, whether the influx of the caloric and of the electric fluid produces the evaporation, or the conversion of the water into vapour draws the caloric and the electric fluid from the contiguous bodies. In the first case, we fee no reason why the caloric and the electric fluid should spontaneously quit the contiguous bodies, and run to the water in order to force it to evaporate, because both the water and the contiguous bodies are in an equilibrium; that is, in the same state with respect to temperature as well as of electricity. In the second case, if the influx of heat and of electricity does not force the water to evaporate, what other cause can produce that effect?

The same reasoning which has been applied to the conversion of water into vapour, may, mutatis mutandis, be adapted to the contrary effect; viz. to the condensation of vapour into water, it being equally difficult to comprehend how the vapour can remain in the elastic state, that is, without being converted into water, at a temperature much lower than 212°, which in the atmosphere is generally the case.

There is one consideration, however, which may throw some light upon this remarkable phenomenon; viz. that in order to deposit the caloric and the electric fluid, which must necessarily take place in the condensation of vapour, there must be a body or bodies ready to receive both. But in the atmosphere, the only body which can receive them is the air, and it is well known, that air is a bad conductor of heat as well as of electricity. The last remark which we have to subjoin is, that it has been observed with several substances, and especially with water, that though placed in a colder temperature, they do not part with their caloric so easily as it might be expected, and this is particularly the case when they are to undergo a change in their state of existence; thus water will sometimes continue fluid when its temperature is 4 or 5 or even more degrees below 32°; though when once formed into ice, this will not melt at a temperature lower than 2°, and yet it will evaporate if exposèd to the air while its temperature is many degrees below 32°.

**CONDENSER.** From *condensare* is an instrument capable of collecting, or of drawing into a smaller space any scattered matter, or quality, or effect. In philosophy and in mechanics, three different instruments have obtained the name of condensers; viz. the condenser of air, the condenser of electricity, and the condenser of force.

The condenser of air, in pneumatics, is a cylinder, by means of which a considerable quantity of air may be forced into a vessel fitted for the purpose. Fig. 1 and 2, Plate XIV. Pneumatics, represent two contrivances of this sort of condenser, which differ but little from each other. They are generally made of brass or of iron. A B, fig. 1, represents a cylindrical tube, at moxt, two inches in diameter, and from 8 to 12 inches in length, or even longer. Its flat bottom B is perforated with a hole, on the outside of which, a valve, (confulting of a piece of oil skin, or rather of leather, stretched over a small flat piece of brass), is adapted, so that if any air be forced from the inside of the cylinder A B, that fluid will easily lift up the valve, and make its exit through the hole at B. But should any fiction take place within the cylinder A B, the air cannot possibility enter through the hole at B, because the valve on the outside prevents it by blocking that hole. The piston c fits the cavity of the cylinder A B pretty tightly, by means of leathers soaked in oil; and it may be moved up or down by the handle E which is fastened to its rod. This piston is perforated with a hole c d, the lower part of which is furnished with a valve d, which, when the piston is drawn upwards, will permit the air to enter the lower cavity of the cylinder; but if the piston be pushed downwards, the air which is contained in the lower cavity of the cylinder, cannot pass through the hole c d, on account of the valve at d; therefore it will come out through the hole at B. At the extremity of the cylinder, a brass or iron cap F G is screwed over the valve, allowing however a little room for its free motion. The end G of this cap is perforated quite through, and its outside is formed into a screw.

Fig. 2 represents a condensing instrument simpler than the preceding, and such indeed is at present mostly used. Neither the cylinder nor the piston of this instrument is furnished with any valve. There is a hole through the screw at the bottom B of the cylinder, and a hole at C through its side, and at about two or three inches below its upper end; the piston has no perforation.
When the condenser, fig. 1, is screwed into the aperture of a glass or metal vessel, and the piston is moved alternately up and down, it will be readily understood, that the air will be forced into the vessel to which the condenser is adapted; for when the piston is pulled upwards, that is, towards A, the air cannot enter the cylinder through the hole at B, but it can easily pass through the hole C D; and when the piston is pulled in, the air which is contained in the cavity of the cylinder, cannot go out of it through the hole C D, but it can pass through the hole at B; hence it is forced to enter the vessel to which the condenser is applied. Thus, by repeating the movements of the piston, more and more air is condensed into the vessel, until the latter is built up by the elasticity of the condensed air, or the same force pushes harder against the valve at B, that the strength of the operator is no longer able to overcome it. The condenser, fig. 2, is used exactly in the same manner; this, however, must be adapted to such vessels as are furnished with a valve within their aperture, which permits the entrance, but not the exit of the air. When the piston of this condenser is drawn towards C, a vacuum is formed in the lower part of the cylinder, until the lower part of the piston is raised above the hole C; then the air rushes through that hole, and instantly fills the cavity, &c.

These instruments are generally used for condensing the air into the air-holders of wind-guns, of certain water fountains, and other machines. By this means, the air has sometimes been condensed to such a degree, as to become fix, eight, and even more times, denser than common atmospheric air. The vessel, in that case, is said to contain respectively fix, or eight, or a greater number of atmospheres.

In a variety of philosophical experiments, substances are frequently placed in a glass vessel in which air is condensed, in order to observe its effects upon the enclosed substances. For this purpose, one of the above-mentioned condensers is affixed to a frame and apparatus, as is represented in fig. 3; and this apparatus, all together, is called a condensing engine.

C D is a brass condenser, which is worked by applying the hand to the handle Z of the piston, and by moving the latter alternately up and down, the air is forced through the brass pipe D N F into the glass receiver A B. This receiver, which must be very thick and well annealed, is fit with its smooth and flat edge upon the brass plate of the machine, which is similar to the plate of an air-pump. A thick piece of brass L M, is applied in a similar manner to the upper aperture of the glass receiver, and a slip-wire passes through a collar of leathers in this brass piece. In order to prevent the lifting up of the brass piece L M from over the glass vessel, or the latter from the plate on the frame of the machine by the force of the condensed air, two pillars of wood with a croose piece G H, likewise of wood, are annexed, for the purpose of keeping down the glass vessel, and the piece of brass L M. The croose piece G H is pressed upon L M by means of the screw-nuts on the pillars I, K. There is a gage E F, annexed to this machine, which indicates the condensation of the air within the glass vessel, and tube of communication. It consists of a strong and narrow glass tube, hermetically closed at E, and connected with the brass tube of communication at F. A small quantity of mercury fills up a short part of the cavity about the middle of the tube, and the space between the mercury and the closed end E of the tube, contains air of the usual atmospheric density. It is by the contraction of this small quantity of air, that the degree of condensation in the glass receiver is indicated; for in proportion as the air is condensed into the receiver, or tube of communication, &c., so the air between the mercury and the closed end of the gage becomes contracted more and more; and the quantity of that contraction is indicated by a scale annexed to the glass tube; for instance, if that air is, by working the machine, compressed into the half of the space it occupied at first, it shows that the air within the receiver is as dense again as it was before the working of the machine. If the air in the gage is compressed into a quarter of its original space, the air within the receiver is shown to be four times as dense as it was before the working of the machine, and so forth; the condensations in the glass receiver being inversely as the spaces occupied by the air in the extremity F of the gage. These degrees of condensation are commonly expressed by saying, that the receiver contains two, or three, or four, or more atmospheres, when the air within it is, twice, or three times, or four times, or more times, denser than the usual air of the atmosphere.

There are certain air-pumps, as those of Smeaton, of Haas and others, the construction of which renders them capable of being used for condensing, as well as for exhausting the air. See Air-pump. In certain forcing water-pumps, in fire-engines, and some other hydraulic machines, there is a vessel, in which the air is condensed by the action of the machine itself; the object of which is to produce a constant stream of water out of the engine, whilst the piston of it is moved up and down in the usual way. This vessel is called the air vessel, and often the condensing vessel, or simply the condenser. See Pumps, and Fire-engine.

The head of an alembic, wherein the vapours are condensed into a liquid, has sometimes been called the condenser of the alembic.

**Condenser of Electricity.** This is an instrument capable of collecting, or of condensing into a small space, such quantities of weak and diffused electricity, as would otherwise remain unperceived, or be insufficient to affect even the most sensitive electroscope. It was originally invented by a very distinguished philosopher, Mr. Votta of Como, and is by himself described in the 72d vol. of the Philosophical Transactions. But, since its original invention, this instrument has undergone several improvements and alterations, which we shall now describe, together with their peculiar advantages and defects.

The action of electric atmospheres is the principle which suggested the construction of this useful electrical instrument. Though the nature of these atmospheres will be treated of in the article ELECTRICITY; it will, nevertheless, be necessary to give, in this place, some idea of their action, by means of an easy experiment, in order to render the principle upon which the electrical condenser acts, manifest to the reader. Affix an electroscope of pitch-balls to an insulated metallic plate; that is, a plate of tin or brass, or other metal, having a glass handle. Communicate some electricity to it, and observe the deficiency of the electroscope. In this state, bring the electrified plate near a conductor which is not insulated, such as the wall of a room or another metallic plate, and you will find that the electroscope collapses in proportion as the electrified plate comes near to the uninsulated conductor. Remove the electrified plate, and the electroscope will diverge again, nearly as much as it did at first; which shows, that by the vicinity of the uninsulated conducting body, which could easily acquire the contrary electricity, the intensity of the electricity in the electrified plate was diminished; or, which is the same thing, the capacity of the plate for containing electricity was increased. Hence, when an insulated metallic plate is situated near another metallic plate not insulated, the
the former will thereby be enabled to absorb a much greater quantity of electricity than it otherwise would, from any source whatever; and if the electrified plate be removed from the other, then that absorbed electricity will be manifested by the divergence of the electrometer, or even by affording a spark. It naturally follows, that according as the conductor which is opposed to the insulated plate, is nearer to, or farther off, the capacity of the plate will be increased more or less. Such an insulated plate, placed upon an imperfectly insulating, or an imperfectly conducting plane, for the purpose of collecting weak and scattered electricity, was called a condenser by Mr. Volta. The reason of using an imperfectly conducting, or imperfectly insulating plane, is, that when the insulated condensing plate is placed upon it, the electricity will not pass from the latter to the former. In short, the following particulars should be attended to in the construction of this, Mr. Volta's, condenser. The metal plate should be about six inches in diameter, with the edge well rounded, and furnished with a varnished glass handle. The inferior plane must be of a very imperfectly conducting nature, such as dry marble, very dry and lightly varnished wood, a common piece of wood covered with oiled silk, or such like substance; but be its substance what it may, its surface must be very smooth, and such as to coincide as well as possible with the surface of the metal plate, viz. the receiving plate; on which account, if a marble slab be chosen for the inferior plane, it will be proper to fit the surface of the metal-receiving plate to that of the marble, by grinding one against the other.

The apparatus, consisting of the above described two planes, being properly constructed, lay the receiving plate upon the other plane, connect the former with an atmospheric conductor, not much elevated above a house, or with the vapour of boiling water, or, in short, with any weak source of electricity, such as could not be discovered by any other means, and after a certain time lift the receiving plate from over the other plane, holding it by the glass handle, and present it to an electrometer, which will be caused to diverge sufficiently to ascertain the presence and the quality of the electricity. Sometimes the receiving plate will even be able to afford a spark. Yet, in several cases, the receiving plate is electrified so slightly, as not to occasion the divergence of the most delicate electrometer. A contrivance of Mr. Cavallo, which is described in his Treatise on Electricity, (fourth edition, vol. ii. p. 265) rendered this weak state of electricity capable of affecting the electrometer in a very sensible degree. His description of this contrivance is as follows:

"I naturally thought that, for the same reason which enabled the condensing plate of Mr. Volta's apparatus, to manifest such small degrees of electricity as could not otherwise be observed, another smaller plate, or small condensing apparatus, might be employed to collect and to render sensible the weak electricity of the large metal plate. Accordingly, I constructed a small plate of about the size of a tuition, having a glass handle covered with sealing-wax; and when the large metal plate seemed to be electrified so weakly as not to affect an electrometer sensibly, I placed the small plate upon the inferior plane, and touched it with the edge of the large plate; then, after removing the large plate, I took up the small one from the plane, holding it by the extremity of the glass handle, and presented it to the electrometer, which generally was so much affected by it as to diverge to its utmost limits.

"In this manner I have often obtained electricity, more than sufficient to ascertain its quality, from a single stroke of the corner of a handkerchief; viz. the large plate being laid upon the proper plane, was furred once with the handkerchief; then, being removed and presented to an electrometer, it appeared not electrified; but by touching the small plate with the edge of it, that small plate acquired thereby electricity sufficient to make an electrometer diverge."
the lower apertures of the tin tubes, and also in the wood in bottom of the frame or machine, at E and F, so that the tin plate, ABCD, is supported by those glass blocks in a vertical position, and is exceedingly well insulated. GHILKM and NOPV, are two frames of wood, which being fastened to the bottom boards, by means of brass hinges, may be placed so as to stand in an upright position and parallel to the tin plate, as shown in fig. 4, or they may be opened, and laid upon the table which supports the instrument, as shown in fig. 5. The inward surfaces of those frames from their middle upwards are covered with gilt paper, X, Y; but it would be better to cover them with tin plates, hammer very flat. When the lateral frames stand upright, they do not touch the tin plate; but they stand at about one-fifth part of an inch above. They are also a little shorter than the tin plate, in order that they may not touch the tin tubes, AD, BC. In the middle of the upper part of each lateral frame is a small flat piece of wood, S and T, with a brass hook; the use of which is to hold up the frames without the danger of their falling down when not required, and at the same time they prevent their coming nearer to the tin plate than the proper limits. It is evident that when the instrument stands as shown in fig. 4, the gilt surface of the paper, X, Y, which covers the sides of the lateral frames stands contiguous and parallel to the tin plate."

"When the instrument is to be used, it must be placed upon a window, a table, or other convenient support, a bottle electrometer is placed near it, and is connected, by means of a wire, with one of the tin tubes, AD, EC; and by another conducting communication the tin plate must be connected with the electrified substance, the electricity of which is required to be collected on the plate, ABCD: thus, for instance, if it be required to collect the electricity of the rain, or of the air, the instrument being placed near a window, a long wire must be put with one extremity into the aperture, A or B, of one of the tin tubes, and with the other extremity projecting out of the window. If it be required to collect the electricity produced by evaporation, a small tin pan, having a wire or foot of about six inches in length, must be put upon one of the tin tubes; so that the pan may stand about two or three inches above the instrument. A lighted coal is then put into the pan, and a few drops of water poured upon it, will produce the desired effect."

"The quantity of electricity, which the tin plate, ABCD, is capable of collecting, principally depends on three circumstances, viz. 1st. On the distance between the tin plate and the conducting lateral surfaces: the smaller that distance is, the greater being the collecting power; 2dly. On the size of the instrument; and 3dly. On the quantity of electricity posseffed by the body from which it must be collected or taken away."

"I need not expatiate on the principle upon which the action of this instrument depends; this being the same as that of the electrophorus of Mr. Volta's conductor, and of many other electrical experiments; namely, that a body has a much greater capacity for holding electricity, when its surface is contiguous to a conductor which can easily acquire the contrary electricity, than when it stands not in that situation."

Though this original conductor, which, by way of description, its inventor called a collector, answers the purpose for which it was intended perfectly well; yet for the common run of experiments, its size may be dispensed with, as it takes up too much room on the table of an electrician. On this account, not only the size of the instrument has been reduced, but its shape also has been varied according to the fancy of almost every philosophical instrument maker. For the sake of simplification in the condensers which are at present in general use, one conducting plane only is opposed to the receiving plate, which answers the purpose sufficiently well; for if the electricity collected by the receiving plate happens to be too weak to affect the electrometer, a smaller condenser may be used, which will condense the electricity of the former, &c.

The forms of the condensers that are mostly used at present, are represented in figs. 6, 7, 8, and 9. Fig. 6 exhibits a vertical section of the condenser constructed by Mr. John Read of Knights-bridge; aa is a circular flat plate of tin, about eight inches in diameter, standing upright, by means of the glass block f, on the wooden plate g; gb is a hollow brass cylinder, terminating in the hollow brass cone ecb; and to this cone the flat perforated brass plate bcb is affixed. The glass block f, which, by means of a brass ferrule, is fastened to the plate aa, has its lower extremity cemented in a cylindrical piece of wood, and this piece of wood is fixed in the bottom g. Now it will be easily perceived, by inspecting the figure, that the hollow cylinder bg may be moved up or down by sliding it upon the cylindrical piece of wood; and that, by fixing the plate bcb may be brought near to, or removed from the plate aa, which is the receiving plate of this condenser: i is a milled-head screw, which serves to fix the plate bb at a proper distance from aa, where a flap is made for that purpose; when i is loosened, the plate bb, with b, which is all one piece, falls in the situation represented in the figure, and in that state an electrometer is put in contact with the plate aa, in order to manifest the electricity which aa condenses while bcb is moved near it.

Fig. 7 represents a condenser of another form, as made by Mr. Cuthbertson. This form of condenser is both simple in its construction, and commodious in practice; ab is a brass plate of about 8 inches in diameter (the instrument being shown in profile), which is screwed tight into the wooden head e, which is cemented on the glass block d, and this is cemented with its lower extremity into the wooden stand ee of the instrument; if is a similar plate of brass, flattened to the brass head and pillar g; the lower part of which turns round a pin at h, so that it may either stand upright, or it may be inclined after the manner of the dotted representation in. It is almost superfluous to add, that ab is the receiving plate of this condenser. Fig. 8 shows a front view of a condenser of this form, placed close to a gold leaf electrometer, furnished with a smaller condenser, viz. such as is represented by itself in fig. 9. The small condenser, fig. 9, is similar to the one represented in fig. 7; having in fig. 9 the receiving plate is affixed to the cap of a gold-leaf electrometer; so that this apparatus, viz. fig. 9, may be used by itself in most experiments; but in certain cases it will be necessary to employ the condenser fig. 7 first, and afterwards the electricity may be farther condensed by means of the apparatus fig. 9, as shown in fig. 8.

There is an instrument contrived by Mr. Wilson, which he calls 'a compound electrical instrument for condensing and doubling.' But as the construction, as well as the principal use of that instrument properly belongs to another class of electrical instruments, its description will be found in another part of this work. See Doubler, and Multiplier of electricity.

Condenser of forces. This name was given by Mr. R. Prony to a contrivance for obtaining the greatest possible effect from a flat mover, the energy of which is subject to augmentation
CON

augmentation or diminution within certain limits; and in general to vary at pleasure the resistance to which the effort of the first mover forms an equilibrium in any machine whatever, without changing any part of their construction. (Bulletin of the Philomathic Society at Paris, No. 83.)

The general problem in mechanics, of which this condenser is intended as a practical solution, is enunciated by Mr. Proy in the following terms:

"Any machine being constructed, to find, without making any change in the construction, a means of transmitting to it the action of the first mover, by fulfilling the following conditions; viz."

"1. That it may be possible at pleasure, and with great speed and facility, to vary the resistance (against which the effort of the first mover must continually make an equilibrium) in limits of any required extent.

"2. That the resistance, being once regulated, shall be rigorously constant until the moment when it is thought proper to increase or diminish the fame."

"3. That in the most sudden variations of which the effort of the first mover may be capable, the variation in velocity of the machine shall never undergo a solution of continuity."

Mr. Proy applies this solution of this problem to the dynamic effect of wind; but it will be easy to make the same general, when other first movers are used. Fig. 10 (Plate XVI. Mechanics) represents the plan, and fig. 11 the elevation of the machine. OQ is the vertical arbor to which windmills are adapted; eces is an assembly of carpentry, of which one of the radii, OQ, bears a curved piece bd, of iron or steel; vertical axes of rotation aqa, being placed round the axis OQ; they also divide the circumference in which they are found, into equal parts. Each of these axes carries a curve af, of iron, steel, or copper; so situated, that when the wind acts upon the sails, the curve bd presses against one of the curves af, and causes the vertical axis to which this last curve is affixed, to make a portion of a revolution. The curves bd, and af, must be so disposed, that when bd ceases to press on one of the curves af, it shall at the same instant begin to act upon the following curve: the number of axes which are provided with these curves, must be determined by the particular circumstances of each case, and it is also practicable to substitute, instead of bd, a portion of a toothed wheel having its centre in the axis OQ, and to place portions of pinsions instead of the curves af; but the dispositions represented in the figure are preferable. Each of the axes aaaa (which are all fitted up alike, though, for the sake of clearness, only one of them has its apparatus represented in the drawing), carries upon it a drum or pulley, ttrr, on which is wound a cord that passes over a pulley p, and serves to support a weight Q, by means of the lever FG, upon which this weight may be silded and fastened at different distances from the point of motion G. The same axes, a, a, pass through the pinsions q, q, to which they are not fixed; but these pinsions carry clicks or ratchets, which bear against rr; so that when the weight Q tends to rife, the ratchet gives way, and no other effort is produced on the pinsions q, q, either by the motion of the axis or of the drum ttrr, excepting that which causes the ascent of the weight q. But the moment that the curve, or tooth bd, ceases to bear against one of the curves af, after having caused the corresponding weight Q to rife, that weight Q tends to re-descend, and then the toothed wheel rr acts against the ratchet, so that Q cannot descend without turning the pinion qq along with the drum ttrr. The pinion q q takes in the wheel ab, from

The motion of which the useful effect of the machine immediately results; so that the effect of the descent of one of the weights Q is to solicit the wheel A B to motion, or to continue the motion in concurrence with all the other weights Q, which descend at the same time. This wheel, A B, carries beneath it oblique or bevelled teeth, GD, which take in a like wheel, CE, and cause the buckets at S to rife.

From the preceding description, it is seen that the machine being supposed to start from a state of repose, the wind will at first raise a number of weights Qs, sufficient to put the machine into motion, and will continue to raise new weights, whilst those before raised are fallen, so that the motion once impressed will be continued.

Among the numerous advantages of this new mechanism, the following may be remarked:

1. No violent shock can take place in any part of the mechanism.
2. The useful effect being proportional to the number of weights Qs, which descend at the same time, this effect will increase in proportion as the wind becomes stronger, and causes the sails to turn with greater velocity.
3. The weights, Qs, being moveable along the levers FG, it will always be very easy to place them in such a manner as to obtain that ratio of the effort of the first mover to the resistance, which will produce the maximum of effect.
4. From this property it results, that advantage may be taken of the weakest breezes of wind, and to obtain a certain product in circumstances under which all other windmills are in a state of absolute inactivity. This advantage is of great importance, particularly with regard to agriculture: the windmills employed for watering lands, are sometimes inactive for several days, and this inconvenience is more particularly felt in times of drought. A machine capable of moving with the lightest breeze, must, therefore, offer the most valuable advantages.

CONDENSING of Wines. See Wines.

CONDEON, in Geography, a town of France, in the department of the Charente; 25 miles S.E. of Saintes.

CONDER, a river of England, in the county of Lancaster, which runs into the Irish sea; 3 miles S. of Lancaster.

CONDERCUM, in Ancient Geography, a station of Britain on the line of Severus's wall at Benwell hill, where the prefect of the first wing of the Aet was placed. Not. Imp.

CONDERS, from the Fr. Condire, to conduct; persons who were employed in the fishery to give notice where shoals of herrings were palling; otherwise called Ballers; which see.

CONDESCENSION, in Ethics, denotes that species of benevolence, which judiciously disregards the supposed advantages of birth, title, or station, in order to accommodate itself to the state of an inferior, and diminish the restraint which the apparent difference is calculated to produce. Accordingly, it greatly enhances the value of every other species of benevolence.

CONDESUYOS DE AREQUIPA, in Geography, a jurisdiction of South America, under the bishop of Arequipa, 30 leagues distant from that city; which extends about 30 leagues, with different temperatures of the air, and consequently produces grains and fruits. In this jurisdiction is bred the wild cochinch, with which the Indians carry on a kind of trade with the provinces in which the woollen manufactures flourish. They first pulverize the cochinch by grinding it, and after mixing four ounces of it with twelve of violet maize, they form it into square cakes called Y y mangoes.
"mango," each weighing four ounces, and sold for a dollar per pound. This country abounds in gold and silver mines, which have of late been much neglected.

CONDITTA, a town of France, in the department of the 
fruits of Calais, and district of Boulogne; 2 miles N. 
of Boulogne.

CONDICA, in Ancient Geography, a town of Asia Minor, 
in Lydia, and in the country called Mysia, according to 
Plutarch.

CONDIGNITY, Merit of, in Theology. See ME-

CONDGRAMMA, in Ancient Geography, a small town of 
Asia, on this side the mouth of the Indus, upon the coast 
of Gedroia, according to Pliny.

CONDILLAC, Stephen Bonnet de, in Biography, a 
French metaphysician, member of the Academy, and suc-
pessor to the infant Don Ferdinand, prince of Parma, an honour 
where he arrived from the highest reputation that he gained 
from his writings. The work by which he was best known 
was an "Essay on the Origin of Human Knowledge," in 2 
vols., published in 1745; in which he endeavors to develop 
the faculties of the mind, by giving a sort of historical ac-
count of its several functions. In 1754, he gave to the world 
a "Treatise on Sentiments," in 2 vols., 12mo: here he con-
siders what would be the conceptions of a robot, provided 
at first with a single sense, and successively with the others; 
and hence he undertakes to account for the origin of me-
memy, judgment, and the mental affections; and the gradual 
formation and correction of foolish ideas. In the course of 
the following year he published a "Treatise on Animals," 
in which he refutes the notions of Descartes and Buffon con-
cerning the merely mechanical nature of brutes, and shows 
in what manner their faculties are acquired. In 1756 his great 
work, entitled, "A Course of Study drawn up for the 
Instructio of the Prince of Parma," was published in 16 vols., 
12mo. As an introduction to these volumes, we have a dis-
course on the different modes of communicating instruction: 
giving a decided preference to the gradual advance from par-
ticular facts up to general principles, instead of the contrary 
method. Metaphysical lectures, logic, and the philosophy 
of the human mind, are among the earliest parts of this course 
of study; and from these, as preliminary steps, he proceeds 
to the study of history, of which he has given an ample and 
well-arranged abridgment, in seven volumes. As an appen-
dix, is added a volume consisting chiefly of political reac-
tions. This ingenious writer published also a final work, 
etitled, "Commerce and Government considered relatively 
to each other." In all his works he exhibits an extensive 
knowledge, a mind well imbued with the principles of hu-
manity, and with the most liberal notions of government. 
He died in the year 1780, highly respected by his country-
men, and characterized for the founders of his judgment, 
for the clearness of his ideas on every subject which he under-
took to discuss, and for his general knowledge in almost every 
department of literature. Nouv. Dict Hill.

CONDITION, in the Civil Laws, an article of a treaty, 
or contract; or a clause, charge, or obligation, stipulated 
in a contract, or added in a donation, legacy, testament, 
&c.

The donee does not lose his domative, if it be charged 
with any dishonest or impossible conditions. Lawyers dis-
inguished three kinds of conditions, under which a legacy or do-
nation may be made: these are the conditional, which depends 
merely on chance; the potestative, which is absolutely in our 
power; and the mixed condition, which is both casual and po-
tentive together.

CONDITION, in Common Law, is a manner, quality, 
or restriction, annexed to an act; qualifying or suspending 
the same, and making it precarious and uncertain, whether 
or not it shall take effect.

Accordingly, it is defined to be what is referred to an 
uncertain chance, which may not may not happen. Or, con-
dition is a modifier, or quality, annexed by him that hath 
the estate, interest, or right to the land, &c. whereby an estate, 
&c. may be either created, defeated, or enlarged upon an 
uncertain event; and it differs from a limitation (which &c.), 
which marks the bounds or compacts of an estate, or the time 
how long the estate shall continue.

A condition is also considered as one of the terms upon 
which a grant may be made; and in this sense a condition in a 
deed is a clause of contingency, on the happening of which 
the estate granted may be defeated; as "provided always, 
that if the mortgagee shall pay the mortgagee 500l. upon 
such a day, the whole estate granted shall determine;" and 
the like.

Of conditions there are various kinds; viz. conditions 
in deed or express, and in law or implied; conditions prece-
dent and subsequent; conditions inherent, and collateral, 
&c.

CONDITION in deed, or express, is annexed by express 
words to the femdiment, lease, or grant, either in writing, or 
without. As, if a man make a lease of lands to another, 
reserving a rent to be paid at such a feast; upon condition, 
if the lessee fall in payment, it shall be lawful for the lessor 
to re-enter.

CONDITION implied, called also condition in law, is when a 
man grants to another the office of a steward, bailiff, keeper 
of a park, &c. for life; though there be no condition ex-
pressed in the grant, yet the law makes one covertly; which 
is, that if the grantee do not duly execute all things be-
longing to the office, it shall be lawful for the grantor to di-
charge him.

CONDITION precedent, is when a lease or estate is granted 
to a person for life, upon condition of the payment of a cer-
tain sum by the lessee to the lessor at a certain day, when he 
shall have a certain sum on such a day, or that his estate shall 
expire: so that here the condition follows the estate, and 
the performance precedes it. From these definitions it ap-
ppears, that a condition precedent gets or gains the thing or 
estate made upon condition by the performance of it; and 
that a condition subsequent keeps and continues the estate 
by the performance of the condition. If one agree with an-
other to do such an act, and for the doing of it the other 
shall pay so much money; here the doing of the act is a 
condition precedent to the payment of the money, and 
the party shall not be compelled to pay till the act is done; 
but when a day is appointed for the payment of money, 
which day happens before the thing contracted for can be 
performed, there the money may be recovered before the 
thing is done; for here it appears, that the party did not 
intend to make the performance of the thing a condition 
precedent. For a further account of these conditions, see the 
article Estate upon condition. There are other conditions, 
besides those already mentioned: such are conditions inher-
tent, being such as depend on the heir with the land grant-
ed; and collateral conditions, being that which is annexed 
to any collateral act. Conditions are likewise affirmative, 
which consist of doing; negative, which consist of not doing: 

some
some are said to be refractory, for not doing a thing, and some compulsory, as that the lessor shall pay the rent, &c. Some conditions are fugitive, to do one thing only; some compulsory, to do divers things; and others dependent, where one thing of several is required to be done. Co. Litt. 207.

Conditions in restraint of Marriage, have not been generally favoured, as contrary to found policy; but where a legacy has been given over to another, the condition has been held void; and it seems, that such conditions as only reasonably restrain children from imprudent marriage will be always supported—that is, when they operate only as particular, not as universal restrictions. Where a legacy is given on consideration that the legatee shall not marry without consent, and there is no devise over, the condition is void. 4 Burr. 2055. Com. Rep. 759. The rule of the ecclesiastical law is, that where a portion is given in consideration that the daughter should not marry, the condition is void. As the intent of the tellator chiefly governs in wills, such construction is always made of the words, as will best support his intent; and therefore these words ad faciendum, fieri nondum, &c. in a will create a condition. Co. Litt. 264 a. A grant to one to the intent he shall do to and fo, is no condition, but a trust and confidence. Some words in a lease do not make a condition but a covenant, upon which the lessor may bring his action. A covenant not to grant, fall, &c. may be a condition; and covenant, that, paying the rent, the lessor shall enjoy the land, is conditional. 2 Danv. 2. 6. Where words are indefinite, and proper to defeat an estate, they shall be taken to have the force of a condition. Palm. 503. For the performance of conditions and relief against the breach of them, see Jacob's Dict. by Tomlins, art. Condition.

Condition of a Bond. See Bond.

Condition without which, sine qua non, is used in Philosophy, in speaking of some accident or circumstance, which is not essential to the thing, but is yet necessary to its production. Thus, light is a condition without which a man cannot see objects, though he have good eyes; and thus fire, though considered in itself, may burn without wood; yet is its presence a condition without which the wood cannot be burnt.

Condition, applied to Horses, is used to signify that a horse is well fed and of good appearance; it also has another signification, that of his being brought by suitable treatment into a state of body, that gives him the fullest advantage of all his faculties in performing any very difficult or arduous exertion or exercice, as for hunting, racing, trotting, or the arts of the manage.

A horse that is moderately fat may be said to be in good condition, and so he is for sale, or for slow heavy draught-service; but such a one would be totally out of condition for any of the above exercises. To condition a horse for these a proper share of clean nourishing food and exercice is necessary, as much only as would confer the utmost point of strength and power, without adding any unprofitable insemination of matter to the body that might clog the freedom of respiration, or increase the weight and bulk of the animal, and impede rather than assist the functions of the organs, vifera, and limbs. This art, if properly understood, should impart the greatest facility of wind, and join to lightness of the body the greatest possible elasticity and strength of the muscular system. Such is properly the art of training, to which we refer the reader, and in which, though great things have been done, more wonderful might be yet effected; if to a well founded view of nature in these animals was added all that concomitant and well-placed art could bring to her aff mammal, for nature we are led to believe has been but too often thwarted instead of assisted by the arts of artful men, jockies, and smiths.

Though mere practice alone will teach much, yet when combined with a just system or knowledge of cause and effect, the art, whatever it be, may be carried to much higher perfection than it can otherwise.

For the present, we only treat of condition in horses, for the common and ordinary purposes to which they are applied.

To artful servants is left in general the phyficking, dieting, and conditioning the horse; and a mystery has often, with the ignorant, more charms than the clear face of truth herself. The effects of drugs upon horses are very little known. Perhaps, except the purgative effect of aloes, and the diuretic effect of foops and purgatives, and neutral salts; we have scarcely any medicine whose effects we really know upon the horse, or that appears at present likely to be known, yet are grooms ever phyticking their horses with fome drugs or other; good clean food in plenty, dry lofty stables, gentle exercice, and attention to the skin in keeping it clean, will bring almost any horse that is out of condition into condition, unless there be some lurking disease; yet native drugs are added to their food, and they are pleased to fancy that the effects they experience result from these, though it is more probably as far as they go, and in the uncertain and often idle doses in which they are administered, that they prevent, rather than affift, the purpose they have in view, and rather disturb their digestion, and weaken the stomach, than affift it; or more certainly render nauseous and loathsome the fome they could otherwise relish; antimony, nitre, brimifone, elecampane root, &c. are among their fecrets for this purpose. Antimony is, however, believed, by better judges than these, to affift the skin of the horse, and promote perpiration; this it may possibly do. We may, how- ever, juft remark, that where it affects the skin, it has the power of affecting the stomach; but with pigs, horses, and a variety of other animals, it does not affect the one, and one should doubt whether, in these cafes, it would affect the other; for in no quantity whatever, and we have given 4 oz. at a dose, does it appear to affect the stomach; nitre in larger quantities than they are used to give, will increase the urine; but how this promotes condition, we have not yet been informed. The rest of their nostrums are obvi- ously inexact, at least their actual effects, when pulped, till they become externally visible, have never been exhibited; and unless we are, we cannot know them. There is, how- ever, another, and a more certain purpose answered, in the administration of their drugs, and to which the science of medicine, in ignorant hands, is but too frequently made subservient; and without which, we believe, there would not be so much anxiety about the administration of them.

There is one influence, however, in which we rejoice to have it in our power to concur with these men in the use of medicine, and that is on horses coming from grafts; this appears to be a really useful practice, and we think, from sufficient experience, we can vouch for the fact, though to give medicines witho a direct indication for their use, would at first appear repugnant to reason, yet it is usual with grooms to give one, two, or more doses of physic, on the horse being brought from grafts "to clear him out," as they say; but if such were the only effect, there would be no occasion for it, as the grafts would very naturally come away from him without its good effects: we shall give a different account of the sudden change of life, from green relaxing watery food, as grafts, to dry hay and stimulating corn; from free open air and nightly dews, and all kinds of weather, to a close...
clef, low, foul, and crowded flable, the air of which is heated to an excess, and filled with stimulating exhalations from the dung; the water which had been received in quantities untrained, is now portioned out (though it is really more necessary) in miserable pittances. The body, before exposed, is wrapped in rugs and cloths, and the whole system becomes heated and inflamed by the sudden changes, inflammatory complaints of the lungs, eyes, palate, throat, intestines and feet, are produced; and it is therefore useless on this account, in keeping off these attacks, to lower the habit by physic, after the horse has been a few days in the stable, and to pass by flow degree to the excessive use of these vigorous stimulants. Dealers like to mix carrots with their corn, and bleed occasionally, and give bran malices, which has the same effect.

In turning out also, grooves are again for physicling their horses, and under the same pretence of clearing them out, and preparing them for grafts. They will, however, be sufficiently lowered and reduced by the grafts itself, without any additional reduction by physic. It may not be an useless precaution, however, to withdraw by degrees the use of corn, previous to turning out, and the removing all sort of clothing, to give water in greater abundance, that the change may not be too suddenly felt, and bring on break wind, farcy, and the diæseis induced by too great debility.

In Arabia, where the finest horses of the world are produced, a late traveller in those countries, (Mr. Barker), informs us of the extraordinary simplicity of their treatment of them. They do not use any instrument for drenching or cleaning them. They merely fallen them to a picket by the leg or a halter, to give them their food, which, during the spring affords us of grafs; and when the earth no longer produces that nutriment, they supply the want by camel's milk, which, he says, is most allur'd preferable to any kind of grain.

Beans, malt, oats, clover, hay, and meadow hay, are the general food of horses in England, and are suppos'd to be stimulant or invigorating to the system of the horse, in the order in which we have placed them. Barley was the ancient food for horses, the discovery of oats being comparatively of modern date.

In the north of Holland, they feed their horses principally on the black four bread called bumpernickle, made of buck wheat, and there it is eaten also by a large share of the inhabitants; for this purpose, they alight from their vehicles, and, without taking the horses out of their hempen traces, cut it in flakes, and give them to eat. We observed that they appeared relaxed by it, but apparently without much debilitating them, as they seem'd to do their work very well.

In the "Museum Rusticum" is a proposition founded apparently on actual experiment of feeding horses on carrots, vol. i. p. 333. The following remarks we think worth recording from that communication: "I have a couple of hunters which I value as being very good horses, and these I feed in the feaon with very little else besides carrots well cleaned from the dirt, and leaves made of the meal of barley and oats, mixed sometimes with a small admixture of coarse but good wheat meal; and if they require to be loosen'd in their bodies, I now and then give them some bran. As to hay, they eat at this seasion but little of it. of oats none at all, yet they go through their work to admiration."

Furze or whins has been found useful food in fattaining horses, after it has been bruised, and the thorns or prickles shredded; this some horses will naturally do with their feet. Dr. Darwin relates, that on one particular common, all the horses do it; and that fresh comes flave, till by imitation they learn this practice, as the common, in other respects, is very barren. In Wales, mills, we understand, have been used for crushing the furze for cattle.

Salt is imagined an useful addition to the food of horses. Salt malices have often a preference given them over other ground for horses and cattle; whether it is the salt that in itself operates bencicially, or whether the herbage itself is altered by it, and is rendered more salutary to the cattle, is not known. The same correpsondent, in the "Museum Rusticum," says that salt is supplied is abundantly distributed in the mountains by the Swifs, for the use of their cattle and horses, who become excessively fond of it, and more healthy in consequence; it is conceived to be an antidote to worms and other formations in the body, and the long continued use of it to cure them when formed, vol. i. p. 92.

Horses, he observes, are fond of it with their oats.

Horses when at liberty are almost ever feeding; therefore long fasting must be injurious to the stomach, and should be as much as possible avoided; they would also naturally, there is reason to believe, feed principally during the night, and sleep during the day; their sleep, however, is hardly ever, in health, profound and fast, but is a state of watchful dozing.

Horses are naturally gregarious, and though they will do very well alone, company, where there is an opportunity for it, is preferable for their health. The stable should be lofty, so as to confine an atmosphere about them, loaded with exhalations from their own bodies and their dung: the loftiness alone of the stable is their best airing; all partial draughts from doors, windows, or holes into the left; as far as they effect them, are injurious; for we have often remarked, that though they bear the coldest weather of our seasons with turn out, yet they easily take cold from partial draughts in stables, inasmuch, that persons not attentive to these effects would hardly believe their facility.

In cleaning the skin, the curry-comb is considered as a necessary implement. In warmer climates, where the scurf comes away more freely, this instrument is not so much used; and here it is often used to horses whose skins are particularly thin and sensitive, yet the difference is made; and though the animal expresses, in every way he can, the excessive torture it occasions, yet it is perfir'd in, and violence is often had recourse to, to enforce it, and horses are thus rendered vicious and untractable. Where this is found to be the case, it would fave much trouble and inconvenience to use a milder kind of comb, or to lay it aside altogether, and use a light brush made for the purpose. It is more easy by violence and punishment to create vice, than to overcome a natural dislike by it.

Warm clothing, on account of its keeping up a free perspiration, tends to render the skin cleaner, makes the coat lie better, and have a more glossy appearance, and saves trouble. It is too often, however, carried to an excess, and two or three hot rugs keep the horse in a perpetual fever; and as they are all taken off, when he is most exposed, on going out, the sudden check given to the perspiration by the elements without, lays the foundation of disease, and occasions inflammations of the lungs, cataracts, and coughs, that might as well be avoided by more moderate and judicious proceedings, besides the weakening effects of such violent perspirations. There
There is a principle in feeding them that ought not to be overlooked; which is, that good food may be carried too far, till, instead of condition, it produces fever and distemper, and destroys the condition it is meant to promote. Green vegetable food fills out the body; and from its weight and watery nature weighs down the abdomen, giving an ungainly appearance. Some horses, however, can work with this, that more stimulating food does not suit so well. The dry diet braces the fyltem, and draws up the abdomen. The food is least imbibed in the large intestines, which occasions the flanks to appear full and rounded, and greatly adds to the beauty of the horse's make in these parts.

Some horses we have noticed have voracious appetites, and devour great abundance of corn, and whatever is set before them, yet always look meagre and out of condition. When this has been the case, we have been led to believe that by too much food, and of too heating a quality, the stomach and intestines have been paralysed, and lost their powers of forming chyle, or absorbing it. Turning out to the green pastures will often bring them into condition, and they fall off again in the flable. Horses of small make and fiery temper are, we have thought, more particularly subject to this disease.

Water, like the food, should be given often, and not in too large quantities: feeding horses is a dangerous cullom; it induces them, where there is an opportunity to take enough at once, to break their wind, or otherwise injure themselves. See art. Broken Wind.

The skin, to look well and healthy, should be smooth, supple, and easy upon the muscles, free from knots, and by no means tight about the ribs. The hair clean, bright, and glossy, lying to the skin, and not disordered, or turning away from it, or twisted, dry, or thirsty. The effects of cold air on the skin of the horse, in setting up the hair, is well known to the grooms, who cautiously avoid it.

Exercise to animals by nature born to be fleet, is particularly necessary; besides the good it does in moving and forwarding all the secretions and excretions. This should be gentle or vigorous, proportioned to the strength and state of the horse, without distressing or too much fatiguing him. A gentle perspiration loosens the fur, and makes him clean better.

The hide soon gets foul, and a groom that has much pride in the appearance of his horse, is almost incessantly curry ing, brushing, and hard rubbing the coat.

It is a customary thing with the dealers in horses, in forming a judgment of the actual state of the horse, and whether his condition will admit of farther advancement, to handle the crest, or upper part of the neck which carries the mane; if this be lax in the hand, and easily plant, it is presumed the condition may be carried farther; if, on the contrary, this part has a stiff tense feel, it is considered that farther improvement is not to be expected. Among the acknowledged indications also of poverty and good condition, is the poor mark in the buttack, that is the channel, or depression running down the buttack, at its posterior part; being a depression formed between the muscles. If this channel is very visible and deep, the horse is out of condition; if obliterated, so as to be hardly visible, he is considered in condition.

Blood horses are more easily cleaned than the common kind of horses; their coat is not so thick, it does not retain the perspiration so much, and the hair takes a better polish; which makes an experienced groom always prefer them.

Too great excitement from the food, and undue fever, may be known by the heat of the mouth, the fulness of the veins of the eyes, the strength of the pulse, and diminished appetite; the skin also, and extremities, are found too hot or too cold, languid and weakens: the remedies are before stated.

CONDITIONAL, something not absolute, but subject to limitation.

Conditional legacies are not due till the conditions are accomplished.

The Arminian divines maintain, that all the decrees of God, relating to the salvation and damnation of men, are truly conditional; and the Calvinists, that they are all absolute. See Arminian, &c.

Conditional conjunctures, in Grammar, are those which serve to make propositions conditional. As, if, unless, provided that, in case of, &c.

Mr. Horne Tooke, in his "Tracts, &c.," has given us a new fyltem, with regard to these conditionals, as well as other conjunctures. Our conjunction if, he says, is merely a verb; being the imperative of the Gothic and Anglo-Saxon verb tifer, tifan, tisan. And in those languages, as well as in the English formerly, this supposed conjunction was pronounced and written as the common imperative, purely tifer, tifan, gif. In proof of the truth of this etymology of the word if, the author observes, that when the datum upon which any conclusion depends, is a sentence, the article that, if not expressed, is always understood, and may be inferred after if. But the article that is not understood, and cannot be inferred after if, where the datum is not a sentence, but some noun governed by the verb if or give. This, he says, will hold universally, not only with if; but with many other supposed conjunctions, such as, but that, unless that, though that, left that, &c. which are really verbs, put in this manner before the article that. An, now indeed obsolete, but formerly often used to supply the place of if, is also a verb; being nothing else but the imperative of the Anglo-Saxon verb dean, which likewise means to give or grant. If recourse should be had for confuting the author's opinion to the conditionals of the Greek and Latin, and Irish, the French, Italian, Spanish, Portuguese, and many other languages, he obviates the objection by alleging, that those words which are called conditional conjunctures, are to be accounted for in all languages in the same manner as he has accounted for if and an. Not that they must all mean precisely as these two do—give and grant; but some word equivalent: such as, be it, buffet, allow, permit, put, suffer, &c.; which meaning is to be sought for from the particular etymology of each respective language. To put this matter of doubt, he says, "I mean to discard all supposed meaning, not only about these conditionals, but about all those words also which Mr. Harris and others distinguish from prepositions, and call conjunctures of finiences. I deny them to be a separate sort of words or part of speech by themselves. For they have not a separate manner of signification; although they are not devoid of signification. And the particular signification of each must be sought for amongst the other parts of speech, by the help of the particular etymology of each respective language. By such means alone can we clear away the obscurity and errors in which grammarians and philosophers have been involved by the corruption of some common words, and the ugly abbreviations of construction." See Conjunction.

Conditional propositions, in Logic are such as consist of two parts, connected together by a conditional particle. Of these, the first, wherein the condition lies, is called the antecedent, and the other the consequent.

Thus, "if the soul be spiritual, it is immortal," is a conditional
CON

conditonal proposition, wherein, "if the soul, &c. is the antecedent, and "is immortal" the consequent.

The truth of these propositions depends on the truth of the connection of them, and they may be properly denied or contradicted when the negation affects their conjunctive particles. See Proposition.

Conditional falsity, is that whose major or minor, or both, are conditional propositions: e. gr. "If there be a God, the world is governed by Providence; but there is a God, therefore the world is governed by Providence." See Syllogism.

Conditional etale, fees, pardons, and regisfations. See the subjunctives.

Conditionals, science of, i.e. of conditional truths, imports that knowledge which God has of things, considered, not according to their essence, their nature, or their real existence; but under a certain proposition, which imports a condition never to be accomplished.

Some of the scholmen deny, that God has the knowledge of conditionals: the Thomists maintain, that God's knowledge of conditionals depends on a predetermining decree; others deny it.

F. Daniel observes, that the truths which compose the knowledge of conditionals, being very different from those which compose the knowledge of intuition, and that of understanding; a third class must be added, and the knowledge of God be divided into intuitive, intellective, and conditional. See Knowledge.

CONDIVI, Ascanio, in Biography, an artit whose works of painting and sculpture are now unknown. He is indeed said to have polished but an humble share of talent, infomuch that although he had the good fortune to be the inmate and disciple of the great Michelangelo Buonarroti for many years, he never attained eminence.

The world however has obligations to Condivi for the life which he wrote of his master, in somewhat the form of a journal, and which he published in 1553, ten years prior to the death of Michelangelo. Mr. Mariette, the celebrated connoisseur, was decidedly of opinion that the greater part of this narrative was written absolutely under the immediate influence and guidance of Michelangelo himself, and of course considered it as infinitely more authentic than the florid, but halit, composition of Vafari. Vafari had published a life of the great Florentine artit in his first edition of 1552. Condivi points out and corrects many of his errors. This Vafari indignantly retells in his second edition of 1568, but as Michelangelo was then no longer alive to decide their respective claims, the veracity of Condivi should suffer no imputation. Vafari however relates many things which the other omits, dwells more largely upon others, and in his second edition gives us the sequel of Michelangelo's life, with a long description of his magnificent funeral, &c. it was therefore desirable to unite these and other facttered materials into one work: this has lately been done by Mr. Duppa in a handfome quarto volume.

The first edition of Condivi is in quarto and become rare. Another edition, with copious notes by Antonfrancesco Gori and Mariette, together with extracts from Vafari, was published in Florence, 1746, in quarto.

CONDIVICUM, in Ancient Geography, Nantes, a town of Gallia Lyonnaensis, according to Ptolemy, and capital of the Nantesti, from whom it took its name.

CONDOCHATES, a river of India, on the other side of the Ganges, according to Pliny and Arrian, which discharged itself into the Ganges, about the 20th degree of latitude.

CONDOLENCE, in Ethics. See Commiseration.

CONDOM, in Geography, a town of France, in the department of the Gers, and chief place of a district, situated in a beautiful valley on the river Baise, 27 miles N.W. from Auch, and 90 S.E. from Bordeaux. It has a sub-prefect and a court of justice. The place contains 1517, and the canton 17,212 inhabitants. The territory of the canton includes 2452 kilometres and 16 communes. The whole district counts 18,8 communes and 67,126 inhabitants, upon a territorial extent of 10628 kilometres. Its soil is in general fertile, except in the southern part, which is an extensive barren beach; but as there are many salt pits, the walle land is improved with muck, which renders it tolerably fertile for a term of 20 years, at the end of which the ground is suffered to lie waste again, and another extent of land is rendered productive upon the same plan. Corn, wine, and brandy are the chief articles of trade, most of which are sent to Mont de Marsan and Bordeaux.

CONDONMOIS, a country of France, before the revolution, of which Condorn was the capital.

CONDONMA, in Zoology, the name given by Buffon to the striped antelope of Fennant, the antelope hreepicos of Gmelin's Linnaeus, the cervus espenisi, or cape deer, of Collin. Ac. Ac. Thod. Palat. 1. 457, the box hreepicos of Aldrovand, the hreepicos of Cans, Geifer, and Johnson, and the wild goat of Kolben, &c. It has long, comprefled, wrinkled, tapering, sharp-pointed spiral horns, with a ridge on one side which follows the wrinkles; the body has a white line along the back, and several white flipes across from that down the sides towards the belly and thighs. This animal inhabits the country near the Cape of Good Hope. It is near nine feet long from the nose to the rump, and four feet high at the shoulders; the body is long, slender, and of a reddish-grey colour; the face is brown, having a white line from the corner of each eye, running forwards and uniting above the nose; the transverse flipes above-mentioned are, in general, even in number, four of which point towards the thighs, and three to the belly; it has a short mane on the neck, and long hains hanging down from the throat to the breast; the breast and belly are grey; the tail, two feet in length, is brown above, white on the under side, and black at the end; the horns are of a dullish colour, and naturally wrinkled, though such as are brought to Europe are highly polished; they are near four feet long, close at the balees, above two feet and a half distant at the points, and have two spiral screw-like turns. The female has no horns. It is said to leep with surprising activity to a great height.

CONDORCET, Jean Antoine, Nicholas Caritat, Marquis de, in Biography, celebrated as a writer and political character, was descended from an ancient family in Picardy in France. He was born in 1743, and was educated at the college of Navarre, where he exhibited an ardent thirll for physical and mathematical pursuits, and acquired the reputation of a hard student. Condorcet first attracted public notice as a mathematician, by his treatise "On Integral Calculations," which he wrote when he was only twenty-two years of age, and in which he proposed to exhibit a general method of determining the finite integral of a given, differential equation, either for differences infinitely small, or finite differences. D'Alembert and Bezout, the commissioners of the academy, employed to examine the merits of this performance, declared that the greater part of the methods were of the author's own invention, that the production itself indicated a degree of knowledge very seldom to be met with at so early an age, and that it afforded a prefiguration of talents worthy of being excited by the approbation of the academy. This was followed by his "Essai on Analysis," and other works, which shewed his skill in analítica.
analytical researches. In the year 1759, he was admitted member of the Academy of Sciences, the memoirs of which were enriched by various disquisitions prefixed by him on the most abstruse subjects. During the administration of Turgot, celebrated no less for his integrity, than for his high talents, Condorcet was applied to for assistance in arranging plans for economical reforms in the state. In 1773 he was appointed secretary to the Academy of Sciences, when he composed eulogies upon several deceased members who had been neglected by Fontenelle. At this period he was the friend and intimate associate of Voltaire, D'Alembert, and other distinguished characters. Like D'Alembert he united in himself the reputation of an elegant writer, and of profound science; and in 1782 he was received into the French Academy, on which occasion he delivered a discourse concerning the influence of philosophy. In the following year he succeeded D'Alembert as secretary to that academy, and pronounced an able eulogy to the memory of his deceased friend, whose literary and scientific merits are yet forth with great ability. The death of Euler afforded Condorcet another opportunity of displaying his own talents by appreciating those of the departed mathematician. In his discourse on this occasion, he exhibited a clear and scientific statement of the improvements and inventions introduced into one department of knowledge by the exertions of an individual. The lives of Turgot and Voltaire, and the eulogy pronounced upon the death of the celebrated Franklin, were decided testimonials to the abilities of Condorcet as a biographical writer. Turgot had occupied much of his time and attention with moral and political sciences, and was particularly anxious, for the good of his fellow creatures, that the certainty of which different species of knowledge are susceptible, might be demonstrated by the assistance of calculation, hoping that the human species would necessarily make a progress towards happiness and perfection, in the same manner as it had done towards the attainment of truth. To second these views of Turgot, Condorcet undertook a work replete with geometrical knowledge. He examined the probability of an assembly's rendering a true decision, and he explained the limits to which our knowledge of future events, regulated by the laws of nature, considered as the most certain and uniform, might extend. If we do not possess a real, yet thought, we have at least a mean probability, that the law indicated by events, is the same constant law, and that it will be perpetually observed. He considered a forty-five thousandth part as the value of the rill, in the case when the consideration of a new law comes in question; and it appears, from his calculations, which we cannot go into, that an assembly confiding of 61 votes, in which it is required that there should be a plurality of nine, will fulfill this condition, provided there is a probability of each vote being equal to four-fifths, that is, that each member voting shall be deceived only once in five times. He applied these calculations to the creation of tribunals, to the forms of elections, and to the decisions of numerous assemblies; inconveniences attendant on which were exhibited by him. This work furnished a grand, and at the same time, an agreeable proof of the utility of analysis in important matters to which it had never before been applied.

Condorcet at this time started the idea of a dictionary, in which objects are to be discovered by their properties, instead of being searched for by their respective names; he also intimated a scheme for constructing tables, by which ten millions of objects might be classified together by means of only ten different modifications. The talents of Condorcet were very various, and he distinguished himself by many philosophical and economical disquisitions, which it is supposed, with great justice, had a great share in producing the subsquent important revolution in France. Without pretending to decide upon the motives of those who were active in achieving the downfall of the French monarchy, we shall bring before the reader a brief account of the part which Condorcet took in this business. Almost all his writings tended to pave the way for that most important change in government which took place in the year 1789. At this period, and in the following two or three years, he engaged in several periodical publications, with a view, no doubt, of guiding the public mind. He was a member of the popular clubs at Paris, particularly that of the Jacobins, celebrated for democratic violence, where he was a frequent but by no means a powerful speaker. He was chosen a representative for the metropolis, when the constituent assembly was diffolved, and joined himself to the Brissotin party which, in point of real talents and integrity, were not inferior to any of the contending factions of the day. But they wanted energy to control the people, and finally fell victims to that revolutionary spirit which they had excited. Condorcet at this period was the person selected from the party to draw up a plan for public instruction, which he comprehended in two elaborate and very striking memoirs; the principles laid down were, perhaps, too abstract for general use, and too refined for the present state of society. He was the author of a manifesto addressed from the French people to the powers of Europe, on the approach of war; and of a letter to Louis XVI., as president of the assembly, which was dictated in terms delitative of that respect and consideration to which the first magistrate of a great people has, as such, a just claim. Condorcet attempted also to justify the insults put upon the sovereign by the lowly, the most iliterate, and most brutal part of a delicious populace. On the trial of the king, his conduct was equivocal and unmanly; he had declared that he ought not to be arraigned, yet he had not courage to defend his opinion or justify those sentiments which he had deliberately formed in the closet.

After the death of Louis, Condorcet undertook to frame a new constitution, which was approved by the convention, but which did not meet the wishes and expectations of the nation. A new party, calling themselves the Mountain, were now gaining an ascendency in the convention over Brissot and his friends. At first the contest was severe; the debates, if tumultuous and dissipated may be so denominated, ran high, and the utmost acrimony was exercised on all sides. Condorcet always timid, always anxious to avoid danger, retired as much as possible from the scene. By this act of prudence he at first escaped the destruction which overwhelmed the party; but having written against the bloody acts of the mountain, and of the moniter Robespierre, a decree was readily obtained against him. He was arrested in July 1793, but contrived to escape from the vigilance of the officers under whose care he was placed. For nine months he lay concealed in Paris, when dreading the consequences of a domiciliary visit, he fled to the house of a friend on the plain of Mont-Rouge, who was at the time in Paris. Condorcet was obliged to pass eight and forty hours in the fields, exposed to all the wretchedness of cold, hunger, and the dread of his enemies. On the third day he obtained an interview with his friend; he, however, was too much alive to the sense of danger to admit Condorcet into his habitation, who was again obliged to seek the safety which unfrequented fields and pathless woods could afford. Wearing at length with fatigue, and want of necessary
necessary fastness, he went to a public-house, and asked
for an omelette, which he devoured with so much greediness
as to induce the suspicion of a municipal officer who was
present. At this period, suspicion and guilt were divided
by very narrow boundaries; the unfortunate man was fixed
and thrown into a dungeon, in order that he might, on the
following day, be conducted to the bloody tribunal at
Paris. The precaution was, however, unnecessary. Con-
dorcet was found dead in the morning; and as it was gen-
erally understood that he was never without a concealed
dote of the most active poison, to this cause his melancholy
end was generally ascribed. Such was the concluding scene
of the career of a man who had sustained a brilliant part on
the stage of life. He died March 25, 1794.

His character has been variously estimated. His manners
were mild, and his talents were unquestionably of the first
order. He is said to have been deficient of those fine feel-
ings which distinguished great and generous minds; and it is
allowed on all hands that he was a prey to timidity; a pas-
sion which at length induced him to commit the act of sui-
cide. By Madame Roland, his contemporary and inti-
mate, he was, in his lifetime, thus described: "The ge-
nius of Condorcet is equal to the comprehension of the
greatest truths: but he has no other characteristic besides
fear. It may be said of his understanding, combined with
his person, that it is a fine essence absorbed in cotton. The
timidity which forms the basis of his character, and which
he displays even in company, on his countenance and in his
attitudes, does not result from his frame alone, but seems to
be inherent in his soul, and his talents furnish him with no
means of furnishing it. Thus, after having deduced a prin-
ciple, or demonstrated a fact in the assembly, he would give
a vote decidedly opposite, overawed by the thunder of the
tribunes, armed with inuicts, and lavished on menaces. The
propensity of life for him was the lifeblood of the academy.
Such men should be employed to write, but never permitted
to act." Condorcet was married, and lived on the most
affectionate terms with his wife. He left one daughter,
who, has, during the present summer (1807), been married to
Arthur O'Connor.

Condorcet was the correspondent of the great Frederic,
and of Catherine, the Empress of Russia. "Letters to the
King of Prussia," he published during his life; and he
left behind him, which appeared as a most delightful work, "A
Sketch of a Historical Draught of the Human Mind." In
this work, he confides man as he has been, as he is, and as
he may be; and he inculcates, with great energy, his fa-
vourite idea of the perfectibility of the human species, and
of its advance to actual perfection. He left behind him
also "A Treatise on Calculation," and "An Elementary
Treatise on Arithmetic." His work on the human mind
was written during the months that he seduced himself
from the favage who was seeking for his blood, with more
than inhuman fury; and it is remarkable, and to the credit
of the writer, that under such circumstances, dreadfully
at every instant, he could compose so able a treatise, and
feel the conviction of the progress of his fellow creatures to-
wards moral improvement. Memoirs of the French Revo-

CONDORE, or Pulo Condore, in Geography, an
island of the East Indian ocean, about 20 leagues from the
cost of Cochin-China, taking its name from two Malay
words, Pulo signifying an island, and Condore a calabash,
of which it produces great quantities. This island is high and
mountainous, and surrounded by several smaller islands, some
of which are less than one, and others two miles distant.
It is of the form of a crescent, extending, says Capt. King,

near 8 miles from the southermost point, in a N.E. direc-
tion, and its breadth no where exceeds 2 miles. Sir Geo.
Stanton says, it is 11 or 12 miles in length, and about 3
in breadth, consisting of a ridge of peaked hills. From
the westemmost extremity, the land trends to the S.E. for about
4 miles, and opposite to this part of the coast there is an
island, called by Monf. D'Après "Little Condore," which
runs two miles in the same direction. This position of the
two islands forms a safe and commodious harbour, the
entrance into which is from the north-west. The distance
between the two opposite coasts is 3/4 of a mile, exclusive
of a border of coral rock, which runs down along each side,
extending about a 100 yards from the shore. The anchorage
is surrounded, from 1 to 5 fathoms water, by the kind of
islands to be felt and clayey, that great difficulty occurs in weighing
the anchors. Toward the bottom of the harbour, there is
shallow water for about half a mile, beyond which the two
islands approach so near each other, as to leave only a pas-
Sage at high water for boats. The most convenient place
for watering is at a beach on the eastern side, where is a
small stream that furnishes 14 or 15 tons of water a day.
Sir George Stanton says, that beyond the beach, which
fletcher across two-thirds of the entrance, at the southern
extremity of the spacious bay on the eastern side of the
island, there is a safe passage to the inner part of the bay,
the north of which is sheltered by a small island lying to the
southeast. The whole of the bay, he says, is formed by
four small islands, which approach so nearly to each other
as to appear, from several points, to join. They all seem to
be the rude fragments of primitive mountains, separated
from the great continent in the lapse of time. This island
has convenient anchoring places in either monsoon; and Sir
Geo. Dedier, a French engineer, who surveyed the island
about the year 1720, says, that none of the fruits or exotical
plants, so common in the other parts of India, are to be
found here, except water melons, a few potatoes, small
gourds, chaballeys (a small species of onion), and little black
beans. At present, besides the buffaloes, of which there
are large herds, it supplies remarkably fine fat hogs, of the
Chinese breed. There are also some of the wild fowl in the
woods, which also abound with monkeys and squirrels. One
species of the squirrel is of a beautiful shining black colour,
and another species is striped brown and white, which is
called the flying squirrel, from its being provided with a
thin membrane, resembling the wing of a bat, extending on
each side of the belly, from the neck to the thighs, which,
in stretching out the legs, spreads, and enables it to fly
from tree to tree, to a considerable distance. Lizards are
found in great abundance; but Capt. Gore says, that none
of his company discovered the guano, and another animal
described by Dampier as resembling the guano, only much
larger. Among the vegetable improvements of the island
are fields of rice and tobacco, and groves of cabbage paln-
trees, plantains, various kinds of pompons, cocoa-nuts, or-
ges, shadoocks, and pomegranates. These improve-
ments are ascribed to the French, for the purpose of making
it
it a more convenient refreshing fixture for any of their ships that may be bound for Cambodia, or Cochinchina; and for this purpose it is well situated. The woods are well stocked with feathered game; and particularly with wild hens and cocks, resembling those of our own country. The land in the neighborhood of the harbour is a continued high hill, richly adorned with a variety of fine tall trees, from the summit to the water’s edge; and among others the tea-tree, defrayed by Dampier.

The town in this island is situated near the sea side, at the bottom of a steep hill, which affords a fine view during the prevalence of the S.W. monsoon. It consists of between 20 and 32 houses, built close together; besides six or seven others that are scattered about the beach. The roof, the two ends, and the side fronting the country are nearly constructed of reeds; the opposite side, facing the sea, is entirely open; but by means of a fold of bamboo screens, they can exclude or let in as much of the sun and air as they please. There are other large screens or partitions, for the purpose of dividing, as occasion requires, the single room, of which the house properly speaking, consists, into separate apartments. The largest house of the town, belonging to the chief, or captain, had a room at each end, separated by a partition of reeds from the middle space, which was open on both sides, and provided with partition-fercons like the others. It had, besides, a pent-houfe, projecting four or five feet beyond the roof, and running the whole length on each side. At each end of the middle room were hung some Chinese paintings, representing men and women in ludicrous attitudes. In this apartment Capt Gore’s companions were usually defrayed to feast themselves on mats, and they were provided with bottles. In one of the apartments, visited by Sir George Staunton, was an altar decorated with images; and the partitions were hung with figures of monstrous deities; but the countenances and deportment of the people exhibited no idea of religious awe, nor was any person observed in the posture of prayer or adoration. A few spears stood against the wall with their points downwards, together with some matchlocks, and a swivel-gun.

The inhabitants of this island, who are fugitives from Cambodie and Cochinchina, are not numerous. They are of a short stature, very swarthy, and of a feeble, unhealthy aspect, but seemingly of a gentle disposition. The dress of these people is composed chiefly of blue cotton, worn loosely about them; and their flat faces and little eyes indicate a Chinese origin or relation. Their colloquial language is altogether different from that which is spoken in China, but their written characters are all Chinese.

The English settled in this island in 1702. When the factory of Chusan, on the coast of China, was broken up, and the English with them some Macassar soldiers, who were hired to assist in building a fort; but the president not fulfilling his engagement with them, they watched an opportunity, and in one night murdered all the English in the fort. Thereafter the fort, hearing a noise, took the alarm, and ran to their boats, very narrowly escaping with their lives; but not without much fatigue, hunger, and thirst, to the Jaffna dominions, where they were treated with great humanity. Some of them afterward went to form a settlement at Banjer-Maffin, in the island of Bornoe. Since this event, no Europeans have ever refixed in this island. The latitude of this island, calculated from a meridional observation, as stated by sir Geo. Staunton, is 8° 40’ N. and its longitude, according to a good chronometer, 107° 55’ E. The harbour in which Capt. Gore was stationed, is in N. lat. 8° 45’ E. long., deduced from a great number of lunar observations, 106° 18’ 46’; dip of the N. pole of the magnetic needle, 2° 18’; variation of the compass, 6° 14’ W.; high water at the full and change of the moon, 4° 16’ apparent time. The water rose and fell 7 feet 4 inches perpendicular. Voyage to the Pacific Ocean, by captains Cook, Clerke, and Gore, vol. iii. p. 450. &c.

Conders, in Ornithology, the Vultur Gryphus of Latham, (Ind. Orn.) Klein, Griffen, Borowski, the conur of Lact and Ray, the conur of Fresner, Condamine, Buffon, and Molini, and the conur of Latham (Syn. and Ship.) is a bird of enormous size, having a longitudinal very wide and circumferential. It inhabits South America; and its size is so enormous that the wings, when extended, measure 9 feet, or even 16 feet from top to tip; the largest quill-feathers of the wings sometimes measure 2 feet in length, and the quill-part 1/5 inch in circumference. The body is of a black colour, with a white back; the neck is surrounded with a collar of longth white feathers; the chin is reddish; the head is clothed with brown down or wool; the eyes are black, with cheetah or light reddish irides; the bill is black, with a whith point; the legs and feet are black, and the claws are flinty; the tail is small. The female is considerably larger than the male, which it resembles, except in having a crown crest or tuft on the forag, or hinder part of the neck. The condore builds its nest on the highest mountains, under the shelter of some projecting shelf of a rock, in which the female lays two white eggs. It preys on calves, sheep, goats, and such animals, and when very much pressed by hunger, it has been known to carry off children of ten years of age; and two of them are said to be able to devour the carcass of a cow at one meal. When it alights upon the ground, or rides from it, the noise it makes with its wings is such as to terrify, and almost to deafen, any one who happens to be near the place. Don Ulloa informs us, that he actually saw one of them rising with a lamb in its talons. The Indians have various ways of catching them: besides traps and snares laid for them near any carrion, they kill a cow or other animal, and moisten its flesh with the juice of some strong intoxicating herbs, and then bury the body till it putrefies. In this state they take it up and lay it on the ground; and when the condores come near to devour it, they are intoxicated and rendered motionless; when the Indians fall upon and kill them.

Condornentes, religious sectaries, whereof there have been two kinds. The first arose in Germany, in the thirteenth century; their leader was a native of Toledo. They held their meetings near Cologne; where they are said to have worshipped an image of Lucifer, and to have received answers and oracles from him: the legend adds, that an ecleclic having brought the emerald to it, the idol broke into a thousand pieces; which put an end to the worship. They had their name from their lying all together, men and women, young and old.

The other species of Condornentes were a branch of Anabaptists in the sixteenth century; so called, because they lay, several of both sexes, in the same chamber; on pretense of evangelical charity.

Condottiére, in the Italian Policy, denoted leaders of bands, who, in the 15th and 16th centuries, made a trade of war, and raised soldiers in order to hire them out to different states.

Condren, Charles de, in Biography, superior general of the fathers of the oratory, was born near Soiffons in the year 1538. By his father, who was in high estimation in the court of Henry IV., he was designed either for a
peft about the king, or for the military profession. His own inclinations, however, led him to think of the church, as most suited to his talents, to which, after some hesitation, his father gave an affent. He accordingly prosecuted his studies in the college of the Sorbonne at Paris, was ordained priest, and admitted a doctor of that society in the year 1614. In the following year he became a member of the congregation of the oratory, and founded some houses belonging to that order. He was not long in obtaining a distinguished reputation for integrity and prudence as a man, and for piety and benevolence as a priest. One of the chief traits in his character he was fixed upon as the most proper person to be confessor to the duke of Orleans, only brother to Louis XIII. In this situation he was successfully employed in confidential business between the duke and the king, and was the happy means of restoring those princes to a mutual good understanding with one another, after long and violent disaffections. For these services he was offered the archbishopric of Lyons, and a cardinal's hat; but he declined accepting of honour and emolument for having performed those acts, which, his religion taught him, were binding upon every Christian. He died in the year 1641, leaving behind him many pieces which evidenced superior talents, and a sincere piety. His principal works are, "Discourses and Letters," 2 vols. 12mo. 1648; and "An Explanation of the Priesthood of Jesus Christ," published in 1677. Father Amelot wrote up an account of his life, in which there is a collection of his letters and maxims with an exposition of his opinions. Nouv. Dict. Hist.

CONDRIEUR, in Geography, a small town of France, in the department of the Rhône, at the foot of a hill on the river Rhône, 21 miles from Lyons. This place is celebrated for its excellent sweet wine.

CONDROS, CONDROZ. in Geography, is a tract of land in the circle of Weilphalia, situated in the bishoppate of Liége, which formed part of the German empire, and is now incorporated with France. Condrus, in ancient geography, was reckoned part of Belgium. Huy, which was considered as the principal town of Condros, is, at present, the chief place of the district of the same name in the department de l'Othe. See Huy.

CONDUCT, f. See Safe-conduct.

CONDUCTOR (from conduct, and to conduct from the French conduire) prn., in Electricity, is a body of a conducting substance (vix. such as will transmit the electric power or fluid) placed immediately before the glasses cylinder, or globe, or plate, or other excitable body, of an electrical machine. Its object is to collect the electricity, and to convey it either in the form of sparks, or electrically, to other bodies that may be presented to it in the course of experiments. Without this prime conductor no large sparks could be drawn immediately from the excited electric, because the electric body, being in its nature incapable of conveying the electric fluid through its subsidence, discharges, on a body which is presented to it, that quantity of electricity only which is accumulated upon its own part of its surface. But when the prime conductor is placed before the excited electric, the former successively collects all the electricity from the surface of the latter, whilst revolving; and if a proper body be brought near its surface, the electricity which has been accumulated, will rush from every part of the surface of the prime conductor in a copious stream, or in a full spark, to that body.

The forms of prime conductors have been continually varied from the very first invention of electrical machines, according as new discoveries, or the progress of experience, have either detected former defects, or suggested more advantageous forms. A gun-barrel, or a metallic chain, supported by silk rings, formed the prime conductor of the earliest electrical machines, viz. such as were used towards the beginning of the fall, or eighteenth century. And in consequence of this usage some distinguished late writers on the continent, have retained the name of chain for the prime conductor, long after the shape of that instrument had undergone a total alteration. See "l'Elettrifico artificiale del P'Becaria."

Though the gun-barrel or the chain would be highly improper for the modern electrical machines, either of them was quite sufficient for those of the old construction, in which the excitation was very slight and difficulty obtained. But when the glass globes of cylinders began to be made much larger, when a better method of excitation was discovered, and especially when Mr. Canton's amalgam was introduced, to which the great power of the modern electrical machines is principally owing; then the chain or the gun-barrel was found incapable of retaining the electric power, so that every narrow edge, or point, or curvature of the frame, was found to dissipate the electricity into the surrounding air, as could be easily perceived in a darkened room. This suggested the idea of enlarging the size, and smoothing the irregularities of the prime conductor, in consequence of which some prime conductors were made of brass, others of tin, or even of gilt paper; and their shape became much more regular and compact. A cylinder with spherical terminations has been the most usual form of prime conductors. A few were made spherical; Dr. Priestley used one of a pear-like figure, and some have also been made of other fanciful shapes. But amongst all those forms, which the practice of the best electricians has found to be, upon the whole, the most eligible, is the abovementioned one of a cylinder with hemispherical terminations. These terminations, in small prime conductors, sometimes are made a little larger in diameter than the cylinder; but in the prime conductors of the larger kind, they do not project beyond the surface of the cylindrical part. As the conducting nature of their substance must be of the kind last, the prime conductors are made of metal, at least on their surface. The small ones are made of hollow brass, or tin plates, or of wood covered with tin-foil. But the large ones are almost always made of wood, or paste-board covered with tin-foil. The prime conductors of tin are frequently covered with a black varnish, which is preferred cleaner than the surface of the tin, and may perhaps in some measure prevent the dissipation of electricity from their surface. In any construction, care must be had, that the surface of the prime conductors be quite free from points, and sharp edges; and if holes are to be made in them, which indeed are necessary for the performance of various experiments; these should be well rounded off and their edges burnished. The prime conductor is generally supported in an horizontal position, by one or two glass dishes, which proceed from the bottom board of the electrical machine, or from separate wooden stands; the extremities of those glass dishes entering a little way within the surface of the conductor. The direction of the prime conductor is mostly perpendicular to the axis of the glass cylinder of the machine; but in some electrical machines, the conductor, or two conductors, are situated parallel to the abovementioned axis. When two conductors are allied to the machine, one of them, which collects the electric fluid from the excited glass, is called the positive conductor, and the other, which is connected with the rubber, is called the negative conductor. At that extremity of the prime conductor, which stands nearest to the glass globe or cylinder, when the former is perpendicular to the
CONDUCTORS.

axis of the latter, or on the side when it stands parallel, the collector is affixed. See Collector.

To the opposite extremity of the prime conductor which stands farther from the glass cylinder or globe, a thick brass wire, with a pretty large and smooth brass ball, is usually affixed, and from this ball the longest and densest spark may be drawn; the greatest endeavour of the electric fluid to escape from the prime conductor being made at that extremity. In plate machines, viz. where glass plates are used instead of a globe or cylinder, the extremity of the prime conductor is furnished with two semicircular projections, which carry the collecting points at their extremities. The size of the prime conductor must be proportionate to the size of the machine; for if the prime conductor be too small, the sparks that are drawn from it will not be of the largest size possible to be obtained with that machine; and, on the other hand, if the prime conductor be too large, the diffuseness of electricity from its surface will be very considerable. It is difficult to determine the exact size which might be the most advantageous for a given machine; for with cylinders of the same size, different prime conductors might be used, according as the glass cylinders are more or less capable of a vigorous excitation. With one of the largest glass cylinders ever made in this country, which measured two feet in diameter, a sponge conductor of wood covered with tin-foil was used, which measured six feet in length and 18 inches in diameter. With a small machine, the cylinder of which was seven inches in diameter, a prime conductor of two feet by three inches and a half was found the most advantageous. When the electrical machine is to be used only for charging a battery, then it will be better to use a very small prime conductor.

The forms of the above-mentioned prime conductors are represented in the various plates relating to electricity that are contained in this work.

Conductor of Lightning. See Conductors.

Conductor, in Surgery, is an instrument which serves as a guide for a scalpel, in several operations which do not allow the surgeon's determining the exact course or extent of a wound. For instance, in opening a fibrilous orifice, or dilating the abdominal ring in a strangulated hernia.

Conductors are either made of steel or of silver; and always have a groove on one side, to direct the cutting instrument. That which the surgeon employs in cutting for the stone is named a GORGET. This is an instrument generally made of steel, and introduced, in the operation of Lithotomy, through the artificial orifice, into the bladder, in order to widen the neck of the bladder, and facilitate the introduction of the forceps, with which the stone is to be extracted. There are two species of this instrument; the one, which is provided with a knob at the top, is termed the male gorget; and the other with an excavation, the female gorget. See Lithotomy.

There is also a machine invented by Mr. Walker, by means of which, a patient labouring under a simple or compound fracture of the leg, may be conducted with safety and convenience from one place to the other, and the extremities of the bones kept in their proper situation during the progress of the cure.

To this head belong the conducting apparatus invented for the same purpose by Mr. Theiden of Prussia, which are used in fractures of the superior and inferior extremities. Machines adapted for fractures of the femur have been described by Mr. Schmiuck, and those for other parts by Mr. Theiden himself. Mr. Richter conceives that these machines may be rendered more serviceable, by constructing them of iron, instead of walnut-tree wood.

Conductors. In two important branches of natural philosophy, a marked distinction has been observed between the various known bodies of the earth; and upon the peculiar properties of the two different classes of bodies, which are discriminated from each other by the above-mentioned distinction, numerous phenomena, of consequence to the human species, are absolutely depending. The two branches, of natural philosophy, above alluded to, are the science of electricity and the subject of heat. In electricity, if an excited piece of glass, or an electrified conductor, be touched with the extremity of a flick of sealing-wax, which a man holds by its other extremity; or if it be touched with the extremity of a silk string, the electric power will not be dissipated; but if the electrified body be touched with the extremity of a rod of iron or brass, held in a manner similar to the flick of sealing-wax, the electric power will be instantly dissipated; viz. it will pass through the metallic rod, and through the person that holds it, &c.

Hence it evidently appears, that iron or brass will permit the transition of the electric power through its subsistence; whereas sealing-wax or silk will not permit it. Therefore, iron, brass, and all those substances through which the electric power can be transmitted, are called conductors of electricity; and all those substances which, like the sealing-wax or silk, will not permit the passage of the electric power, are called non-conductors of electricity.

A similar distinction has been remarked in the subject of heat and cold. Take a small piece of charcoal, make it red hot at one end, and in that state it will be found that a person may hold it with his fingers within about a quarter of an inch of the red hot extremity, without feeling any unpleasant degree of heat; but if an iron rod as thick as the charcoal be rendered red hot at one end, a person will not be able to hold it within less than four or five inches, at least, of that end; and such is the case with all metallic bodies, as well as with some other substances; which shews that heat will pass through certain bodies much more easily than through others. Hence those bodies which, like the non-rod, will easily transmit the heat through their subsistence, are called conductors of heat; and those which will convey it with great difficulty, are called non-conductors of heat. It must be observed, however, that though heat will pass incomparably more easily through certain bodies than through others; and all those substances that are known to be either perfect conductors or perfect non-conductors of heat.

And indeed, the like observation, though in a much more limited manner, may be made with respect to the conductors of electricity.

In magnetism also, the name of conductor of that power has been given to a single substance, namely, to felt iron; but the peculiar nature of iron in that respect, or rather the passage of the magnetic power, will be explained under the article Magnetism. We shall now in an orderly manner state the various particulars which have been ascertained with respect to the above-mentioned two classes of bodies; viz. first, with respect to electricity, and then with respect to heat.

Conductors of Electricity. In endeavouring to point out the true nature of electrical conductors, it becomes necessary to give a hint likewise of the non-conductors of that power, since these two classes of bodies gradually approach each other, in proportion as they are less perfect of their kind, as far as certain substances, which seem to stand in an intermediate state between conductors and non-conductors, so as to participate of both. Glafs, sealing-wax, amber, fik
CONDUCTORS.

Silk, and several other bodies, which, by means of friction with a dry and clean hand, are capable of being excited, so as to exhibit electrical phenomena, are called electrics; and these identical bodies have been found to be non-conductors of electricity; hence electrics and non-conductors mean the very same class of bodies. In the same manner it has been found, that those bodies, which will easily transmit the electric fluid through their substance, cannot be excited in the above-mentioned manner; hence conductors and non-electrics do also denote the same bodies.

Strictly speaking, as we have already hinted above, there is no substance which may be called a perfect conductor or a perfect non-conductor of electricity; the electric power finding some resistance in its passage through the belt conductors, and being in some degree capable of passing through the belt electrics, at least under certain circumstances. The following lists contain the conductors and the electrics, or, which is the same thing, the non-electrics and the non-conductors. They are disposed in the order of their perfection; that is, the belt conductors and the belt electrics are placed at the heads of their respective lists; and those which participate of both, meaning those which are partly electrics and partly conductors, will be found towards the end of each list. In this, however, no great accuracy must be expected; first, because a very accurate discrimination is impracticable when substances are expressed under general denominations; and, secondly, because the precise degree of conducting or non-conducting power in most substances cannot be determined on account of their fluctuating nature.

Conductors.

Metallic ores; of which the best are those which contain a greater proportion of metallic parts, and nearest to a guinean state.

Charcoal, either of animal or vegetable substances. The conducting power of charcoal is very equivocal; for some pieces of it will hardly conduct at all, and others will suffer the passage of the electric fluid over their surface only, and not through their substance. The reason of this difference is not quite understood; but it seems owing to the degree of heat that is applied in the process of making them. See Priestley's second volume of Observations on different Kinds of Air, sect. xiv.

Electrics.

Gla's, and all vitriifications, even those of metals.

All gems, of which the most transparent are generally the best.

All resins and resinous compounds.

Amber.

Sulphur.

Baked wood, if not suffered to imbibe moisture.

All bituminous substances.

Wax.

Sik.

Cotton.

All dry and external animal substances, as feathers, wool, hair, &c.

Paper.

White sugar and sugar-candy.

Air, and other gases.

Oils.

Dry and complete metallic oxides.

The ashes of animal and vegetable substances.

All dry vegetable substances.

All hard stones, of which the hardest are the best.

Soft stones when heated, according to Delaval.

Powders not metallic, according to Delaval.

Ice, at the temperature of $-13^\circ$ of Fahrenheit's thermometer, according to Achard.

According to Mr. Walsh's, and Mr. Morgan's experiments, the Torricellian vacuum ought to be placed at the head of the list; but the singular nature of a vacuum, though a non-conductor, will hardly entitle it to the name of an electric. We must, however, refer all farther observations, respecting electrics, to the article of that denomination; the
the above lift having been inserted in this place merely to elucidate the nature of conductors.

Thus far we have stated the number of conductors, and their gradation, with respect to common electricity; but that lately discovered branch of this science, which is at present avidly cultivated under the title of Galvanism, has pointed out a peculiar arrangement of conductors with respect to the order of their capability of conducting that power which affects the limbs of a prepared animal, and of conveying the power of a galvanic, or rather a voltaic, battery. See the article Galvanism. Concerning the former of these powers, we transcribe a lift, followed by a few remarks, from Cavalli's Treatise on Electricity, 4th ed. vol. iii. p. 29; and with respect to the latter, we subjoin an abridged extract from a paper of Erman, in the Annales de Chimie, Feb. 1807.

Conductors of Animal Electricity, according to Dr. Lind's and Mr. Cavalli's experiments, which however are arranged with indifference by the latter, considering the difficulty of making the arrangement, and that, in this branch of electricity, the metals do not seem to act merely as conductors—The lift begins with the bat.

1. Maleable platina.
2. Silver.
4. Quicksilver.
5. Copper.
7. Tin.
8. Lead.
10. The human body.
11. Salt water.
12. Fresh water.

The metallic ores are not so good conductors as the purified metals themselves, and their conducting power is various according to the nature of the ores, but even the metallic faults are tolerably good conductors.

It is very remarkable, that the flame of tallow candle, which is a good conductor of common electricity, will not conduct the animal electricity, when placed in a short interruption made in the circuit of communication. Charcoal, placed in the flame situation as the flame of the candle, was also found to be a non-conductor, except when it was actually burning, in which state it conducted tolerably well; but Mr. Volta says that he has found some pieces of charcoal that acted as well as the metals. Dr. Valli observed, that human bodies are not all equally good conductors. Out of four persons in a company, he found that when two of them formed the circuit of communication between the nerve and the muscles of a frog, the motions took place very readily. When a third person formed the circuit, the motions were very weak; but that when the fourth person formed the communication no motion took place. This experiment, he adds, was often repeated with the same success. The effect, however, may be owing to the different dryness of the skin. Vitriolic acid, and what is very remarkable, alcohol, appear to conduct this property rather better than water.

The arteries and the veins are not so good conductors as the nerves; for when a blood-vessel forms part of the circuit of communication, the contractions will take place only when nervous ramifications are adhering to it, and if these be carefully separated, the motion will not take place. The same thing may be said of the tendons, the bones, and the membranes; for when either of these parts is separated from the body, and is introduced in the circle of communication between the muscles and nerves of a prepared frog, no motion will ensue, excepting, indeed, when those parts are full of moisture, and are in immediate contact with the nerve of a prepared frog. Dry nerves are not conductors of animal electricity. Dr. Valli found that the internal fibres of a nerve conducts much better than its external, or coat.

Silver and zinc, profcssor Aldini says, will produce contractions in the muscles of a frog, many hours after it has become insensible to the action of either of them, separately used.

Mr. Erman, in his paper on two new classes of galvanic conductors, says that the bodies which may be applied to the poles of a galvanic pile are, I. Non-conductors. II. Conductors. The conductors are either perfect or imperfect; and the imperfect conductors are fo, either with respect to both poles, or with respect to one of the poles of a galvanic battery.

I. The perfect non-conductors prevent the communication of the power of both poles effectually; and such are galls, refins, ice, and the vapour of water, sulphur and its flame, amber, but not its flame.

II. The perfect conductors, which discharge both poles completely, are the metals, and all in the same degree.

The imperfect conductors of both poles. These, though capable of forming the galvanic circuit, exhibit in their extent effects of two different kinds. Fluid water and bodies impregnated with water are of this nature.

The imperfect conductors of the positive pole only. These are incapable of forming the galvanic circuit; for when interposed between the two poles of the pile, they infupe the negative power and conduct the positive; whence it follows, that the negative becomes charged, whereas the positive is conducted. The flame of hydrogen gas, and the flame of the hydrocarbonated bodies, have this property.

Lastly, the imperfect conductors of the negative pole only impufl the power of the positive, and conduct the power of the negative pole. Of this sort are the flame of phosphorus and of alkaline foams.

There now remain two other particulars, which demand our examination with respect to the conductors of electricity. These are the method of ascertaining their peculiar degrees of conducting power, and their nrcs. The simplest method of determining whether any given body be a conductor or not, is to affix an electrometer to the prime conductor of an electrical machine, and when the machine is in action, and of course the electrometer is diverging, to touch the prime conductor with one extremity of the given body, which the operator holds in his hand by the other extremity; for if, in so doing, the electrometer collapses, the body in question is a conductor; but if the electrometer continues to diverge, that body is a non-conductor. Its degree of conducting power may also be, in great measure, estimated from the quickness with which the electrometer loses its divergency. In the performance of this experiment, the operator should take care that the electric fluid does not run over the surface of the body under trial to the hand that holds it, which generally takes place when the machine acts powerfully, and the body in question is not much extended. In this case, it becomes proper to stop the revolution of the glass globe or cylinder, when the body is to be put in contact with the prime conductor. But if the body be very small, it will be sufficient to use a simple electrometer only, which may be easily caused to diverge by means of an excited flock of sealing-wax, and may then be touched with the body in question. Yet all this is not sufficient.
sufficient to discriminate the peculiar powers of substances that are of the same class, such as the various metallic substances, the different classes, &c. And for this purpose various other means may be adopted, according to the nature of the bodies under examination. The best way of determining the peculiar conducting powers of metallic substances, is to have wires of the different metals drawn through the same hole, so as to be precisely of the same diameter, and then melt them by the discharge of a battery; viz. take a wire, of about one-fiftieth of an inch in diameter, and connect it with the outside of a battery, containing at least thirty square feet of coated surface, and connect the other extremity of the wire with one branch of the discharging rod. Then, when the battery is charged, touch the wires which proceed from the inside of it with the other branch of the discharging rod, which will force the expulsion to pass through the wire that has been interposed between the battery and the discharging rod, generally melting a greater or a smaller part of it, according to the nature of the metal. Thus by repeating the experiment successively with wires of the same length and diameter, but of different metallic substances; charging the battery constantly to the same height, which may be easily accomplished by means of a quadrant electrometer; and measuring the length of each wire that has been melted by the explosion; their various conducting powers may be ascertained; observing that the worst conductors are more easily melted, and vice versa.

Mr. Henley found that the same charge melted 4 inches of gold wire, 6 of brass, 8 of tinned copper, 10 of silver, and rather more than 10 of iron. In melting wires of a considerable length, as for instance two or three feet, it often happens that the force of the explosion barely renders it red hot, without actually melting it. In this case, it is curious to observe that the redness appears first on that extremity of the wire which communicates with the positive side of the battery, and thence proceeds towards the other end of the wire, which furnishes ocular proof of the theory of a single electric fluid; the wire, however, is not rendered red hot at one extremity before the other, in consequence of the progressive motion of the electric fluid through it, but because that fluid loses some of its impetus in going through the wire, so that the wire suffers the greatest effect of the shock on that end which the electric fluid enters; in consequence of which, that end will be rendered red hot much sooner, and in a greater degree, than those parts which are more remote from it.

When the conducting powers of different fluids are to be ascertained, the best method of performing the experiment is to fill very narrow glass tubes, such as are used for spirit thermometers, with the fluids in question, introducing a point at each end of the tubes; and to present them successively to the prime conductor, after the manner already described. For other kinds of bodies other methods may be adopted for ascertaining their conducting powers. Thefe, however, need not be particularly described; first, because they may be easily derived from the fole that have been described above; and, secondly, because they must be varied according to the nature of the bodies in question. After all, it must be acknowledged, that the metals excepted, no very great degree of accuracy can be expected with other substances; since the fluctuation of their conducting powers arises from a variety of places, and almost imperceptible differences, such as the difference of temperature, of moisture, of admixture with other substances, &c. Thus, glass itself becomes a conductor, when heated to a certain degree; and the very same body will conduct more or less readily, even by being placed nearer to or farther from certain other bodies.

In considering the conducting power of natural bodies, one may naturally ask, whence does that property arise; or how is it, that certain bodies will, whilst others will not, conduct the electric power? The present state of knowledge, however, does not afford a satisfactory answer to this question. Various suppositions have been offered by the late Dr. Priestley and others; but as they are insufficient for the explanation of the phenomena, we shall not attempt to state them in this place.

The uses of conductors are remarkable and extensive, though they are not yet fully ascertained to the entire satisfaction of the speculative philosopher. In the first place, the science of electricity, or the existence of the electric power, would be absolutely unknown, were it not for the difference of conducting and non-conducting bodies; for otherwise the electric fluid which is manifested to us, and operates merely by its passage from one body to another, could neither be confined nor accumulated in any place; in consequence of which, its uniform dispersion throughout the universc would remain invisible, and unsuspected.

But the movements of conducting and non-conducting bodies in the world, their contact, or even their approach without any actual contact, condenses the electric fluid in one place, and rarefies it in another; and this takes place between the clouds and the earth, &c. By the change of their states of existence, some bodies absorb from other bodies, and others deposit upon other bodies considerable quantities of electric fluid. Thus, a perpetual and ample circulation of this fluid is continually kept up amongst all the substances of the terrene globe, whence thunder and lightning, vaporization, and probably several other important operations of nature, are derived. In order to understand the action of conductors when opposed to each other, see the nature of electric atmospheres under the article Electricity.

The greatest advantage which mankind have derived from the knowledge of the present subject, is the adoption of a conductor for the preservation of buildings and vessels against the dire effects of lightning. The identity of electricity and lightning proved by Dr. Franklin, and his subsequent introduction of conductors for preserving buildings, form two of the grandest discoveries of the last century. It was proposed by the above-mentioned philosopher to raise a metallic conductor some feet above the highest part of the building, to continue the same down along the outside of the wall, and below it, deep into the earth, or, which is preferable, to connect it with some well or drain. By these means the house would have little to apprehend from a stroke of lightning; for, since an electrified body is well known to strike the nearest and belt conductors that may happen to be in its way, it is evident that the conductor fixed in the abovementioned manner, being of metal, and higher than any part of the building, would naturally be struck by the lightning in preference to any other part, and would conduct it to the ground, without any damage to the building.

This reasonable proposal was no sooner offered by the sagacious Franklin, than it was adopted in America, in Europe, and elsewhere. Numerous facts soon proved the usefulness of such conductors, and extended its adoption; by flying that several houses, which before had been repeatedly struck by the lightning, escaped unhurt after the application of the conductor; that, in many places, the conductors of houses were actually struck by the lightning, which melted them about their extremities, yet the houses themselves received no injury; and so forth.

Though the conductors were instantly adopted, yet their
most useful form, especially with respect to their upper termination, has been much controverted; and it is but lately that the true state of the question has been elucidated. The question was, whether the conductors should terminate in a point, according to Dr. Franklin's original proposal, or in a ball. Mr. B. Wilson exhibited some experiments, in which a point was struck at a greater distance than a ball; whence he concluded, that as the point would attract the lightning from a greater distance, a blunt termination ought to be preferred, since, in certain cases, it would avoid a stroke of lightning, which the pointed termination would not. (Phil. Trans. for 1778.) Mr. Nairne, on the other hand, showed some experiments, in which a ball was struck in preference to a point. And this indeed is confirmed by a great variety of other experiments. In short, a pointed conductor will draw the electric fluid from an incomparably greater distance than a blunt one; but it will draw that fluid gradually, in a dream, or fluent manner; whereas the blunt termination will receive it in a full spark, or at once; hence a pointed conductor will tend to diminish the quantity of electricity in a cloud, previous to its coming too near, and thus it may protect a greater extent of building than a conductor with a blunt termination, since the object of fixing a conductor to a house is to protect the house from the effects of lightning, and not the conductor from transmitting the matter of the lightning.

Upon the whole, considering the immense quantity of electricity in a thunder cloud, and the little difference between the action of a blunt or a sharp conductor with respect to that quantity, the difference of those terminations seems to be of little consequence than it was apprehended in the fervour of the dispute. After all the experiments and the discussions made for the purpose, "A conductor," Mr. Cavallo observes, "to guard a building, as it is now commonly used in consequence of several considerations and experiments, should consist of one iron rod, (copper would do much better, it being a more perfect conductor of electricity, and at the same time not being so subject to contraction as iron,) about threequarters of an inch thick, fastened to the wall of the building, not by iron cramps, but by wooden ones. If the conductor were quite detached from the building, and supported by wooden poles at the distance of one or two feet from the wall, it would be much better for common edifices; but it is more particularly advisable for powder magazines, powder-mills, and all such buildings as contain combustibles ready to take fire. The upper end of the conductor should be terminated in a pyramidal form, with the edges, as well as the point very sharp; and if the conductor be of iron, it should be gilt or painted for the length of one or two feet. This sharp end should be elevated above the highest part of the building, (as above a flake of chimney, to which it may be fastened,) at least five or six feet. The lower end of the conductor should be driven five or six feet into the ground, and in a direction leading from the foundations; or it would be better to connect it with the nearest piece of water, if any be at hand. If this conductor, on account of the difficulty of adapting it to the form of the building, cannot conveniently be made of one rod, then care should be taken, that where the pieces meet they be made to come in as perfect a contact with one another as possible; for the electricity finds considerable obstruction where the conductor is interrupted. For an edifice of a moderate size, one conductor, in the manner already described, is perhaps sufficient; but, in order to secure a large building from fulfilling any damage by lightning, there should be two, three, or more conductors, in proportion to the extent of the building."

"In ships a chain has often been used for this purpose, which, on account of its pliability, has been found very convenient, and easy to be managed among the rigging of the vessel; but as the electricity finds a great obstruction in going through the several links, for which reason chains have been actually broken by the lightning, so their use has now been almost entirely laid aside; and in their stead, copper wires, a little thicker than a goose-quill, have been substituted, and have been found to answer very well. One of these wires should be elevated two or three feet above the highest mast in the vessel; this should be continued down the mast, as far as the deck, where, by bending, it should be adapted to the surface of those parts, over which it may roll conveniently be placed, and, by continuing it down the side of the vessel, it should be always made to communicate with the water of the sea."
Rarefaction or condensation alters the conducting powers of several bodies. Yet the rarefaction of air is by no means accompanied with a proportionate diminution of its conducting power.

Professor Pictet supposes that heat ascends within solid bodies more readily than it descends; *viz.* that in communicating heat to a solid body by the lateral application of a hotter body, the upper parts of the former are heated sooner than the lower. This effect, however, may with propriety be attributed to the ascending current of heated air which rises along the surface of the body, and causes colder air to approach the lower part of the body; hence the heat is continually carried upwards.

The conducting power of a body changes likewise, in consequence of an alteration of the surface; so that polished and figured are likewise concerned in the reception as well as in the propagation of heat. These particulars, however, together with the reflection and refraction of heat, from the surface or through the substance of bodies, will, with more propriety, be explained under the article Heat.

Fluids are, upon the whole, very imperfect conductors of heat, and Count Rumford was led, by his experiments, to conclude that heat is not at all propagated through them by contact, as it is in solids. (See Rumford's paper on the Conducting Property of Fluid, *&c.* Phil. Trans. 1805.) Whatever permits or promotes the motion of the particles of a fluid, contributes to the propagation of heat—*viz.* obstacles that motion, retards the propagation of heat through them. The particles of air which come in contact with an heated body, being thereby heated and rarified, become specifically lighter than the surrounding air, and of course ascends; other air then comes in contact with the heated body, and this also being heated is caused to ascend, and so forth. Thus is heat conveyed from the original hot body, by the air, to a distance from it; but if that motion of the air be obstructed, as by the intervention of partitions of paper, wool, cotton, furs, and the like, then the communication of heat is prevented more or less effectually. It is principally on this account, that furs, feathers, sable, down, cotton, and other similar things, form warm coverings; *viz.* because, by preventing in great measure the motion of the air between their filaments, they prevent at the same time the dissipation of heat.

The like observations are applicable to water, and perhaps to all other fluids. When a vessel full of water is set upon the fire, the particles of water that are close to the bottom of the vessel are first heated and rarified; in consequence of which they ascend, and other colder particles take their place, which, being heated, likewise ascend, and so on. If the fire be applied to the upper part of the water, the fluid will not be heated, or at most it willsurname the surface. Count Rumford (see his 7th Essay) confined a piece of ice at the bottom of a pretty tall glass vessel full of water nearly boiling, and noted the time it took up to melt the ice. The experiment then was repeated with this difference, *viz.* that a similar piece of ice was placed on the surface of the hot water, instead of the bottom. It was found that the ice melted more than eight times quicker in this last situation than in the former. The result of this remarkable experiment is explained in the following manner. When the ice swims on the surface of the hot water, the particles of the latter, that are contiguous to the ice, being cooled by it, descend, and other hot particles of water take their place, which deposit their heat upon the ice, and, being thereby rendered specifically heavier than the next particles of water, also descend, and so forth. But when the ice is confined, the
The bottom of the vessel, the particles of hot water which come first in contact with it, are cooked, and are rendered specifically heavier, in consequence of which they remain in their place, and no motion will take place within the water; hence the ice is not melted nearly so readily as in the former situation. Now count Rumford contends that it is by means of the above-mentioned motion only that heat is propagated through fluids, and not otherwise. This conclusion was no sooner published to the scientific world, than it was opposed in an able paper by very skilful philosophers. See Dalton's paper. Nich. Journ. vol. iv. p. 75. Tralli's paper, ibid. 1805, p. 33; and Murray's paper, ibid. vol. i. From these papers we shall make the following abridged extracts, which seem necessary for the elucidation of the subject; and in the first place we shall state Mr. Murray's experiments.

Into a glass cylindrical vessel water was poured, till it covered the bulb of a thermometer; its temperature was 46°, which was likewise the temperature of the air of the room. One ounce of olive oil, heated to 140°, was poured on a small piece of cord, suspended on the surface of the water, and the cord was slowly withdrawn. Any motion of the water was thus avoided. In the course of a minute the thermometer began to rise slowly; in five minutes from the commencement of the experiment, it had risen 4°, in ten minutes 6°, in fifteen minutes 8°. It then became stationary, and continued so for seven minutes, before it began to fall. Its descent was slow. This experiment was repeated with a hot metallic ball (instead of oil) immersed in the water above the thermometer, and it was attended with a similar effect.

From these results the conclusion might seem just, that the fluid must possess a conducting power. Yet this is rendered doubtful by the circumstances, that in all experiments of this kind, a quantity of caloric must be conveyed by the sides of the vessel. In order to avoid this source of error, Mr. Murray employed a vessel of ice. But water could not be used in this case, because that fluid expands from 40° to 32°; therefore oil and mercury were used.

A quantity of almond oil was poured into the ice vessel, so as to cover the bulb of the thermometer a quarter of an inch. A small cylindrical iron cup, two inches in diameter, and having a flat bottom, capable of holding two ounces by measure, was suspended so as merely to touch the surface of the oil, and was filled with boiling water. At the beginning of the experiment, the thermometer stood at 32°. In a minute and a half it had risen to 32°, in three minutes to 34°, in five minutes to 36°, in seven minutes to 37°. At this point it became stationary, having risen 5° in seven minutes. The temperature of the water in the cup had in this time fallen to 96°. The thermometer, after remaining stationary at 37° for five minutes, began to fall, and it continued to descend at the rate nearly of a degree in a minute and a half, till it returned to 32°. The experiment was repeated with this variation, viz. that the thermometer was placed lower, so that half an inch of oil flowed over its bulb. It was also repeated with mercury instead of oil. But in both cases the results were similar to that of the first experiment.

"This rife," Mr. Murray says, "it appears to me impossible to ascribe to any other cause than to a power in the fluid to conduct caloric. Thus it is evident, that the sides of the vessel cannot convey to the fluid in contact with the bulb of the thermometer any part of the caloric it received. Ice, in common with any other solid, may, at temperatures below its melting point, conduct caloric; but as it cannot possibly exist with a temperature above 32°, it cannot communicate any temperature above that to a fluid in contact with it, and consequently it would not contribute in the above experiment to raise the thermometer above that temperature. Caloric does not radiate through transparent fluids, and it cannot even be supposed capable of passing by radiation through an opaque fluid as mercury.

If it be proved that oil and mercury are capable of conducting caloric, it will be admitted as sufficiently probable, that other fluids may have a similar power. Of these two, mercury, it is probable from these experiments, is the better conductor, as the rise of the thermometer took place in it much more rapidly than in the oil. Dr. Tralli's experiments for ascertaining the conducting powers of divers fluids, were performed in the following manner:

A cylindrical vessel was turned out of wood, having its sides half an inch thick, its height four inches and its diameter two. It has a moveable wooden top or cover, perforated with a hole in its centre, a little more than an inch in diameter, into which an iron cylinder, of one inch in diameter, could be easily introduced. This cylinder is supported by a flight flange, or shoulder-piece, and can be taken up by means of a string attached to its top. When the iron bar is in its place, its flat lower extremity is half an inch distant from the bulb of a delicate mercurial thermometer, which is fixed by wax in a hole perforating the cylinder near its bottom. This thermometer is bent to a right angle, so that its bulb and part of its stem lie in the axis of the wooden cylinder. This shape was preferred, because the item could be little affected by the caloric transmitted by the sides of the vessel, till after the bulb was acted on by the caloric of the iron bar.

A variety of experiments was performed with this apparatus in the following manner: The temperature of the room being nearly 67°, Fahrenheit, during the trials, a kettle of water was kept boiling over the fire. Its temperature was between 211° and 212°, and this is the cylinder of iron was suffered to remain, at each experiment, for fifteen minutes. The liquid to be examined, and all the apparatus (but the iron bar) were at each experiment ascertained to be at 67°. The liquid was poured into the wooden vessel, till it could rise 1/5 of an inch on the side of the iron cylinder when in its place. The wooden top was put on, and the iron was drawn out of the kettle of boiling water by means of the attached string, and instantly let down through the hole of the cover. The time the thermometer took to rise through 3° (viz. from 67° to 70°) was accurately marked by means of a stop-watch, and the results of the experiments on several fluids, are exhibited in the following table.

"If
"If I am not deceived," says Dr. Traill, "we may conclude, from what I have above adduced, that liquids, as well as solids, are conductors of caloric; that the transmission of it through them follows a particular law depending on the properties of the particular liquid; which is not in the exact ratio of any of their mechanical properties, though nearer that of their density, than any other.

A circumstance, deserving the attention of the speculative philosopher, respecting the conductors of electricity and of heat, has been observed; viz. that most of those bodies which are good conductors of the one, are likewise good conductors of the other. This law, however, is not without exceptions. Thus, metallic bodies are good conductors of both: but charcoal is a good conductor of electricity, though a very bad conductor of heat.

The last particular, which we shall briefly notice, with respect to the conductors of heat, is their use. This, on the lead examination, will be found to be very extensive. Nature and art avail themselves of these peculiar properties of bodies, and without them both animal and vegetable life could not subsist. The atmospheric fluid which envelops the earth, is a very bad conductor of heat, undoubtedly created for the purpose of not dissipating the heat of the earth and terrestrials bodics. The coverings of animals, such as furs and feathers, being extremely bad conductors, confine the heat on the animal body. The bark and ligneous part of plants, in consequence of their imperfect conducting powers, tend to prevent the freezing of vegetable juices. The industry of man has not omitted to use the worst conductors of heat for coverings, for the defence of his habitations, for the confinement of heat in certain furnaces, &c. In short, numerous and admirable effects are produced by Providence, and several efficient advantages are obtained by art, from a proper application of the various conducting powers of natural bodies.

Conductors, in the Military Art, are auxiliaries to the commissary of stores in conducting depots and magazines from one place to another. They take charge of the ammunition wagons in the field, make their reports to the commissary, and are under his authority and command.

Conductos ad præstitendum, in Law. See Cafras.

Conduit, a canal, or pipe, for the conveyance of water, or other fluid matter.

In the earth are several subterraneous conduits, through which the waters pass that form some Springs; and through which also pass the vapours which form Metals and Minerals.

Artificial conduits for water are made of lead, stone, cast iron, potter's earth. See Plumbery.

In the province of New Mexico, there is said to be a subterraneous conduit, in form of a grotto, extending six hundred miles in length. See Duct. Tubs, &c.

Conduit d'une Troops. A troop that marches has always an officer, who commands independently of the other officers that may accompany it.

Conduskeg, in Geography, a settlement of America, in the district of Maine and Hancock county, containing 557 inhabitants.

Condyliæ, in Ancient Geography, a town of Arcadia, near Caphia, and N.W. of Orchomenus. In this town was a temple of Dana, and near it a grove. Paufians.

Condyliæ, in Anatomy, an appellation bestowed on several portions of the bones.

Condylopa, from σδομο, s'di'ti articulæ, in Surgery. By this term is understood almost every hard excrescence or sarcoma, that appears in the parts about the anus and the pudenda of both sexes; which is generally pinxt, or at least troublesome, and sometimes of a venereal origin. According to the different forms which they acquire, they are termed condylopa, condyl.]"
care not to let any part of them come into contact with the rectum, which would produce very dangerous consequences. The extirpation by means of ligatures may be employed when the number of the excrescences is but small, and they hang by small stalks to the surface; for otherwise it is a painful remedy. The most certain method of removing them is by means of the knife, only they frequently grow again within a short time; nor ought this remedy to be employed in venereal cafes, till a sufficient quantity of mercury has been administered. In cutting them off, all the adjacent diseased parts must be taken away; and in order to prevent inflammation, the blood may be suffered to flow for some time, after which the parts may be covered with lint, and treated as a common wound.

CONDYLON, in Ancient Geography, a fortress of Greece, between Connas and Tempe, towards Thessaly.

CONE, in Geometry, a solid body, having a circle for its base, and terminated at the top in a point, or vertex. See Plate 1, Conics, fig. 4.

The cone is generated by the motion of a right line, KM, round an immovable point, K, called its vertex, along the circumference of a plane, called its base, MN; or it may be conceived as generated by the revolution of the triangle, KLM, about the right line, KL, which is called the axis of the cone, and KM its latus or side. If the axis be perpendicular to the base, it is said to be a right cone; and if inclined, or oblique, an oblique or slanted cone. Scalenous cones are again divided into obtuse-angled, and acute-angled.

An equalateral cone, is a right cone, whose side is equal to the diameter of the base.

Euclid defines a cone a solid figure, whose base is a circle, as CD (fig. 5.), and is produced by the entire revolution of the plane of a right-angled triangle CAD, about the perpendicular leg AB. If this leg, or axis, be greater than CB, half the base, the solid produced is an acute-angled cone; if less, it is an obtuse-angled cone; and, if equal, a right-angled cone.

But Euclid's definition only extends to a right cone; that is, to a cone whose axis is at right angles to the base; and not to oblique ones, whose axis is not at right angles to the base.

For a more general and comprehensive description of a cone, which may take in both right and oblique ones, suppose an immovable point A (fig. 6.), without the plane of the circle BDEC; and suppose a right line, AB, drawn through that point, and produced infinitely both ways, to be moved quite about the circumference of the circle; the two superficies that will arise from this motion are each called conic superficies; but, taken conjunctly, they are called superficies vertically opposite, or only opposite superficies. The immovable point, A, common to both the superficies, is called the vertex; the circle BDEC, the base; the right line AC, drawn through the vertex A, and C, the centre of the base, and if infinitely produced, the axis; and the solid, comprehended under the conical superficies and the base, is a cone.

Cone, Properties of the.—1. The area or surface of every right cone, excluding its base, is equal to a triangle whose base is the perimeter, and its height the slant side of the cone.

Take the very small arc IK (fig. 7.), and draw IA, AK. Then the part of the surface AIK coincides with the small isosceles triangle AIK, whose base is IK, and height AI. In like manner, the whole surface of the cone may be opposed to confit of such triangles whose common height is AI, and bases so many K's as are contained in the circumference of the base, all which triangles are equal to the triangle whose height is AI, and base, the sum of all the K's, or the circumference BKDB. Hence, the curve surface of a right cone is equal to half the rectangle of the side AB, and circumference of the base, BKDB. For the half of that rectangle is equal to a triangle of the same base and height. Moreover, the curve surface of a right cone is equal to a circle, whose radius is a mean proportional between the side AB, and the radius of the base BC. For the conic surface is \( \frac{AB \times BKDB}{2} \), and the area of the base BD = \( \frac{BC \times BKDB}{2} \) (see Circle).

Let the radius, R, represent the mean proportional between AB and BC, or let \( R = \sqrt{AB \times BC} \); and the area of the whole radius is \( R = A \). Then the conic surface = circle BD :: \( \frac{AB \times BKDB}{2} \) = circle A :: \( AB \times BC \). Hence, also, the curve superficies of a right cone is to the area of its circular base, as AC (fig. 5.), the length of the hypotenuse of the right-angled triangle describing it, is to CB, the base of the fame triangle; that is, as the slant side of the cone, to the semidiameter of the base.

Hence also, the surface of a right cone is equal to a sector of a circle described on the slant side of the cone, as a radius, whose arc is equal to the semidiameter of the base of the cone; and has therefore the fame proportion to its semidiameter, which the diameter of the base has to twice the side of the cone. Hence we have a method of describing a rete or cage that shall just cover a cone.—Thus, with the diameter of the base AB (Plate, Conics, fig. 8.), describe a circle, and produce the diameter to C, till AC be equal to the side of the cone. To 2 AC and AB, determined in numbers, and 360°, find a fourth proportional: and with the radius CA, on the centre C, describe an arc DE equal to the number of degrees found: the sector CDE with the circle AB will be a rete for the right cone.

If, then, the side of a truncated cone be set off from A to I, and an arc GH be described with the radius CF; by finding a fourth proportional to 360°, to the number of degrees of the arc GI, and to FC; and thence determining the diameter of the circle IF, we shall have a net or cover of the truncated cone.

For CDBAE is a net for the entire cone; CGFII for the cone cut off; therefore, DBEHIG for the truncated cone.

2. Cones and pyramids, having the same bases and altitudes, are equal to each other.

Now, it is shown, that every triangular prism may be divided into three equal pyramids; and therefore, that a triangular pyramid is one third of a prism, standing on the same base, and having the same altitude.

Hence, since every multangular body may be resolved into triangular ones, and every pyramid is a third part of a prism, having the same base and altitude; since a cone may be esteemed an infinite-angular pyramid, and a cylinder an infinite-angular prism; a cone is a third part of a cylinder, which has the same base and altitude. Hence, cones of equal bases are as their heights; cones, and also frustums of cones, of equal altitudes, are as the bases: cones are to one another in the compound ratio of the bases and heights; and in equal cones, the bases and heights are reciprocally proportional.

3 A 2. Hence
Here we have a method of measuring the surface and solidity of a cone. Thus, for the solidity: find the solidity of a prism, or cylinder, having the same base with the cone, or pyramid, or, multiply the base by the altitude; then divide by : the quotient will be the solidity of a cone, or a pyramid. Thus, if the solidity of a cylinder be $60552660$, the solidity of the cone will be found $201794320$.

For the surface: that of a right cone is had by multiplying the semi-periphery of the base into the side, and adding the product to the base.

All cones, which have their altitudes and the diameters of their bases reciprocally proportional, are in the triplicate ratio of their altitudes, being each to other in the same proportion with prisms of equal base and altitude, of which they are like parts. See Prin.

Suppose, e. g., the diameter of the cone $NM$ (fig. 4) 36, the periphery will be $17550266$, and the base $24530144$. Suppose the altitude or axis $KL$, 246; since $LM = \frac{3}{4}$ $NM = 28$, and $KM = KL = 6056 + 784 = 61300$, $KM = 24755$, &c. Consequently the superfiences of the cone, exclusive of the base, is $21771388$; and the whole together $242433224$.

The solidity of an oblique cone is obtained in the same manner with that of the right cone: but it is much more difficult to find its surface, since it cannot be reduced to the measure of a factor of a circle, because all the lines drawn from the vertex to the base are not equal. See a Memoir on this subject, by M. Euler, in the Nouv. Mem. de Pæthburn, tom. i. Dr. Barrow has demonstrated, in his Lectiones Geometricæ, that the solidity of a cone with an elliptic base, forming part of a right cone, is equal to the product of its surface by a third part of one of the perpendiculars drawn from the point in which the axis of the right cone intersects the ellipse; and that it is also equal to one third of the height of the cone multiplied by the elliptic base; and therefore that the perpendicular to the height of the cone, as the elliptic base to the surface.

For the measure of the surface, and solidity of a truncated cone, or frustum, $ABCD$ (fig. 8). Its altitude $CH$, and the diameters of its bases $AB$ and $CD$, being given, find their circumferences; to the square of the altitude $CH$, add the square of the difference of the radii $AH$, and from the aggregate extract the square root, which will give the side $AC$: the semi-sum of the peripheries, multiplied by that side, gives the superficies of the truncated cone or frustum.

To find the solidity: as the difference of the semi-diameters $AH$, is to the altitude of the truncated cone or frustum $CH$, so is the greater semi diameter $AP$ to the altitude of the entire cone $EF$. This being found, subtract the altitude of the truncated cone $GF$, which will leave that of the cone taken off, $EG$. Find the solidity of the cone $CED$ and $AEB$; subtract the other from this; the remainder will be the solidity of the truncated cone $ACDB$. Or, add into one sum the areas of the two ends of the frustum and the mean proportional between them; multiply that sum by the perpendicular height, and \(\frac{3}{4}\) of the product will be the solidity. For the method of finding the surface and solidity of a cone, &c. by fluxions; see Superficies and Solidity.

**Cone, Ungula of.** See Ungula.

For the sections of the Cone, see Conic section.—For the ratio of Cones and Cylinders. See Cylinder.—For the centers of gravity and of oscillation of a Cone, see Center.

Cone of the higher kinds, are those whose bases are circles of the higher kinds; and are generated by supposing a right line fixed in a point, on high, though conceived capable of being extended more or less, on occasion; and moved or carried round the said circle of the higher kind.

Cone of rays, in Optics, includes all the several rays which fall from any point of a radiant, on the surface of a glafs.

Cone, abline, or spindie, in Mechanics, is a solid formed of two equal cones joined at their bases. If this be laid on the lower part of two rulers making an angle with one another, and elevated above the horizontal plane, it will move towards the raised ends, and seem to ascend, though it really descends. Let $ABD$ (Plate XVI. Mechanics, fig. 7) be a common base of the two cones: its centre $C$ will be the centre of gravity of the whole solid: therefore, if $DF$ represents one of the rulers elevated to an angle $FDG$, whose sine $FG$ is less than the semidiameter of the cone $CD$, it is plain that the centre of gravity $C$ at the position of the cone $D$, is more distant from the centre of the earth, to which all heavy bodies tend, than in its position between the legs of the ruler at $F$; and therefore it will descend, as on an inclined plane $CFE$, from $C$ to $F$, where it will stop, being supported on the raised ends of the rulers.

Cone, in Affixing. See Melting-cone.

Cone, in Botany, a hard dry seed-veil of a conical figure, co-mitting of several woody parts; and is, for the most part, fealy, adhering clofsly together, and separating when ripe.

Cone-flone, in Natural History, the name given by many to a species of Turbulus marinus, not known to us in its recent state, but frequently found fossil in the Swedish flones used in pavements.

Cone, and key. Bradton, lib. ii. cap. 37. num. 7. says, Fumina in tali estate (i.e. 14. or 15. annorum) potest disposita donum facer, et habere cone et key.

The words come from the Saxon cova, i. e. calculate, and key, elvis; so that a woman was then held to be of competent years when she was able to keep the accounts and keys of the house: and Gram. lib. viii. cap. 9. has somewhat to the same purpose.

Cone, in Conchology. See Conus.

CONESTE, Thomas de, in Biography, a monk of the order of the Carmelites, born in Bretagne, towards the close of the fourteenth century, and distinguished as the most popular and imprefive preacher of his time. In his discourses he did not confine himself to subjects of religion and morality, but he attacked with vehemence the reigning follies and fashionable foibles of the age. The head drefs of the ladies in particular was the subject of his repeated remonfances. At this period, says Bayle, "the head-dresses were of such a prodigious height, that the highest top-knots now are but dwarfs to them." Coneste reformed the women, and obliged the ladies to drefs themselves more decently and with a flrtct regard to decorum. It was not, however, so much by the force of the reasons with which he represented the evangelical duties, as by exciting boys and the commonalty to infult those of the other sex, who would not introduce a reformation into their dress. Whether, however, he aimed at vice or folly, he was so famed as an orator, that no churches were sufficiently spacious to contain the crowds, that followed him wherever he went; he therefore chose as the display of his eloquence, public squares and other places where immense scaffolds were erected, from which he could make himself heard by many thousands.
funds at the same time. When he travelled from place to place, it was on a mule attended with many monks and priests on foot. As soon as he arrived in the vicinity of any town, the most considerable persons for rank and property came out to meet him, in order to conduct him to the house provided for his lodging, which was commonly the best in the place. His labours were not confined to his own country; from France he proceeded to the Netherlands, and Italy, exciting everywhere the same attention which he experienced in his native land. At Venice he gained so much reputation, that the embassadors from that republic to the pope, invited him to accompany them to Rome. But the freedom and spirit of his declamations against the corruption of the clergy and the court, roused the resentment, and passions of the papal state; he was accordingly tried and condemned for heresy, and burnt at Rome in the year 1434. His motives were questioned by some of his contemporaries, but the readiness with which he submitted to a cruel death, in defence of his conduct, rather than retract the charges which he had exhibited against the profaneness of the Romish hierarchy, was sufficient evidence of his sincerity in a good cause. Baily.

CONEGLIANO, Gio Battista Cima, called II. from the vicinity of that city, a small city in the state of Venice, became, under the patronage of Giovanni Bellini, a painter of considerable eminence; and indeed so entirely did Conegiano polish himself of the style of Bellini, that the works of the scholar are frequently confounded with those of the master; even by good judges. It was however much the custom with the older Venetian painters to subscribe their names to their works; many therefore of this artist are still known, as well by the inscription as by the mountainous view of the town of Conegliano with which he usually enriched his back grounds. A juvenile performance of this master with the date 1491, is in the duomo of Conegliano: a more excellent picture by him is in the church of Santa Maria dell' Orto, at Venice. It represents St. Peter, St. Paul, St. Mark, and St. Jerome, with a magnificent architectural background. But in the opinion of Lanzi, the chef-d'œuvre of Conegliano is an altar-piece in the duomo at Parma, the subject of which however he has neglected to mention. This master is supposed to have died shortly after 1517. Lanzi. Storia Pittorica. Zanetti. Pittura Veneta.

CONEGOCHEAQUE CREEK, in Geography, a creek of America, which runs near Martinsburg, in Franklin county and state of Pennsylvania, runs southerly in a winding course, and after supplying a number of mills, discharges itself into the Potowmac at William Port, in Washington county, Maryland; 19 miles S.E. of Hancock, and 8 miles S. of the Pennsylvania line.

CONEI or CONE, George, a native of North Britain, and a zealous catholic, went to reside at Modena, in Italy, at an early age. He afterwards settled at Rome, and was celebrated, during the pontificate of Pope Paul V., for his profound knowledge of the Greek and Latin languages. His own good character recommended him to the patronage of the cardinals Montalto and Barberini. The latter being nephew to pope Urban VIII., Conei soon obtained so much of the favour and confidence of the pontiff as to be entrusted with the office of nuncio to Maria Henrietta, queen of England, which he discharged completely to the satisfaction of the papal court. As a reward for his conduct he would have been raised to the dignity of cardinal, had not death cut off his prospects. He died in 1640, at the age of forty-two; leaving behind him, among other works of merit, "The Life of Mary Stuart," "De Institutione primiis," "De Duplici Statu Religionis apud Scotos," &c. &c.

CONENGAUGH RIVER, and Little Conenough, in Geography, are the head waters of Kilkenmaraas, in Pennsylvania. After passing through Laurel hill and Cheat ridge, Conenough takes that name, and discharges itself into the Alleghany, 29 miles N.E. of Pittsburgh. It is navigable for boats, and there is a portage of 18 miles between it and the Franklin branch of Juniata river. -- Also, a town of Pennsylvania, 15 miles E. of fort Ligoner.

CONENOS, Las, a city of La Plata or Paraguay, in South America, in the diocese of Buenos Ayres.

CONEPATL, in Zoology, an American animal of the weasel kind mentioned by Herand., and also by Ray under the title of Trigipata. It is described as being a strong resemblance to the racoon in shape, but variegated with two long flocks of white, one on each side of the ridge of the back, which run even into the tail. This animal is laid to be of a harmless disposition, but of a skilling smell, and when pursued, or provoked, will discharge its excrements at the person who offers it to fix or eight feet distance; these have a very bad smell and spoil peoples clothes by leaving invisible yellow spots on them. Little is known of this animal than is above related. It inhabits New Spain, and was placed by Linneus in his Systema as the same species with his Vivera Memphitus, the memphitic weasel, and chinese of Buffon. Gmelin considers it as a distinct species, and describes it specifically under the name of conepat. This animal may prove to be a variety only of the fratercul weasel, or perhaps only of the memphitic weasel to which Linneus at first alligned it. See Vivera.

CONEFFREIT, in Geography, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles N.N.E. of Amberg.

CONESI, or CONETI, in the Materia Medica, a bark brought from the East Indies. It is frequent in Ceylon, and Malabar, where the natives take it in diarrheas, linteries, and dyentaries. We use it in powder for the same purposes, the dose being from half a dram to a dram. It is proper to give a dose of ipecacuanha before taking it.

This tree grows also on the Coromandel coast, in the East Indies, and is not unlike the radgeopa of the buttus Malabaricus. The bark should be fresh powdered, and the electuary prepared with syrup of oranges every day or every other day. Med. Eff. vol. iii. art. 4.

CONESTEO, in Geography, a north-western branch of Tioga river in the state of New York, America.

CONESTOGA, a township of America, in the county of Lancaster and state of Pennsylvania.

CONESUS, a small lake of America, in the county of Genesee and state of New York, which conveys its waters N.W. to Genesee river.

CONFESSION, a ceremony among the ancient Romans, used in the marriage of persons whose children were destined for the honour of the priesthood. Confession was the most facet of the three modes of contracting marriage among that people; and confided, according to Servius, in this, that the pontifex maximus and flamen dialis joined and contracted the man and woman, by making them eat of the same cake of salted bread; whence the term, for signifying meal or flour.

Ulpian says, it confided in the offering up of some pure wheaten bread; rehersings, at the same time, a certain formula,
CON

formula, in presence of ten witnesses. Dionysius Halicarnassian adds, that the husband and wife did eat of the same wheaten bread, and threw part on the victims.

CONFECTION, in Pharmacy, a kind of compound remedy, of the confipence of a soft electuary, or electuary.

Confections and electuaries are composed chiefly of powders, mixed up with sirups or honey, into which the confection, that the powders may not separate by keeping. They are chiefly the milder medicines, and such as are not very ungrateful to the palate, that enter into the composition of the electuaries; for as they are taken somewhat "ad libitum," it would be unsafe to trust this mode of exhibition of the more active drugs. The lighter powders require about twice the weight of sirup to be brought to the proper confidence of an electuary. The ordinary dose is a piece about the bulk of a nutmeg. See ELECTUARY.

Several electuaries were formerly designated by the name of confections; some of which, in the medical language, are corroborative, and others purgative.

Of the number of the corroborative confections, were those of alkerms, of hyacinth, and the anacardium: a purgative one is the confection Hamech. The confection of alkerms has its name from the principal ingredients therein; which is the kermes, or alkerms, or scarlet-grain. The other ingredients were pearls, muka, cinnamon, ambergis, leaf-gold, juice of pippins, and rose water. It was ranked among the belt cardias, and frequently used for the palpitation of the heart, or scyndome; and sometimes in the small-pox and scrofula.

The confection of hyacinth was said to have nearly the same virtues with that of alkerms; but, besides, it was frequently used as an alaragent. It consisted of nearly triple the number of drugs; whereof the precious stone, called the hyacinth, was esteemed the principal; the chief of the rest were, red coral, bole armonica, terra nigrita, myrrh, the fanta, burnt hartthorn, camphire, faphire, emerald, topaz, and most of the ingredients of the confection of alkerms. The anacardium confection was composed chiefly of anacardium; whence the name. The other drugs were long pepper, black pepper, most kinds of myrobalans, salicorum, &c. It was used to purge the blood, and deemed proper in cold diseases.

The confection Hamech, took its name from that of its inventor, an Arabian physician. Its ingredients were, poly-poly, myrobalans, agaric, fenna, tamaraminds, red roses, manna, colocynth, &c. It was applied as a draffic for the purging of the grosser humours and viscidities; it was also of some reputation in vertigoes and cancers. But all these, though we have thought it proper to mention them, are excluded from the modern dispensatories.

CONFECTION aromatic. See the next article.

CONFECTION cardiae, a name given in the late London Dispenfatory to the so much esteemed medicine commonly known by the name of the confetia Raleighana, and now denominated confection aromatic. The composition is also altered, as well as the name, and is ordered now to be made in the following manner: Take zedoary, in coarse powder, and miferon, of each half a pound, and of distilled water, three pints. Macerate for twenty-four hours, and then press out and strain. Evaporate the strained liquor to a pound and a half, and add of compound powder of crabs-claws, sixteen ounces by weight; cinnamom and nutmeg, of each two ounces by weight; cloves, one ounce by weight; lesser cardamom, half an ounce by weight; and double refined sugar, two pounds.

Powder the spices together very finely, and adding the sugar, make a confection. This is an improvement of the confection cardia of the former dispensatory. The essential oil of the cardamon appeared, on an experiment made at the Hall, to be lost in the evaporation of the tincture; and, therefore, the cardamon is now more properly added in powder.

CONFECTION Darmocratis. See Mithridate.

CONFECTION Frasylir. See Discordium.

CONFECTION Japonica, was prepared of Japa earth, three ounces; tormentil root, nutmeg, and olibanum, of each two ounces; opium, dissolved in Lisbon wine, a dram and a half; simple sirup and conserve of roes, of each fourteen ounces. An electuary of these ingredients supplied the place of discordium; and the dose was from a scruple to a dram.

CONFECTION Opia, confection of opium, is prepared in the following manner: Take of hard purified opium, powdered, six drams by weight; long pepper, ginger, and caraway, of each two ounces by weight; sirup of white poppy, boiled to the confidence of honey, three times the weight of the whole. Mix the purified opium with the heated sirup, and add the rest in powder.

CONFECTION Paulina, a name given in the late London Dispenfatory to the composition which used to be called confection archigenis. It was ordered to be made in the following manner: Take curds or zedoary, cinnamon, long pepper, black pepper, strained flowers, galbanum, opium, and Ruffin calfor, of each two ounces; of simple sirup, boiled to the confidence of honey, an equal weight to thrice the species. Pemberton's London Pharm. p. 317.

CONFECTOR, among the Ancient Romans, a sort of gladiator, hired to fight in the amphitheatre against beasts; hence also denominated bestris. See GLADIATOR.

The confectioners were thus called a confectionis bestris, from their dispatching and killing beasts.

The Greeks called them mepodot, q. d. daring, robust, desperate; whence the Latins borrowed the appellations parabolani, and parabolarii. The chariots were sometimes condemned to this sort of combat.

CONFECTS, or CONFECTIONS, a denomination given to fruits, flowers, herbs, roots, and juices, when boiled and prepared with sugur, or honey, to disposte them to keep, or render them more agreeable to the taste.

The ancients only confection with honey; at present, sugar is more frequently used. Confects half-fugared are those only covered with a little sugar, to leave more of the natural taste of the fruit.

Confects are reduced to eight kinds; viz. liquid confects, marmalades, jellies, pastes, dry confects, conserve, candies, and drages, or sugar plums.

Liquid confects are those whole fruits, either whole, in pieces, in seeds, or in chippers, are conficled in a fluid transparent sirup, which takes its colour from that of the fruits boiled in it. There is a good deal of art in preparing these well; if they be too little sugared, they turn; and if too much, they candy. The most esteemed of the liquid confects are plums, especially those called mirables, barberries, quinces, apricots, cherries, orange flowers, little green citrons from Madeira, green callya from the Levant, myrobalans, ginger, cloves, &c.

Marmalades are a kind of pastes almost liquid, made of the pulp of fruits, or flowers, that have some confidence; such as apricots, apples, pears, plums, quinces, oranges and ginger. Marmalade of ginger is brought from the Indies by way of Holland: it is esteemed good to
to revive the natural heat in old men. See Marmalade.

Jellies are juices of several fruits, wherein sugar has been dissolved, and the whole, by boiling, reduced into a pretty thick consistence; so as, upon cooling, to form a kind of thin transparent glue, or paste. Jellies are made of various kinds of fruits, especially gooseberries, currants, apples, and quinces: there are other jellies made of beet, rhubarb, &c. but they are not to be kept, being very subject to corruption. See Jelly.

Pudding is a kind of marmalades, thickened to that degree by a proper boiling, as to assume any form, when put into little moulds, and dried in the oven. The most in use are those of gooseberries, quinces, apples, pears, and orange flowers: those of pillachoes are the most esteemed; those of ginger are brought from the Indies.

Dry Confiters are those whole fruits, after having been boiled in the syrup, are taken out again, and drained, and put to dry in an oven. These are made of so many kinds of fruits, that it would be hard to explain them all: the most considerable are citron and orange-peel, plums, pears, cherries, apricots, &c.

Confiters are a kind of dry confecys, made with sugar, pastes of flowers or fruits, &c. The most usual among these, are those of roses, malows, rosenmary; of heps, of orange flowers, violets, jefamin, pillachoes, citrons, and floes.

Note. The apothecaries, under the title of confevers, comprehend all kinds of confecys, both dry and liquid; whether of flowers, fruits, seeds, roots, barks, or leaves, prepared with sugar or honey, to preferve, &c. See Confever.

Candles are ordinarily entire fruits, candied over with sugar, after having been boiled in the syrup; which renders them like little rocks crystallized; of various figures and colours, according to the fruits enclosed within them. The best candys are brought from Italy. See Candy.

Sugar-plums are a kind of little dry confecys, made of small fruits or seeds, little pieces of bark, or odoriferous and aromatic roots, &c. inclosed and covered over with a very hard sugar, ordinarily very white. Of these there are various kinds, distinguished by various names; some made of rabbberries, others of barberries, melon-seeds, pillachoes, filberts, almonds, cinnamon, orange-peel, coriander, aniseeds, caraways, &c.

CONFERENCES of Poland. See Poland.

CONFEDERACY, Fr. Confederation; an alliance, compact, or league between different princes and states, for the support of a common cause. See Confederation.

Confederacy, in Latin, is when two or more persons combine to do any damage to another, or to commit any unlawful act.

Confederacy is punishable, though nothing be put in execution: but then it must have these four incidents; 1. That it be declared by some matter of prosecution; as by making of bonds or promises to one another; 2. That it be malicious, as for unjust revenge; 3. That it be false; i.e. against the innocent; and, lastly. That it be out of court, voluntarily. See Conspiracy.

CONFEDERATE Troops, troops of different nations united together in one common cause against an enemy.

CONFEDERATION of the Rhine, in French la Ligue du Rhin, is the act by which several German states, situated between the Rhine and the Mayne, separated themselves from the Germanic body, and associated as confederated states of the Rhine, under the protection of the French empire. The instrument of this confederation was signed at Paris, on the 12th of July 1806, and the ratifications were exchanged at Munich on the 23rd of the same month. The contracting parties were the emperor of the French, on the one part, and on the other, the kings of Bavaria and Württemberg, the archbishops of Ratibson as prince possesses the grand dukes of Baden, Berg, Hesse Darmstadt, and Nassau, and Napoleon, the prince of Baden, Hesse-Cassel, Hesse-Hanau, Hesse-Darmstadt, Hesse-Cassel, Nassau, and Nassau-Frankenstein, the prince of Nassau, and the prince of Lein. They declared that they would admit other German princes and states to this confederation where their union with the confederation might be considered as a difficult with the general interell, and thus virtually annulled the inconsiderable part that was left of the German empire. This induced Francis II., last emperor of Germany, and his fl. of Austria, formally to abdicate the German empire, by his proclamation of the 6th of August 1806. It was then expected that a similar confederation would be formed on the north of the Mayne under the protection of either Prussia or Russia: but the king of Prussia having declared war against France, in October 1806, and having been completely overthrown at the battle of Jena, on the 14th of the same month, several other German states hastened to join the confederation of the Rhine, as Lippe-Detmold, Schaumburg-Buckeburg, Saxony-Weimar, Saxe-Coburg, and the newly created kingdom of Saxony. By the peace of Tilsit, which cedes the Prussian provinces on the right bank of the Elbe, and the possessions of Heffel-Cassel, Orange-Olda, and other petty German states into a new kingdom, to be called the kingdom of Weilphalia, the confederation of the Rhine is extended to the banks of the Elbe, and will probably receive considerable modifications from such a large and important accession of new members. Its original stipulations were that the confederated states

Art. I. are for ever separated from the Germanic body, and united by a particular confederation, under the designation of the "Confederated States of the Rhine."

II. Renounce the laws; and

III. The titles of the empire.

IV. The elector arch-chancellor takes the title of prince primate and most eminent highness, which title shall convey no prerogative derogatory to the entire sovereignty which every one of the contracting parties shall enjoy.

V. The elector of Baden, duke of Berg, and landgrave of Heffel-Darmstadt, take the title of grand dukes; the chief of the house of Nassau that of duke; and the count of Leyn that of prince.

VI. The affairs of the confederation shall be discussed in a congress at Frankfort on the Main; divided into two colleges, that of the kings and that of the princes.

VII. The members of the league must be independent of every foreign power. They cannot enter into any other service but that of the states of the confederation and its allies. Those who have been in the service of a foreign power, and choose to continue in the same, must abdicate their principalities in favour of one of their children.

VIII. Any prince he disposed to alienate the whole or any part of his sovereignty, he can only do it in favour of a confederate.

IX. All disputes are settled in the assembly at Frankfort, where

X. The prince primate prudens. But if the two colleges deliberate
deliberate separately, he presides in the college of kings, and the duke of Nassau in the college of princes.

XI. The fundamental statute is to be framed by the prince primate.

XII. The French emperor is protector of the confederation, and names the successor of the prince primate.

XIII. to XXI. Enumerate the cessions made by members of the league: thus, Nassau cedes to Berg the town of Deutz and its territory; Bavaria acquires the imperial city of Nuremberg and its territory; and

XXII. The prince primate receives Frankfort on the Main, and its territory, as his property.

XXIII. and XXIV. Enumerate the lordships over which the members of the confederation exercise the rights of sovereignty.

XXV. They also enjoy the sovereignty over the imperial kingdoms included within their boundaries.

XXVI. The rights of sovereignty confind in legislation, administration of justice, military recruitment or recruiting, and levying taxes.

XXVII. Between the prince primate and the subordinate princes and counts, their domains cannot be sold or given to any prince out of the confederation, without being first offered to the prince under whose sovereignty they are situated.

XXVIII. These subordinate princes and counts preserve the privilege of being tried by their peers. Their fortune cannot be confiscated, but their revenues may be sequestered during the life-time of the criminal.

XXIX. and XXX. Regulate the payment of debts.

XXX. The subordinate princes or counts may take up their residence where they choose, and draw their rents or capitals without any revere.

XXXI. Public functionaries not retained by the new sovereign, receive a pension proportionate to the situation they held.

XXXII. The same takes place with respect to religious orders losing their income.

XXXIV. The confederates renounce all reciprocal claims except the eventual right of succession.

XXXV. Between the French emperor and the confederates there shall be federative and individually an alliance, by virtue of which every continental war in which either is engaged shall be common to all.

XXXVI. In the event of any power making preparations for war, the contracting parties, in order to prevent surprise, shall, upon the requisition of the minister of one of them at the assembly of the league, arm likewise. And as the contingent of the allies is subdivided into four parts, the assembly shall decide how many are to be called into activity. The armament, however, shall only take place upon the summons of the French emperor to each of the confederates.

XXXVII. The king of Bavaria binds himself to fortify Augsburg and Landau, and to form and maintain artillery and arming establishments in the said places.

XXXVIII. The contingent of each confederate is: France 200,000 men, Bavaria 90,000, Wirtemberg 12,000, Baden 5,000, Berg 5,000, Darmstadt 4,000, Nassau, Hohenzollern and others 4,000.

XXXIX. Admits of the accession of other German princes; and,

XL, as the concluding article, stipulates the exchange of the ratifications.

Of the two principal articles of the new constitution of the confederation of the Rhine, one relates to the establishment of a superior court of appeal, in which all cases between the sovereigns and their subjects shall be finally decided. The other stipulates that the manufactures of each state shall be allowed to be freely imported into all the other states of the confederation. Several new roads are to be made in order to facilitate commerce.

CONFERENCE, in its first and primary sense, denotes mutual discourse, and more especially such discourse on serious and important subjects. It also denotes an appointed meeting for discussing some point, by personal debate; of this kind was that held at Ratibon, in 1607, at the joint desire of Maximilian, duke of Bavaria, and Philip Lewis, elector Palatine, between some eminent Lutheran doctors on one side, and three celebrated Jesuits on the other. The dispute turned upon the two great points, to which almost all the contests between the Protestants and the Roman Catholics are reducible, viz. the rule of faith and the judge of controversies. In 1615, another conference was held at Neuberg between James Hellbroner, a learned Lutheran, and James Keller, a celebrated Jew, by the name of Wolfgang William, prince Palatine, who held till before that time embraced the Romish faith. But the most famous of all these conferences was that held in the year 1645 at Thorn, by the express order of Audibus IV. of Poland, between several eminent doctors of the Romish, Lutheran, and Reformed churches. As this meeting was intended to heal the divisions that prevailed among these churches, and to discover some method for healing their differences, and for effecting a reunion, it was on this account called the "Charitable conference." But the issue of this conference was very far from being favourable to the projected union. Some time after this, Ernef, landgrave of Helf, in order to give a plausible colour to his apostacy from the Protestant religion, and make it appear to be the result of examination and conviction, obliged Valerianus Magnus, a learned chaplain, to enter the lists with Peter Habercorn, a reformed minister, in the castle of Rheinfield. Besides these public conferences on the continent, there were others of a more private nature held, during the 17th century, between the doctors of the contending churches. The most remarkable of these was the famous dispute between John Claude, the most learned of the Reformed divines in France, and Jacques Besaigne de Bediffet, whose genius and erudition placed him at the head of the Romish doctors in that country. This dispute, held in the year 1683, terminated, like all the rest, in widening the breach instead of healing it. Neither of the contending parties could be prevailed to yield; but, on the contrary, they both returned from the field of controversy more rivetted in their own opinions, and more averse from those of their adversaries. Another conference was held at Leipzig, in 1631, between three Saxon doctors on the one side, and some of the most eminent divines of Helf-Cassel and Brandenburg on the other, with a view of representing, with fidelity and precision, their respective doctrines, and for the purpose of discovering the obliques which prevented the union of the Lutheran and Reformed churches. The conference, however, though amiably conducted, broke up without having contributed in any respect to promote the salutary work of peace. The conference held at Cassel in 1661, by the order of William IV, landgrave of Helf, between two professors at Rintelen, on the side of the Lutheran, and two others of the university of Marburg on that of the Reformed, was attended with much greater success than that of Thorn above mentioned: for, though it did not bring about a perfect uniformity of opinion, it produced an effect, which
was in reality, much better, a spirit of Christian charity and forbearance.

The most famous conferences of a similar kind, held in England, were those of Hampton-Court in 1604, and of the Savoy in 1661. The former was held by order of James I., on pretence of finding expedients, which might terminate the religious disputes between the church and the puritans, and reconcile both parties. The professed design of this conference was to examine the objections of the puritans against the doctrine, government, and discipline of the established church, and to rectify its abuses. But the progress and result of it evidently showed, that it was the design of the king to make an odious exhibition of his learning, and to mortify the puritans, who had favourable expectations from James's education in Scotland, and his professed attachment to the church established in that country, but who found, in the event, that he had conceived invincible prejudices against them. The disputants on both sides were nominated by the king. For the church, there were nine bishops, and about as many dignitaries; and for the puritans, there were only four ministers. This conference continued three days, viz. Jan. 14th, 16th, and 18th. The first day's conference was with the bishops and deans; the puritan ministers not being present; when the king made a speech in commendation of the hierarchy of the church of England, congratulated himself, that he was now come into the "promised land," &c. &c.; and informed them, that the reason of his confuting them by themselves was to receive satisfaction from them: 1. About some things in the Common Prayer. 2. Concerning excommunication in the ecclesiastical courts. 3. About providing some well qualified ministers for Ireland; that if anything should be found to be redressed, it might be done without their being confronted by their opponents. After some alterations of no great importance, agreed on between the king and the bishops, with regard to the confirmation of children, the abolition of the church, private baptism, and baptism by women, and excommunication for killer crimes, his majesty's subjects were satisfied; and thus ended the first day's conference.

On the second day, Jan. 16th, the four ministers on the side of the puritans, together with Patrick Galloway, minister of Perth in Scotland, and two bishops and six or eight deans on the other side, were convened. The king, seated in his chair, with his nobles and privy councilors around him, informed the puritanical ministers that he was ready to hear their objections against the establishment. Upon which Dr. Raynolds, one of their number, in the name of his brethren, humbly requested: 1. That the doctrine of the church might be preferred pure, according to God's word. 2. That good pastors might be planted in all churches, to preach in the same. 3. That the book of Common Prayer might be fitted to more increase of piety. 4. That church government might be sincerely ministered according to God's word. In the discussion of these points, Bancroft and the king took an active part. At the close of this day's debate, his majesty highly incensed at the complaints stated by Dr. Raynolds, told the ministers, that he found they were aiming at a Scots prebytery; "which," says he, "agrees with monarchy as well as God and the devil;" there Jack and Tom and Will and Dick shall meet and confute me and my council. Therefore I reiterate my former speech: "Le Roi s'aviera." Stay, I pray, for one year before you demand; and then, if you find me grow purer and fat, I may perchance hearken unto you. For that government will keep me in breath, and give me work enough. I remember how they used the poor lady, my mother, in Scotland, and me in my minor-
They were to continue four months from the 22d of March 1601, and then present the result of their conferences to his majesty under their several hands. When the conference opened on the 15th of April, some difficulties occurred about the proper mode of proceeding; some of the presbyterian party were for infiling only on a few matters of importance, judging that if these were gained, and an union followed, it might be more easy to obtain the others afterwards. But the majority, by the influence of Mr. Baxter, were for extending their desires to the utmost, and thought themselves bound by the words of the commission, to offer every thing which they thought might conduce to the peace of the church; but when they were put in mind, that the king’s commission gave them no power to alter the government of the church, nor to infile upon archbishop Usher’s model, nor so much as to claim the concession of his majesty’s late declaration, they were much discouraged; for they were now convinced that all they were to expect were a few amendments in the liturgy and Common-Prayer Book. They wished also to have consulted their abettion brethren, and to have received from them a commission in form; but this was denied. Instead of drawing up a few supplemental forms and making some amendments to the old liturgy, Mr. Baxter composed a new one, in the language of scripture, which he called “The Reformed Liturgy;” not with a design entirely to set aside the old one, but to give men liberty to use either according to their own choice and approbation. This was presented to the bishops in the conference, together with exceptions to the “old liturgy.” This gave great offence, partly because a liturgy, composed by a single person in fourteen days, was set in competition with one which had been received in the church for a whole century; and partly, because it was inconsistent with the commission, and the bishops’ declaration of varying no further from the old standard than should appear to be necessary; and, therefore, the reformed liturgy was rejected at once without examination. When the presbyterians presented their exceptions to the liturgy, they accompanied them with “a petition for peace,” beseeching the bishops to yield to their amendments; to free them from the subscriptions and oaths in his majesty’s late declaration, and not to insist upon the re-ordination of those who had been ordained without a dioecesan bishop, nor upon the surplice, the cross in baptism, and other indifferent ceremonies, enforcing their petition by various arguments and motives. These exceptions were canvassed, and produced a variety of alternate objections and replies. The bishops, however, would make no concession to the prejudices of the presbyterianists; upon which they sent them a large expostulatory letter, in which, after having repeated their objections, they lay the wounds of the church at their door. The term for the treaty being almost expir’d in a paper controversy, about 10 days before the commission expired, a disputation was agreed on, to argue the necessity of alterations in the present liturgy. Three of each party were chosen to manage the argument. The dispute, however, terminated without effect. From arguments the presbyterian ministers defended to interessees, and befought the bishops to concassionate ferocious minds, and not to delibe their weaker brethren; to all which the bishops replied, that they were only commissioned to make such alterations in the liturgy as should be necessary, and such as should be agreed upon. Mr. Baxter says, that the bishops would not abide the small act ceremony, nor correct the grosser error, for the peace of the church. Thus the king’s commission expired July 25, and the conferences ended without any prospect of accommodation. It was agreed at the conclusion, that each party might represent to his majesty, that they were all agreed upon the ends of the conference, which were the welfare, unity, and peace of the church, but still disagreed as to the means of procuring them. The bishops thought they had no occasion to reprecipitate their plea in writing, but the presbyterian commissioners met by themselves, and drew up an account of their proceedings, with a petition for that relief which they could not obtain from the bishops. Hume’s Hist. vol. vi. 16. 13., vol. vii. 369.

Gen. Clar. Fibres simple, uniform, capillary, filamentous. Linn. “Filaments capillary, simple or branch’d, jointed; joints numerous, often unequal.” Lam. Vent. “Seeds produced within the substance of the capillary or jointed frond, or in closed tubercles united with it.” Dr. Smith.

Species. 1. Simple.

* Lambeifed.

1. C. conferticola. Conferua upon conferva. Dillw. conf. Dill. Mufc. 552. tab. 85. fig. 21. “Filaments simple, minute, somewhat crowded, acute; partitions obscure; joints cylindrical, unequal in length.” Dillw. Filaments rarely more than an eighth of an inch long, of a dark glaucous colour, tapering, Common in the latter months of autumn on various fuel and conferve. 2. C. fucata. Dillw. 49. “Filaments simple, very slender, minute, fuscous; partitions transparent; joints very short.” Growing in loose patches of a green colour, about half or three fourths of an inch long. Joints scarcely half so long as broad. Parataxic on conferve, and the smaller fuel in the neighbourhood of Swansea. 3. C. ficuloida. Vellely Mar. Plant. Pl. 4. Dillw. C. Withen. 4. 156. “Filaments cluttered, simple, obtuse; partitions transparent, slightly contracted; joints rather long.” Dillw. Filaments very numerous, thickly clustered at the root, diverging while in the water, from four to fix lines long, of a dirty yellow or brown colour, somewhat glossy when dried. Joints about twice as long as broad, filled with minute granules. Parataxic on fucum, and sometimes on nodous. 4. C. curta. Dillw. 76. “Filaments cluttered, simple, somewhat cartilaginous or horny, erect, short, attenuated at both ends; partitions transparent, slightly contracted; joints rather short.” Filaments seldom more than three or four lines long, of an olive-brown colour, obtuse, growing in roundish tuftt fusts. Joints not much longer than thick. Parataxic on fuci. 5. C. carnea. Dillw. 84. “Filaments simple, cluttered, somewhat knotty, flesh-coloured; joints rather short, attenuated at both ends; juice collected into solitary globules.” Filaments from a quarter to half an inch long, rather obtuse. Parataxis dark-coloured. Joints sometimes about twice the length of the diameter, sometimes little more than the length; colourless, except where the juice is collected. Parataxic in loose tufts on other conferve. 6. C. capillaris. Linn. Sp. Pl. 14. Linn. 14. Dill. p. 25. tab. 5. fig. 25. A. Dillw. 9. (C. limon, Flor. Dn. 771. C. palustris, live linum marimum Ancebus, Ral. Syn. p. 60. n. 16.) “Filaments simple, cylindrical, rather rigid, curled, entangled, brittle; partitions transparent; joints cylindrical, short; capsules fuscous.” Filaments three or four feet long, about the thickness of large thread, pale yellowish green, entangled, but never adhering together; perfectly acid after it has been exposed a few minutes to the
the air. Partitions quite transparent, with a thin blackish line on each side. Joints, when dry, generally appearing alternately compressed. Found in the ditches and flagrant pools of flat marches. 7. C. tortuosa. Dillw. 46. "Filaments simple, rather rigid, entangled, slender; partitions transparent; joints cylindrical, rather long." Reminiscent of the preceding species in miniature. Filaments as fine as human hair, less brittle than those of C. capillaris; joints nearly twice as long as broad. Found in salt-pools, and on rocks in the sea. 8. C. areu. Dillw. 80. "Filaments simple, rather rigid, nearly straight; partitions glabrous-transparent, contracted; joints oblone, short." Filaments several from the same root, from six to fifteen inches long, sometimes nearly the thickness of a crow's quill, generally about that of a large thread, dark or bluish-green, brittle. Joints not so long as broad, rounded at each end. On flakes in the sea.

†† In fresh water.

9. C. fasciculata. Dillw. 66. "Filaments simple, slender; partitions ring-like; joints rather long, transparent." Filaments very long, extremely slender, entangled. Joints about four times as thick as the slender tubes, and ditches frequent. In forests forming a semi-transparent cloud like mist round the grass or reed on which it grows, of a yellowish-green colour. In small currents, floating, in denier matts, on the surface. 10. C. inflata. Smith Eng. Bot. 1670. Conjugata inflata; Vaucher conf. 68. tab. 5. fig. 8. "Filaments simple; joints three times as long as broad; when fertile, swelling and elliptical." Filaments but the 720th part of an inch in diameter, transparent, almost colourless. Joints at first exactly cylindrical, marked with green colouring matter in spiral lines; afterwards swelling, elliptical, each protruding a lateral tube, so as to unite with similar tubes of a neighbouring plant. The colouring matter of one joint passes into the other, its spiral appearance being entirely lost. At length each joint which has received it swells still more, growing quite elliptical, and filled with a fold green body, which M. Vaucher has proved to be a single feed, producing in due time a solitary young plant. These appearances cannot be perceived without the aid of a microscope. Found by Mr. W. Borer at Henfield in Sussex. 11. C. pandurata. Dillw. 51. "Filaments simple, filigree; very slender; partitions obconic; joints rather short, cylindrical, joint above finally collected into foliaceous globules." Filaments from one to two inches long, so slender, as when single, scarcely to be distinguished by the naked eye. In ditches and pools not frequent. 12. C. bipunctata. Dillw. 2. Smith Eng. Bot. 1610. Roth Cat. Bot. ii. p. 204. (C. tellina; Muller in Nov. Act. Pet. iii.) "Filaments filiform, yellowish, joints short, cylindrical, with two spots." Joints remarkable in having each two dark spots, frequently furnished with a green longitudinal streak running through them; these spots sometimes fill nearly the whole, sometimes only a small portion of the joint, and, when upon varying decay, assume a flutted appearance, but are not visible without the aid of a microscope. 13. C. nitida. Dillw. 4. Flor. Dan. tab. 819. (C. vulgaris; Hufi. Flor. Ang. 176. C. teresia efferior & varie extensa. Dill. p. 13. tab. 2. fig. 2. C. decimina. Mull. nov. act. Pet. iii. C. setiformis; Roth. Cat. Bot. Flac. 1. p. 171. 2. p. 103. Byflas palustris confervor des. Mich. Gen. tab. 59. fig. 6.) "Filaments simple, shining, filigree; joints rather long, cylindrical; granules of the fructification doubly spiral." Filaments a foot or more long, about the thickness of a human hair, dark green, growing at the bottom of the water in loose irregular patches, not sufficiently matted as to contain air bubbles, nor so much entangled as in any others. 14. C. filaris. Dillw. 13. Smith Eng. Bot. 1616. Roth Cat. Bot. ii. p. 202. (C. guina; Mull. nov. act. Pet. 91.) "Filaments simple, filigree; joints cylindrical, rather long; granules of the fructification, spiral spirals." Filaments longer and more slender than those of nitida, anthetic like those of C. inflata. 15. C. jugata. Dillw. 5. Flor. Dan. tab. 883. (C. Scalaris; Roth. Cat. Bot. ii. p. 196.) "Filaments simple, filigree, often conjugate by pairs; granules of the fructification doubly spiral; finally collected into globules." In pools and ditches. Mr. Dillw. strongly suspects, that C. nitida (n. 13.), is only the present plant in an earlier period of its growth. 16. C. geniculata. Dillw. 6. Roth. Cat. Bot. ii. p. 199. (C. serpentina; Mull. nov. act. Pet. iii.) "Filaments simple, very slender, brittle, here and there knee-bent and conjugate; joints rather long, cylindrical; granules collected into lines." Filaments as far as can be judged, considering their brittle state, not more than one or two inches long, anathematic occasionally at very uncertain distances, and only where they are general, not regularly paired as in C. jugata, but connecting themselves with any other that is near them, and manifesting a strong affinity to the next species. In pools and ditches. 17. C. repanda. Linn. Sp. Pl. 1753. Smith Eng. Bot. 1658. Dill. p. 20. tab. 4. fig. 14. (Hydrodictyum; Vaucher Conf. 88. tab. 60.) "Filaments united into the form of a tubular net." Filaments green, tubular, forming a very delicate net, open at both ends; meshes generally with five sides, sometimes with four or fix. M. Vaucher found the old plants in a stationary condition during winter; but in spring the joints swollen, and gave out simple cylindrical masses of green matter. Each mass soon became a reticulate tube, which in two or three months grew to the full size of the parent plant. It grows loosely, floating in full water; but not very common. 18. C. crateriaris. Linn. Sp. Pl. 1. Linn. 1. Dillw. 79. Smith Eng. Bot. 1594. (C. compta; Roth. Cat. Bot. i. p. 170. C. florivialis sericea, vulgaris & fluviatus; Dill. p. 12. tab. 2. fig. 1. C. Pinni Rai. Syn. p. 58.) "Filaments simple, dark green, slender, very long, very densely compact, frequently twisted; joints rather short." Filaments often two or three feet long. 19. C. hasci. Dillw. 47. Smith Eng. Bot. 1655. "Filaments simple, slender, glaucescent, filigree; joints shortish; granules collected in small globules. Filaments kildum more than three inches long, tapering. On rocks and flakes in clear rapid rivulets. 20. C. diffusum. Dillw. 193. "Filaments simple, fringy, brittle; partitions but little contracted, often loose; joints short, with a dark spot in the middle." Filaments from three to six inches long, less than a human hair in diameter, dark green, often breaking at the partitions and remaining connected at one extremity; joints about half as long as thick. In ditches on reeds and other aquatic vegetables. 21. C. pecilialis. Dillw. 24. Smith, Eng. Bot. 1611. Mull. nov. act. Pet. iii. (C. bronchialis; Roth. Cat. Bot. i. p. 186.) "Filaments simple, transparent, broken, acuminate; partitions often loose; joints very short, crystalline-transparent in the middle." Filaments seldom half an inch long, dirty green, to the naked eye resembling decayed vegetable matter, when entirely gradually tapering to a point, and bearing some resemblance to the antennae of a lobifera, frequently breaking at the partitions, and remaining connected at one extremity. Joints appearing coloured at each end by a green fluid, which, as the plant approaches to decay, collapses, sometimes forming into small globular affers, and sometimes disappearing entirely. In rivers and flagrant waters, adhering to decaying wood and vegetables. 22. C. florulenta. Dillw. 8. Roth. Cat. Bot. i. p. 192. tab. 4. fig. 4. and tab. 5. fig. 6. "Filaments most commonly simple, minute; partitions loose; joints prismatic, alternately refract. ed." Filaments seldom more than a quarter of an inch long.
CONSERVA.

Varving from a pale to a greenish brown. Joints with a double line running through the middle, and frequently with some transversal bands; as they adhere to each other mainly in a single point, and always at alternate ends, they give the plant the appearance of a string of parallelograms, united at the corners. It might be taken for a much broken joint of C. pectinata, but the joints cannot be so divided as to form one regular line. In pools and slow streams, adhering to decaying vegetable and to other conservae, especially to C. glomerata. 25. C. foliata. Linn. Sp. P. 2. Lam. 2. Flor. Dan. tab. 651. [fig. 2.] Dilw. & C. (C. minima byfi foliata) Dilw. p. 14. tab. 12. fig. 30. Filaments simple, cylindrical, dark green, glaucous; partitions obtuse; joints very short.

Filaments without any apparent root, equally obtuse at both ends. Common in rivers, pools, and ditches, generally floating in loose masses on the surface. 24. C. limosa. Dilw. 20. (C. gelatinosa, omnium terrae et minima aquarum limo inane:; Dilw. p. 15.) "Filaments simple, very slender, rather mucous, compact, bluish green, flat; partitions indistinct." Common on the muddy edges of rivers, ditches, and ponds, resembling to the naked eye, except at the margin, where it is thinnest, a widely expanded, thin, seiflike gelatinous mass, sometimes floating at the top of the water. In either case only mode to examine it, is to carry it home, without allowing it to dry, and to put it in a pan of water, where, in the space of a night, it will swell out an immense number of threads, visible to the naked eye only from their number; these viewed through a microscope appear oblate at each end, and rough on each other without any regular order. Mr. Dilwyn is inclined to think that this is only the last species in a younger stage; the principal difference is in the size and colour; in C. foliata the filaments are much larger, broader, and not glossy; the joints also are far more divided, and more regularly disposed. 25. C. viridaca. Hudf. Flor. Ang. p. 592. (C. confugosa.) Lightf. Flor. Scot. p. 975. Dilw. p. 15. tab. 2. fig. 4. "Filaments simple, equal, violat." Filaments about half an inch long, of a beautiful violat or indigo colour, of a slippier mucous substance, so extremely fine as to be undistinguishable by the naked eye, and so crowded together as to form, when moist, a gelatinous mass, and when dry, a membranous lamina. Found by Lightfoot on the rocks in the waterfalls of the mountain of Goatfield in the Isle of Arran, and said by Dillenius to grow in Alpine rivulets near Llanberis. 26. C. obvoluta. Smith. Eng. Bot. 1578. "Glaucescent, flaccid, spreading everywhere from a centre, and forming a globe." Sent by the Rev. Mr. Davie from a lake in Anglesea. It covers the surface of the water in the months of July and August, and consists of innumerable minute globules of a glaucescent or verdigrasse green, all nearly of a size. When examined with a microscope each globule appears to be composed of a number of simple cylindrical short filaments apparently springing from a solid centre. Under a very high magnifier these filaments are found to be formed of short uniform joints, each of which is of an equal thickness throughout, but the upper ones gradually diminish in size. Mr. Davie Turner suggests that this minute vegetable ought probably to be referred to Roth's new genus rivalaria, to which Uva inerissa and U. pruniformis of English botany belong. These species are of a pulpy substance, clothed with jointed filaments.

**Not immersed.**

* Not immersed.
† In full-water.

30. C. polymorpha. Linn. Sp. Pl. 17. Dilw. 44. L. marina geniculata nigra palma:; Dilw. p. 32. tab. 6. fig. 52. Ceramium futilatum. Roth Cat. Bot. ii. p. 173. "Filaments dichotomous, futilate, somewhat cartilaginous; joints short; capsules on the upper branchlets, egg-shaped, sessile." Filaments about the thickness of horse hair, repeatedly dichotomous, with rather acute angles, of a dark purple colour when young, afterwards becoming black. Common on the large flat rocks, mostly commonly on F. nodosus, in thick tufts, two or three inches long. 31. C. langiyo$. Dilw. 45. "Filaments nearly simple, very minute; of a dull colour; joints rather long, polygonal in the middle; capsules fultate, unilateral." In the sea, adhering to other conservae. 32. C. nigra. Hudf. Flor. Ang. p. 597. "Filaments equal, branched, very long; branches alternate, many-eleft, very short." Filaments five inches long, black, flaccid; branches faciculated. On the Yorkshire coast. 33. C. effusae. Dilw. 58. Eng. Bot. 547. "Filaments more than twice pinnated; branches and branchlets alternate; uppermost ones extremely short, somewhat faciculated; partitions from the union of the veins; joints rather long; capsules egg-shaped, sessile." Filaments extremely flaccid, zig-zag, transparent, beautifully iriated by longitudinal veins, each of which arch over at or near the same place, and appear to form the partition. Common on most of our shores, from three to five inches long, varying in colour from a reddish brown to a light or purplish brown. 34. C. parviflora. Hudf. Flor. Ang. p. 604. Eng. Bot. 1429. "Filaments branched; branches double and alternately pinnated; capsules axillary, solitary, oblong." Filaments an inch long or more, purplish-brown, slender, cylindrical, with the same jointed and tubular structure as the preceding. Parasite on fucce, found rarely on the coast of Yorkshire, Devonshire, and Cornwall. Dr. Smith observes that the last two species have the jointed structure of conferva, but agree better with the character of fucce in their fructification. The same observation will apply to several of the following species. 35. C. nigricens. Hudf. Fl. Ang. p. 602. Smith. Eng. Bot. 1717. "Filaments much branched; branches alternate, elongated; ultimate ones short, crowded, axil-shaped; joints rather broader than long, compound." Filaments from four to six inches long, blackish. Joints a little contracted, confiding of a circular double series of numerous parallel tubes, similar to those of C. hyfideae. Mr. Stackhouse is said to have found the fructification in small lateral nodules on the coast of Scotland, Devonshire, and Cornwall. 36. C. foetid. Hudf. 602. "Fila-
Confervae.

C. CONGEE.

more than an inch long, purple-brown, lying one over another, on the round pebbles in the sea. so as to have a flirking resemblance to an infant’s head. 51. C. tomentosa. Huds. Flor. Ang. 394. Dillw. 56. (C. marina tomentosa, minus tenera et ferrugineus. Dill. 19. tab. 3. fig. 15.) “Filaments much branched, very slender, thickly matted, divaricated, extreme branchlets simple; joints long.” Filaments from three to five inches long, of a pale greenish or rufescent-brown colour; branches fo slender as to be scarcely visible without a microscope, fluffing at right angles. Joints at least three times as long as thick. Partitions dark brown. Frequent, generally parasitical on fucus vesiculosus. 52. C. alpina. Huds. Flor. Ang. 395. (C. marina tomentosa, teneror et albicans. Dill. 19. tab. 3. fig. 12.) “Filaments much branched, very slender, equal; branchlets simple, fasciculated, white.” Filaments scarcely separately visible to the naked eye, pale green, soft, reftilling remake. Found in falt water, ditches, and pools in the island of Selsey in Sussex. 53. C. fetacea. Huds. Flor. Ang. 595. Smith Eng. Bot. 1689. Dillw. 81. (C. m. gelatinosa corallina inear genculata, teniior. Dill. 32. tab. 6. fig. 37.) “Filaments alternately and repeatedly branched, taper-pointed, fasciculated, fferphiy; joints a little dwelling, at least four times as long as broad; lateral shoots bearing tufts of filaments containing many gloomular seeds. Seldom exceeding four or five inches in length, of a rich crimson colour. On rocks and fones in the sea, not unfrequent at the latter end of summer and beginning of autumn. 54. C. borrici. Smith Eng. Bot. 1741. “Filaments capillary, repeatedly branched; branches alternate, spreading in two directions, zig-zag; ultimate ones falkipate; joints cylindrical, about twice as long as broad.” Filaments in tufts, about two inches long, of a delicate pink colour, turning orange when dry. Fertificaticn unknown, but conjectured by Dr. Smith to refeemble that of C. fetacea. Gathered on Yarmouth beach by W. Borric, esq. F. R. S. 55. C. spinca. Dillw. 40. “Filaments somewhat dichotomous, fasciculated, veined; joints long.” Filaments in thick bundles, many from the same rock. C. fesca. Huds. Flor. Ang. 596. Smith Eng. Bot. 1089. Dillw. 82. (C. m. gelatinosa corallina inear genculata, teniior. Dill. 32. tab. 6. fig. 37.) “Filaments alternately and repeatedly branched, taper-pointed, ffaciculated, fferphiy; joints a little dwelling, at least four times as long as broad. On rocks in the sea, at Dover and Swanage. 56. C. rothii. Turton’s Syst. Nat. 6. 1866. Dillw. 73. Eng. Bot. 1792. (C. violacea. Roth. Cat. Bot. 1. 190. tab. 4. fig. 1.) “Filaments erect, dichotomous, short, densely tufted, crimson; branches alternate; joints very short.” Filaments very fnder, from three to twelve lines long. Joints cylindrical, about twice as long as broad. On rocks by the sea-flore. 57. C. corallina. Linn. Sp. Pl. 15. (C. marina gelatinosa corallina inear genculata caflerif. Dill. 32. tab. 6. fig. 36.) “Filaments dichotomous; joints thicker at the top.” Filaments bright red or white, sliferiy, very tender, almost disappearing when dry. On fones on the sea-flore. 58. C. tubulosa. Huds. Flor. Ang. 600. (C. marina fihuloa. Dill. 34. tab. 6. fig. 30.) Ulva confervoides. Linn.) “Filaments much branched; joints oval, alternately compressed.” Filaments from two to four inches long, yellowish green; branches knotted, hollow. On rocks, fones, and fuci. 59. C. ctenata. Linn. Sp. Pl. 16. Lam. 16. (C. ramosa, genicus longioribus cateniformibus. Dill. 27. tab. 5. fig. 27.) “Filaments branchet, green; joints oblong, forming a kind of chain, with links alternately broader and narrower.” On the coasts of Carolina, the Bahama islands, and the south of Europe. 60. C. floparia. Linn. Sp. Pl. 9. Lam. 9. Smith Eng. Bot. 1572. Dillw. 52. (C. marina penata. Dill. 24. tab. 4. fig. 23.) “Filaments much branched, rigid; branches fasciculated, ultimate divi- sions alternate, acuminate; partitions obtuse; joints short.” Whole plant of a brownish olive, elongating when dry to a rufescent-brown colour. Filaments from two to six or nine inches long; upper branches longer and more clustered than the lower, giving the plant a bruih-like appearance. Joints about as long as thick. Frequent on the sea coast on fones and pebbles. 61. C. penata. Huds. Flor. Ang. 624.—Dillw. 85. “Filaments branched; upper branches pinnate; pinnae nearly opposite, nearly horizontal, approximate, fluff and ftraight; partitions obtuse; joints short; tubercules flile, spherical.” Often confounded by botanists with the preceding. Filaments in fluffy tufts from half an inch to two inches long, olive green, brown when dry. On rocks, fuci, & corallines. 62. C. verrucosa. Smith Eng. Bot. 1688. “Branches irregularly flattered and subdivided, scarcely jointed, fluffed with rough warts.” Filaments three or four inches long, pale reddish brown, capillary, but uneven, somewhat twisted, not perceptibly jointed, except in the youngest shoots, where an interruption of colour is sometimes perceived at intervals. Found on the coast of Hampshire and Cornwall. 63. C. infacea. Huds. Flor. Ang. 603.—Smith Eng. Flor. 546.—Dillw. 37. “Filaments branched; branches and branchlets opposite, diffuse; joints very short: partitions obtuse, villosus.” Stem from six inches to three feet high, greenish yellow, seldorn more than thrice divided; hairs in whorls on about every fourth or fifth joint, extremely flender, brittle; partitions not readily discooverable except in the verticillated hairs. On sub-marine rocks and fones. 64. C. ciliata. Ellis in Philos. Trans. vol 57. p. 425. tab. 18. f. 4. H.—Dillw. 53. (C. piocia; Roth Cat. Bot. 2. 245. tab. 5. fig. 2.) “Filaments dichotomous, incurved at the tips in a forceps-like manner; partitions biflet with verticillated ciliate, reddish at each end, pellicul in the middle; capsules somewhat glo- bular, lateral.” Filaments in fluffy tufts, seldom more than two inches long, varying from a bright to a purplish red. On rocks, fones, and fuci, frequent. 65. C. equilirifolia. Ligh. Flor. Scot. 964.—Smith Eng. Bot. 1479.— Dillw. 54. (C. imbricata; Huds. Flor. Ang. 603, and multifida. Huds. 663, as appears from an authentic speci- men communicated by Mr. Goodenough to Mr. D. Turner.) “Filaments much branched; branches acini- mated, elongated; branchlets verticillated, dichotomous; joints of the branchlets long.” From three to eight inches long, the thickness of a crow’s quill, bright red when young, afterwards dull brown. Stem and branches everywhere cloathed with numerous whorled branchlets, which, being longer than the joints, are tilled upon each other, and give the plant a rough spiny ap- pearance. On rocks and fones in the sea, not unfrequent. 66. C. lapa. Huds. 596.—Dillw. 42. (Fucus hirintus; Linn. Mutt. 134.—Mucilus marinus hirintus; Morifi. 3. 650. tab. 9. fig. 6.) “Filaments branched, branchlets very short, cimple, imbricated on all sides; joints short; capsules oblong, pedicelled.” Seldom more than three inches long, olive-coloured. Branchlets not whorled but dif- posed without any regular order, not dichotomous. Capsules small, on rather long pedicel, discharging the seeds at the summit. Rocks in the sea, not uncommon. 67. C. ver- ticillata. Ligh. Flor. Scot. p. 964.—Smith Eng. Bot. 1718.—Dillw. 55. (C. Miynorthymum; Roth in Schrader’s Journ. 5. 535.) “Filaments cartilaginous, variously bran- ched; branchlets at the partitions, verticillated, very short, incurved, frequently forked; joints about as broad as long.” Four or five inches long, of a dull olive colour. On rocks and fones in the sea. 68. C. arbycula. “Primary filaments thick, not jointed, naked near the bottom, much branched above; branchlets crowded, somewhat verticilli-
lateral, short, branched, jointed; joints cylindrical, short." About three or four inches long, of a beautiful deep-red brown colour when fresh, dull brown when dry without glos. On submersed calcareous rocks in the north of Ireland. 69. C. concilia. Linn. Sp. Pl. 10. Lam. 10. —Huds. Flor. Ang. p. 596.—Dill. 24. tab. 4. fig. 27. "Filaments branched and in water.; those short, much divided, digitate." Three or four inches long, of a pale dirty colour, irregularly branched; branches an inch and half or two inches long; branches capillary, numerous, incurved, leaving a hollow space between them and the branch. On stones and rocks in the sea. 70. c. reniform. Dillw. 18. Smith Eng. Bot. 1628. (C. fulva; Huds.7) "Filaments minute, creeping, densely matted; partitions scarcely contracred; joints cylindrical, twice as long as they are broad." Seldom more than three or four lines long, the thicknesses of human hair, or of a more or less vivid red colour, inveting the larger fuic and conferee in minute denfe tufts like velvet or plush; branches and branchlets generally unilateral. 71. C. fuscina. Dillw. 10. "Filaments dichotomous, rather rigid; branches zigzag; branchlets generally simple, very slender, alternately unifal, spreading; joints cylindrical; partitions obfolute." Filaments in closely entangled maffles, from four to eight inches long, finer than human hair, pale yellowish green in the branchlets, very dark green in the main shoots. In the sea coast and in salt-water pools at Yarmouth. 72. C. Leti virgata. Dillw. 48. "Filaments much branched, rather rigid, curved; branches twice alternately unilateral; partitions pelliculae; joints long." Filaments from three to six inches long, light green, irregularly branched, growing in a buily manner. On rocks, fucis, and corallines on the Welsh coast. 73. C. diffusa. Dillw. 21. Roth Cat. Bot. 2. 207. tab. 7. "Filaments branched, diffusè; branches somewhat dichotomous, zig-zag, remote; branchlets short, approximate, obtuse; partitions pelliculæ; joints rather long." Filaments in loosely entangled bundles, from two to fix inches long, pale green, more rigid than in most other species, not collapsing when drawn out of the water. On rocks in the sea. 74. C. rotundif. Linn. Sp. Pl. 20. Lam. 20. Dillw. 23. Smith Eng. Bot. 1629. (C. glauca; Roth Cat. Bot. 2. 228. tab. 6. C. trichodes ramiforius. Dill. 28. tab. 5. fig. 29.) "Filaments much branched, faciculated, rigid, straught, obtuse; joints long, even; partitions but little contracred, colourless." From three to fix inches long, dull green, in denfe tufts upon rocks, pebbles, or dead shells. 75. C. pellicula. Huds. p. 9. Smith Eng. Bot. 1718. "Filaments erect, much branched; branches mostly ternate, cylindrical; joints even, cylindrical, four times as long as broad." Filaments about six inches long, green, shining, pelliculæ, somewhat wiry and elastic to the touch, naked and flaxen-like towards the bottom. On the coasts about Yarmouth. 76. C. faniculata. Huds. p. 594. Dillw. 16. tab. 2. fig. 8. "Filaments sparse, much branched; branches and branchlets very long, scattered," Filaments irregularly divided like the leaves of fennel, soft and greenish when young, brownish and fluffier when old. On the shores of Cornwall and the Isle of Man. 77. C. spiculifera. Linn. Sp. Pl. 7. Lam. 7. (C. marina capillacea brevis, viridifima mollis; Dill. 23. tab. 4. fig. 20.) "Filaments branched, soft, shorter than the human finger, very green." Filaments numerous, very fine, shining and silvery when dry, retaining their elegant cerulean green colour. On fucis, not very common. 78. C. vagabunda. Linn. Sp. Pl. 18. Lam. 18. (C. marina trichodes, late in ter expansa; Dill. 30. tab. 5. fig. 32.) "Filaments zig zag, much branched; branch-
CONFERVA.

pound, twisted; partitions contracted; joints short." Various in length from half an inch to three inches, and from a slight to a dark green. Main stems remarkably pale and slender; branches darker, joints short. In pools and ditches, not uncommon. 86. C. atræ. Hudf. p. 597. Smith Eng. Bot. 68. Dillw. 11. (C. juncta, nodosa, lirubica, filamentos usina; Dill. 37. tab. 7. fig. 46.) "Filaments much branched, beaded, somewhat gelatinous; branchlets br. thickened; joints dilated towards the tip, dilated; edge punctilious, umbilicated." Varying in colour, during different stages of its growth, from a pale to a dark green, and finally becoming black. In clear rivulets and springs. 87. C. turkofolafa. Roth Cat. Bot. 21. 222.) "Filaments branched, rather rigid; branches and branchlets generally alternate, attenuated each way; partitions subequale, tubercled; joints long, dilated at both ends." Filaments fixed or eight inches long, dull olive or greenish purple; sometimes nearly simple, when they are shorter, thicker, and more rigid. Dill. 48. Dillwyn has seen these different filaments growing from one root. In rapid, rocky streams. 88. C. lirubica. Dillw. 37. "Filaments much branched, slender, very long, shining, filfy; branches thin-like, joints rather short." Filaments from six inches near to a foot long, green, with a flight tinge of blue, branches scattered, forming an acute angle with the stem. In clear rivulets attached to stones and wood in large gelatinous masses. 89. C. pro- tophi. Dillw. 67. "Filaments much branched; branches dilute, much lengthened out, pelliculat at the tip; joints rather long." Filaments from two lines to a half or three quarters of an inch long, light green. In rivulets and springs, on stones and aquatic plants. 90. C. glomerata. Linn. Sp. Pl. 19. Lam. 19. Flor. Dan. tab. 631. fig. 2. Dillw. 15. (C. fontinalis ramifilis glomerata convoluta. Dill. 28. tab. 5. fig. 31. critata; Roth Cat. Bot. 3. p. 153. 2. p. 220.) "Filaments much branched; branches alternate; branchlets unilateral, fasciculated, pencil-form; partitions pelliculat; joints cymodial, rather long." Filaments from two or three inches to a foot long, yellowish green. On stones and wood in clear rivers and streams. 91. C. rigida. Hudf. Flor. Ang 594. (C. flavatulus frîbil- flosa frigida; Dill. 21. tab. 4. fig. 17.) "Filaments much branched; branches alternate; partitions pelliculat; joints cymodial, rather short." Filaments varying from the same base, so as to have a clustered appearance, and sometimes to cover the pebbles to which they are attached, dull green, often inclining to brown. Somewhat hairy; branchlets most numerous near the summit of the filaments. In clear streams. 92. C. canalicula- ria. Linn. Sp. Pl. 4. Lam. 4. (C. raviolus epispicae den- filinum convolutus ramulis; Dill. 17. tab. 4. fig. 15.) "Filaments most branched near the base; branches long." Filaments one or two inches long, flender, deep green, filmy or but little branched above the middle, of a spongy soft substance, densely mixed together so as to resemble a piece of velvet, soft and herbaceous when fresh, but when dry blackish, and acquiring almost a flaky hardness from the mud adhering to it. In pure streams and mill-pond water spouts. 93. C. bulbifora. Linn. Sp. Pl. 3 Lam. 3. (C. palustris bom- bivcna; Dill. 18. tab. 3. fig. 11.) "Filaments branched, made including air bubbles." Filaments from three to six inches or a foot long, flender, dus yellowish green. In clear waters, soft, somewhat pinky, and of a lovely green; in stagnant muddy waters, paler, tammous, resembling dirty cotton. Professor Mitten is of opinion that C. fratica is the plant incided by Linnæus, and hence called C. bu- lifornia; but Mr. Dillwyn observes that the specimen in Dill- wyn's herbarium, here described, is certainly another species, and agrees with Mr. D. Turner in thinking, that several distinct plants which have the property of returning bubbles of air have been confounded by authors, and consequently that the confervæ bulbifora are a family and not a species. The confervæ when dried have been used as wadding for stuffing garments, and have been woven into coarse household linen. 94. C. elongata. Flor. Dan. tab. 520. Dillw. "Filaments branched, jointed, fasciculated with transverse lines; branches and branchlets dilute; partitions oblong; joints thin and clear, thickened at first inch long, extremely slender, of a beautiful dark green col- or varrying to a lighter colour as they approach to decay; branches seldom numerous, but with a very peculiar twist at their ramifications. Parastal in short thick tufts on decaying grass, attached to small pieces of which it frequently floats on the surface of the water. Hitherto found in Great Brit- ain, only by Mr. Dillwyn, in a hoggy pool on Sketty Bur- roughs, near Swansea. 95. C. aggrapina. Linn. Sp. Pl. 21. Lam. 21. Smith Eng. Bot. 1577. Dillw. 87. "Filaments much branched, cluttered into a globe and divaricat- ing from the centre; branches and branchlets nearly unila- teral, straight, obtuse; joints long, cylindrical." From the size of a pea to three or four inches in diameter, always pretty exactly spherical, hollow within, without any solid body, or root, to which the filaments might originally have been attached. The specific name alludes to the hairy balls found in the bosom of goats. In lakes lying in great abundance at the bottom of the water. 96. C. nana. Dillw. 50. "Filaments branched, very minute; branches and branchlets generally alternate, acuminate; partitions pelliculat; joints cylindrical." Filaments seldom much more than half a line long, of a pale brown colour tinged with brown, resembling C. littarum in its ramifications, and remarkably acuminate branches. Parastal on decayed confervas, &c. in rocky rivers. 97. C. tephaloderma. Dillw. 83. "Filaments nearly simple, densely matted; partitions obscure; joints short." The extreme tenuity and entangled growth of the filaments makes it impossible to ascertain their length; their colour is a dull olive green. Observed in a bottle which contained a solution of gum dragon in water, the surface of which was covered with a mass of filaments so densely interwoven as to form a film about two lines in thickness, bearing a considera- ble resemblance to the skin of a mole. 98. C. ochracea. Dillw. 62. Roth Cat. Bot. 1. 65. tab. 5. fig. 2. "Filaments much branched, very flender, very brittle, clothe compact, constituting an ochraceous jelly, which at length breaks into fragments of separate filaments. The filaments are so extremely fragile that the slightest touch of any con- siderable agitation of the water breaks them into a thou- sand pieces, which at first remain suspended, and afterwards sink to the bottom in the form of an ochraceous powder. In this state only can the plant be examined, but the fragments are so small that it is impossible to ascertain their original length, and under the highest magnifiers their thickness scarcely seems equal to that of the human hair. In pools and ditches common, of a dull yellow colour. 99. C. latia. Dillw. 79. Roth Cat. Bot. 1. p. 216. 3. p. 292. (C. pu- filla; Roth Flor. Germ. 1. 524.) "Filaments much branch- ed, gelatinous, filfy; branches rod-like, alternate from each partition; partitions contracted; joints very long, glazy-transparent." Filaments growing in gelatinous masses at the bottom of ditches and rivulets, from half an inch to three or four inches long, of a dirty white colour; branches clustered, so as to give them a brush-like appearance; parti- tions of a dusky colour. Joints at least ten times longer than
then thick. 100. C. myceliodes. Dillw. 17. Smith Eng. Bot. 1552. "Filaments very densely matted, branched; branchlets simple, generally unilateral, in pairs, incursed." Filaments sometimes quite simple, generally branched, seldom more than half an inch long, as fine as the finest wool. On the rocky beds of torrents in the vale of Bedegerec, in Caernarvonshire, matted the stones with a velvet covering, three or four lines in diameter, of a dark glossy brown colour, soft to the touch, which, when taken out of the water, might be compared to the skin of a mouse. 101. C. vesicata. Dillw. 74. Muller in Nov. Act. Pet. 3. "Filaments branched, somewhat jointed, rigid; vehicles innate, solitary, elliptical, broader than the filament; capsules generally in pairs, pear-shaped on short peduncles." Filaments in bulky masses at the bottom of the water, so extremely brittle that their length cannot easily be ascertained, yellowish green, cylindrical, filled with minute granules which issue from them when broken; very tough to the touch; branches few, dilated, generally making an obtuse angle with the stem. Stems of the branches frequently swollen, with bladder-like vehicles, four or five times thicker than the filaments, resembling those of fucus nodosus. Partitions irregularly disposed, always at a great distance from each other. 102. C. amphibia. Linn. Sp. Pl. 5. Lam. 5. Dillw. 41. (C. amphibia frillifera et piongiodes; Dill. 22. tab. 4. fig. 7. B and C.) "Filaments somewhat jointed, branched, densely matted; branches spreading, remote; branchlets, when not immersed, collecting into sharp brilhly points; partitions but little contracted; capsules fuscous, somewhat elliptical." β. branches elongated (C. fuscata; β. Hudf. Ceramium coerpi tofum; Roth Cat. Bot. 1. p. 154. 2. p. 156. C. palustris filaments brevioribus et crenulosis; Dillw. 17. tab. 3. fig. 10.) Filaments very various in length, according to the situation, bright green, becoming ash-coloured with age; a is the plant as it grows on the edges of ditches, and in shallow water, where it is not wholly immersed. In such situations, it frequently occurs in masses, so densely matted as to hold water like a sponge, with its surface breath, which give it a bulky appearance. In floods, when the waters subside, the length of the filaments is gradually increased, and forms Mr. Dillwyn’s β; but when the waters subside, the filaments, again exposed to air, take of course an horizontal direction, and again throw out erect spreading branchlets, which, on being dried, collapse so as to form rather stiff points. In rivers, the branches are frequently carried out by the force of the stream to a great length, and in that case do not assume a brilhly appearance when exposed to air; probably owing to the less spongy nature of the mafs, in consequence of which the water is not so readily transmitted to the upper surface, as to enable it to make fresh shoots. The plant has a mouldy ungrateful smell, and is much used as a shelter by aquatic insects.

* * * Not immersed.

103. C. atro-virens. Dillw. 25. "Filaments rather rigid, branched; branches divericated, somewhat unilateral, attenuated at both ends, rather obtuse; partitions peduncled; joints very short, marked with three points." Filaments from a quarter to half an inch long, growing in thick bulky tufts, of a blackish green colour, not uninteresting interspersed with moss. On the wet rocks, forming the banks of the river Dylais, near Neath. 104. C. frigida. "Filaments not jointed, creeping, branched; Dillw. 16. (Ceramium Dillwynii; Roth.) "Filaments not jointed, creeping, branched; branches alternate; capsules fuscous, yellowish, bullet-shaped, often with a stiff tuft, six to ten inches in length, growing into the naked eye like brick-dust. Parasitical on crustaceous rocks.
... joints which azot microscope partly is making observed authority •ftru.cture Roth and reigning... Di£fionaire he partly and Mufcorum," I...

Filaments to some extent, which are already described by that great cryptogamist, omitting such as he was not able to identify, and considering some as mere varieties. La Marcht, in Encyclopédie Methodique, has done nothing more than copy the Linnaean species, in exactly the same order, 

Hudfon, in the second edition of his "Flora Anglica," has introduced several species, not known either to Dillenius or Linnaeus. Lightfoot, in his "Flora Scotia," has also made one or two additions. But it is not more than six or seven years since rapid advances have begun to be made in the knowledge of Confera. Mr. D. Turner and Mr. Dilwyn are now diligently employed in the investigation of the British species; several foreign botanists, professor Roth in particular, are successfully engaged in the same pursuit; and we are informed by Bofc, in "Nouveaux Dictionnaire d'Histoire Naturelle," that professor Draparnaud of Montpellier is now busy in preparing a Monographia Confervarum, and has already determined several hundred species. We have been induced to confine ourselves, with a single exception, to the British species; partly by our inability to procure all the works which are necessary for a complete account of what has hitherto been done by foreign botanists; but chiefly by the consideration, that the species which belong to the Flora of the British islands, are the only ones accessible to the greater part of our readers. Our knowledge of these plants is indeed still very imperfect, and no generic character has yet been formed, which is sufficiently discriminating and comprehensive. The jointed structure of the filaments has generally been considered as an essential character; but we have been led by the high authority of Mr. Dilwyn to admit one species (n. 104.) which has not this conformation. We have already seen that the fructification of several species does not consist of "elided tubercles," as is described even in Dr. Smith's last improved generic character, but of "capitates" opening at the apex, and discharging the seeds in a manner similar to that observed in many fungi. These have been separated by Dr. Roth into a distinct genus which he calls ceramium; and it is probable that further researches will prove the propriety of making other separations. M. Vauquelin of Geneva thinks, that he has discovered five different modes of propagation in the plants usually called conserver; which has induced Decandolle to form them into six genera. Consera. Filaments carthagineous or herbaceous, divided by partitions; seeds enclosed between the partitions, and not escaping but by the destruction of the tube itself. Ceramium. Filaments membranous, cartilagineous, without partitions; capsules monoporous, adhering to the external surface of the filaments. Vaucleria. Filaments herbaceous, simple or branch- ed, without partitions; seeds attached to the exterior side of the filaments, and generally pedunculated. Botrychium. Filaments knotty, jointed, gelatinous; knots formed of filaments, simple or compound, between which are found feeds or hoots (cavex) detaching themselves, and confining of filaments already jointed. Chantras. Filaments solid, knotty; knots separating and becoming new plants, in the way of flaps or cuttings. Hydrocladium. Tube cylindrical, closed at the two extremities, and anastomosing into pentagonal meshes; filaments of the pentagon feeding at their extremities, separating and becoming themselves cylindrical tubes, closed at the ends, and composed of pentagon meshes. The last three genera, according to his ideas, have no proper feeds.

See some curious experiments by Dr. Prieišley on a species of conserver or water-moss of a peculiar kind, the manner of its production, and its effect, by the concursing action of light upon it, in dephlogismating or depraving the air to which it has access, and thereby increasing the quantity of it; in "Observations on Air," vol. iv. p. 335. & c. vol. v. 2, 3, 4, 5. The feeds of this plant, says Dr. Prieišley, float every where; in the air, on the earth, on the sea, in the Alps, in the plains, under the poles and the equator, in summer and winter, and in all seasons; and they are received into the water, insinuating themselves into vessels of water through the smallest apertures, where they germinate. Dr. Ingeniheiz made a variety of experiments on this singular substance; from which he concludes, that the water itself, or some substance in the water, is converted into this kind of vegetation. It is a real transmutation, which may appear incomprehensible to the philosophical mind, but which, in reality, is not more extraordinary than the change of the earth and other vegetables into gramine in the bodies of granivorous animals, and the change of the aqueous juice of the olive into oil. Dr. Prieišley, however, observes, that the change of water into an organized plant is a thing of a very different nature from thefe, and tends to revive the long exploded doctrine of equivocal or spontaneous generation. Dr. Girtanner of Gottingen (see Annales de Chemie, No. 102.) traces its formation from azot, which is a confluent principle of bodies, in the following manner. When water is exposed to the sun the light decomposes it, and diffuses the oxygen in a large quantity. The hydrogen then retains the tail portions of the oxygen; azot is formed, and announces itself by its green colour; the water is more decomposed; more of the oxygen, which, in the opinion of this writer, is the principle of life and irritability in organized nature, becomes fixed; and this azot, produced from water by means of the sun, is an organized body, the "consera forinalis;" a plant which lives, expands, and perpetuates its species. The influence of the solar light is, he conceives, absolutely necessary for this conversion of water into a plant or organized azot. No degree of heat can supply its place. Mr. Senger of Reik, in Wellphalia, has lately discovered, that the conserver affords next to sage, one of the fittest materials for the making of paper; in conformance of which he obtained the honour of a gratuity from the court of Berlin, and also a patent for the manufacture of paper from this substance. From his experiments it likewife appears, that the conserver, after a previous preparation, might be made a sublimate for cotton-wool, and a succedaneum for feathers in beds.
CONFESS and avoid, in Law, a species of replication, in which the plaintiff introduces some new matter or disclaimer, consistent with his former declaration; as, in an action of trots upon lands of which the defendant is seised; if the defendant pleads a title to the land by descent, the plaintiff may either deny the fact, or confess and avoid it, by replying, that such defect happened, but that the defendant hath since demised the lands to the plaintiff for the term of life. Blackl. Com. vol. iii. p. 310.

CONFESSTo and, in Retort, the same with what is otherwise called paronomology.

Confession, in a Civil Suit, a declaration or acknowledgment of some truth, though it be against the interest of the party who makes it, whether it be in a court of justice, or out of it. It is a maxim, that in civil matters, the confession is never to be divided, but always taken entire; and that a criminal is never condemned on his simple confession, without other collateral proofs; nor is a voluntary extra-judicial confession admitted as any proof. A person is not admitted to accuse himself, according to that rule in law, non auditer peruere volens.

Confession of Action, in Law, is a species of plea to the action, in which the merits of the complaint are answered, by confessing either wholly, or, which is most common, in part. A confession of the whole complaint is not very usual, for then the defendant would probably end the matter sooner; or not plead at all, but suffer judgment to go by default. Yet sometimes, after tender and refusals of a debt, if the creditor harasses his debtor with an action, it then becomes necessary for the defendant to acknowledge the debt, and plead the tender; adding that he has always been ready, "tou temps prit," and will is ready, "uncore prit" to discharge it: for a tender by the debtor, and refusals by the creditor, will, in all cases, discharge the debts. (1 Vent. 21.) but not the debt itself; though in some particular cases the creditor will totally lose his money. (Litt. § 338. Co. Litt. 200.) But frequently the defendant confesses one part of the complaint (by a "cognizit actionem" in respect of it,) and traverses or denies the rest; in order to avoid the expense of carrying that part to a formal trial, which he has no ground to litigate. A species of this sort of confession is "the payment of money into court;" which is for the most part necessary upon pleading a tender, and is itself a kind of tender to the plaintiff; by paying into the hands of the proper officer of the court as much as the defendant acknowledges to be due, together with the costs hitherto incurred, in order to prevent the expense of any farther proceedings. This may be done upon what is called a "motion," which is an occasional application to the court by their parties or their counsel, in order to obtain some rule or order of court, which becomes necessary in the progress of a cause; and it is usually grounded upon an "affidavit" (the perfect tense of the verb "aflido") being a voluntary oath before some judge or officer of the court, to evince the truth of certain facts, upon which the motion is grounded; though no such affidavit is necessary for payment of money into court. If, after the money paid in, the plaintiff proceeds in his suit, it is at his own peril; for, if he does not prove more due than is paid into court, he shall be non-suited and pay the defendant's costs; but he shall still have the money paid in, for that the defendant has acknowledged his due. Blackl. Com. vol. iii.

Confession of Indictment, is a prisoner's acknowledgment of the offence, when he is brought to the bar to be arraigned; upon a simple and plain confession, which the court is backward in receiving and recording, nothing re-
more partial and restricted fences, it is a declaration of a person’s sins, made to a priest, in order to obtain absolution for the same. The Roman church makes confession a part of the sacrament of penance.

Confession was anciently public and general, in the face of the church; though the Romanists have since altered it, and made it private and auricular.

Confessions are to be buried in eternal silence, under pain of the greatest punishment to the priest who reveals them. Bellarmine, Valentin, and some other Roman controversial writers, endeavor to trace up auricular confession to the earliest ages; and thus contend for a point given up by the ref. M. Fleury owns, that the first instance of auricular confession he can meet with, is that of St. Eloi, who, being grown old, made a confession to a priest of all his sins from his youth upwards.

Secret confession was first decreed and established in the 4th council of Lateran, under Innocent III., in 1215, cap. 21. And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent (fess. 14. cap. 5.), which expressly ordains, that confession was instituted by Christ, and that by the law of God it is necessary to salvation; and that it has been always practised in the Catholic church. Hard. Concil. tom. vii. p. 35. and tom. x. p. 92. See Povera.

The Indians, according to Tavernier, have a kind of confession; and the same may be said of the Jews: they have, of late, have formulas for those who are not capable of detail all of their sins: the ordinary form is in alphabetical order, each letter containing a capital sin. They usually rehearse on Mondays and Thursdays, and on fast-days, and other occasions; some every night and morning. When any of them find themselves near death, they find for ten persons, more or less, one of them a rabbinc; and in their presence recite the confession. See Leo de Modena.

Confession of faith, denotes a list, or enumeration and declaration of the several articles of belief, in a church. See Articles of faith.

In the council of Rimini, the Catholic bishops found fault with dates in a confession of faith, and observed that the church never used to date them.

Confession, Augsburg or Augsflam. See Augustan Confession.

Confessional, or Confessionary, in Church History, a place in churches, usually under the main altar, wherein were deposited the bodies of deceased saints, martyrs, and confessors.

Confessional is also used in the Roman church for a little box or desk in the church, where the confessor takes the confessions of the penitent.

Confesso, Pro-Confesso. See Pro-Confesso.

Confessor, Pro-Confessor. See Pro-Confessor.

Confessor, a Christian, who has made a solemn and redoubled profession of the faith, and has endured torments for its defense. A mere fiant is called a confessor, to distinguish him from the roll of dignified saints; such as apoiiets, martyrs, &c.

The time of confessors was given in the early ages of the church, and particularly towards the commencement of the first century of the Christian era, to those who, in the face of death, and at the expence of honour, fortune, and all the other advantages of the world, had confided with constance, before the Roman tribunals, their firm attachment to the religion of Jesus.

In ecclesiastical history we frequently find the word confessors used for martyrs; in after-times, it was confined to those who, after having been tormented by the tyrants, were permitted to live and die in peace. And at last it was also used for those who, after having lived a good life, died under an opinion of necessity. According to St. Cyprian, he who preferred himself to torture, or even to martyrdom, without being called to it, was not called a confessor, but a professore: and if any out of a want of courage abandoned his country, and became a voluntary exile for the sake of the faith, he was called estra." The veneration that was paid to both martyrs and confessors in the early ages of the Christian church is hardly credible. The distinguishing honours and privileges they enjoyed, the authority with which their councils and decisions were attended, was such as never had any model for an interesting history. Without doubt it was both wise and just to treat with respect, and to invest with extraordinary privileges, those Christian heroes, since nothing was more adopted to encourage others to suffer with cheerfulness in the cause of Christ. Nevertheless, as the bell and wire institutions were generally permitted by the weakens or corruption of men, from their original purpose; so the authority and privileges granted, in the beginning, to martyrs and confessors, became, in process of time, a support to superstition, an incentive to enthusiasm, and a source of innumerable evils and abuses. See Martyr.

Confessor is also a priest, in the Roman church, who has power to hear sinners in the sacrament of penance, and to give them absolution. See Shiray-car

The church calls him in Latin confessor, to distinguish him from confessor, which is a name consecrated to saints. The confessors of the kings of France, from the time of Henry IV. have been constantly called: before him the Dominicans and Cordeliers shared the office between them. The confessors of the house of Austria have also, ordinarily, been Dominicans and Cordeliers; but the latter emperors have all taken Jesuits.

Confessor to his Majesty. See Clerk of the Closet.

Confidence, in the English Language, denotes a firm reliance on the skill, courage, conduct, &c. of an individual. It is of the first importance for the commander of an army to have the entire confidence of the officers and soldiers under his command. This was remarkably the case with Hannibal, Julius Caesar, &c. among the ancients, and with the marshal de Turenne, John duke of Marlborough, &c. among the moderns. A general, in whom his troops have confidence, may gain a victory without employing much military skill; and on the other hand, the most skilful general may lose one, who has lost the confidence of his army.

Configuration, the exterior surface, that bounds bodies, and gives them their particular figure.

That which makes the specific difference between bodies, is the different configuration, and the different situation of their parts. A short, or a long fight, depend on the different configuration of the crystalline.

Configuration of the planets, in Astronomy and Astrology, is a certain distance or situation of the planets in the Zodiac, whereby they are supposed to aid, or oppose each other. See Aspect and Satellites.

Configurations of falls, a term used by some to express the combinations of the particles of the falls of plants, and other substances, into certain figures, on evaporating the water in which they had been dissolved, so hastily as not to admit of their forming into their own regular crystals. See Crystalization.

Confession to the realm. See No exact vagrum.

Confirmation, in a general sense, the act of ratifying or rendering a title, claim, pretention, report, or the like, more sure and indisputable. See Confirmation.
CONFIRMATION.

Confirmation, in Law, denotes the conveyance of an estate, or right in estate, which a person hath in or to lands, &c. from one man to another that hath the possession or some estate in it, whereby a voidable estate is made sure and unavoidable, or a particular estate is increased, or possession made perfect; and it is particularly used for the strengthening or homologating an estate of one already in possession of it by a voidable title. Thus, if a bishop grant his chancellorship by patent, for term of the patent's life; this is no void grant: yet it is avoidable by the bishop's death, except it be strengthened also by the confirmation of the dean and chapter. (1 Litt. 295.)

Confirmation is also defined to be the approbation or assent to an estate already created: so far as it is in the power or consent of the confirmer, makes it good and valid; so that the confirmation doth not regularly create an estate, yet such words may be blended in the confirmation as may create and enlarge an estate; but this takes place by the force of such words as are foreign to the business of confirmation, and by their own force and power, tend to create the estate. Gibb. Ten. 75. A confirmation, says judge Blackstone, is of a nature nearly allied to a release; and the words of making it are these "have given, granted, ratified, approved, and confirm'd." (Litt. § 516.) An instance of the first branch of the above definition is, if tenant for life leave the for 40 years, and die hath during that time; here the lease for years is voidable by him in reversion; yet, if he hath confirmed the lease of the lifetime for years, before the death of the tenant for life, it is no longer voidable but sure. (Litt. § 516.) The latter branch, or that which tends to the increase of a particular estate, is the same in all respects with that species of release, which operates by way of enlargement.

Madox says, that most ancient confirmations, made after the conquest, often ran like feoffments; and are distinguishable from them chiefly by time words indicating a former feoffment, or grant. In former times, when feoffages were frequently divided of their lands upon some testament or other, charters of confirmation seem to have been in great request. Possessions of lands, &c. seem'd not to have thought themselves secure against the king, or the great lords who were their feoffors, or in whose lands their fees lay, unless they had repeated confirmations from them, their heirs or successors. And these ancient confirmations seem to have been sometimes made, either by precept or writ from the king, or other lords, to put the feoffees, or their heirs or successors into feoff, after they had been divided, or to keep them in their feoff undiverted, or eile by charter of express confirmation. Confirmation is "perficient, crecent, or diminutum" perfect, as if feoffee upon condition make a feoffment, and the seoffor confirm the estate of the second seoffee;—crecent, which always enlarges the estate of a tenant;—as tenant for years to hold for life, &c.:—and diminutum, as when the lord of whom the land is helden, confirms the estate of his tenant, to hold by a lease rent. 5 Rep. 142.

The lord may diminish the services of his tenant by confirmation; but not referve new services, so long as the former estate in the tenancy continues; and therefore if he confirm to the tenant, to yield him a hawk, &c. yearly, it is void. (Litt. § 519. 1 Co. Litt. 296.) Leases for years may be confirmed for part of the term, or for part of the land, &c.; but an estate of freehold, being entire, cannot be confirmed for part of the estate. (5 Rep. 51.) There may be a confirmation implied by law, as well as express by deed; where the law by construction confirms a grant made to another purpose: and a confirmation may enlarge an estate, from an estate held at will to term of years, or a greater estate, from an estate for years to an estate for life; from an estate for life, to an estate in tail, or in fee; and from an estate in tail to an estate in fee-simple. (1 Litt. 355. 9 Rep. 142. Dyer. 263.) But if the confirmation be made to lie for life or years, of his term or estate, and not of the land, this doth not increas the estate; though if the liege confirm the land, to have and to hold to the liege and his heirs, this will enlarge the estate, and so of the rest. Co. Litt. 299. Plowd. 40.

In every good confirmation, there may be a precedent rightful or wrongful estate in him to whom made, or he must have the possession of the thing as a foundation on which the confirmation is to be edifying; the confirmer must have such an estate and property in the land, that he may thereby be enabled to confirm the estate of the confirmer; the precedent estate must continue till the confirmation come, so that the estate to be increased comes into it; and it is required that both these estates be lawful. Co. Litt. 296. 1 Rep. 146. Dyer. 189. 5 Rep. 15. If tenant for life make a lease for years to one perfon, and afterwards leave the land to another perfon for years; and he in reversion confirms the last lease, and after that the first lease, this is not good; the second lease hath an interest before the confirmation of him in reversion. But in a free cafe, confirmation of the first lease, after the second was confirmed, has been held good; for the lease takes no interest by the confirmation, but only to make it durable and effectual. Moor. e. 180. 1 Litt. 296. Plowd. 15.

If a difference confirm the land to the difeover but for one hour, one week, a year, or for life, &c. it is a good confirmation of the estate for ever; and if he confirm the estate of the difeover without any word of heirs, he hath a fee-simple; and if a difeover make a gift in tail, and the difeover dath confirm the estate of the donee, it shall endure to the whole estate. (Co. Litt. 291, 297, 298.) But where the estate is divided, it is otherwise; and if there be an estate for life, the remainder over, there the confirmation may be of either of the estates; and if the lease of a difeover of a lease for 20 years, make a lease for 10 years, the difeover may confirm to one of them and not to the other. (1 Cro. 472. 5 Rep. 51.) The tenant in tail in land hath a reversion in fee expectant; in this case, the confirmation of the estate tail will not extend to the reversion: &c. (Co. Litt. 297, 298.) If liege for years, without imprecation for waite, accept a confirmation of his estate for life, he hath by this loll the privilege annexed to his estate for years. (8 Rep. 76.) Acceptance of rent in some cases makes a confirmation of a lease: (2 Danv. 128, 123.) What a perfon may defeat by his entry, he may make good by his confirmation. (Co. Litt. 390.) But none can confirm, unless he hath a right at the time of the grant: he who hath but a right in reversion cannot enlarge the estate of a lease. (2 Danv. 140, 141.) As confirmation is to bind the right of him who makes it, but not alter the nature of the estate to his convenience, it shall not discharge a condition. (Poph. 51. 1 Rep. 147.) A confirmation will take away a condition annexed by law; and by confirmation, a condition after broken in a deed of feoffment is extinguished. (1 Co. Rep. 146.) Confirmations may make a detestable estate good; but cannot work upon an estate that is void in law. (Co. Litt. 295.)

A confirmation of letters patent, which are void as they are against law, is a void confirmation. (1 Lil. Abr. 295.)

Grants and leases of bishops, not warranted by the lit t. 52 Hen. VIII. c. 28. must be confirmed by dean and chapter.
CONFIRMATION.

chapter: and grants and leaves of parsons, &c. by patron and ordinary. (1 Indl. 247. 302, 303.) Bishops may grant leaves of their church-lands for 3 lives, or 21 years, having the qualities required by the fore-cited act, and concurrent leaves for 21 years, with confirmation of dean and chapter. (See 1 Eliz. c. 4, 10.) If a prebend be vacated by the death of its prebendary, and the bishop, who is patron, confirms it; this shall not hinder the succeeding bishop, without confirmation of dean and chapter, because the patronage is parcel of the possessions of the bishopric; but it shall hinder the present bishop, &c. (2 D. Nov. 1571.) If a parson grants a rent, the confirmation of the parson and bishop is sufficient without the dean and chapter, and shall be good against the succeeding bishop. (Ibid. 142.) The dean of Wells may put his possessions, with the affent of the chapter, without any confirmation of the bishop. (Ibid. 175.) See LEASE.

To the grants of a "flee corporation," as parson, prebendary, vicar, and the like, the patron must give his consent; because such a fole corporation has not the absolute fee; but a "corporation aggregate," as dean and chapter, matter, fellows and scholars of a college, &c. or any fole corporation that has the absolute fee, as a bishop with a conflict of the dean and chapter, may by the common law make any grant of their possessions without their founder's consent; and it shall be conclusive against the founder.

A confirmation, as we have already observed, is in nature of a release, and in some things of a greater force: and in this deed, it is good to recite the estate of the tenant, as also of him that is to confirm it, and to mention the confirmation; the words ratify and confirm, are commonly used; but the words grant, give, grant, stipufer, &c. by implication of law, may enter as a confirmation. (1 Indl. 295. Wilt. Symb. 1. p. 457.)

Confirmation, in Rhetoric, is, according to Quintilian, the third part, but according to Cicero, the fourth, of an oration, wherein the orator undertakes to prove, by laws, reasons, authorities, and other arguments, the truth of the propositions advanced in his narration. Cicero. De Inven. lib. i. cap. 14. 24. Quint. Inst. Orat. i. iii. e. 9.

Confirmation is either direct, or indirect: he first confirms what the orator has to urge for strength of his own cause; the second, properly called confirmation, refutes the opposite arguing of the adversaries. The two parts together are sometimes placed under the head or title of CONTENTION.

As to the forms of reasoning used by orators, for the purpose of confirmation, the Greek writers distribute them under four heads; viz. Syllogism, Ethymeme, Induction, and Example. (See each article, and also ARGUMENT and ARGUMENTATION.) Cicero reduces the rhetorical modes of reasoning to two, which he calls rationation and induction, comprising both syllogism and enthymeme under ratification, and example under induction; so that the difference lies in their manner of dividing them. As to the use of these modes of reasoning, it is proper to vary them in a discourse, and not to adhere too closely to the same form; for want of variety in this, as well as in other cafes, will soon create diggret. With regard to the disposition of arguments, or the order of placing them, some advise to put the weaker, which cannot wholly be omitted, in the middle; and such as are stronger, partly in the beginning, to gain the eftem of the hearers, and render them more attentive; and partly at the end, because what is last heard, is likely to be retained longest; and if there are but two arguments, to place the stronger first, and then the weaker; and after that to return again to the former, and induct principally upon that. But this must be left to the prudence of the speaker, and the nature of the subject. Nevertheless, it can never be proper to begin with the strongest, and to gradually descend to the weakest; for this would be a kind of antithesis in reasoning, which would be likely to destroy the effect. Arguments ought not to be crowded too closely upon that point; for then their force would be weakened, and the attention of the hearers would be so distracted, that they could not have sufficient time duly to consider them. Besides, more arguments than are necessary should not be used, because the fewer they are, the more easily they are remembered. In this respect, the observation of a great master of eloquence is very just, that "arguments ought rather to be weighed than numbered." Cic. de Orat. lib. ii. c. 76.

The confirmation is, as it were, the life and soul of the oration; in this the main ftrein of the argument lies. Whence Aristotle, properly enough, calls it ταύτας, διάτας.

Confirmation of Bishops. See BISHOP.

CONFIRMATION. in Theology, the ceremony of laying on of hands, for the conveyance of the Holy Ghost. When the apostles at Jerusalem heard that many of the inhabitants of Samaria had embraced the Gospel, and had been baptized, they sent thither Peter and John, who laid their hands on those new converts, and prayed that they might receive the Holy Ghost, and the Holy Ghost descended upon them. (Acts, 8.) And when the men of Ephesus had been baptized, "Paul laid his hands upon them, and the Holy Ghost came upon them." (Acts, xix. 6.) And St. Paul, in his epistle to the Hebrews, (vi. 2.) mentions the doctrine of the laying on of hands immediately after the doctrine of baptism. Upon these authorities was founded the practice, which prevailed in the primitive church, of persons receiving from the bishop immediately after baptism, a solemn benediction, accompanied with imposition of hands, upon the forehead with the holy chrism (made of oil and balsam), the sign of the Cross, and a prayer for the deponent of the Holy Ghost.

Among the ancients it was conferred immediately after baptism; and was esteemed in some measure, to be a part thereof: whence the fathers call it the accomplishment of baptism. The ground of the practice was an opinion of the imperfection of baptism, which in their apprehension was only prepared persons for the reception of the graces of the Holy Spirit, which were actually conferred in confirmation. To this purpose Tertullian says, "when we come out of the water, we are anointed with a blearied ointment, according to that ancient rite by which men were to be anointed for the priest's office with ointment out of a horn, ever since the time that Aaron was anointed by Moses; so that Christ himself had his name from chrisma. (See CHRISt.) Then we have the imposition of hands on us, which calls down and invites the Holy Ghost." (Tertull. de Baptism. c. 7.) King's Hist. of the Prim. Church, chap. v. p. 80, &c.) This ceremony was called confirmation, as it completed the admittance of the person into the Christian church, and qualified him to partake of the Lord's Supper. It was not confined to adults, but infants also received confirmation as soon as they were baptized, and an opportunity offered of presenting them to the bishop.

Among the Greeks, and throughout the East, it still accompanies baptism; but the Romanists make it a distinct and independent sacrament. The first express institution of this ceremony as a sacrament occurs in the decree of pope Eugenius in 1439, in which he says, "the second sacrament is confirmation, the matter of which is chrism blessed by the bishop, and though the priest may give the other unction, the bishop only can confer this." Peter Lombard, however, who lived in the 12th century, seems to have been the first who
who reckons seven sacraments, and mentions confirmation as one of them. Although this ceremony was generally performed by bishops, yet in some countries, as at some periods, it was performed by presbyters; but in that case it was necessary that the chrism should have been previously conferred by the bishop. St. Cyprian, and many of the fathers, speak of it in such terms as to imply, that the administration of it was confined to the bishop alone. Jerome tells us, that in his time, confirmation was always performed in the Latin church by bishops, as it had been in earlier times; and some have supposed that the custom of receiving the imposition of hands after baptism, to be performed by the bishop alone, commenced in the time of this father; though he himself did not think that the Holy Spirit was given by the imposition of the hands of the bishop only: and he says, they are not to be lamented, who, being baptized by presbyters or deacons in little villages, and cells, have died before they were visited by bishops. Hilary says, that in Egypt the presbyters confirmed in the absence of the bishop, but that the form was also determined by the council of Orange: and this was the practice of the Greek church, which did not allow confirmation to be a sacrament. From one of the canons of the council of Liberius we learn that, in the time of Cyprian and of Augustine, confirmation was performed by bishops. Hence Tertullian, and many of the moderns, lay it down as a distinguishing character between the offices of a priest or deacon, and that of a bishop, that the former might baptize, but the latter alone might anoint and confirm; by virtue of their succession to the apostles, to whom it originally belonged. But from some passages in St. Gregory, &c. others gather, that the priests, on occasion, had likewise the power of confirming.

It has been alleged, that, as confirmation always succeeded baptism, and made a necessary part of it, and several of the primitive Christians esteemed both necessary to salvation, it must have been performed by presbyters as well as by bishops; because the bishop of a church might be absent for a considerable time, as was the case with Cyprian, or the fee might be very small fee paid to the presbyters baptized, it is reasonable to conclude that they also confirmed. Lord King has shewn that confirmation and absolution were the same thing; and that presbyters, sometimes with the bishop, and sometimes without the bishop, did absolve by imposition of hands: and he has cited several ancient authorities in order to prove, that confirmation was frequently repeated with respect to the same persons. (Hist. Prim. Church, p. 91, &c.)

It is certain, among the Greeks, the priest who baptizes also confirms: which practice, Lucas Hellenius shews, is of so old a standing among them, that it is now generally looked on as belonging properly, and of right, to the priest: though some have it to have been borrowed by them from the bishops. Hence, some of the Latin divines acknowledge, that though the bishop be the ordinary minister of confirmation, yet, that the priest, in his absence, may also confer it, in quality of minister extraordinary.

The Council of Rouen, held in 1017, decrees that confirmation must be conferred falling, both on the side of the giver, and that of the receiver.

The ancients, and in this respect they are followed by the moderns, did not think this rate of confirmation to absolutely necessary, that the want of it would exclude from the kingdom of heaven those who had already been baptized; but they attributed to it so much importance, that they punished the neglect of it with marks of disgrace and public censure; and denied the privilege of ecclesiastical promotion and holy orders to such persons as had voluntarily and carelessly omitted it.

"After this example of the primitive Christians," says Dr. Tomlins, the bishop of Lincoln, "our church requires all who have been baptized to appear publicly in the congregation, and renew their baptismal vow according to the form prescribed in our liturgy." The order of confirmation requires, "that none shall be confirmed but such as can say the Creed, the Lord's Prayer, and the Ten Commandments, and can also answer to such other questions as in the Short Catechism are contained," &c. The bishop then questions them, whether they renew the solemn promise and vow that was made in their name at their baptism; ratifying and confirming the same in their own persons, and acknowledging themselves bound to believe and to do all those things which their god-fathers and god-mothers then undertook for them? The bishop in his general prayer declares before God that he hath vouchsafed to regenerate these, his servants by water and the Holy Ghost, &c. bath given unto them forgiveness of all their sins; and then laying his hand upon the head of every one severally, offers a prayer for each individual. Moreover, in the collection which forms a part of this service, he prays for those that are confirmed, saying, "upon whom, (after the example of thy holy apostles,) we have now laid our hands, to certify them (by this sign) of thy favour and gracious goodes towards them." The order forbids any to be admitted to the holy communion, but those who have been confirmed, or who are ready and desirous to be confirmed. This order of confirmation does not mention the proper age of the person to be confirmed.

This ceremony, says the bishop, "falls within the authority of the church, and may be considered as included in the general precept of doing all things in order and unto edifying;" especially since the now universal practice of infant baptism makes confirmation more necessary than it was in the primitive church, when chiefly adults were baptized. It seems highly reasonable that they, who, at the time of their baptism, were incapable of making any engagement, should, when they arrive at a proper age, ratify and confirm those promises which were made in their name. And to give this ordinance the greater solemnity, it is performed only by the higher orders of the church, the archbishops and bishops. Thus far our church receives confirmation, confining it to prayer and imposition of hands, without the chrism, or the sign of the cross, and believes it to be derived from the practice of the apostles. But as it is not a regular constitution of Christ and his apostles, like baptism and the Lord's supper, with a written command that it should be continued in future ages, and a promise that it will be attended with inward grace, we reject it as a sacrament. There is, indeed, not a single precept upon the subject in the New Testament; nor is there any episcopal authority for the use of the chrism or the sign of the cross; and Bingham thinks that the chrism made no part of confirmation before the latter end of the second century; though other writers attribute an earlier date to it. It must be admitted by all, that imposition of hands was not peculiar to confirmation; (See Matt. xix. 14.) Mark vii. 37. Luke, iv. 40;) and that no separate efficacy is ascribed to it different from the prayers which accompanied it; and prayer and imposition of hands are not sufficient to constitute a sacrament; we, therefore, consider confirmation as nothing more than a solemn manner of persons' taking upon themselves their baptismal vow; and as such, it is a ceremony of high importance, calculated to impress youthful minds with a just sense of the great obligations of the Christian profession, and to excite
excite in them an earnest endeavour "faithfully to observe such things as they, by their own confession, have assented unto." Elements of Christian Theology, vol. ii. p. 416.

It has been urged, however, that this ceremony, with respect to the real importance and utility of it, was peculiar to the times of the apostles: and though it is retained among Protestants, it is doubted whether it be a necessary instrument of grace.

Some have thought it a remnant of the pagan sacrament of confirmation; and that there is no more authority for retaining this remnant, than for any thing that is omitted in the ceremony. It has been said that the texts of scripture, repeatedly alleged in favour of this rite, have no weight.

To this purport it has been argued, that Peter's and John's going down to Samaria to pray, and to lay their hands on those whom Philip had baptized, furnishes no precedent, no direction, no institution, nor command for our bishops, to do likewise. The aid for which the apostles did it, as it is expressly fall (Acts vii. 15, 17.), was, "that they might receive the Holy Ghost," i.e. its miraculous gifts, such as prophesying, speaking with tongues, &c. necessary for forming them into a church; in proof of which it is urged, that they were something visible and obvious to sense; something which excited the wonder and ambition of the wicked persecutors; for it is said, "When Simon saw that through laying on of the apostles' hands the Holy Ghost was given, he offered them money." Bishops, Dr. Whitby has observed, that if they laid not their hands on all who were baptized, it makes nothing for confirmation; if they did, then Simon Magus also was confirmed, and received the Holy Ghost; which is not admissible. Our bishops, it has been said, disclaim the powers exercised by the apostles. As for the open and solemn renewal of the baptismal covenant before God, which baptized persons ought to make, when they come to years of discretion, this, it is said, is done in the sacrament of the Lord's supper, which Christ himself has appointed, and which is the only institution his wisdom has thought fit to appoint for this purpose. It has also been alleged that the ceremony of confirmation, however solemnly practiced, has a tendency, the more from the solemnity of its administration, to cherish in men's minds a presumptuous and false hope, and to decide them into wrong notions as to the safety of their state, and as to the terms of acceptance and favour with God. What warrant, it has been asked, has the bishop to pronounce a man's sins all forgiven, and himself regenerated by the Holy Ghost, when no other grounds than his being able to repeat the Lord's Prayer, Credo, and Ten Commandments, and the articles of the Short Catechism? Can it be said, that this is the Christian doctrine concerning the terms of acceptance and favour with God? Are good works and resolutions, declared in the church, infallible or proper proofs of a regeneration by the Holy Ghost? Is a man's professing that he repents, and promising that he will live a godly life, that actual repentance and amendment of life, which alone can ensure the divine pardon and favour? The multitudes, it is further said, who come to be confirmed, are taught to consider the bishop, in the exercise of that part of his office, as an ambassador of Christ, a successor of the apostles, and a special minister of God; and therefore, when they hear this sacred person, solemnly declaring that they are truly justified, pardoned, and regenerated by the Holy Ghost, can they be blamed if they believe it, and reft satisfiyed with regard to the safety and happiness of their state? And as full remission of sins, and the favour of God are to be had on such holy terms, is it matter of wonder, that thousands should eagerly flock from all quarters to accept it?

Or that persons of very vile and profligate characters should too often thrust themselves in to partake of this benefit, and be seen receiving upon their knees episcopal absolution, and solemn assurances of God's favour and peace?

It has been further argued by those who object to the continued practice of this ceremony of confirmation in the Christian church, that Tertullian is the most ancien author who has mentioned it, and that in his time, a great variety of forgeries, and ridiculous and foolish rites had been introduced and actually substituted in the Christian church.

Confirmation was then always performed, as we have already mentioned, (not as it is with us, but) immediately after baptism. The expression in our order of confirmation, by which the bishop declares to God, "that he hath vouchsafed to regenerate these his servants by water and the Holy Ghost, and to give them the forgiveness of all their fins," was probably taken from some ancient liturgy, and was suitable and well adapted to the practice of those times, but is incongruous and unuitable to ours. Then, as Dr. Cave observes, (Primitive Christianity, pt. i. p. 174, 228.) "although infants were undoubtedly taken into the church by baptism, yet the main body of the baptized were adult persons; who, flocking over daily in great numbers to the faith of Christ, were received in at this door. Usually they were for some considerable time catechized, and trained up in the principles of the Christian faith; till having given testimony of their piety in knowledge, and of a liberal and regular conversation, they became candidates for baptism," or, as Lord kay says, (Inquiry into the Constitution, &c. pt. i. p. 102.) "the catechumens enjoyed not the privileges of the faithful, till they had, in a sense, merited them, which was, when, through a considerable time of trial, they had evidenced the sincerity of their hearts, by the sanctity and purity of their lives. And then, as Origen says, we initiate them in our mysteries, when they have made a profession in holiness, and according to the utmost of their power have reformed their conversation. When they had changed their manners, and rectified their irregular carriage, then they were washed with the water of baptism, and not before. For, as Tertullian observes, we are not baptized that we may escape to sin; but because we have already escaped."

In these circumstances, it is said, the bishop or the presbyter might use an expression similar to that already cited with propriety; but the case is different, say the objectors to the permanent use of this rite, with the multitudes who flock to modern confirmations. Pierce's Vindication of the Church of England, is applied to goods forfeited to the exchequer, or public treasury.

The word is derived from δικαίωμα, a ransom, panion, or balsam, wherein the emperor's money used to be kept.

The title to goods, which are not claimed by any other, is given by law to the king. If a man, indicted for healing the goods of another, in which case they become, in effect, the proper goods of him indicted, be asked about them in court, and disclaim them; he thereby loses the goods, though he be afterwards acquitted of the theft; and the king shall have them as confiscate; but otherwise, if he had not disclaimed them. Thus afo, when goods are found in the possession of a felon, if he disavows them and afterwards is attainted for other goods, and not for the goods, the goods which he disavows are confiscated to the king; but if he had been attainted for the fame goods, they would have been said to be "forfeited and not confiscated." So an appeal of robbery be brought, and the plaintiff leaves out some of his goods, he shall not be allowed to enlarge his appeal; and because there is none to receive the goods so left out, the
king shall have them as confiscate, according to the rule, "Quod non caput Christian, caput infidelis." Staund. P. C. 1, c. 21. See Forfeiture.

CONFISCATION, a legal adjudication of goods or effects to the fice, or treasury.

Thus, the bodies and effects of criminals, traitors, &c. and merchandise that are contraband, prohibited, or brought aboard or afloat, without paying the duties, when seized, are confiscated.

It is an axiom in law, that he who confiscates the body, confiscates also the effects, to the profit of the king, or the lord of the fice, i.e. he who is condemned to lose his life, must also lose his goods; yet the widows of criminals do not lose their dowries, nor their share in the goods of the community, by the forfeiture of their husbands. See Forfeiture.

CONFABULATION, a general burning of a city, or other considerable place. In which sense, Nero is said to have procured the Christians to be sacrificed on the confabulation of Rome, which was done by his own order.

But the word is more ordinarily restrained to that grand period, or catastrophe of our world, wherein the face of nature is expected to be changed by a deluge of fire, as it was anciently by that of water. The ancient Chaldzeans, Pythagoreans, Platonists, Epicureans, Stoics, Celts, and Etrurians, appear to have had a notion of the confabulation; though whence they should derive it, uncles from the fabled books, it is difficult to conceive; except perhaps, from the Phcenicians, who themselves had it from the Jews.

The Celts, whose opinions resembled those of the eastern nations, held, that after the burning of the world, a new period of existence would commence. The ancient Etrurians, or Tuscan, also concurred with other western and northern nations of Celtic origin, as well as with the Stoics, in ascertaining the entire renovation of nature after a long period, or great year, when a simular succession of events would again take place. The cosmogony of an ancient Etrurian, preserved by Suidas, limits the duration of the universe to a period of 12,000 years, 6000 of which passed in the production of the visible world, before the formation of man. The Stoics also maintained, that the world is liable to destruction from the prevalence of moisture, or of drought; the former producing an universal inundation, and the latter an universal confabulation. Thus, they say, succeed each other in nature, as regularly as winter and summer. When the universal inundation takes place, the whole surface of the earth is covered with water, and all animal life is destroyed; after which nature is renewed, and subsists as before, till the element of fire, prevailing in its turn, dries up all the moisture, converts every habitation into its own nature, and at last, by an universal confabulation, reduces the world to its primitive state. At this period all material forms are lost in one chaotic mass, all animated nature is reunited to the Deity, and nature again exists in its original form, as one whole, consisting of God and matter. From this chaotic state, however, it again emerges, by the energy of the efficient principle, and gods and men, and all the forms of regulated nature are renewed, to be dissolved and renewed in endless succession. The doctrine of confabulation is a natural consequence of the general system of Stoicism. For, since, according to this system, the whole process of nature is carried on in a necessary series of causes and effects, when that operative fire which at first, burrowing from chaos, gave form to all things, and which has since pervaded and animated all nature, shall have consumed its nutriment, that is, when the vapours, which are the food of the celestial fires, shall be exhausted, a deficiency of moisture must produce an universal conflagration. This grand revolution in nature is, after the doctrine of the Stoics, thus elegantly described by Ovid, (Metam. l. i. v. 256):

"Esse quoque in fatis reminiscitur auro tempus
Quo mare, quo tellus, correptraque regio celi
Ardest, et mundi nubes operosa laboret;"
or, as Dryden has translated the passage,

"Remembering in the fate a time when fire
Should to the battlements of heaven aspire,
When all his blazing worlds above should burn,
And all the inferior globe to cinders turn."

Seneca, speaking of the same event, (Ad Marcum, c. ult.) says expressly, "Tempus advenit quo sidera sideribus incurren, et omni flagrante materia uno igne, quaeque nunc ex dep Scout lect, erubebit, &c. i.e. the time will come when the world will be consumed, that it may be again renewed, when the powers of nature will be turned again herself; when flares will rush upon flares, and the whole material world, which now appears repleteness with beauty and harmony, will be destroyed in one general conflagration. In this grand catastrophe of nature, all animated beings (excepting the universal intelligence), men, heroes, demons, and gods, shall perish together. Seneca, the tragedian, who was of the same school with the philosopher, writes to the same purpose, ( Herc. Od. iii. 1112.)

"Caeli regia concedens
Ortas atque obitus tetrab,
Atque omnes pariter deos
Perdit mortis atque, et chaos."

i.e. "The mighty palace of the sky,
In ruin fall'n a doom'd to lie,
And all the gods, its wreck beneath,
Shall sink in chaos and in death."

During the course of this vast conflagration, the Stoics conceived that the world would expand, and in its chaotic state continue to fill a much larger portion of infinite space than it had required, or would again require, in a state of orderly arrangement. After an interval of rest, says Seneca, (Epist. 9. Qu. Nat. c. ult.) in which the Deity will be intent upon his own conceptions, the world will be entirely renewed; every animal will be reproduced; and a race of men, free from guilt, and born under happier flares, will repeople the earth. Degeneracy and corruption, will, however, again creep into the world; for it is only while the human race is young, that innocence remains upon the earth. The grand course of things, from the birth to the destruction of the world, which, according to the Stoics, is to be repeated in endless succession, is accomplished with in a certain period. This period, or fate round of nature, is probably what the ancients meant by the "Great Year."

From this brief account of the doctrine of the Stoics concerning the final conflagration, it evidently appears, that it differs in several essential particulars from the Chaldee doctrine on this head. It is the work of fate, performed by natural and mechanical laws, and repeated eternally at certain periods, without any good reason, since with every revolution the same disorders and vices return. Philo justly ridicules this dogma; remarking, that the Stoics make their deities act like children, who raise up piles of sand only for

Vol. IX.
The pleasure of beating them down. Several of the Stoics themselves were aware of the absurdity of this systen; and rejected it; particularly Boethus, Pythodorus, Diogenes the Babungian, and Pausanias. This general dissolution of the Stoics called "fzvulxvov. The Pythagoreans also maintained the dogma of conflagration. To this purpose the Hippophus, of Metaponto, taught that the universe is finite, is always changing, and undergoes a periodical conflagration. Philo, who flourished in the time of Plato, maintained that the world is liable to destruction, both by fire and water.

Mention of the conflagration is also several times made in the books of the Sibyls, Sophocles, Hylas, Eucus, Lucan, &c. Dr. Burnet, after F. Tachard, and others, relates, that the Samosela believe, that the earth will at last be parched up with heat; the mountains melted down; and the earth's whole surface reduced to a level, and then conformed with fire. And the Baramis of Sam do not only hold, that the world shall be destroyed by fire; but also, that a new earth shall be made out of the cinders of the old.

The sacred scriptures announce this event in a variety of passages; some of which, however, have been applied by Dr. Hammond, and others, to the destruction of Jerusalem; but others have universally allowed to refer to this awful catastrophe. See 2 Pet. iii. 12; Jer. 25. 1. Dr. Hammond to the destruction of Jerusalem, and the dissolution of the Jewish state, but generally, and, with just reason, applied to the end of the world. (See Ray's Difcourfe p. 371, &c.) 2 Theff. ii. 7. Rev. vi. 12, 13, 14. Rev. x. 6. Rev. xxi. 1. Heb. xii. 26, 27. All these passages, and others, which more immediately relate to the time of this event, are applied by Dr. Hammond to the destruction of the city, temple, and polity of the Jews: and, indeed, he leaves only one place in the New Testament, as a proof of the general conflagration of the world; viz. 2 Pet. vii. 7. Other passages have been cited from the Old Testament that seem to indicate and foretel the dissolution of the present globe: such are Heb. xiv. 12. Pl. cix. 5, 6. If. li. 6. Joel. ii. 31. Malachi. iv. 1. Deut. xxxii. 12. But it must be allowed that the prophetic books abound with figurative expressions, the precise object of which cannot be so satisfactorily ascertained. The ancient fathers of the church, and Chiliasm writers, in successive periods of its duration, have frequently referred to this event, and tried to fix its belief of its advent. Some of the first Chiliasm apprehended it to be near at hand; and many of the ancients conceived that it would take place in a single thousand years. In this number we may class Justin Martyr, Irenaeus, Lactantius, Eusebius, &c.; but their opinion, with regard to the precise time of this event, is proposed by them not as an undoubted truth, but only as a matter of conjecture. It was the general opinion of the ancient Christians, that this world shall not be annihilated or destroyed, but merely renewed and purified. To this purpose we might cite the testimonies of Eusebius, Cyril, Oecumenius, Jerome, and others.

Various are the sentiments of authors on the subject of the conflagration; the cause whence it is to arise, and the effects it is to produce. Divines ordinarily account for it metaphysically; and will have it take its rise from a miracle, as a fire from heaven. Philosophers contend for its being produced from natural causes; and will have it effected according to the laws of mechanics: some think an eruption of a central fire sufficient for the purpose; and add, that this may be occasioned several ways; viz. either by having its intensity increased; which, again, may be effected by the earth being driven into less space by the encroachments of the superficial cold, or by an increase of the inflammability of the fuel whereon it is fed: or by having the residence of igniting earth weakened; which may happen, either from the diminution of its matter, by the consumption of its central parts; or by weakening the cohesion of the constituent parts of the mass, by the excess or the defect of moisture.

Others look for the cause of the conflagration in the atmosphere; and suppose, that some of the meteors there engendered in unusual quantities, and exploded with unusual vehemence, from the concurrence of various circumstances, may be made to effect it, without seeking any further.

The astrologers account for it from a conjunction of all the planets in the sign Cancer; as the deluge, they say, was occasioned by their conjunction in Capricorn. This was an opinion adopted by the ancient Chaldeans.

Lastly: others have recourse to a still more effectual and flaming machine; and conclude the world is to undergo its conflagration from the near approach of a comet, in its return from the sun. Those wandering bodies do indeed seem to menace us a little; being able, both by their tranverse motion across the earth's way, by the hugeness of their size, and the intense fire wherewith they glow in their recells from the perihelion, to produce the most frightful changes and revolutions in the system of things.

Mr. Wilfon has shewn, that they are extremely well fitted to produce the phenomena of the deluge; and has gone a good way towards proving, that the comet of 1680—was the very body to which that event was owing; as being then in its approach towards the sun, and its atmosphere crowded with the watery vapours, which it had gathered in those inconceivably cold regions, into which it had fled off in its aphelion.

This same comet, for Isaac Newton has calculated, when in its perihelion, December the 8th, was heated, by the vicinity of the sun, to a degree two thousand times more hot than red-hot iron: he shews, likewise, that it would be cool again in fifty thousand years.

This same comet, Dr. Halley observed November the 11th, was not above a semidiameter of the earth from the earth's way: so that had the earth, at that time, been in that part of its orbit, something very extraordinary might have been apprehended; but whether in the way of fire, or water, may, perhaps, to some, leave room to doubt. But it is fearlessly conceivable, that the comet should bring anyvehement degree of heat, out of those regions it comes from, whatever heat it might carry with it. See Comet. See on the subject of this article Theory of the Earth.

CONFLANS, in Geography, a small town of France, in the department of Mont-blan, and chief place of a canton in the district of Moutiers, 18 miles N.E. from Moutiers. The place contains 1152, and the canton 5472 inhabitants. The territory includes 1824 square kilometres and 10 communes. Alto, a small town of France, in the department of Mofelle, and chief place of a canton in the district of Broye, situated at the confluence of the Iron and Or, 15 miles E. from Metz. This place contains but 347, and the canton 7495 inhabitants, and 31 communes, upon a territorial extent of 240 square kilometres. Alto, a town of France, in the department of the Upper Saone, in the district of Lure; 4 leagues N. of Vélon, and 23 W. of Luxeuil. Alto, a town of Savoy, near the conflux of the Iere and Daron; 18 miles E. of Chambery.

CONFLANS, or Conflant, was, before the revolution, the name of a valley of France, in Rouillon, surrounded by the Pyrenees, and watered by the river Tet. Villefranche sur le Tet was its capital.

CONFLANS
CONFLANS St. Honorine, a town of France, in the department of the Seine and Oise: 5 leagues S.W. of Paris.

CONFLICT. See Combat.

CONFLUENCE, Confluent, the place where two rivers join, and mix their waters.

CONFLUENT, in Medicine, literally flowing together, is a term applied to cutaneous eruptions, which, though confluent, on their first appearance, of separate and distinct spots, form themselves subsequently into extensive patches, by the spreading of the individual spots, which coalesce with each other. This epithet is most frequently applied to the smallpox, which, when confluent, becomes a very formidable and fatal disease, and requires a treatment in its latter stages, different from that which is beneficial in the mild form of the disease, when the pustules are few and distinct. See Small-Pox.

CONFLUENTA, in Ancient Geography, a town of Spain, belonging to the Vandaeans, S.E. of Palentia.

CONFLUENTES, who contend, that reflected light becomes of different colours, according to the different conformations of the bodies that reflect it. The conformation of the members of an embryo is not perfect enough to allow of distinction.

CONFORMITY, in the Schools, is the congruence, or relation of agreement between one thing and another: as between the measure, and the thing measured: the object, and the understanding: the thing, and the conception: the thing, and the division thereof, &c.

CONFORMITY, Non. See Non-conformity.

CONFORMITY, Occasional. See Occasional Conformity.

CONFRERES, from con, and frere, brother; denote brethren in a religious house, or the fellows of one and the same society. 3° Hen. VIII. c. 24.

CONFRACTION, the act of bringing two persons, in preference of each other, to discover the truth of one fact, which they relate differently.

The word is chiefly used in criminal matters; where the witnesses are confronted with the accused; the accused with one another, or the witnesses with one another.

CONFUCIUS, or Kong-Fu-tse, in Biography, the most celebrated ancient philosopher of China, descended from the imperial family of the dynasty of Shang, was born in the reign of the emperor Lu, about four centuries and a half before Christ. He was accordingly a contemporary with Pythagoras, and flourished at a period prior to that in which Socrates rose to celebrity. At fifteen years of age, he engaged in the study of the ancient learning of his country; and, before he had arrived at the years of manhood, he had made astonishing proficiency in the doctrines attributed to the legislators Yao and Chun, which the Chinese consider as the source of all their science and morality. The reputation which Confucius acquired, and the uncommon wisdom which he discovered, were the means of advancing him, while he was yet but a youth, to the office of minister of state. The duties of this, and of other posts assigned to him, he performed with honour to himself, and signal benefit to the kingdom. The rank which he held in public life, enabled him to form an accurate judgment of the state of morals among his countrymen. He devised a plan for a general reformation, which he endeavoured to carry into execution, as well by inculcating a strict and pure morality, as by using the influence of his authority in recommending it. His efforts were crowned with so much success, that the whole nation became, at first, a pattern of order, decency, and strict justice. This reformation was not, however, permanent; the butts of the flate was abandoned to men of licentious habits, and in a short time an universal effeminacy and disfigurements of manners prevailed. Confucius exerted all his powers to stem the torrent of vice; and when he found that his endeavours were fruitless, he resolved to quit his station and country, and seek an asylum in some other kingdom where his efforts in the cause of virtue might be more availing. He, at length, devoted himself to the task of private instruction in philosophy and morality. His great celebrity, and his personal virtues, soon procured him many scholars; and he is said to have had several thousand disciples to whom he taught morals, the art of reasoning, and the principles of policy. From these he selected seventy-two, who were distinguished from the others on account of their superior attainments. These were divided into classes, defined for different purposes. The butts of the first class was the study of morals; of the second, that of reasoning and eloquence; of the third, that of the rules of good government; and the immediate predecessor of the fourth was forming similar to our public preaching. The exertions of Confucius in the cause of virtue, were too great for the frame of body with which he was endowed; his natural strength became impaired, and his mental powers failed. During his last sickness, he declared that his heart was overpowered with grief, on beholding the disorders which prevailed in the empire, and which he had in vain endeavoured to suppress: "The kings," said he, "will not follow my maxims; I am no longer useful on earth; it is, therefore, time that I quit it." This exclamation was followed by a lethargy from which he never recovered. He died in his seventy-third year. B. C. about 479. (Blair.) By his sage counsels, his moral doctrine, and his exemplary conduct, he obtained an immortal name as a reformer of his country. After his death, his name was held in the highest veneration, and his doctrine is still regarded among the Chinese, as the basis of all moral and political wisdom. His natural temper was excellent, and his conduct irreproachable and exemplary. He was particularly praised for his uprightness, sincerity, temperance, dissimulation, and coetum of riches. Confucius seem to have been taught by heaven to reform, both by his doctrines and example, the corruptions which prevailed, as well as the civil, as in the religious establishments of China. He condemned the idolatry which his found exciting among his countrymen, and endeavoured to introduce a purer form of religion. He did not attempt to dive into the impenetrable secrets of nature, nor bewilder himself in abstruse researches on the essence of a first cause, the origin of good.
and evil, and other subjects which seem beyond the limits of the human mind. He maintained that the Deity was the most pure and perfect principle, and fountain of all things; that he is independent and almighty, and watches over the government of the universe, so that no event can happen but by his command; that our most secret thoughts are open to his view; that he is holy without partiality, and of such boundless goodness and justice, that he cannot possibly permit virtue to go unrewarded, or vice unpunished.

So high is the respect paid to the memory of this great man, even in the present day, that his descendants enjoy, by inheritance, the title and office of mandarins, and are allowed the privilege in common with the princes of the blood, of exemption from the payment of all taxes to the emperor. The works which Confucius composed for the use of his disciples, and the preservation of his philosophy, are looked upon by the Chinese as of the first authority, next to the classical books, by way of eminence, "the Five Volumes;" and to these, indeed, he declares himself indebted for the information and wisdom, which his own are calculated to convey. Moreci. Hist. Univ. D'Anquetil. Eschfield's Hist. of Philosophy.

Confused notion and fiction. See the substan
tives.

Confusion, in a general sense, is opposed to order; in a perturbation whereof, confusion confounds: e. g. when things prior in nature do not precede; or posterior do not follow, 

In a logical sense, confusion is opposed to distinctness, or periscopacy; and may happen, either in words, as when misconstrued or misapplied; or in ideas, as when the idea of any thing presents something with it, which does not properly belong to that thing.

In a physical sense, confusion is a fort of union, or mixture by mere contiguity. Such is that between fluids of contrary nature; as oil and vinegar, 

Confusion, property is, in Law, denotes the intermi
ixture of the goods of two persons in such a manner, that their respective portions cannot be ascertained. It is by

Content, they have a common interest, both by the Eng

lish and civil law, in proportion to their shares. But, if

One wilfully intermixes his money, corn, or hay, with that of another person, without his approbation or knowledge, or casts gold in like manner into another's pot or crucible, the civil law, though it gives the sole property of the whole to him who has not interfered in the mixture, yet allows a satisfaction to the other for what he has so improperly lost. (Int. 2. 1. 25.) But our law, to guard against fraud, gives the entire property, without any account, to him, whose original dominion is invioled, and endeavored to be rendered uncertain, without his own consent. Poph. 38. 2 Bulltr. 325. 1 Hal. P. C. 513. 2 Vern. 516. Bl. Comm. ii. 455.

Confusion of tongues, in the History of the World, is a memorable event, which happened in the one hundred and fifteenth year, according to the Hebrew chronology, after the flood. B. C. 2247, at the overthrow of Babel; and which was providentially brought about, in order to fa
cilitate the dispersion of mankind, and the population of the earth. Until this period, there had been one com
mon language, which formed a bond of union, that pre
vented the separation of mankind into distinct nations; and some have supposed, that the tower of Babel was erected as a kind of fortress, by which the people intended to de
fend themselves against that separation, which Noah had projected.

There has been a considerable difference of opinion, as
to the nature of this confusion, and the manner in which it was effected. Some learned men, propounded with the notion that all the different idioms now in the world did at first arise from one original language, to which they may be reduced; and that the variety among them is no more than must naturally have happened in a long course of time by the mere separation of the builders of Babel, have main

tained, that there were no new languages formed at the confusion; but that this event was accomplished by creating a misunderstanding and variance among the builders, without any immediate influence on their language. But this opinion, advanced by Le Clerc, 

seems to be directly con-trary to the obvious meaning of the word כְּפָרִי, shapha, שפרי, used by the sacred historian; which, in other parts of scripture, signifies speech. (See Ps. xxxvi. 5. Is. xxviii. 11. xxxiii. 19. Ezek. iii. 5.) It has been justly remarked, that unanimity of sentiment, and identity of language, are particularly distinguished from each other in the history; that the people is one, and they have all one language. (Gen. xi. 6.) It has been also suggested, that if disagreement in thought and conceptions arose out of that. This tended, it would have had a contrary effect; they would not have deceived from their project, but frequently have maintained their respective opinions, till the greater number of them had compelled the minority either to fly or to submit. Others have imagined, that this was brought about by a temporary confusion of their speech, or rather of their apprehensions, causing them, whilst they continued together and spake the same language, to understand the words dif
differently: Scaliger is of this opinion. Others again account for this event, by the privation of all language, and by supposing that mankind were under a necessity of associating together, and of imposing new names on things by common consent. Another opinion ascribes the confusion to such an indistinct remembrance of the original language which they spake before, as made them speak it very dif
differently; so that by the various inflections, terminations, and pronunciations of divers dialects, they could no more understand one another, than they who understand Latin can understand those who speak French, Italian, or Spanish, and the like.

This opinion is adopted by Caufaban, and by bishop Patrick in his Commentary in loc. and is certainly much more probable than either of the former; and Mr. Shuckford maintains, that the confusion arose from small beginnings, by the invention of new words in either of the three families of Shem, Ham, and Japhet, which might contribute to separate them from one another; and that in each family new differences of speech might gradually arise, so that each of their families went on to divide and subdivide among themselves. Others, again, as Mr. Jof. Mele and Dr. Wotton, 

not satisfied with either of the foregoing methods of accounting for the diversity of languages among mankind, have recourse to an extraordinary interposition of divine power, by which new languages were framed and communicated to different families by a supernatural infusion or inspiration; which languages have been the roots and originals from which the several dialects that are, or have been, or will be spoken, as long as this earth shall last, have sprang, and to which they may with more or less be reduced. This opinion is adopted and vindicate
d by Dr. Hartley, in his Observations on Man,

p. 170, where says, that it seems impossible to explain how the human languages should arise from one flock. Upon the whole, we may observe, that there evidently seems to have been something miraculous in the transmutation; and if it be supposed that nothing more was meant than a confusion of design, counsels, and opinions; so that they could not
agree together in the execution of their scheme (which, as we have shown, is not very probable); this would be sufficient to answer the purpose of Divine Providence, which was to prevent the children of Noah from preserving their union in one body, and to spread them over the face of the earth, that it might be peopled and cultivated. If the confusion of tongues was an actual change of languages, it was probably accomplished by degrees; nor does it appear to be so fundamental and radical an alteration as some have imagined. In proof of this, we may allege the free intercourse which subsisted in early times between persons of different ages and countries; the uniformity of the Eastern languages, which plainly shows that they have one common radix; and the manifold derivation of the Greek and Latin from the same source.

As to the number of languages thus introduced, many opinions have been adopted. If there were no more than there were nations or heads of nations, then the number would be seven for Japhet, four for Ham, and five for Shem; but if there were as many as there were families, which is the more probable opinion, their number cannot be certainly ascribed. However, the Hebrews fancy they were seventy, because the descendants of the sons of Noah, enumerated Genesis x., were just so many. Allowing then the languages of the chief families to have been fundamentally different from each other, the sub-languages and dialects within each branch would probably have had a mutual affinity, greater or less, as they settled nearer or farther from each other. But whichever of these hypotheses is adopted, the primary object of the confusion at Babel was the separation and dispersion of mankind. Cleric. Com. in Gen. i. Scaliger Exerc. in Cardan. §§ Culfauon. Distr. de Ling. Heb. Mede's Works, vol. i. p. 276. Wotton's Difc. and Brett's Eff. on the Confutation of Languages. Univerf. Hist. vol. i. part i. chap. 2. § 5. Shuckf. Conr. vol. i. p. 146.

The ingenious and learned Dr. Bryant has, in the third volume of his "Analysis of Ancient Mythology," advanced a new and singular hypothesis, both with respect to the confusion of tongues and the dispersion. He supposes that the confusion of language was local and partial, and limited to Babel only. By מיל, Gen. xi. 1 and 8, which our translators render the whole earth, he understands every region: and by the same words in ver. 9, the whole region, or province. This confusion was occasioned, as he supposes, by a labial failure; so that the people could not articulate. Thus their speech was confounded, but not altered; for as soon as they separated, they recovered their true tenor of pronunciation, and the language of the earth continued for some ages nearly the same. The interviews between the Hebrews and other nations, recorded in Scripture, were conducted without an interpreter; and he farther observes, that the various languages which subsisted at this day retain sufficient relation to show, that they were once dialects from the same matrix, and that their variety was the effect of time. See Dispersion.

CONFUTATION, in Rhetoric, &c. a part of an oration, wherein the orator secedes his own arguments, and strengthens his case, by refilling and destroying the opposite arguments of the antagonist. This is done by denying what is apparently false, by detecting some flaw in the reasoning of the adverse party, by granting their argument, and shewing its invalidity, or retorting it upon the adversary.

Confutation makes a branch of what we call confirmation. The confirmation and confutation are sometimes called content. Rhetoricians generally place confutation after confirmation, which seems agreeable to the natural method of thinking on any subject. For persons first endeavour to find out such arguments as are proper to maintain that side of a question which they defend, before they consider what objections may be offered against it: although in speaking it may be necessary to vary the order, according to the nature of the discourse. The method preferred by Quintilian (Inst. Orat. i. c. 13.) is this, that, "if we bring a charge, we should first prove it, and then answer objections; but if we stand upon the defence, we ought to begin with confirmation." The forms of reasoning are the same here as those that occur under confirmation. But it is of importance to keep him with his own weapon. Sometimes practiced by orators, which is often the more difficult task; because he, who is to prove a thing, comes usually prepared; but he, who is to confute it, is frequently left to a sudden answer. Hence Quintilian says, that, in judicial cases, "it is as much easier to accuse than to defend; as it is to make a wound than to heal it." In all disputes it is of the greatest consequence to observe, where the fires of the controversy lies; and in confutation, what the adversary has advanced ought carefully to be considered, and in what manner he has expressed himself. Those things, which relate to the merits of the cause, may be confuted either by contradicting them, or by shewing some mistake in the reasoning, or their invalidity when, granted. There are various ways in which things may be contradicted; what is apparently false may be expressly denied; and things which the adversary cannot prove may be likened denied. A thing may be also contradicted by shewing that the adversary himself maintained the contrary. When you can fix contradictions on an adversary, you effectually silence him; for this is stabbing his heart; this is not to express terms denied, but repressed to be utterly incredible; and this method exposes the adversary more than a bare denial. There is, likewise, an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the adverse party. A second mode of confutation is by observing some flaw in the reasoning of the adverse party. The last method of confutation is, when the orator does in some measure grant the adversary his argument, and at the same time shews its invalidity. This may be done in a variety of ways, according to the different nature of the subject. Sometimes he allows that what was laid may be true, but pleads, that what he contends for is necessary. At other times the orator pleads, that although the contrary opinion may seem to be attended with advantage, yet that his own is more just and honourable. Another way of confutation is by retorting upon the adversary his own argument. The orator takes this advantage, when an argument proves too much, that is, more than the person designed it for, who made use of it. See Inversion. Sometimes orators in confutation raise false objections themselves, to what they have said, as they imagine may be made by others; which they afterwards answer the better to induce their hearers to think, that nothing considerable can be offered against what they have advanced, but what will admit of an easy reply. See PROLEPSIS. See the several modes of confutation above noted, illudinated by appropriate citations from Cicero's Orations in Ward's Oratory, vol. i. p. 17.

As to the order and disposition of the arguments, proper to be used in confutation; whether to follow the adverse party, or alter his method, and range them in a different manner
maner, as likewise whether to attack the weak-fl or strong-

est arguments first; these things must be left to the direc-
tion of the speakers.

CONG, in Geography, a village of the county of Mayo, Ireland, situated in the neck of\nland between the Loughs, Mallow and Corrib. Large caverns and subterraneous
taters are frequent in the neighbourhood; especially at the
back of the village, a very broad river rushes at once from
beneath a gently sloping bank, and after a rapid course of
about a mile loses itself in Lough Corrib. It is supplied
with the outlet of a subterraneous channel, through which
the superfluous waters of Loughs Mallow and Carrall are dis-
carged into Corrib. Cong is about 108 miles west from
Dublin, and 20 south from Castlebar.

CONG, a town of China of the third rank, in the pro-
vince of Honan; 15 miles south of Honanking.—Allo, a
town of China of the third rank, in the province of Se-
chuen; 25 miles south of Soui-teou.

CONGO, a town of Peru, in the province of Irish-
Agemi; 100 miles N.W. of Ipapan.

CONGAREE, a considerable river of America, in the
state of S. Carolina, formed by the conjunction of Saluda
and Broad rivers. The union of the waters of Congaree and
Waterco forms the Santee.

CONGHO, in Ancient Geography, a station on the
live of Severus wall in Britain, mentioned in the Notitia
Imperii, and supposed to be at Stanwix.

CONGE, APOGOGIE, Gr. Sopus, Lat. in Architec-
ture. The extremities of the frail of a column when they
are worked circularly to unite gradually with the foilets of
the bafe and capital are thus named.

CONGE, in the French Law, a licence, or permission,
granted by a superior to an inferior, which gives him a dis-
fpenation from some duty to which he was before obliged.
The word is French: Menage derives it from the Latin
communiatus, used for communis, and commune, often seen
among ancient writers: the Italians say, congolo.

A monk cannot go out of his convent, without the conge
of his superiors.

CONGE d’accorder, i.e. leave to accord, or agree, is used in
the statute of fines, anno 1 Edw. I. to the following pur-
pose: "When the original is delivered, in presence of the
parties before justice, a plainer shall say this: Sir justice,
conge d’accorder, and the justice shall saie to him, What
faith in R. and shall name one of the parties, &c."

CONGE d’honneur is the king’s privilege royal to a dean
and chapter, in time of a vacancy, to choose a bishop. See
BISHOP, CANON, AND COLLAETION.

Gwyn observes, that the king of England, as sovereign
patron of all bishops and other benefices, had, according to the
free appointment of all ecclesiastical dignities; investing,
first, per baculum & annulum; and afterwards by letters pa-
tent: but that, in passage of time, he made the election
over to others, under certain forms and conditions; as,
that they should at every vacancy, before they chose, demand of
the king conge d’honneur, i.e. leave to proceed to election; and
after election to crave his royal assent, &c. He adds, that
king John was the first who granted this; which was after-
wards confirmed by flat, Welfm. 3 Edw. I. cap. 1. and
again in the Articuli Cleri, 25 Edw. III. cap. 1.

CONGE, in Military Language, leave of abasement
given to an officer or soldier from his corps, from the army or alto-
tgether from the service. The old service of France admitted
of two kinds; namely, the conge limite, a specific or li-
mitted leave, and the conge absolu, or an absolute discharge.
In the latter case there was delivered to the soldier a cir-
touch, with all the signatures on it necessary for the good
order and regularity of the service, and for the tranquility
of the person, who obtained it. The conge absolu was al-
ways followed in time of war.

CONGEABLE, from the French conge (i.e. have, li-
ence, or permission), signifies as much as lawful, or lawfully
done, or done with leave or permission; as, then entry of the
difficulty is congeable.

CONGELATION (from the Latin congello), means the
transition of a solid into a fluid state, in consequence of the
abstraction of heat; thus metals, butter, oils, water, &c. are
said to congeal, when, from a fluid state, they pass into that of
a solid.

Congelation and freezing mean, in fact, the same effect;
yet the term congelation is indiscriminately applied to all the
above-mentioned transitions; whereas the word freezing is
more commonly used for denoting the congelation of water,
of vinegar, of brandy, of mercury, and in that of all those
substances which, in order to become solid, must be cooled be-
low 32° of Fahrenheit’s thermometer. We shall, however,
in this work, divide the subjéct of congelation under the
two above-mentioned denominations; freezing, under the pre-
fent article, whatever relates to natural congelation, and un-
der the article FREEZING, whatever relates to the artificial
methods of freezing.

Another important process, much connected with con-
gelation, has been improperly separated from it. And this is
crystallization, or the arrangement of certain substances
into regular figures, in their transitions from the fluid into
the solid state; but water and several other bodies likewise
crystallize in congelating, which shows that the two process-
can hardly be separated; and this is rendered still more evi-
dent by a due consideration of other phenomena that accom-
pany both processes. Allowing therefore that crystalliza-
tion and congelation are essentially of the same clafs, a flight
differentiation may be formed by applying the term crystal-
lization to the formation of those regular forms or crystalls,
which are of a compound nature, and which, when once
formed, generally require a much greater degree of heat for
their liquefaction, than that in which they were formed.

By far the greater number of liquids we are acquainted
with, have been found capable of congelation in a proper
temperature; and on the other hand most of those solids
which are both in the usual temperature of the atmosphere
may be rendered fluid by the application of certain appro-
priate degrees of heat: hence we are led by analogy to sup-
pose, that every fluid might be congealed, if it were possible
to cool it sufficiently; or that fluidity is the effect or con-
sequence of heat. Every particular kind of substance re-
quires a different degree of temperature for its congelation;
hence it appears why certain substances remain always fluid,
while others remain always solid, in the ordinary tempe-
ration of the atmosphere, and why certain other substances
are sometimes fluid, and at other times solid, according to
the vicissitudes of the weather, the difference of seasons, and
the variety of climates.

Heat, or sensible caloric, continually tends to pass from
those bodies which have more of it than their proper share,
to those contiguous bodies which have less of it than their
proper share; hence, when a body is placed among other
bodies of a lower temperature, its heat gradually passes to
those other bodies, until the whole acquires the same tempe-
ration; and this transition proceeds regularly, excepting,
however, when the body is in the act of affuming the solid
state; for at that moment a sudden extraction of heat is
observable. Place a thermometer in a glass full of water,
and place the glass in a freezing mixture of broken ice, and common salt, the thermometer will be found to descend gradually as low as 39, or 25 degrees of Fahrenheit's thermometer, and sometimes even much lower, whilst the water remains fluid; but, at last, the water begins to freeze, and at that very moment the thermometer rises suddenly to 32°, and it remains at that point until the whole of the water is congealed. If then the application of the freezing mixture is continued, the thermometer will sink gradually several degrees below 32°, according to the activity of the freezing mixture. We may, Dr. Black observes, easily satisfy ourselves, that the water, while congealing, is continually imparting heat to the surrounding air; for, if we suspend a delicate thermometer immediately above the water, we shall find the instrument affected by an ascending stream of air, less cold than the air around.

Not only pure water, but all aqueous fluids, may be cooled down 7, or 8, or 10 degrees without freezing; but if in that state they be affected with a tumultuous motion, or if they be touched with a slender piece of ice, they will instantly cool into beautiful spicules, the thermometer in it rising at the same time. This striking phenomenon of the sudden rising of the thermometer at the moment of congelation, which has also been remarked in wax, spermaceti, and other substances, has not yet been fully or satisfactorily explained. It is true that ice has not so great a capacity for containing heat as water has; (see the capacities of bodies under the article Caloric and Heat;) but why should water so reluctantly part with such a superfluous quantity of heat as to suffer itself sometimes to be cooled several degrees below 32°, before it will assume the solid form?

Since water, when it has once begun to congeal, remains at the apparent temperature of 32° until the whole of it is congealed; and since water cannot remain congealed in a temperature higher than 32°; therefore the congealed point of water has been fixed at 32°, of Fah.

The congealing points of several other substances have also been ascertained with considerate accuracy. In some, however, it is not the congealing, but the melting, point that has been ascertained. These two points, if they be not quite the same, may naturally be supposed not to differ more than about a degree or two; hence from the latter the former may be easily deduced. In the following table, however, we shall set down the one or the other of those points, according as either of them has been more accurately determined.

Lead fixes, according to Crichton of Glasgow 619° F.

Bismuth melts { according to Irwin 472°

A mixture of one part of tin and four of lead, melts 476°

Tin melts { according to Irwin 443°

The last mentioned gentleman says, "In melted tin the thermometer funk gradually till it arrived at 442°; then it instantly funk to 439°; and as instantly rose to 442°. At this temperature the mercury remained perfectly stationary for five minutes, at which time the metal became solid to the centre of the crucible.

A mixture of three parts of tin and two of lead, melts 334°

A mixture of two parts of tin, and one of bismuth, melts 283°

A mixture of tin and bismuth, in equal parts, melts 212°

A mixture of three parts of tin, five of lead, and eight of bismuth, melts 219°

Serum of blood begins to coagulate at 125°

Albumen, or the white of an egg, coagulates at 155°

Bee's wax melts 134°

Tallow melts 127°

Spermaceti melts 112°

Ice, or congealed water, begins to melt 52°

The increase of the bulk of water previous to, as also following, its point of congelation is a remarkable property, which has been more or less observed with all aqueous fluids, viz., they are contracted by cold, until a certain limit, which generally is about 7 or 8 degrees higher than their congealing point; they then expand again as they are cooled farther, and if they are not agitated, they will remain liquid at a temperature lower than their congelation point. The greatest density of water, Count Rumford says, is some what lower than 40°. Professors Hope of Edinburgh places it between 39°.5 and 40°. Mr. Dalton says, that the greatest density of water is at the temperature of 42°.5. And that the expansion of water is the same at the distance of the same number of degrees above and below 42°.5. Thus the expansion is the same at 32° and 52°; the same at 16° and 75°, c. The increase of bulk in freezing water is not owing to the formation of air bubbles, for water, which has been deprived of air, will also expand in freezing. The bulk of ice, at a mean, is to that of the water which it produces, as 10 to 8. This enlargement of bulk is attributed to a crystallization; the particles of water in freezing tend to arrange themselves so as to form angles of about 60 and 120 degrees; and this tendency is exerted with a prodigious force. Mr. Leslie says, "water necessarily discharges its air previous to the act of congelation; a circumstance which sometimes retards that species of crystallization. Hence it is, that water freezes sooner which has been boiled. When exposed to cold, crude water will present a lake of ice crowded with large bubbles entangled in the mass; but boiled water will contain a solid lump, almost pellicid, with only some minute specks or bits floating from the centre." Dr. Black says, that boiled water begins to freeze as soon as the air has cooled it to 32°. Iron likewise occupies less room when fluid than when solid. And the same thing has been ascertained of two or three other metallic substances.

Vinegar
Vinegar congeals at about **28° F.**

Human blood congeals at **25°.**

Strong wines congeal at about **20°.**

A mixture of one part of alcohol and three of water congeals at **7°.**

A mixture of alcohol and water, in equal parts, congeals at **minus 4°.**

A mixture of two parts of alcohol and one of water, congeals at **minus 7°.**

Mercury congeals at **minus 39°.**

Mercury exposed to cold, and at about the point of congealation, contracts its bulk irregularly. This fluidity may be cooled some degrees below its freezing point, before it assumes the solid form; but as soon as it begins to harden, the thermometer rises to its freezing point, which, from a variety of experiments made by Mr. Hutchinson at Hudson's Bay, appeared upon his thermometer to be **-40°.** But (Mr. Cavendish observes in the Phil. Trans. vol. lxxiii. p. 321.) as it appeared from the examination of his thermometer, after it came home, that **-20° thereon answers to -58° on a thermometer adjusted in the manner recommended by the committee of the Royal Society; it follows, that all the experiments agree in showing that the true point at which quicksilver freezes, is -76°, or in whole numbers **39° below nothing.**

In becoming solid, mercury sometimes flows into crystals or longitudinal filaments like pins. The first observations concerning the natural congelation of mercury were made by Mr. Gmelin about the year **1735,** at Yenpeck in lat. **58° 3' north,** at Yakutsk in lat. **62° 6' north,** at Rivengo, lat. **53° 6' north,** and elsewhere. (See the Peterburg Commentaries for the years 1756 and 1763.) Professor J. A. Braun, of Peterburg, in the year 1759, first accomplished the congelation of mercury by art, viz. by means of snow and aqua fortis. But with respect to the artificial methods of congealing mercury, and their history, see the article Freezing.

Nitric acid is said to congeal at **minus 46°.**

With respect to the congelation of the sulphuric, or vitriolic acid, the greatest number of experiments seems to have been made by Mr. Keir, and from those experiments he infers: *1.* That the vitriolic acid has a point of eafeful freezing, and that this is when its specific gravity is to that of water as **1762** to **1000.** *2.* That the greater or less disposition to congelation does not depend on any other circumstance than the strength of the acid. *3.* That the freezing and thawing degree of the most congealable acid is about **4° 5′** of Fahrenheit's scale. It is, however, to be observed, that this degree is inferred from the temperature indicated by the thermometers immered in the freezing and thawing acids; but the congelation of the fluid acid could never be accomplished without exposing it to a greater degree of cold, either by exposing it to the air in frosty weather, or to the cold of melting snow. *4.* Like water, this acid possesses the property of retaining its fluidity when cooled several degrees below the freezing point; and of rising suddenly to it when its congelation is promoted by agitation, or by contact even with a warmer thermometer. *5.* That, like water and other congealable fluids, this vitriolic acid generates cold by its liquification, and heat during its congelation, though the quantity of this heat and cold remains to be determined by future experiments. *6.* That the acid, by congelation, when the circumstances for distinct crystallization are favorable, assumes a regular crystalline form, a considerable solidity and hardnefs, and a densiity much greater than it possessed in its fluid state."

The heat of the earth, at least on the surface of it, is derived entirely from the sun; for the heat arising from combustion, as about volcanoes, or from decomposition of bodies, is trifling and partial. The direct rays of the sun on the same spot of the surface of the earth heat it more or less, according to the time of the year, cleanness of the atmosphere, state of the winds, color and quality of the spot. In Great Britain, during the hottest time of the summer season, the direct rays of the sun seldom raise the mercury in the thermometer to high as **110°.** But in other climates, especially within the tropics, the mercury is raised considerably higher by the direct exposure. Yet we must not believe the idle stories of the sun's heat melting lead, or setting fire to gunpowder, without the assistance of lenses, spectacles, or other artifice.

It is not on account of the sun's being nearer or farther from the earth, that we receive much more or less heat in the summer than in the winter time; since the difference of that through the rays of the sun is relatively small; but we receive more heat in the summer than in the winter season. 1. Because the sun comes nearer to our zenith in the summer than in the winter time, in which situation its rays pass through a shorter portion of the atmosphere, and of course are less intercepted by it. 2. Because, when the sun is nearer to the zenith, a greater quantity of its rays falls upon a given horizontal part of the surface of the earth, than when luminaries falls lower, and its rays fall more obliquely upon the same spot. 3. Lastly, because the sun remains longer above the horizon during a summer day than a winter one.

The hottest part of the day is not at noon, nor that of the year when the sun passes nearest the zenith of a given country; but the hottest part of the day, when no accidental circumstance intervenes, is some time in the afternoon, and nearer to noon in the winter than in summer. In this country and in summer, the hottest part of the day generally is either precisely at, or a little before, two o'clock. The hottest time of the year in this country generally takes place in July, viz. after the fulltide. The reason of this is, that although the rays of the sun give more heat when the sun stands higher, and of course at two o'clock they must give less than at noon; yet the earth, and the air contiguous to it, are hotter at two o'clock, because, besides the heat which they are actually receiving from the sun, they retain considerable portion of the heat acquired before that time; so that as long as they acquire at any particular time, a greater quantity of heat than they lose of that which they had previously acquired, their temperature must continue to increase. The same thing must be understood with respect to the communication of cold, which, for similar reasons, is greatest some time after midnight, and some time after the shortest days of the year. The earth acquires heat in the day time, and loses it during the night. In the summer season the loss of heat during the night is less than the acquisition of it during the day; therefore that excess of heat is gradually communicated from the surface to the more internal parts of the earth. But when the above-mentioned summer heat has penetrated a certain way, the winter cold begins to counteract it; and when that cold has penetrated a certain way, the next summer heat begins again to counteract it, and so on; hence, below a certain depth there is no alteration of temperature at any time of the year; unless some local combustion or other source of heat should interfere, which, however, seldom occurs. This fixed degree of temperature at a certain depth below the surface of the earth, varies in different countries, and nearly coincides with the mean temperature of the particular country. Thus in London the mean temperature is **50°;** and if a bucket of water be drawn from a pretty deep well, and a thermometer be
be instantly placed in it, the temperature of that water, (which is the same as that of the ground surrounding the bottom of the well) will also be found to be 50°. In processes of time the mean temperature of a country is liable to some alterations arising from cultivation, clearing of grounds, draining of marshy grounds, &c. See Climate.

With respect to the temperature at different altitudes, it has been found that a thermometer placed close to the ground is sometimes affected by heat or cold, sooner, or in a greater degree, than a thermometer placed 20, or 30, or 60 feet, higher up; and that at other times the latter is affected sooner, or in a greater degree, than the former. In the middle night, especially when the air is still, and the sky quite free from clouds, a thermometer close to the ground generally indicates a greater degree of cold than in a higher situation. The true cause of this phenomenon is not fully understood; though it is attributed to evaporation, or according to Mr. Six, to the coolness which the dew or vapours may acquire in their descent.

At great heights above the surface of the earth, either in the free air, or on the summit of high mountains, the cold is much greater, and it increases more suddenly: but, because they are much more exposed, and daily, because they are more remote from the body of the earth, which, as has been observed above, tends to equalize the temperature, by retaining in the winter time a considerable degree of the heat acquired in the course of the summer. The winds to which mountains are exposed, especially those which, after having blown over the plains below, rise along their sides, have a peculiar refrigerating power, arising from the expansion of the ascending air, which becomes capable of absorbing more heat in proportion as it is more rarefied. See Dr. Darwin's Paper, Phil. Trans. for 1788.

Thus we have briefly stated the natural sources, and the principal causes which check or promote the heat and cold, that are usually experienced in the world, at different times of the day, of the year, and in different countries; whence alone one may pretty well conceive where and when natural congelation may be expected to take place. Yet it is necessary to subjoin some farther observations, that have been made with respect to natural congelation at different times and different places.

The greater obliquity with which the sun's rays fall upon the northern and southern parts of the earth, than they do upon such parts as are near the equator, undoubtedly produces the variety of the mean temperatures that are observed in different latitudes; the higher latitudes being generally colder than the lower, and vice versa. But this gradation is partly counteracted by a variety of other circumstances; and such are the vicinity of large tracts of land or great extent of sea, the face of the country being flat or hilly, the disposition of the hills and mountains, the prevalence of rain and of certain winds, the state of cultivation, &c. The influence of winds in certain latitudes is so very great that a fruit or thaw is brought on within a remarkably short time by a change of the wind. The action of winds on the temperature of a country principally depends upon three circumstances, viz. on their bringing a quick succession of new air in contact with the bodies that are exposed to it, on their having passed over the surface of hotter or colder tracts of water or land, and upon their increasing the evaporation. Sauvages found that when the wind moves at the rate of forty feet per second, it triples that quantity of evaporation that would take place in calm air; hence it follows that frequently unusual heats or colds come on at unexpected times, and that the higher strata of the atmosphere are often warmer than the lower; for the heat of the atmosphere is derived not from the immediate action of the sun's rays which pass through it, but from the warmer and more solid bodies with which it has been, or is, in actual contact. In consequence of these various circumstances, it has been observed that the north Pacific Ocean, above latitude 40°, is much colder than the north Atlantic, between the same parallels of latitude. The interior parts of Siberia, call of longitude 100°, are much colder than the parts equally distant from the meridian on the western side. The coast and interior parts of the western regions of America are much colder above the latitude of 40°, than the corresponding tracts of the continent of Europe. Large seas, which are agitated by winds and currents; and thereby so little affected by cold winters or hot summers, as to prefer a temperature nearly uniform in every season, like the internal parts of the earth.

With respect to the mean temperature of places at different altitudes above the level of the sea, in the same country, or nearly about the same spot with respect to latitude, the heat diminishes nearly one degree of Fahrenheit for every 200 feet of elevation, according to Dr. Black. Other writers find reasons to assert, that the diminution of one degree takes place at every 290 feet of elevation.

From the statement of all the above, particularly the reader may form some idea of the time and place of natural congelation, may be expected, and he will at the same time be able to perceive that close to the surface of the earth, no great regularity can be expected. On the continent of Europe congelation formerly took place at a lower latitude than it does at present, when natural congelation is seldom observed lower than the latitude of 40°. In America congelation has been observed at a much lower degree; and it is remarkable that great degrees of heat, as well as great degrees of cold, are alternately experienced on the same spot of that continent. In the more northern parts of the world the degrees of cold are very extraordinary. At Tornaco, Reaumur's spirit thermometer fell to minus 34°. In Siberia the spirit thermometer has been known to descend as low as minus 121°. Even at the Glasgow observatory in the year 1780, the mercury of the thermometer exposed to the ambient air was found to stand at minus 14°.

The altitude on the sides of mountains, at which constant congelation takes place, seems to be less fluctuating, though not accurately ascertained. This altitude varies with the latitude; but even in the torrid zone, it has been observed (according to Bouguer and others) at the altitude of about 1500 feet. This altitude, at which the congelation is constant, or where water ceases to be a fluid; and beyond which visible vapour does not seem to ascend, is called the upper line of congelation. The lower line of congelation is where it freezes at night only. The upper line of congelation, within the tropics, has been observed at the altitude of 15000. Near the tropics, on the sides of the temperate zones, it lies at the height of about 15428 feet. On the island of Tenerife, lat. 25° 25' N., it lies at the altitude of about 10000 feet. In Avergne, lat. 43° N., the line of congelation is at the altitude of 6740 feet. In latitude between 51° and 54° N. it seems to be at the altitude of about 5800. In latitude 80° north, lord Mulgrave found the line of congelation at the altitude of about 12000 feet above the level of the sea; whence, if the progress of cold continues uniformly, as general Roy observes, we may conclude that the surface of the earth, at the pole itself, is forever covered with congelation. Mr. Kirwan, however, places the upper line of congelation considerably higher. See his paper on the variations of the atmosphere, in the 8th vol. of the Trans. of the Royal
CONGER, or Conger Eel, in Ichthyology, the largest of the Murcena tribe. This voracious fish grows to the length of five or six feet, and the thickness of a man's thigh. The colour of the upper part is dark grey, sometimes inclining to olive, and the belly pure white; but it is principally distinguished from the other species of the murcena genus by having the lower jaw rather shorter than the upper; nose with two tentacula, and the lateral line whitish, with a row of spots. See Murcena.

CONGERIES, a Latin word, sometimes used in our language for a collection or heap of several particles, or bodies, united into one mass or aggregate.

CONGERIES, in Aetiology. See SYNARTHROSIUS.

CONGESTION, in Medicine, has been used to denote an enlargement of any part of the body, especially when accompanied with hardness, or alteration of structure, which, in the opinion of the humoral pathologists, was produced by a collection of morbid humours, deposited in the part. The term is still employed, chiefly to express the morbid increase of distention in the blood-vessels in inflamed parts, or morbid effusions of blood or lymph in the viscera. Thus, a congestion of blood in the vessels of the brain is said to have produced apoplexy, when, on distention, vessels which are usually invisible, are observed to be filled with red blood; and congestion is said to exist in the lungs, when the circulation of the blood through the minute ramifications of the blood-vessels is impeded, or when lymph is poured out into the cells of the bronchiae, as in the catarrhus fenalis, and p. rippenennum.

CONGHEE LAKES, in Geography, a lake of Thibet, which intervenes between the Mangavar lake, and the head of the river Saperon.

CONGIRUM, Congiary, among Medallists, a gift or native, represented on a medal.

The word comes from the Latin congius, because the first portions made to the people of Rome consisted of wine and oil, which were measured out to them in congii. The congiary was properly a present made by the emperors to the people of Rome. Those made to the folders were not called congiaries, but donancies.

The legend on medals representing congiaries, is congiarum, or liberalitas.

Tibersius gave a congiary of three hundred pieces of money to each citizen: Caligula twice gave three hundred fettarii a head. Nero, whose congiaries are the first that we find represented on medals, gave four hundred. The congiaries of Nerva had on the reverse five figures.

CONGIO, or Congie, Camillo, in Biography, was a delineator and engraver of considerable talents. He was born at Rome about 1604. Little is known of his life, except that he followed his profession at the place of his nativity, and at Florence. About the year 1650, he engraved several of the plates for the Galleria Futiiniana. Most of the twenty plates for Tasso's Jerusaleme, from the designs of B. Calcelli, are by Congio, as likewise several of the engravings in the fine work entitled Odes Barcerinse. Besides the above, we have many prints by him executed in a bold and firm manner, from the designs or pictures of Tempesta Lanzanco, Pomeraccio, and other masters, and from his own drawings. His plates are generally marked with two C's, the top of one joined to the bottom of the other; or in this manner: C.C.P. The F. standing for feet. Strutt. Huber, Manuel des Arts.

CONGITELLA, in Antiquity, half a congius.

CONGIUM, in Ancient Geography, a town of Spain, placed by Ptolemy in the Tarragonese territory; the country of the Vacceans, supposed to be the present Cebescon.

CONGIUS, an ancient Roman measure of capacity, or for things liquid, = 1 of a cubic old Roman foot, = 8 sextaries, = 157.137 cubic English inches, = 1.141 cubic English feet.

From the original standard of Vespasian extant at Rome, Greaves deduced the value of the Roman pound to be 5.56 Troy grains. See DEXARIUS. But Mr. Raper, in an excellent paper on this subject, has suggested several objections against the accuracy of this conclusion. Phil. Trans. vol. lxi. part ii. p. 456.

The congius has also been used in England, as appears by a charter of king Edmund in 946.

CONGLETON, in Geography, a small corporate town in Cheshire, England, is situated near the upper part of the river Dane, on the borders of Staffordshire, and governed by a mayor and six aldermen. It possesses two churches, both subject to the mother church of Albire, a village two miles distant. The town was formerly celebrated for the manufacture of tagged leather laces, called Congleton points; but the chief employment of the poor is now derived from a very capital silk mill erected on the river; and from a ribbon manufactory. In the church-yard of Albire are two ancient Roman monuments, ornamented with the insignia of knighthood; but the families whose memory they were intended to record are now unknown. Congleton is 163 miles N.W. from London; has a market on Saturdays.
CON

In the return under the late act the houses were estimated at 857; the inhabitants at 3861, of whom 1713 were males and 2148 females.

CONGLOBATE glands, in Anatomy, those glands whose substance is not divided, but firm, entire, and continued; and their surface smooth and uniform.

They are thus called, in opposition to conglutinate glands. Conglobate glands have each of them an artery which brings them blood, a vein which carries it back again, after the proper juice has been filtrated, and several excretory ducts.

Some of them have a cavity in the middle, with lymphatic vessels, which discharge themselves into a common reftervoir, or canal.

CONGLOBATE flowers, are those with globular heads.

CONGLOMERATE glands, are those which are composed of several little ones; or they are several glandulous bodies joined together under the same common membrane. See GLAND.

Such are the salivary glands, biliary glands, the pancreas, &c. which see under their proper articles.

The conglutinate glands, besides their arteries, veins, and nerves, are also furnished with an excretory vessel, ramified throughout their own substance; by means whereon they discharge the liquid they have filtraled into the ranx.

CONGLOMERATE flowers, are those which are irregularly crowded together.

CONGLOMERATION, in Mineralogy, is the term used to express confused mixtures or concretions of different mineral substances. Kirwan's Geol. Essays, p. 323 and 306.

CONGLOMULATION, the act of gluing, or adhering two bodies together, by the intervention of some third, whose parts are undisposed and tenacious, in the nature of a glue, glutin; from whence the word is formed.

In the animal economy, the parts of the body are so arranged as to be conglutinated by means of their natural consistence; by the help of bandages, as in several cases of surgery; or by the supply of viscid particles. In which last acceptation, conglutination differs little from accretion, or nutrition.

CONG-MOU-JING, in Geography, a town of China, in the province of Se-tuchuen; 42 miles N.W. of Hoc-hi.

CONGO, or KONGO, a name given to the country of Africa, otherwise called Lower Guinea, which see. It is commonly divided into Lowango, Angola, Benguela, and Congo Proper.

Congo, or Kongo, Proper, a kingdom of Africa, bounded on the north by the famous river Zair or the river of Congo, which divides it from that of Loango, on that side; on the south by that of Dando, which separates it from the kingdom of Angola; on the east by the kingdom of Funguno and Metamba, and the burnt mountains of the fun, those of crystal or salt-petre and silver, and by the rivers Verbele and Cualanda; and on the west by the Ethiopean sea, called the Sea of Congo. Its extent from N. to S. and from E. to W. has not been accurately ascertained; but according to the relation of John Anthony Cavazzi de Monte Cenro, a Capuchin missionary, the dominions of the kings of Congo were much extended towards the east and the south, before the introduction of the Christian religion; but since this event, many of the remote provinces in these directions have been subdued, so that Congo was reduced from above 600 leagues in circuit to less than one-half of that extent. Being situated under the torrid zone, it is subject to the excessive heats peculiar to that climate; however, they are considerably mitigated by winds and breezes, rains and confluent dews; as well as by the more equal length of days and nights. Their summer and winter, which compose their year, are divided into six ra-

CON. which they call mafluza, neafu, coundi, quitombo, qulifo, and quinbanga. The first commences with the month of October; which is the beginning of their spring, when the rains begin to fall; and they continue during the two, and sometimes the three, next months. The floods that are thus occasioned are commonly followed by a famine. Their second season begins about the end of January, which is followed by harvest and new sowing; their lands commonly yielding them two harvests. The third and fourth seasons are frequently followed towards the beginning of March, when the more gentle rains begin to fall and continue till the month of May; at which time the air is clear and dry, but occasional clouds burst forth into tremendous lightnings whereon the earth and trees of their verdure, till the next maffuza, or spring, restores their venal bloom. The Congofect divide the year into twelve lunar months, commencing like that of the Jews, in September. Their week consists of four days; three of which are appointed for labour, and the fourth for rest or religious exercises. The general indolence of the inhabitants prevents their deriving any substantial benefit from the fertility of their soil, which duly cultivated would yield a double, and sometimes a triple, crop yearly. But the negroes, averse from labour, spend their time in dancing, leaping, hunting, and shooting, or in smoking and more idle in
dolence; whilst they commit to their slaves, or their wives, the operations of digging, sowing, reaping, cutting woods, gridding corn, and fetching water. Their ground produces a variety of grain, but no gourd or rice bushes that is cultivated by the Portuguefe. Of their maife, of which they have regularly two crops, they make their bread. They have three other sorts of grain, which they apply to the same purpose. They also cultivate a variety of pulse, as beans and peas of different sorts, which serves them for part of their food. Their fruit-trees have been chiefly trees planted there by the Portuguefe; and of palm-trees, which are exotic and brought from America, they have no less than eight sorts, which are all excellent in their kind. If we may credit the accounts that are given of the productions of the country, which sometimes border on the fabulous, they have a tree called Aliconda, so large that ten men cannot fathom it, yielding a fruit which resembles a gourd, and which serves for vessels of various uses; the bark of which furnishes them with a coarse thread, which they form into ropes and into a cloth, with which the natives cover their middle from the girdle to the knees; and the small leaves of which supply them with food in a time of scarcity, while the large ones are used for covering their huts, or by burning for the manufaets of good foam. Of the bark of the infanta tree, and also of the mulemba, resembling in many respects our laurel, they form a kind of stuff or cloth, which is fine and used for cloaks and girdles by persons of the highest rank. The oil of their palm-trees is used instead of butter; with the moss that grows about the trunk, the rich commonly stuff their pillows; and the Gi-
gas apply it to their wounds with good effect; with the leaves the Moors cover their houses, and they draw from those trees, by incision, a pleasant liquor like wine, which however turns four in five or six days. From the Congo palm-tree, so called, because it thrives better in that country than any of the other sorts, they obtain a liquor, which is reckoned as valuable as the wine that is brought from Eu-

lope, though it is rather a kind of milk, sweet and agree-

3 E: ably
peeled in the melon, and it has been said that the Europeans only burn it in their lamps. Of their shrubs we shall only mention that which they call capano, or "the fig of hell," from the root of which they extract an oil for the lamp, and which they also use in the composition of theirointments and plasters. The leaves burnt to ashes, afford a good lye, with which the natives wash their bodies. The Portuguese have observed to plant few of these fruits, as oranges, lemons, citrons, granate, cedar, and others, which thrive as well as in their native soil. Vines have also been brought hither from Candia; and they yield excellent grapes twice a year. They have also plants of the aromatic kind, which yield substitutes for cinnamon and pepper. Their maio, of which they make bread, is the same which is used in Asia and America; their potatoes and other roots of a like kind yield a grateful nourishment. Wheat is the only grain which the ground will not produce, as it floats up into straw and ear, the former being high enough to hide a man on horseback, and the latter being unfilled. Their grains grows to a great height, and affords sheltering places for a variety of wild and voracious beasts, and venomous insects; so that it is dangerous to travel through the country on this account. Their lilies, tulips, tuberose, hacinths, &c., grow wild, and are singularly beautiful.

The principal rivers of this country are the Zair, into which fall the Bancaro, Vamba, Congo, and Barabela or Verac, the Dando, which see respectively. Between the Zair and Dando, are the Lechucos, Ambriz, Loez, Oaza, and Luilana, with several others of less note.

Congo is divided into fix large provinces, under the titles of duchies, counties, and marquises, and these again are subdivided into lesser fignitaries or lordships. The situation of these provinces is as follows: along the sea coast lie the counties of Songo, and the great duchy of Bamba; on the north, the duchy of Sandi, and the marquisate of Pango; on the west, the duchy of Batta; and within land, the marquisate of Pemba. See each respectively. The capital of the whole kingdom is Banza, or St. Salvador, which see.

Independent of the six districts above enumerated, Congo has several other lesser provinces, most of which are covered with forests or mountains, and inhabited by a race of men in a barbarous and savage state: their names, as we learn from Cuvazzi, are Zuins, Juzamasando, Nambu, Nifio, Nichtejua, Alombo, Nioi, Nzanga, Maranga, and Morenda; the three last of which border upon the country of Ajacan, a nation more barbarous than any of the rest.

The kingdom of Congo, like most other parts of Africa, breeds a prodigious variety of living creatures, both wild and tame, and particularly those of the former sort: such as elephant's and hens, of a monstrous size, leopards, tigers, wolves, and other voracious animals. The zebra of this country is a beautiful animal, which the natives hunt, on account of its flesh, which they esteem a dainty food, and for its hide which they sell to Europe as a valuable commodity. In this country they have also a great abundance of buffaloes and wild asse. The "Dante" seems peculiar to this country; in shape and colour it resembles an ox, but is not so large; its horns are like those of a hog, but very smooth and shining, and of a blackish hue, of which the natives make a variety of pretty bangles; the skin is commonly bought by the Portuguese, and sent into Germany, to be tanned and made into targets, called "Dantes;" and of the raw hide dried, the natives make their shields, which are impenetrable to arrows and darts, and so large as to cover the whole body. Camelions swarm in Congo, and it has several forts of wild rats, as the nongi, niffo, and maimont, whose fur excels those of the fuch tygers, in the beauty, variety, and regularity of their breaks and spots. The fores also swarm with wild dogs, which are extremely fierce and voracious. It has also one singular quadruped, which abides constantly in the trees, and which is laid to die immediately upon setting its feet on the ground; it is called "cutting," and is very small; its fur is so beautifully spotted, that none but the kings of Congo, the princes of the blood, and such nobles as obtain the privilege from him, have the liberty of wearing it. And even the kings of Lovango, Cacango, and Gay, receive this extraordinary fur, as a valuable present.

The tame animals of Congo, such as oxen, sheep, horses, mules, and asses, which might be rendered useful and profitable, are much neglected. The Portuguese, however, have directed their attention to the cows, sheep, and goats, chiefly on account of their milk, though they have not learned to make butter or cheese. The land and sea fowls of this country are very numerous; its oifriches are very large and beautiful; the feathers of which, mixed with those of peacocks, do not los numerous and beautiful, are used, instead of ensigns and standards, and made into umbrellas. Turkeys, geese, hens, and ducks, both wild and tame, and also peafants, pigeons, doves, woodcocks, and other smaller birds, abound in this country. Of parrots there is a great variety, distinguished both by their fize and colour; the most esteemed of these are such as they denominate, by way of excellence, the birds of night, which are kept by persons of rank in cages and aviaries, for the sake of their surprising melody. Here are other birds which the superstitious natives regard with horror; the flight or cry of which throws them into a general panic, and occasions them to disperse with the utmost precipitance and confusion. The most dreaded of the ominous kind are crows, ravens, bats, owls, and especially the great owl, which they call, in their language, "karim pemba," the name they give to the devil. Birds of prey, such as eagles, vultures, falcons of various sorts, sparrow-hawks, and others of a similar kind, are found in great numbers. Herons, bitterns, and some others of the like voracious kind, commonly abound in their marshes, lakes, and other waters. Amongst these they have a bird, in shape and fize like a crane, and one in particular, called by the Portuguese the pelican, of a large size and white, or colour; and also another called the fisher, which dart from a surprizing height in the air on the fish which he perceives in the sea or on rivers. Of fish, the sea adjoining to this country, and its rivers, afford great plenty and variety. The inhabitants are likewise infested with a great variety of serpents, very long and thick, rattle-snakes, vipers, and other venomous reptiles, scorpions, and other venomous insects, both flying and reptile, of various kinds, are found in this country. This country is fated to possess mines of silver and gold, as well as of iron and copper; but the people are too indolent to work them, or to derive any great advantage from them.

When the Portuguese first discovered this country, in the reign of John II., in the year 1484, they found it for the most part covered with towns and villages, swarming with inhabitants; the cities being well filled with people, and particularly the metropolis, which contained above 50,000 persons. We may form some judgment of the population of the country by this circumstance, viz. that the army of the king of Congo, in the year 1665, consisted of no less than
than 500,000 fighting men; and, besides, the number of converts to Christianity, which a small number of Capuchin friars made among the more civilized fort, within the space of a few years, is affirmed to have amounted to 6,000.

The surprising fecundity of their women, the hardship with which they bring up their children, and the robust healthy constitution of their men, if we may credit Cuvier, and the renown of their villages and hamlets to swarm with men, women, and children that a father will exchange one or two of the latter for some commodity he wants, or even some trifling balhie which he facts—ip information that the number of slaves they fell abroad, both by sale, communius annis, fall short of 15 or 16 thousand. Notwithstanding the indolence and consequent poverty of the Congolese, they entertain the most extravagant conceits both of themselves and of their country; so that it is one of the articles of their belief, that the rest of the world was the work of angels, but that their kingdom of Congo, in its full and ancient extent, was the immediate production of the Supreme Architect himself, and most of course enjoy singular advantages and prerogatives above all others; and that their monarchs must be the most opulent, wise, and powerful, and their subjects the noblest, richest, most ingenious, and happiest in the universe. They imagine also, that the natives who traffic with them are forced to undertake that servile employment by their poverty and the fertility of their respective countries, rather than induced to it by their luxury and avarice; whilst they themselves, with the utmost ease and content, can indulge their natural indolence, though attended with hunger and misery, rather than dispensing the nobleness of their blood by any kind of industry; which, however laudable and beneficial, is regarded by them as a lesser degree of labour. However, since the settlement of the Portuguese, they have been routed by their example from this kind of fantastic pride and thraldom flotilo into occasional and partial exertion; in weaving nets, and other coarse stuffs, sawing of boards, several branches of carpentry, and other manufactures and trades. But though they think it beneath their dignity to apply to any useful work, they deem it no disgrace to beg and steal.

The complexion of the genuine natives, that both of the men and women, is black, but some of them are of a deeper dye than others. Since their intermarriages with the Portuguese, they have varied from their native hue; some to a dark brown, some to an olive, and others to a blackish red. Their hair is black and curled, and in some cafes of a dark sandy; their eyes are generally of a fine lively black, but some are of a dark sea-colour; they have neither flat noses nor thick lips, like the Nubians and other negroes; their nature is moily of the middle size; and, excepting their black complexion, they much resemble the Portuguese, though none of them are more fat and flabby. In their disposition, they are generally mittrfully, jealous, envious, and treacherous, and much inclined to revenge. They are so far devoid of natural affection, that a father will sell his son or daughter, and perhaps both, for a piece of cloth, a collar or girdle of coral or beads, and often for a bottle of wine or brandy. A husband may have as many wives, or if a Christian, as many concubines, as he pleases, and repudiate, or even kill them, though with child, at his pleasure. The religion of the country, before the Portuguese introduced their Christianity into it, was, and still is, among the unconverted, a monstrous compound of idolatry and superstition, and of the most absurd and detestable rites and customs, invented by their "gangas," or priests, for the purpose of keeping the people in a state of the most abject subsjection, and cruel tyranny and wretchedness. They do, indeed, acknowledge one supreme being, called "Nzambimpong," believed to be all-powerful, and to whom they ascribe the creation of their country; but they suppose that he has committed the care and government of all subhuman things to great variety of subordinate or inferior deities, appointed to preside over the air, sea, and earth; lakes and rivers, winds and storms, rain, lightening, drought, heat and cold, men, beasts, fruits, and fruits, trees, fruit, and other productions of nature, and made them healthy and sickly as he pleased. Hence proceeds that momentous mixture of white deities, idols and stars, and that prodigious variety of gangas or priests, and superstitious rites, still found in those parts of the kingdom, where Christianity has not been introduced. These imaginary deities are represented under various forms, at the pleasure of the worshipper, either of living creatures, as serpents, crocodiles, lions, tigers, he-goats, &c. or of trees and plants of different kinds, or of statues and images, skilfully carved or painted, some of which they worship in their houses, and others in temples of mean construction. Their worship consists in genuflections, prostrations, fummoniations, and other such superstitious rites; and also, agreeably to the injunctions of the gangas, in offerings of their most valuable effects, for food, apparel, &c., from which the principal revenue of the gangas is derived, who contrive to sell the favour of these deities at the most exorbitant price. Such is the superlition of the people, and the unbounded influence of these gangas, that they will not attempt to build a house or hut without consulting some ganga, and putting the edifice under the protection of a deity; nor can the owner take possession of it without employing the gangas to make the necessary sacrifices and fummoniations, and performing other ceremonies, in order to secure that protection. Even the gangas, who are the most barbarous people of this kingdom, never venture to begin their harvet till they have offered various, and even human victims to their gods, and gorged their gangas themselves with human flesh. Excepting their new moons, they have no fest festivals or fasts of worship, besides those which the president of the gangas appoints, after a victory, a good harvest, &c. to whom it belongs, to appoint the attendant sacrifices and rites, to receive the offerings of the people, and to prescribe the various ceremonies which accompany them. The highest power and dignity, pertaining to the priestly tribe, are those which are vested in the "halome" or "chalome," whom the people revere as a kind of deity, and to whom whole rank and office various privileges belong. The influence of the gangas is so extensive and so powerful, that the kings of Congo, though devious of extirpating idolatry from their dominions, have been unable to effect it. With regard to the establishment of Christianity in the kingdom of Congo, the first preachers commissioned by the court of Portugal for this purpose, were priests and monks of the church of Rome; so that the Roman religion became the established religion of all the conquered provinces of the kingdom. But Christianity, even under that form of it, has been so much neglected, that in the greater part of these extensive dominions, nothing now remains but the mere name of Christian. It is said, indeed, that the catholics in the duchy of Sogno, are better Christians than others, as they pay a peculiar regard to the external forms of the popish worship. The princes of this province, as well as those of Bamba and Temba, have always distinguished themselves by their zeal for the Christian religion, under that external mode of it in which they have been instructed; and they have been careful to preserve their respective governments from being corrupted by the heathenish gangas or priests;
prides; and if any such are ever found within their dominions, they are treated with a severity, which prevents their attempting to repeat their visits.

The government of Congo is monarchical and despotic. The kings are the sole proprietors of all the lands within their dominions; which they parcel out to individuals on condition of a certain tribute and of the performance of particular services. The tribute is ordered to be brought in once in three years at the feast day; and the rigorous demand of it is the cause of many cruel extortions, which often terminate in a revolt, or open rebellion. The crown is partly hereditary, and partly elective, for that no candidate can be chosen, unless he be of the royal blood; and since the introduction of Christianity, a Christian of the church of Rome. The whole process of his coronation and his mode of living after his advancement to the throne are attended with various circumstances of splendour and magnificence. Whenever he goes abroad, which is seldom the case, he is attended by a numerous guard, confiding of Anfiki (See Ando), and some others of neighbouring nations in whom he reposes the greatest confidence, musicians, knights of the holy crosses, (an order instituted by the first Christian king of Congo) and a number of officers, richly accoutred. The respect that is paid him approaches idolatry. His court is numerous and brilliant; and the royal palace is spacious, grand, and commodious. His feragho, in which he keeps a great number of concubines, though he is allowed only one wife, is a kind of prison; as the women that enter it are confined during the remainder of their lives. His lawful wife prefides in the feragho over all the other women; who indulge themselves in the most licentious gratifications. The royal revenue consists chiefly in the tribute that is paid him by several vassal princes; free-will offerings, in acknowledgment of the lands which are held under him; the property of all the zimbis, or cockle-bells, that constitute the current coin of this and other neighbouring kingdoms; mines of silver and gold, which, however, are much neglected; and the renewal of fees and intemperance, fines and confiscations. He has also the prerogative of levying taxes upon his subjects whenever he pleases. His flinding forces are neither numerous, nor well-disciplined, and very badly armed and clothed. Their mode of fighting is tumultuous and ferocious, nor do they give any quarter. Those that are taken alive are hurried to the sea-side, or to some inland market, where they are sold for slaves to the Europeans. The funeral obsequies of the monarchs of Congo before they were converted to Christianity, consisted of various kinds of sacrifices and superstitious ceremonies, accompanied with music, howling, dancing, and feasting, which lasted a whole week, and were resumed once a year, on the anniversary of the king's demise. It was also the custom to bury alive a certain number, nor exceeding twelve, of his favourite concubines, or young ladies belonging to his court; but Christianity has abolished this inhuman custom, though it has not suppressed the drunken revels that take place on this occasion.

It is considered as a great crime and liable to punishment on conviction to shed tears even for the king. But certain persons are kept in pay to go to all the public places of the city or town, to remind the subjects of his death by the mournful sound of their ivory cornets. The princes and nobles are interred in wainscotted vaults hung with black; and two of their old domestics defined absolutely to guard the entrance, and to pray for the deceased. Other prayers are to be offered on the anniversary of their decease, and on All-hallows day, at which times their graves are opened, and the hangings exchanged for new ones. The gaggas dance about the graves of the deceased in a frantic manner, and bring them viuets, drink, and other conveniences. The dances that are performed at the funeral of their great men last eight whole days, without intermission: and upon these occasions, they never fail sacrificing a number of human victims, the flesh of which they devour with peculiar relish. Mourners of the common class shrow their whole heads, and anoint themselves with oil, upon which they rub such a quantity of earth and dust, and dried leaves, as to give them a shocking appearance. Thieves of higher ranks shave only the upper part of their heads and bind it with a lint of cloth, linen, or leather, and confine themselves to the outside for eight whole days. The Congolese conceive concerning dying persons that they are just passing from a wretched life into a state of tranquillity and happiness; and therefore they think they cannot act a kinder part than to accelerate their deliverance. Among the vulgar this notion leads to the barbarous practice of flapping the mouth and nose of a dying person, and thumping upon the breast with violence, that he may the sooner pass into a state of felicity.

The Congolese have no written laws; but custom and tradition serve them instead of a code and commentaries, unless favour or bribery interpose. Every province has a chief justice for civil and criminal affairs from whom an appeal may be made to the king; and under him are inferior officers in every town and community. Three offences, viz.: treason, murder, and forcery, are deemed capital; and the two first are punished with decollation, and the latter by being burned alive. The punishments of lesser offences are the batonade, hanging, fines, and imprisonment.

The traffic of the Congolese with the Europeans consists chiefly in slaves, and St. Salvador is the principal mart of the country. The traders who reside in this place bring thither the products of Brazil, such as grain, fruit, plants, and other provisions, and the manufactures of Europe, which are usually Turkey carpets, English cloth, and other fluffs; copper and brass vessels, blue earthen ware, rings, and ornaments of gold, silver, and base metals, coral, glass beads, bugles, and other trinkets; tobacco, wine, brandy, and other spirituous liquors; light fluffs made of cotton, linen, and woollen, for clothing; and a great variety of tools and utensils. In return they carry off a number of slaves, amounting annually to 15 or 16,000. Slaves indeed are employed at home in all their laborious occupations, and are reckoned the most valuable commodities, which a man possesses or is able to bequeath to his children or relations. Among the Congolese every kind of manufacture is in a very imperfect state. The roads through different parts indicate the inattention and indolence both of the government and the people, as they are either extremely bad in themselves or infested with banditti, and a variety of pernicious animals.

The houses of the Congolese are low, ill-built huts, thatched with straw or fern, without windows and with doors so low, that the shortest man is obliged to stoop when he enters them. They are so lightly built, as to be liable to be blown away by a gust of wind. Thieves, however, belonging to the Portuguese are built of brick and mortar, and generally well-furnished and adorned. The furniture of the Congolese houses consists chiefly of some few ill-strung instruments for agriculture, a hatchet to fell timber, a cutlass for travelling or for war, some few calabashes for containing their provisions, a pot, kettle, and ladle, a few earthen platters, and a hand-mill for grinding their corn. Their bed bedding is a large coarse sackcloth, filled with straw or leaves, with a slight covering, and perhaps a log of wood instead of a pillow. But the Portuguese have introduced
introduced among the superior classes, and particularly in the palaces of the princes and viceroys, various articles of luxury.

Polygamy was universally allowed in Congo before the introduction of Christianity; and since that period, the millionaires have in vain endeavoured to persuade the inhabitants to be contented, each of them, with one wife. Previous to marriage the perfom is allowed three years trial; and when this term is expired, the priest performs the ceremony, and the stipulated dowry is paid. This ceremony is preceded by a sumptuous banquet, and dancing and drinking are continued till the next morning, when the parties retire.

The martial instruments, now used by the Congolese, are such as the Portuguese have introduced; such as the trumpet, cornet, French-horn, and fife; but the common people are contented with their flits and tabors at their weddings and other rejoicings. They have also stringed instruments, which by their rude construction seem to be natives of the country; of which are their "nfambi," resembling the Spanish guitar, and the "mambo," consisting of fifteen or sixteen small calabashes, of different sizes, fastened to a flat board by strings that pass across their mouths, and which, being touched by small pieces of wood, like the ducks of ourvilicers, yield an agreeable variety of sounds. Their drums are made of a long hollow trunk of a tree, with a single skin stretched over one end of it, the other being left open; they are beat either with the fist, or by sticks of heavy wood, and are used at their festivals as well as in the army; they are called "ngambo" or "ingambo," and give but a dull heavy sound, which is raised either by that of the fist, or the "longa," which consists of two or more small bells. The dancing of the Congolese consists in a promiscuous round of men and women, all dancing who shall have the greatest agility and variety of gambols, contortions, and indecent postures.

The history of the foundation of the monarchy of Congo is uncertain and fabulous. It is ascribed to the son of a neighbouring prince, whose small territory was situated on the banks of the Zair, a language of the whole province of Npemlacaffi, since called Congo, and extended his conquests from the mouth of the Zair to the city of St. Salvador. His successors, it is said, have maintained themselves on the throne ever since his time. This country was discovered by the Portuguese in the reign of king John I., who employed Diego Cam, a person of enterprise and a famous navigator, in an expedition for making discoveries on the coasts of Ethiopia. Cam, on his arrival near these coasts in the year 1455, fell inadvertently upon the rapid stream of the river Zair, as he was endeavouring to double the cape Catalina; and having cast anchor at its mouth, he explored the country situated on its banks, and was well received by the inhabitants, who conducted four or five of his officers to St. Salvador. Before their return, he determined to set sail for Portugal, and took with him four of the natives. King John was so pleased with the account which he received of the country, that he ordered Cam to return with his companions as speedily as possible, and furnished him with valuable presents for the king and his court. He charged him, moreover, to exhort the monarch of Congo, in his name, to become a convert to the worship of the only true God, and to permit the Christian religion to be propagated through his dominions. Cam, in the year 1,457, arrived at Congo, and was very favourably received. No time was lost in establishing an alliance between the two crowns of Portugal and Congo, which has continued to subsist, though often suspended by intervening wars. This alliance was followed by the conversion of the king to the Christian faith. For a further account of the hereditary sovereigns of Congo, too minute in detail to be introduced into our work, we refer to the "Modern Universal History," vol. xii.

Congo money, or Guinea money, a name given to a peculiar species of coinage of copper, or porcelain tiles, which pass by way of money among the natives of those places. It is distinguished from the other porcelains by having a dentated mouth, and five gibbous protruberances on its surface.

Congo, or Guinea, a town of Pería, in the province of Irak; 75 miles N.N.E. of Amadan.

Congo, or Guinea, a town of Pería, situated on the eastern side of the Perían Gulf. N. lat. 25° E. long. 52°.

Congratulation, denotes the immediate expression of our joy, on account of any favourable event that has occurred in any of our connections.

Congregation, an assembly of several ecclesiastics, united for to constitute a body.

The term is principally used for assemblies of cardinals, appointed by the pope, and distributed into several chambers, for the discharge of certain functions and jurisdictions, after the manner of our offices and courts. The decisions of these societies are generally sanctioned by the approbation of the Roman pontiff, who has not a right, without alleging the most weighty and evident reasons, to reverse what they pronounce to be just and expedient. This form of ecclesiastical government is, without doubt, a check to the authority of the pope; and hence it is, that many things are transacted at Rome in a manner that is in direct opposition to the sentiments of its spiritual ruler. This may serve to correct a mistaken notion concerning the nature and limits of the papal hierarchy maintained by thfe, who pretend, that all the iniquitous proceedings of the court of Rome, the calamities it has occasioned, the contentions, rebellions, and tumults it has excited, are to be wholly laid to the charge of the Roman pontiff. Hence it also arises that important dilhension that has been frequently employed by the ecclesiastics and other nations in their debates with the Roman pontiff, that is, the distinction between the pope of Rome, and the court of Rome. The one is often loaded with the bitterest reproaches and the heaviest accusations, while the other is spared, and in some measure excused. Nor is this distinction by any means groundless; since the cardinals and congregations, whose rights and privileges are held sacred, undertake and execute many projects without the knowledge, and sometimes against the will and confederacy of the Roman pontiff.

The principal congregations of cardinals are these:

1. "The Congregation of the Pope," instituted first by Sixtus V., to prepare the matters that were to be brought before the conclave, at which the pope is always present. Hence this is called the "colloquial congregation," and in it are treated all affairs relative to the creation of bishops and cathedral churches, the reunion or suppression of episcopal sees, the alienation of church goods, and the taxes and annates that are imposed upon all benefices in the pope's gift. The cardinal-dean presides in this assembly.

2. "The Congregation of the Inquisition," or, as it is otherwise called, "of the holy office," instituted by Paul III., or, as others say, by Pius IV., and reformed by Pius VI., which takes cognizance of heretics, apostates, magic, and profane writings.
ings, assembling thrice in the week, and every Thursday in presence of the pope, who presides in it. This congregation consists of at least 12 cardinals, with several other prelates and divines of different orders, who were called consultors of the holy office. The office of grand inquisitor, which encroached upon the prerogatives of the pontif, has been long suppreffed, or rather distributed among the cardinals who belong to this congregation, and whose decisions are understood with the supreme cognizance of his holiness. See 

**Inquisition.** 2. "The congregation for the propagation of the Roman Catholic faith," founded under the pontificate of Gregory XV., and composed, (fays the translator of Moffen's Eccil. Hist.,) of 18 cardinals, one of the secretaries of state, a protonotary, a secretary of the inquisition, and other inferior members. (See *College de propaganda fide*.)

In this congregation are carried on the deliberations which relate to the extirpation of heresy, the appointment of missionaries, &c.; this congregation has built a most beautiful and magnificent palace in one of the most agreeable situations that could be chosen at Rome, where professors to popery from foreign countries are lodged and maintained gratis in a mansion suitable to their rank and condition, and instructed in those branches of knowledge to which their genius inclines. The prelates, vicars, and curates, who are obliged, without any fault on their own part, to abandon the places of their residence, are entertained charitably in this noble edifice, in a manner corresponding to their rank in the church. 4. "The congregation designed to explain the decisions of the council of Trent." 5. "The congregation of the Index," whose principal business is to examine MSS. and books that are designed for publication, to decide whether the people may be permitted to read them, to correct those books whose errors are numerous, and which contain nefulous and subversive truths, to condemn those whose principles are heretical and pernicious, and to grant the peculiar privilege of publishing heretical books to certain persons. This congregation, which is sometimes held in the presence of the pope, but generally in the palace of the cardinal-prefident, has a more extensive jurisdiction than that of the inquisition, as it not only takes cognizance of those books that contain doctrines contrary to the Roman Catholic faith, but of those also that concern the duties of morality, the discipline of the church, and the interests of society. Its name is derived from the alphabetical tables, or indexes, of heretical books and authors, which have been compiled by its appointment. 6. "The congregation for maintaining the rights and immunities of the clergy, and of the knights of Malta." This congregation was formed by Urban VIII., to decide the disputes and remove the difficulties and inconveniences that arose from the trials of ecclesiastics before princes, or other lay judges. 7. "The congregation relating to the Bishops and regular clergy," established by Sixtus V., to decide the disputes and remove the difficulties that arose between the bishops and their dioceses, and to compose the differences that happened to be frequently among the Monastic orders. 8. "The congregation," appointed by Gregory X IV., for examining into the capacity and learning of the bishops. 9. "Another," for inquiring into their lives and morals. 10. "A third," for obliging them to reside in their dioceses, or to dispense with that obligation. 11. "The congregation for suppressing monasteries," i.e. such whose revenues are exhausted, and which therefore become a charge upon the public. 12. "The congregation of the Apolitic Veneration," which names the visitors who perform the duties and visitations of the churches and convents within the jurisdiction of Rome, to which the pope is obliged, as archbishop of that city. 13. "The congregation of Relics,"

designed to examine the marks, and to augment the number of those instruments of superstition. 14. "The congregation of Indulgences," designed to examine the case of those who have recourse to this method of quiting the confessions. 15. "The congregation of Rites," appointed by Sixtus V., to regulate and invent the religious ceremonies that are to be observed in the worship of each new saint that is added to the calendar. Such are the congregations of cardinals, set apart for administering the spiritual affairs of the church; and they are undeniably, in some respects, a check upon the power of the pontif, enormous as it may be. There are few men, which relate to the temporal government of the papal territories. In these congregations, where the pope is never present, all things are transacted which relate to the execution of public justice in civil or criminal matters, the levying of taxes, the providing of good governors for the cities and provinces, the relief of those who are unjustly oppressed by subordinate magistrates, the coinage, the care of the rivers, aqueducts, bridges, roads, churches, and public edifices.

**Congregation** is also used for a company or society of religious cantoned out of this or that order; and making, as it were, an inferior order, or a subdivision of the order itself. Such are the congregations of the Oratory, and those of Cluny, &c., among the Benedictines.

The word is also used for assemblies of pious persons, in manner of fraternities; frequent among the Jesuits in honour of the Virgin, &c.

**Congregation of Aids, or de Auxiliius,** was established in consequence of a dispute between the Dominicans and Jesuits. The former had long cherished a deep rooted and invincible hatred against the latter; and having a favourable opportunity of venting their indignation, exhausted their furious zeal against the doctrine of Molinus, notwithstanding the public edict, issued by Clement VIII., in the year 1594. They incessantly wrested the Spanish monach, Philip II., and the Roman pontiff, Clement VIII., with their importunate clamours, till at length the latter found himself under a necessity of assembling at Rome a fort of council for the decision of this controversy. Thus commenced, about the year 1598, those famous deliberations concerning the contest of the Jesuits and Dominicans, which were held in the congregation of aids. This congregation was afterwards held at Rome in the year 1610, and was attended by the most eminent prelates. The history and transactions of this congregation are related and illustrated by several writers of different compositions, by Jesuits, Dominicans, and Jesuits. After all it is still a matter of doubt, which party was most favoured by the court of Rome on this occasion, the Jesuits or the Dominicans, and which of these two parties defended their cause with the greatest dexterity and success.

**Congregation of the Immaculate Conception.** See Immaculate.

**Congregation of the Lateran.** See Lateran.

**Congregation of the Lord, in Ecclesiastical History, an association of reformers in Scotland, formed in the year 1557 by the earl of Argyle, his son lord Lorne, the earl of Morton and Glencarne, Erskine of Dun, and others, who, observing the danger to which they were exposed, and desirous of propagating their principles, entered privately into a bond or association; and assumed this appellative.
CONGREGATIONALISTS. See INDEPENDENTS.

CONGRESS, CONGRESSUS, is used for an assembly of commissioners, deputies, envoys, &c. from several courts or provinces, meeting to settle terms for a general pacification or to concert measures for their common good.

The congress at the Hague, while held during the course of the war, terminated in 1697, by the treaty of Ryfwick, was composed of the envoys of all the princes in the confederacy against France.

CONGRESS, in Modern History, denotes that body, in which, by the constitution of the United States of America, all legislative powers are vested. It consists of a senate and house of representatives. The house of representatives is composed of members chosen every second year by the people of the several states; and the electors in each state shall have the qualifications requisite for electors of the most numerous branch of the state legislature. No person shall be a representative under the age of 25 years, who has not been seven years a citizen of the United States, and who, shall not, when elected, be an inhabitant of the state in which he shall be chosen. The number of representatives, apportioned among the several states, which may be included within this union, according to their respective numbers, to be ascertained by actual enumeration within three years after the first meeting of congress, and within every subsequent term of ten years, shall not exceed one for every thirty thousand; but each state shall have at least one representative. In case of vacancy in the representation of any state, writs shall be issued by the executive authority for filling such vacancies. The house of representatives chuse their speaker, and other officers, and have the sole power of impeachment.

The senate of the United States is composed of two senators from each state, chosen by its legislature for six years; and each senator has one vote. The senators are divided into three classes; the seats of those of the first class being vacated at the expiration of the second year; of the second class at the expiration of the fourth year; and of the third class at the expiration of the fifth year; so that one-third may be chosen every second year.

No person shall be a senator, under the age of 30 years; after being nine years a citizen of the United States, and who is not, when elected, an inhabitant of the state for which he is chosen. The vice-president of the United States is president of the Senate, but has no vote, unless the votes be equally divided. The Senate chuses its other officers, and also a president pro tempore, in the absence of the vice-president, or when he shall exercise the office of president of the United States. The Senate has the sole power to try all impeachments; and no person shall be convid without the concurrence of two-thirds of the members present.

The Congress shall assemble at least once in every year, and such meeting shall be on the first Monday in December, unless they shall, by law, appoint a different day. Each house has its peculiar powers; but neither house, during the session of congress, shall, without the consent of the other, adjourn for more than three days, nor to any other place than that in which the two houses shall be sitting. The senators and representatives shall receive a compensation for their services, fairest by law, and payable out of the treasury of the United States. They are, in all cases, except treason, felony, and breach of the peace, privileged from arrest during their attendance at the session of their respective houses, and in going to, and returning from, them; and for any speech or debate in either house, they are not to be questioned in any other place. No senator or representative shall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which shall have been created, or the emoluments of which shall have been increased, during such time; and no person holding any office under the United States shall be a member of either house, during his continuance in office.

All bills for raising revenue shall originate in the house of representatives; but the senate may propose or concur with amendments, as on other bills. Every bill, which shall have passed the house of representatives, and the senate, shall, before it become a law, be presented to the president of the United States; if he approves, he shall sign it; but if not, he shall return it, with his objections, to that house in which it has originated, who, having entered the objections on their journal, shall proceed to reconsider it. If, after reconsideration, two-thirds of that house shall agree to pass
the bill, it shall be sent, together with the objections, to the other house, by which it shall likewise be reconsidered, and, if approved by two thirds of that house, it shall become a law. In such case the votes of both houses shall be determined by yeas and nays, and the names of the persons voting for and against the bill shall be entered on the journal of each house, respectively. If any bill shall not be returned by the president within ten days (Sundays excepted) after it has been presented to him, the same shall be a law, as if he had signed it, unless the congress, by their adjournment, prevent its return, in which case it shall not be a law. Every order, resolution, or vote, to which the concurrence of the senate and house of representatives may be necessary, shall be subject to the same rules and limitations as are prescribed in the case of a bill.

By the constitution the congress shall have power—to lay and collect taxes, duties, imposts, and excises—to pay the debts and provide for the common defence and general welfare of the United States—to borrow money on the credit of the United States—to regulate commerce with foreign nations, among the several states, and with the Indian tribes—to establish an uniform rule of naturalization, and uniform laws on the subject of bankruptcies, throughout the United States—to coin money, regulate its value, and that of foreign coin, and to fix the standard of weights and measures—to provide for the punishment of counterfeiting the securities and current coin of the United States—to establish post offices and post-roads—to promote the progress of science and useful arts, by securing for limited times to authors and inventors, the exclusive right to their respective writings and discoveries—to constitute tribunals inferior to the supreme court—to define and punish piracies and felonies committed on the high seas, and offenses against the law of nations—to declare war, grant letters of marque and reprisal, and make rules concerning captures on sea and land—to raise and support armies, but without appropriating money to that use for a longer term than two years—to provide and maintain a navy—to make rules for the government and regulation of the land and naval forces—to provide for calling forth the militia to execute the laws of the Union, suppress insurrections, and repel invasions—to provide for organizing, arming, and disciplining the militia, &c. referring to the states, respectively, the appointment of the officers, and the authority of training the militia, according to the discipline prescribed by congress—to exercise exclusive legislative, judicial and executive power over such districts, (not exceeding ten miles square) as may, by cession of particular states, and the acceptance of congress, become the seat of the government of the United States, and to exercise like authority over all places, purchased by consent of the legislature of the state in which the same shall be, for the erection of forts, magazines, arsenals, dock yards, and other needful buildings—and to make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this constitution in the government of the United States, or in any department or officer thereof.

The powers of congress, however, are subject to certain limitations; e.g. the privilege of the writ of habeas corpus shall not be suspended, unless the public safety requires it in cases of rebellion or invasion. No bill of attainder, or ex post facto law, shall be passed. No exaction, or other direct tax, shall be levied, unless in proportion to the census, or enumeration, herein before directed to be taken. No tax or duty shall be laid on articles exported from any state; no preference shall be given by any regulation of commerce or revenue, to the ports of one state over those of another—no shall vessels bound to or from one state be obliged to enter, clear, or pay duties, in another—no money shall be drawn from the treasury, but in conformance of appropriations made by law; and a regular statement and account of the receipts and expenditures of all public money shall be published from time to time. No title of nobility shall be granted by the United States; and no person holding any office of profit or trust under them shall, without the consent of the congress, accept of any present, emolument, office, or title, of any kind whatever, from any king, prince, or foreign state. With regard to individual states it is provided, that no state shall enter into any treaty, alliance, or confederation; grant letters of marque and reprisal; coin money; emit bills of credit; make any thing but gold and silver coin a tender in payment of debts; pass any bill of attainder, ex post facto law, or law impairing the obligation of contracts; or grant any title of nobility. Moreover, no state shall, without the consent of the congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws; and the net produce of all duties and imposts, laid by any state on imports or exports, shall be for the use of the treasury of the United States; and all such laws shall be subject to the revision and control of the congress. No state shall, without the consent of congress, lay any duty of tonnage, keep troops or ships of war in time of peace, enter into any agreement or compact with another state, or with a foreign power, or engage in war, unless actually invaded, or in such imminent danger as will not admit of delay. The congress, under certain limitations, whenever two-thirds of both houses shall deem it necessary, may propose amendments to the constitution, established Sept. 17, 1787; or, on the application of the legislature of two-thirds of the several states, shall call a convention for proposing amendments, which, in either case, shall be valid, to all intents and purposes, as part of the constitution, when ratified by the legislatures of three-fourths of the several states, or by conventions in three-fourths thereof, as the one or the other mode of ratification may be proposed by the congress. The senators and representatives before-mentioned, and the members of the several state legislatures, and all executive and judicial officers, both of the United States, and of the several states, shall be bound by oath or affirmation, to support the constitution; but no religious test shall ever be required as a qualification to any office, or public trust, under the United States. The executive power is vested in a president of the United States of America. See President.

Congress, in Law, is also used for an essay, or trial, made by appointment of a lay, or spiritual judge, in the presence of furgons and matrons, to prove, whether or no a man be or be not impotent; in order to the dissolution of a marriage See Impotence.

Neither the civil nor canon law make any mention of this trial of virility by congress; it had its origin in France, from the boldness of a young fellow, who, in an open court, being hard pressed by his wife, demanded the congress. The judge, surprised with the novelty of the demand, found it could not be denied; as being the first evidence the court could admit of.

In time it became a branch in the French jurisprudence, and was authorized by decrees and arrêts; it obtained for about the space of one hundred and twenty years, and was annulled by an arrêt of parliament in 1677, as being found precarious; some having failed under the experiment cut of mere modesty and shame, which is found to have the same effect with actual impotency.

CONERE,
CONGREVE, William, in Biography, a celebrated English dramatic writer, descended from an ancient family in Staffordshire, which traces its lineage beyond the Norman conquest. Neither the time nor the place of his birth can be ascertained with any degree of precision; according to the inscription on his monument, it was in the year 1672, and he himself declares that he owed his nativity to England; though by many of his biographers it has been asserted that he was born in Ireland. Wherever he was born, it is known that he was educated, first at Kilkenney, and afterwards at Dublin, his father having some military employment that stationed him in Ireland. After he had made the usual preparatory studies, he was sent, at the age of sixteen, to study the law in the Middle Temple. For this his genius does not appear to have been adapted: he looked, at a very early period of life, to polite literature as that by which he might be distinguished. By a signed name he published the "Inconstancy, or Love and Duty reconciled," a novel, which has been characterized as frigintly in dialogue, intricate in plot, and unnatural; and Dr. Johnson says "he would rather praise than read it." As a dramatic writer, Congreve's first piece was the "Old Bachelor," written at the age of twenty, and, according to the author's own account, to amuse himself in a slow recovery from a fit of ficklness; but which was regarded by Dryden, and others who were his contemporaries, as a very wonderful performance. Its success was very great; few plays have been so beneficial to the writer, for it procured him the patronage of the earl of Halifax, who was the Mecenas of the day, and who deferves the praise of having bestowed more public patronage on the muses than they have ever received before, or perhaps since, in this country. Upon Congreve the noble lord bestowed the office of commissioner for licensing coaches; and soon after gave him a place in the pipe-office, and another in the customes of 1697, per annum.

If the Old Bachelor be nearly examined, says Dr. Johnson, "it will be found to be one of those comedies which may be made by a mind vigorous and active, and furnished with comic characters by the perusal of other poets, without much actual commerce with mankind. The dialogue is one constant recreation of conceits, or claff of wit, in which nothing flows necessarily from the occasion, or is dictated by nature. The characters both of men and women are either fictitious or artificial; and the catastrophe arises from a mistake not very probably produced, by marrying a woman in a mask. Yet this gay comedy, when all these deductions are made, will still remain the work of very powerful and fertile faculties; the dialogue is quick and sparkling; the incidents such as seize the attention, and the wit so exuberant that, it "o'er-informs its temenent."

Congreve's next play was "The Double Dealer," which was not received with equal kindness by the public, but which was honoured with the patronage of the queen, on whose death he wrote a poetical tribute to her memory; in which, says his biographer, "all is unnatural, and yet nothing is new." In the year 1695, his prolific pen produced "Love for Love," a comedy of nearer alliance to life, and exhibiting more real manners, than either of the former. This proved a very popular and profitable piece; and in the same year he published an irregular ode to King William, on the taking of Namur; which exhibited less of the powers of poetry, than of the spirit of loyalty. With the comedy of Love for Love, the new theatre was opened, under the direction of Betterton the tragedian; where, in 1697, was exhibited "The Mourning Bride," a tragedy, so written, as to shew that the author was sufficiently qualified for either kind of dramatic poetry.

About this time began a long and bitter controversy between Jeremy Collier and the poets. In the reign of Charles I, the puritans had raised a violent clamour against the drama, which they regarded as unfit for the encouragement of Christians. This had in a great measure subsided, when, in 1668, Collier published "A Short View of the Immorality and Profaneness of the English Stage," in which he attacked with great justice, though perhaps with some degree of aggravation, the licentiousness of the dramatic writers, among whom Congreve was included. The poet replied, and endeavored to palliate the alleged enormity of particular passages, though it was impossible to vindicate the general character and tendency of his pieces. Collier in reply, and Congreve retired from the contest; and shortly after published his last comedy of "The Way of the World." This was reckoned the most perfect of his dramatic pieces; but it was received with so little favour on the stage, that, being in a high degree offended and disturbed, he resolved to commit his quiet and his name no more to the caprices of an audience. From this time his life ceased to the public; he lived for himself and for his friends; and among his friends he was able to name every man of his time whom wit and elegance had raised to reputation.

Congreve continued to write copious verses upon particular occasions, and in the year 1710, he published a collection of his plays and miscellaneous poems, dedicated to his patron lord Halifax, to whose person and party he remained attached in all fortunes. Such was the respect which Congreve inspired, as well by his private character as his pen, that in the great political change which brought the tones into power, his places were untouched, and he was allowed to maintain a dignified neutrality, praised and complimented on both sides. On the return of his own friends to power, his emoluments were increased by the fine place of secretary to the island of Jamaica, which raised his public income to full 1200l. a year; yet, says Dr. Johnson, his honours were far greater than his profits. Every writer mentioned him with respect; and, among other testimonies to his merit, Steele made him the patron of his "Micellaneous," and Pope inscribed to him his translation of the Iliad.

Indolence was the result of Congreve's affluence. He not only ceased to make any literary exertions, but seems, with a considerable degree of affectation, to have declined the character of a man of letters; and when he received a visit from Voltaire, the topic of his writings being introduced, Congreve spoke of them as trifles beneath him, and hinted that he expected to be visited only as a gentleman. Voltaire replied, that had Mr. Congreve been so unfortunate as to be a mere gentleman, he should never have been amusing of seeing him.

The latter years of his life were clouded with a considerable portion of fickleness and infirmity. Cataract in his eyes at length terminated in total blindness. The melancholy care was aggravated by the pain, for which he fought relief by a journey to Bath; but, being overturned in his chariot, he returned to his house in London, where he died, Jan. 26, 1728-9, in the sixtieth year of his age. Having lain in state in the Jerusalem chamber, he was buried in Wemminster Abbey, where a monument is erected to his memory by the duchess of Marlborough; to whom, for reasons either not known, or not mentioned, he bequeathed a legacy of ten thousand pounds, in preference to the claims of kindred, at that time reduced to difficulties and disfets.

It does not appear that any peculiar moral excellencies, or any remarkable talents for local intercourse, obtained for Congreve those marks of attachment and regard which
we have seen that he enjoyed. He lived in an easy independent, and, by the exercise of a polished good nature, pleased and flattered those who associated with him, and never offended any one. He stands first among the English writers of comedy: a distinction for which he is indebted, not to such a lively and humorous delineation of natural characters as delights and instructs in the scenes of Molière, but to a continuation of wit and repartee in the dialogue, joined with originality of plot. His personages are always strongly marked and well supported. One or two of his comedies are still exhibited, and beheld with pleasure, though so little resembling the productions of the present age. His "Mourning Bride" is interesting, and its principal characters well contrasted; it maintains its place in our theatres, and has, during the present season, been represented with the highest applause. Biogr. Britan. Johnson's Lives of the English Poets.

CONGRIER en Ponce, in Geography, a town of France, in the department of the Mayenne; 6¼ leagues S.W. of Laval.

CONGRUITY, or Congruency, in the Schools, a suitableness or relation of agreement between things; whereby we come at the knowledge of what may be expected from them.

The system of congruity in matters of grace consists in this; that God, who knows perfectly the nature of grace, and the dispositions of the will in all the circumstances that shall befall a man, gives graces, wherewith, by virtue of their congruity with the will of a man, confedered in those circumstances, man will always inafterily, but not necessarily, do what God would have him do; because the will, in the language of the congruits, does always inafterily, though voluntarily, choose what appears best.

CONGRUITY, merit et. See Merit.

CONGRUITY, in Geometry, is applied to figures, lines, &c. which exactly correspond when laid over one another; as having the same terms, or bounds.

Those things between which there is a congruity are equal and similar.

Euclid, and by his example, most other geomctricians, demonstrate all their elements from the sole principle of congruity: M. Leibnitz, and after him Wolfius, subliterate the notion of similitude in lieu of that of congruity.

CONGRUITY, in a lax sense, is used to express an aptitude, in some bodies, to unite, or incorporate; by reason of some similitude or fitness of their figures, as incongruity denotes an unsuitableness of their surfaces for joining together. Thus, quicksilver will unite with gold, and many other metals, but will roll off from wood, bone, glass, &c.; and water, which will wet salt, and disolve it, will slip off from tallow without adhering to it; as also from a dusty surface, and from the feathers of water fowl.

Two drops of water or of mercury, will, on contact, immediately join and coalesce; but oil of tartar, poured upon quicksilver, and spirit of wine and oil of turpentine on that, and air over all, will remain in the same vellum without any manner of union, or mixture with each other. And the cause of this phenomenon is, that the figures of some bodies will not admit other bodies near enough to be within their spheres of attraction, whence they cannot join and cohere; but where their fitnese of figure will let them approach near enough to feel each others' attractive power, then they close and hold together. See Cohesion.

CONG-TCHIN, in Geography, a town of China, of the third rank, in the province of Quang-si; 20 miles N.E. of Pien-lo.

CONGUSTUS, in Ancient Geography, a town of Asia, in Galatia. Ptolemy.

CONHOCTON CREEK, in Geography, a creek of America, in the western parts of the state of New York, in the Genesee country, which runs over a bed of gravel at the foot of the hills that surround the newly established post-town, called Bath, and, about 20 miles below this town, falls into the Chag river. In this creek there is a considerable fall, just above the town, which affords a very fine stream for mills. Extensive saw and flour mills have already been erected upon it; the principal saw in the former of which, gave, when Mr. Weld visited the mill, 120 strokes in a minute, sufficient to cut, in the same interval of time, 7 square feet, superficial measure, of oak timber; and yet capable, when the water is high, of producing effect much more expeditiously. During floods, light batteaux may pass along the creek, Tyoga and Susquehannah rivers, from Bath to Chieflapay bay, without interruption.

CONI, a large fortified town of France, in the department of Stura, which was formerly a part of Piedmont in Italy, belonging to the king of Sardinia. It is situated on the confines of the Geff and the Stura, 42 miles S. from Turin, 54 N.E. from Nice, and 820 kilometres, from Paris. As chief place of the department, it has a prefect, a court of justice, and several tax offices, and is the residence of the brigade-general commanding the department. The fertility of the soil of its district, equally abundant in corn and pastures, and the advantage of a canal which goes from the river Stura to the Po, and facilitates its communication with the interior parts of France, render Coni the centre of a considerable commerce. Its inhabitants amount to 16,500. The population of the canton, including 16 communes, is 17,775. The whole district comprises 85 communes with 121,433 inhabitants, upon a territorial extent of 2,530 kilometres.

Coni is said to have been first founded in 1520, during the pontificate of Calixtus II.; and the following account is given of its origin. The inhabitants of some villages having been grievously oppressed by their lords, who, among other enormities, pretended a privilege granted by the emperor to deflower the brides before the husbands touched them, the people, at length, attacked their lords, expelled them the country, and destroyed their castles, which had served as their protection, and left their oppressors should return with foreign aid, they left their home and founded Coni. Their number daily increasing, they formed an alliance with the city of Atri, and Lucchin, duke of Milan, and became a flourishing republic, which form of government continued for some years. At length they submitted to Charles of Anjou, count of Provence. Some time after his death, they came under Jane, queen of Naples, who was incapable of supporting the weight of government; and therefore the town of Coni, in order to ensure protection, voluntarily submitted to Amadeus VI., count of Savoy, to whom it afterwards continued faithful. After valiantly defending itself against many succedaneous sieges, for near three centuries, the rapid feculences of the French in Piedmont, during the months of April and May in 1796, obliged the king of Sardinia to make overtures for peace, and to surrender Coni, with Alexandria, Susa, and Turin, into the hands of the French, as hostages of his good faith; and it afterwards became the principal place of a district, as we have already stated, in one of the six Piedmontese departments, called Stura.

CONIA, in Botany, the name of a genus formed by Ventenat, for the powdery biff of Linnaeus and other authors.

CONIACI,
CONIC SECTIONS.

CONICI, in Ancient Geography, a people of Spain, placed by Strabo near the sources of the Ebrus, in the vicinity of the Cantabri.

CONIC SECTIONS, as the name imports, are such curve-lines as are produced by the mutual intersection of a plane and the surface of a solid cone. The nature and properties of these figures were the subject of an extensive branch of the Ancient Geometry, and formed a speculation well fitted to the subtle genius of the Greeks. In modern times, the conic geometry is intimately connected with every part of the higher mathematics and natural philosophy. A knowledge of those discoveries, that do the greatest honour to the last and the present centuries, cannot be attained without a familiar acquaintance with the figures that are now to engage our attention.

In this article we shall treat of the cone, and the more general properties of those figures called the conic sections; and we shall conclude with a short historical account of this branch of mathematical learning. The more particular properties of each figure will be delivered under the proper heads in the progress of our work.

We begin with premising a few lemmas, on which the theory of conic sections, we are to deliver, is founded.

**Lemmas.**

**Definition.** If a right line, A B (Plate II. Conics. fig. 1.), be so divided in the points D and E, that A D is to D B as AE is to EB; then that right line is said to be harmonically divided.

Cor. If a right line, A B, be divided in E, then it cannot be cut in D and d, so as to be harmonically divided both in E and D, and in E and d.

Cor. If it were possible, it is plain that A D would be to D B as A d to D b, 11. 5. E: which is absurd, 14. 5. E.

**Lemma I.** Fig. 1.

If a right line, A B, be divided in C, and cut in E and D, so that C A or C B is a mean proportional between C E and C D: then A B is harmonically divided in C and D.

For, because C D : C A :: C A : C E, therefore, CD + CA : CD = CA : CE; CA : CE = CA : CE that is, A D : D B = A E : E B.

Cor. If A B be divided in C, and harmonically divided in D and E, then A C or C B is a mean proportional between C D and C E. Cor. Def. 1.

**Lemma II.** Fig. 2.

If two tangents of a circle be drawn from the same point, A, then any chord of the circle, as E D, which, being produced, passes through A, and cuts the line, B C, that joins the two points of contact, in F, is harmonically divided in the points F and A.

Let O be the centre of the circle, and draw O H perpendicular to E D, and draw O B and O C to the points of contact. Because the angles at B, H, and C, are all right angles, 18. 3. E, the circle described on the diameter A O will pass through A, B, H, O, and C. 31. 3. E; therefore A F x F H + F H x H = F C x E F = E F x F D; 25. 3. E; therefore, A F x F H + F H x H = E F x F D + F H x F H, or A H x F H = E F x F D + F H x F H = (because E D is bisected in H) H D x D. 5. 2. E. Therefore E D is harmonically divided in F and A, Lem. 1.

Cor. And if a chord, as E D, which, when produced, passes through A, be harmonically divided in A and F, then F is a point in the chord B C.

For, if not, then the chord, DE, could be harmonically divided at A and F, and also at A, and another point, different from F, which is absurd, Cor. Def.

**Lemma III.** Fig. 3 and 4.

Let C be the centre of a circle, and let D and E be two points in a diameter, A B, and both on the same side of the centre; and let the radius of the circle be a mean proportional between C D and C E: draw M N perpendicular to A B through E; then any chord, as H K, which, being produced if necessary, passes through D, and cuts M N in F, is harmonically divided in D and F.

Draw C L perpendicular to H K from the centre C. Because C A² = C D x D E, therefore C A² = C D x C F; or A D x D B = E C x C D + C D x C F; or C D x C E, or C D x D E. And because the angles at E and L are right angles, therefore L D x D F = C D x D E = A D x D B = H D x D K, 35. 3. E. = (because H K is bisected in L), L K² = D L² (or D L² = L K²). Therefore, L K² = D L² + L D x D F (or D L² = L D x D F); therefore H K is harmonically divided in D and F. Lem. 1.

**Lemma IV.** Fig. 5 and 6.

The same construction being made as in the last lemma, if H K be a chord, which, when produced if necessary, passes through D; then tangents of the circle drawn from the extremities of H K will meet one another in the line M N. And if tangents of the circle be drawn from a point afiinued to M N, the chord drawn through the two points of contact, being produced if necessary, will pass through the point D.

Let H K be a chord passing through D, and let tangents drawn from H and K meet in F: draw C F (cutting H K in L) to the centre of the circle, and join K C and F E. It is manifest that F C x C L = C K², 8. 6. E = C D x C E, hyp. Therefore a circle described through D, F, and L, will pass through E, 36. 3. E; and therefore the angle F E D = the angle F L D, 21. 1. E. Therefore F E is perpendicular to A B, and F is a point in M N drawn from E perpendicular to A B.

Next, let F be in M N, and let H K and A B, both produced if necessary, intersect in d. Because the angles F L D and F E D are right angles; therefore F C x C L = C K², 36. 3. E. But F C x C L = C K² = C D x C E; therefore C E x C D = C D x C E; therefore the point d, in which H K and A B intersect, is the same as the point D.

**Lemma V.** Fig. 7.

If the bafe of a triangle, A B, be bisected in D, and C G be drawn parallel to A B through the vertex; then any line, as E F, parallel to C D, and terminated by C D and C A, produced if necessary, is bisected by C G.

Draw B H K parallel to C D. Because A D = D B; therefore A C = C K², 2. 6. E. Therefore B H = H K, and, it is plain that E F, parallel to B K, is likewise bisected.

**Lemma VI.** Fig. 8 and 9.

If A B, the bafe of a triangle, be harmonically divided in D and E, and the lines C D and C E be drawn; then any line, as H F, parallel to C E, and terminated by B C and C A, produced if necessary, is bisected by C D.

Draw L K parallel to C E through D. Because A D : D B : A E : E B. Alternando, A D : A E : D B : E B.

But, on account of equiangular triangles, A D : A E : D L : C E, 4. 6. E. and D B : B E : D K : C E, therefore D L : C E : D K : C E.

Therefore
CONIC SECTIONS.

Therefore $DL = DK$, $p. 5$, E. Therefore any line parallel to $L K$, as $F H$, is bisected by $CD$.
Cor. If $L H$ be bisected by $C D$, and $C E$ be parallel to $L H$, then $A B$ is harmonically divided in $D$ and $E$.
For, if not, then $L H$ could be bisected by two lines drawn through $C$; which is absurd.

Of the Cone and its Sections.

Definitions.

Fig. 10. 1. Let $A D B$ be a circle, and $V$ a fixed point without the plane of the circle; then, if a right line, falling continually through the point $V$, be carried round the whole periphery of the circle $A D B$, that right line, being extended indefinitely on the same side of $V$ as the circle, will describe a conic surface; and, if it be likewise extended indefinitely on the other side of $V$, it will describe two opposite conic surfaces.

Cor. A straight line drawn from the vertex to any point in a conic surface, being produced indefinitely, is wholly in the opposite surfaces.

For a line, so drawn, will coincide with the line that generates the cone surfaces, when this line, by being carried round the circumference of the base, comes to the proposed point.

II. The solid figure, contained by the conic surface and the circle $A D B$, is called a cone. The point $V$ is named the vertex of the cone; the line $V C$, drawn to the centre of the circle, the axis of the cone; and the circle $A D B$, the base of the cone.

III. A right cone is when the axis is perpendicular to the plane of the base; otherwise, it is a falcate, or oblique cone.

IV. A right line that meets a conic surface in one point only, and is everywhere else without that surface, is called a tangent.

Prop. I. Fig. 10.
The common intersection of a conic surface and a plane $V D E$, that passes through the vertex, and cuts the base of the cone, is a rectilinear triangle.
For the common section of the plane of the base, and the plane drawn through the vertex, (which is a right line, $5. 11$, E.), will cut the periphery of the base in two points, $D$ and $E$, and in these two points only: then, having drawn $D V$ and $E V$ to the vertex of the cone, these lines will both be in the conic surface (Cor. Def. 1.), and also in the plane surface; and there are no points, excepting in these lines indefinitely produced, which are common to both the surfaces. Therefore the figure $D V E$, which is the common intersection of the cone and a plane through the vertex, is a rectilinear triangle.

Prop. II. Fig. 11 and 12.
If two points, $D$ and $E$, (not in the same right line with the vertex) be assumed in a conic surface, the right line that joins them falls wholly within the conic surface, and when produced both ways it falls wholly without the surface; but if the assumed points be in opposite surfaces, the right line that joins them falls without the conic surfaces, and, when produced, it falls within one conic surface on one side, and within the other conic surface on the other side.
From $V$, the vertex of the cone, draw the lines $V D$ and $V E$, cutting the periphery of the base in the points $B$ and $C$; then, a plane being drawn through the vertex and the points $D$ and $E$, that plane will cut the base in the chord $B C$, and the common sections of the plane and the conic surfaces are the two right lines $V B$ and $V C$ indefinitely produced, $P r. 1$. Now the right line $D E$, which is wholly contained in this plane, can meet the lines $V B$ and $V C$ only in the points $D$ and $E$. When the points $D$ and $E$ are in the same conic surface, then the line $D E$ is contained in the angle $B V C$ within the conic surface, and, produced both ways, it is contained in the adjacent angles $B V M$ and $C V N$ without the conic surface. On the other hand, when $D$ and $E$ are in opposite surfaces, $D E$ is contained in the angle $B V M$, or $C V N$, without the conic surfaces, and, being produced both ways, it is contained either in the angle $B V C$, or in the angle $M V N$, within the conic surfaces.
Cor. A right line cannot meet a conic surface in more than two points.

Prop. III. Fig. 11.
If a point, $E$, be assumed in a conic surface, and a line, $P Q$, be drawn through it, so as to be parallel to a right line, $V E$, passing through the vertex, and contained in the conic surfaces; then the right line, $P Q$, will not meet either of the opposite surfaces in another point, but it will fall within the surface, in which the assumed point $E$ is, on the one side, and it will be wholly without both surfaces on the other side.
For if a plane be conceived to be drawn through the line $V E$ and the point $P$, the line $P Q$, parallel to $V E$, will be wholly in that plane, $7. 11$, E.; and the common sections of the plane and the conic surfaces will be the line $V E$ and the line $V E C$ drawn through the vertex and the point $E$, $P r. 1$. Now the line, $Q P$, does not meet either of the lines $V B$ or $V C$ in another point different from $E$. Also if $Q E$, the part of the line that is contained in the angle $B V C$, is within the cone; and $P E$, the part of it that is contained in the angle $C V N$, is without both the opposite surfaces.

Prop. IV. Fig. 12.
If a plane be drawn through the vertex of a cone and a tangent of the conic surface $G H$, it will meet the conic surface only in the line, $V D$, drawn through the vertex of the cone and the point of contact of the tangent.
For, because the point $D$ and the vertex $V$ are common both to the plane surface and to the conic surface, therefore the line $V D$, indefinitely produced, is likewise common to both surfaces. And because $G H$ meets the conic surface only in the point $D$, and is every where else without the surface, therefore any line (different from $V D$), as $V F$, drawn in one of the conic surfaces, is contained on one side of the plane; and the same line contained in the opposite conic surface, as $V K$, is contained on the other side of the plane.
Cor. 1. Any straight line, drawn in the plane, $V G H$, so as to meet the line $V D$, is a tangent of the conic surfaces.
Cor. 2. No other plane, besides the plane $V G H$, can be drawn so as to touch the conic surfaces in the line $V D$ without cutting them.
For, $R S$ the common section of the plane $V G H$, and the plane of the base, is a tangent to the periphery of the base, $C o r. 1$. And, if there were two such planes, there would likewise be two tangents of a circle drawn through the same point of the periphery, which is absurd.

Prop. V. Fig. 13.
If either of two opposite conic surfaces be cut by a plane parallel to the base of the cone, the section is a circle, having its centre in the axis of the cone.
Through VC, the axis of the cone, let two planes be drawn cutting the base in the lines CD and CE; and the plane parallel to the base, in the lines GH and GL; and the conic surfaces in the lines VHD and VLE; then, because the base is parallel to the cutting plane, therefore CD is parallel to GH and CE to GL, 15. 11. E. Therefore, on account of equiangular triangles, 4. 6. E.

DC : CV = HG : GV
CV : CE = GV : GL

Ex æquo DC : CE = HG : GL

But DC = CE, therefore HG = GL. And in like manner it may be shown that any right line, drawn from G to a point in the intersection of the plane, and the conic surface, is equal to GH; therefore the section is a circle.

Cor. 1. If, through a point situated within or without a conic surface, two straight lines, both parallel to the plane of the base of the cone (that is, parallel to straight lines in that plane), be drawn to cut, or touch the conic surface: then the rectangle contained by the two segments (between the point and the conic surface), of one of the lines when it cuts, or the square of its segment when it touches the conic surface, is equal to the rectangle contained by the two segments of the other line when it cuts, or to the square of its segment when it touches the conic surface.

For a plane drawn through the two lines will be parallel to the plane of the base, 15. 16. E; and it will intersect the conic surface in the periphery of a circle: whence the corollary is manifest, 35 and 39. 3. E.

Prop. VI. Fig. 14.

If two diameters of the base of a cone, as AB and CD, intersect one another at right angles, a plane drawn through the vertex of the cone, and one of the diameters, CD, will bisect any straight line, as EF, terminated both ways by one of the conic surfaces, and parallel to the other diameter AB.

Through V and EF draw a plane cutting the conic surface in the lines VG and VK, and the plane of the base in the line GHK; because EF is parallel to AB; therefore GK is parallel both to AB and EF, 16. 11. E; and it is perpendicular to CD; therefore GK is bisected by the diameter CD, 3. 3. E. And, because GK is bisected in H, therefore EF, parallel to GK, is bisected by VH, that is, by the plane drawn through V and CD.

Prop. VII. Fig. 15. Plate III.

If a point, as B, be assumed in the plane of the base of a cone, but without the periphery of the base, and, from that point, two tangents, BP and BQ, be drawn to the base, and likewise a straight line, BV, to the vertex of the cone: then any straight line, as EF, parallel to BV, and terminated both ways by one of the conic surfaces, is bisected by a plane drawn through V, the vertex of the cone, and cutting the plane of the base in the chord PQ, 16. 11. E.

Because BV and EF are parallel to one another, therefore they are in one plane, 7. 11. E: let the plane, drawn through BV and EF, cut the conic surface in the lines VEG and VFK; and let the same plane cut the plane of the base in the line BGK, and the plane passing through V, and the chord PQ in the line VDH. Because GK is harmonically divided in H and B, Lem. 2. therefore EF, parallel to VB, is bisected by the line VH, Lem. 6. But D, the point where VH cuts EF, is the point where the plane drawn through V and the chord PQ cuts EF; therefore EF, parallel to BV, is bisected by that plane.

Prop. VIII. Fig. 16.

Let a plane, passing through the vertex of a cone, cut the plane of the base in a diameter of the base CD; and let AB, a diameter of the base, be perpendicular to CD; and let MN be drawn through the vertex of the cone parallel to AB; then if a right line GK, in the plane CVD, and terminated by one of the conic surfaces, be bisected by a plane passing through MN, this plane will bisect all right lines terminated by one of the conic surfaces and parallel to GK.

Let the plane which bisects GK cut the plane of the base in the line PQ, and the plane CVD in the line VHO: through V draw VL parallel to GK, and let it meet CD produced in L. Because MN is parallel to AB; therefore PQ (the common section of two planes drawn through MN and AB) is parallel to MN and to AB, 16. 11. E; therefore PQ is perpendicular to CD. Because GK is bisected by VO, and is parallel to VL; therefore CD, the base of the triangle CVD, is harmonically divided in L and O, Cor. Lem. 6. consequently, if two tangents of the base be drawn from L, the chord that joins the points of contact of these tangents will pass through O, Cor. Lem. 2; and it will be perpendicular to the diameter CD; therefore that chord will coincide with the line PQ, which is the only line that can be drawn through O perpendicular to CD. Therefore all right lines, terminated by one of the conic surfaces, and parallel to VL or GK, are bisected by the plane VQP drawn through MN to bisect GK, Pr. 7.

If GK be parallel to CD, then CD will be bisected in O, and PQ will coincide with AB; so that this proposition, in this case of it, is the same as Prop. 6.

Cor. If a plane be drawn through MN to bisect any right line terminated by one of the conic surfaces, and parallel to a line GK in the plane VCD, the same plane will bisect all right lines terminated by one of the conic surfaces and parallel to GK.

For, if not, then the same straight line could be bisected by two planes both passing through MN, which is absurd.

Prop. IX. Fig. 17.

Let a plane, passing through the vertex of a cone, cut the plane of the base in a line CD, not passing through E the centre of the base: draw the diameter, AB, perpendicular to CD, and produce it to M; so that EM may be a third proportional to EF and EB the radius of the base of the cone, and draw MVM through the vertex: then, if a right line GK, in the plane CVD, and terminated by one of the conic surfaces, be bisected by a plane passing through MN, this plane will bisect all right lines terminated by one of the conic surfaces and parallel to GK.

Let the plane which bisects GK cut the plane of the base in the line PQM, and the plane CVD in the line VHO: through V draw VL parallel to GK, and let it cut CD produced in L. Because VO bisects GK, and VL is parallel to GK, therefore CD, the base of the triangle CVD, is harmonically divided in O and L, Cor. Lem. 6; therefore if two tangents of the base be drawn from L, the chord that joins the points of contact of these tangents will pass through the point O, Cor. Lem. 2; but the same chord, being produced, likewise passes through the point M, Lem. 4: therefore that chord will coincide with PQ, which is the only right line that can pass through both the points O and M, therefore all right lines terminated by one of the conic surfaces and parallel to LV, or GK, are bisected by the plane VQP drawn through MN to bisect GK, Pr. 7.

Cor.
CONIC SECTIONS.

Cor. If a plane be drawn through MN to bisect any one right line, terminated by a conic surface, and parallel to a line G K, in the plane V C D, or parallel to the plane V C D, that plane will bisect all right lines terminated by a conic surface, and parallel to G K.

For, if not, then the same right line could be bisected by two planes, both passing through M N; which is absurd.

Prop. X. Fig. 18.

Let a plane, passing through the vertex of a cone, cut the plane of the base in a line C D, which neither cuts nor touches the periphery of the base: draw A B E, through E, the centre of the base, perpendicular to C D, and take E M, a third proportional to E F, and the radius of the base of the cone; and draw M V through the vertex: then if a right line G K, parallel to the plane V C D, and terminated by one of the conic surfaces, be bisected by a plane passing through M V, this plane will bisect all right lines terminated by one of the conic surfaces, and parallel to G K. But the point H, in which the plane, that bisects G K, cuts G K, must not be in the same right line with the point M, and the vertex of the cone.

Let the plane, which bisects G K, cut the plane of the base in the line P Q, draw V P parallel to G K; and because G K is parallel to the plane V C D, therefore V L parallel to G K, is in the plane V C D, and it will cut the plane of the base in L, a point of the line C D. And, because G K is parallel to V L, therefore they are contained in one plane; 7. 11. E. Let this plane be drawn, and let it cut the conic surface in V R and V S, the plane of the base in L R S, and the plane V P Q, in V O. Because G K is parallel to V L, and it is bisected by V O, therefore S K, the base of the triangle S V R, is harmonically divided in O and L, Cor. Lem. 6; therefore, if two tangents of the base be drawn from L, the chord that joins the points of these tangents will pass through the point O, Cor. Lem. 2; but, because the point O does not fall upon M, therefore the chord will coincide with P Q, which is the only line that can pass both through O and M. Therefore, all right lines, terminated both ways by one of the conic surfaces, and parallel to V L, or G K, are bisected by the plane, V P Q. Pr. 7.

Prop. XI. Fig. 19.

Let a plane touching a conic surface cut the plane of the base in a line, C D, which touches the periphery of the base in P; then, if a right line, G K, terminated by one of the conic surfaces, and parallel to the touching plane, V C D, be bisected by a plane drawn through V P; this plane will bisect all right lines parallel to G K, and terminated by one of the conic surfaces.

Through V draw V L parallel to G K: because G K is parallel to the plane V C D, therefore, V L, parallel to G K, is in the plane V C D, and it will cut the plane of the base in L, a point in C D. And, because V L is parallel to G K, therefore they are contained in one plane, 7. 11. E.; let this plane be drawn, and let it cut the conic surface in the lines V M and V N, the plane of the base in the line L M N, and the plane V Q P, in the line V O. Because G K is parallel to V L, and it is bisected by V O, therefore, M N, the base of the triangle V M N, is harmonically divided in O and L, Cor. Lem. 6. Theretore, if two tangents of the base be drawn from L, the chord that joins the two points of contact of these tangents will pass through the point O, Cor. Lem. 2; but the same chord likewise passes through Q, which is one of the points of contact of tangents drawn from L; therefore, the chord coincides with the line Q P. Therefore the plane V Q P, bisects all right lines terminated by one of the conic surfaces, and parallel to V L, or G K, Pr. 7.

Fig. 20, 21, 22, 23. If a cone be cut by a plane P Q, which neither passes through the vertex, nor is parallel to the base, then, a plane, as V M N, being drawn through the vertex parallel to the cutting plane, it will necessarily meet the plane of the base of the cone. The line of common section of the parallel plane, and the base of the cone M N, may have one or other of three different positions; viz.

Def. V. If the line of common section, M N, (Fig. 20.), be without the base of the cone, then the plane V M N, drawn through the vertex, will be entirely between the two conic surfaces, not meeting either of them. In this case, the cutting plane P Q, will meet every line drawn from the vertex in one of the conic surfaces, and the curve line of common section will surround that conic surface, and will completely enclose a space. In this position of the cutting plane, the conic section is called an ellipse.

Def. VI. If the line of common section M N, (Fig. 21.) touch the periphery of the base, then the plane drawn through the vertex will touch the conic surfaces, Pr. 4. And the opposite surfaces will be on different sides of it. In this case also the cutting plane will meet every line drawn from the vertex in one of the conic surfaces, excepting only the line of contact, V B, in which the touching plane meets that conic surface: and as the cutting plane is indefinitely extended along the touching plane without meeting it, it is obvious that the curve line formed by the common section of the cutting plane and the conic surface does not return into itself so as to enclose a space, but it is open on the side opposite to the vertex of the cone. In this position of the cutting plane, the conic section is called a parabola.

Def. VII. If the line of common section MN (Figs. 22 & 23.) cut the periphery of the base, then the plane drawn through the vertex will divide each of the opposite conic surfaces into two parts lying on opposite sides of it. In this case the cutting plane being indefinitely extended will meet every line drawn from the vertex in those parts of the two conic surfaces that lie in the same side of the plane, through the vertex, as the cutting plane itself; and thus two curve lines will be formed by the common intersection of the cutting plane, and the two opposite conic surfaces. It is obvious that these curve lines may be indefinitely extended, and that they do not return into themselves so as to enclose a space. In this position of the cutting plane the conic section, formed by its intersection with one of the conic surfaces is called a hyperbola; and the two conic sections formed by its intersections with the two opposite conic surfaces, are called opposite hyperbolas, or opposite sections.

Def. VIII. The nature of the several conic sections defined in the three last definitions depends entirely, as we have seen, on the relative position that the line of common section of the plane of the base and the plane drawn through the vertex parallel to the cutting plane, has in respect to the circle
CONIC SECTIONS.

cle that forms the base of the cone. As there will be frequent occasion to refer to this line, in the following theory of the conic sections, it will be requisite, for the sake of abbreviating language, to distinguish it by a peculiar name. For this purpose we shall call it the determining line.

Def. IX. Let a plane, as P Q, (fig. 20 and 22,) cut a conic surface, or opposite surfaces, and let M N be the determining line, or the common section, of the plane of the base and the plane drawn through the vertex parallel to the plane P Q; from C, the centre of the base of the cone, draw C D perpendicular to M N, and take C E a third proportional to C D and C A or C B, the radius of the base; then, a line being drawn from the vertex V to the point E, it will meet the plane P Q in a point G, which is called the centre of the conic section, or opposite sections, formed by the common intersection of the plane P Q, and the conic surface, or opposite surfaces.

But, if the determining line M N (fig. 23,) cut the base of the cone, and pass through its centre, then, the diameter A B being perpendicular to M N, and V G being drawn through the vertex parallel to A B; V G will meet the plane P Q in a point G, which, in this case, is the centre of the opposite sections.

Fig. 22, 22, 23. Cor. 1. The centre of an ellipse is a point within the figure; but the centre of two opposite hyperbolas is a point without both hyperbolas, and situated between them.

For, when the line M N is without the base of the cone, the point E and the line V E are within the conic surface; but, when M N cuts the base, then E and V E are without both of the two conic surfaces and between them.

Cor. 2. A parabola has no centre.

Def. X. A right line drawn in the plane of a conic section so as to meet the curve of the section in one point only, and which, being produced both ways, is contained on one and the same side of the section, is called a tangent of the section.

Cor. 1. A tangent of a conic section is a tangent of the conic surface.

For it can meet the conic surface only in the point in which it meets the section.

Cor. 2. There cannot be more than one tangent of a conic section at the same point of the curve.

For if there were two tangents, then two planes drawn through them and the vertex of the cone would meet the conic surface in the same right line without cutting the conic surface, which is absurd.

Cor. 2. Pr. 4.

Prop. XII.

A right line, drawn in the plane of a conic section, cannot meet the curve in more than two points.

For such a line does not meet the conic surface in more than two points.

Cor. 2.

Prop. XIII.

A right line drawn through a point in a conic section, in the same plane with it, and parallel to a line drawn from the vertex in the conic surface, does not meet the curve of the conic section again in another point.

For it does not meet the conic surface in another point.

Vol. IX.

Pr. 3. Thus, in the parabola, if P Q be drawn parallel to V B, (fig. 21,) then P Q meets the curve only in the point P.

Prop. XIV. Figs. 24, 25, and 26. Plate IV.

Every right line, as F H, drawn through G, the centre of an ellipse, or opposite hyperbolas, and terminated both ways by the curve, or opposite curves, is bisected in the centre.

I. When the determining line M N, (fig. 24 and 25,) does not pass through the centre of the base. Through V, the vertex of the cone, and the line F H, draw a plane cutting the conic surface in the lines V H L and V F K, and the plane of the base in the line L M, and the plane V M N in the line V M. Because the point G is in the line V G E; therefore, the line L M K will pass through the point E.

And because F H and V M are the common sections of the plane V K L, and two parallel planes (viz., the plane of the section and the plane V M N), therefore F H is parallel to V M, and E. And, because C B or C A, the radius of the base of the cone, is a mean proportional between C D and C E, and M N is perpendicular to A B; therefore, the chord K L is harmonically divided in E and M, Lem. 3. And because K L is the base of the triangle K V L, and F H is parallel to V M, therefore, F H is bisected by V E, Lem. 6.: that is, T F G = G H.

In the ellipse, when F H (fig. 20) is parallel to M N, it will be perpendicular to a diameter of the base drawn perpendicular to the diameter A B; therefore, it is bisected by the plane V A B, which cuts it in G, Pr. 6.

II. When the determining line, (fig. 26,) passes through the centre of the base. In this case, V G is parallel to the diameter A B, Def. IX. And L K, the common section of the plane V K L, and the plane V Q K (drawn through V, and the line F G H), is parallel both to A B and to V G, 7. 11. E. But the diameter M N is perpendicular to the diameter A B; therefore, it is also perpendicular to K L, and bisects K L, 3. 3. E. And because F H and V M are the common sections of two parallel planes (viz., the plane of the conic section, and the plane V M N), therefore F H is parallel to V M. And because V M bisects the base of the triangle K V L, and V G is parallel to that base, therefore V G bisects F H parallel to V M. Lem. 5.

Definitions.

XI. A right line drawn through the centre of an ellipse, or opposite hyperbolas, and terminated both ways by the curve or opposite curves, is called a diameter of the ellipse, and a transverse diameter of the opposite hyperbolas.

XII. A right line in the plane of a parabola, as P Q, (fig. 21,) drawn parallel to the right line V B, in the conic surface (which passes through the vertex of the cone, and the point in which the determining line touches the periphery of the base), is called a diameter of the parabola.

Cor. All the diameters of a parabola are parallel to one another.

XIII. A vertex of a diameter is a point where the diameter meets the curve of the conic section.

Cor. A diameter of a parabola has only one vertex,

Pr. 13.

XIV. A right line (which is not a diameter of an ellipse), terminated both ways by the curve of a conic section, and bisected by a diameter of the section, is said to be ordinately applied to that diameter; or it is called a double 3 G ordinate;
Conic Sections.

Prop. XV. Fig. 24, 25, and 26.

If a straight line be ordinarily applied to a diameter of an ellipse, or a parabola, or to a transverse diameter of a hyperbola, then all right lines parallel to it and terminated both ways by the same curve, or by the opposite curve, are ordinarily applied to the same diameter.

Let $RST$ (fig. 24 and 25.) be ordinarily applied to $FH$, a diameter of an ellipse or a parabola, or a transverse diameter of a hyperbola, or opposite hyperbolae; then all other right lines, as $PQ$, parallel to $RT$, and terminated by the same curve, or the opposite curve, are ordinarily applied to the same diameter $FH$. Draw a plane through $V$, the vertex of the cone, and the diameter $FH$. Then, in the case of the ellipse and hyperbola, when the determining line does not pass through the centre of the base, this plane will necessarily pass through the line $VE$. And, because the plane of the conic section is parallel to the plane $VMN$, therefore $RT$, in the former plane, is parallel to the latter plane. And because the plane drawn through $V$, and the diameter $FH$, passes through $VE$, and bisects $RT$, which it cuts in $S$, a point not in the same right line with $V$ and $E$; therefore, the same plane will bisect all right lines in either of the opposite cones that are parallel to $RT$. Pr. 10. and Cor. 9. Therefore, the diameter $FH$ in that plane will bisect all the right lines which it meets, that are parallel to $RT$, and terminated by the section, or either of the opposite sections.

And, when the determining line passes through the centre of the base (fig. 26), as before, $RT$ is parallel to the plane $VMN$. And the diameter $AB$ is perpendicular to the diameter $MN$, and $V$ is parallel to $AB$, Diff. IX; therefore, the plane drawn through $V$ and $H$, which bisects $RT$, will bisect all right lines in either of the opposite cones that are parallel to $RT$, Pr. 8. Therefore, $FH$ in that plane will bisect all the right lines which it meets, that are parallel to $RT$, and terminated by either of the opposite hyperbolas.

In the parabola, because the plane of the section is parallel to the plane $VMN$; therefore, $RT$. (fig. 27.) in the former plane, is parallel to the latter plane. And because $AB$ is parallel to $FH$, therefore a plane may be drawn through them both; let this plane be drawn, and it will bisect all right lines in either of the opposite cones that are parallel to $RT$, Pr. 11. Therefore, $FH$, in that plane, will bisect all the right lines which it meets, that are parallel to $RT$, and terminated by the curve of the parabola.

Prop. XVII. Fig. 24 and 27.

A diameter of a conic section being given, to draw a right line that shall be ordinarily applied to that diameter.

Fig. 24. Let $FH$ be a diameter of an ellipse; draw a plane through the vertex $V$, and the diameter $FH$, cutting the plane of the base in the chord $KL$, which necessarily passes through the point $E$; draw tangents of the base from $K$ and $L$, and let them intersect in $O$. Then $O$ is a point in the determining line $MN$; Lem. 4; and $VO$ being drawn to the vertex of the cone, it is in the plane $VMN$, and parallel to the plane of the ellipse. Now, all straight lines, as $PQ$ and $RT$, in the plane of the ellipse, drawn parallel to $VO$, are ordinarily applied to the diameter $FH$; for these lines are all bisected by the plane $VKL$, that is, by $FH$ in that plane, Pr. 7.

The construction is exactly the same for the hyperbola.

Fig. 27. In the parabola the plane drawn through the diameter $FH$, passes through $VB$, parallel to $FH$, and it cuts the plane of the base in a chord $DK$, drawn from the point where the determining line $MN$ touches the periphery of the base; in this case draw $KO$, a tangent of the base, intersecting $MN$ in $O$; then, as before, $VO$, drawn to the vertex, is parallel to the plane of the parabola; and all right lines, as $RT$, $PQ$, in that plane, parallel to $VO$, are ordinarily applied to the diameter $FH$, Pr. 7.

Fig. 25, 21, 22. and 23. In all the conic sections, when the plane drawn through the vertex of the cone, and a diameter $PQ$, cuts the plane of the base in a diameter of the base $AB$; then all right lines, as $RT$, in the plane of the section, drawn parallel to the determining line $MN$, are ordinarily applied to the diameter $PQ$. For, if a diameter of the base be drawn parallel to $MN$, that diameter will be parallel to $RT$, and perpendicular to the diameter $AB$; therefore $RT$ is bisected by the plane $VAB$, that is, by $PQ$, the diameter of the section in that plane, Pr. 6.

Prop. XVIII.

Tangents drawn from the vertices, of a diameter of an ellipse, or of a transverse diameter of a hyperbola, are parallel to one another; but tangents of a conic section, drawn from the vertices of two different diameters, are not parallel.

Let a right line be ordinarily applied, to a diameter of an ellipse, or to a transverse diameter of a hyperbola, Pr. 17; and the tangent of the curve at either vertex of the diameter is parallel to that right line; consequently, the two tangents at the extremities of the diameter are parallel to one another.
And because a right line ordinarily applied to one diameter of a conic section is not ordinarily applied to another diameter; therefore a tangent at a vertex of one diameter is not parallel to a tangent at a vertex of another diameter.

Cor. If there be two parallel tangents of an ellipse, or of opposite hyperbolas; these tangents are drawn from the extremities of a diameter of the ellipse, or of a transverse diameter of the hyperbolas.

Prop. XIX. Fig. 23.

A straight line terminated both ways by the curve of a conic section, and parallel to a tangent, is ordinarily applied to the diameter drawn through the point of contact.

Let RT, terminated by the curve of a conic section, be parallel to a tangent of the curve, and through the point of contact. Draw P Q, ordinately applied to F H, Pr. 17. Then P Q is parallel to the tangent F M, Cor. 1. Pr. 15; therefore P Q is also parallel to R T. Consequentially, R T is ordinately applied to F H, Pr. 15.

Fig. 29.

A straight line G T, drawn from the centre of opposite hyperbolas so as to be parallel to F O and H I lines touching the curves at the vertices of a transverse diameter F H, bisects all lines, as R S, terminated by the opposite hyperbolas and parallel to the transverse diameter: and if a transverse diameter, F H, be drawn parallel to a straight line, as R S, terminated by opposite hyperbolas, and bisected by a line G T drawn through the centre, this line is parallel to F O and H I the tangents at the vertices of the transverse diameter.

Draw the diameter R P, join S, P, and produce F H to E P in Q. Because R S is parallel to F H, and R G = G P; therefore S Q = Q P; therefore S P is parallel to H I or F O, Cor. 1, Pr. 16. But G T is parallel to F O or H I; therefore G T is parallel to S P; therefore it is manifest that G T bisects R S, 2, 6, E.

Again, if G T bisects R S, then is G T parallel to H I or F O; for, because R T = T S, and R G = G P, therefore G T is parallel to S P, 2, 6, E. And because F H is parallel to R S, therefore S Q = Q P, 2, 6, E.; therefore S P is parallel to H I, Cor. 1, Pr. 16. Therefore G T is parallel to H I or F O.

Def. XV. Let the determining line M N (fig. 30.) of two opposite hyperbolas cut the periphery of the base of the cone in M and N, and let tangents of the base be drawn from these points (which tangents will pass through the point E when M N does not pass through the centre of the base of the cone, Lem. 4; but they will both be parallel to the diameter A B and to the line V G, when M N does pass through the centre): through the line V G, and the two tangents P M and Q N, let two planes be drawn cutting the plane of the hyperbolas in the lines G P and G Q, intersecting in the centre of the hyperbolas: then these lines are called asymptotes of the hyperbolas.

Cor. 1. The asymptotes do not meet the hyperbolas.

For the planes V P M and V Q N meet the conic surfaces only in the lines V M and V N produced, Pr. 4; therefore the lines G P and G Q, in these planes, are without the conic surfaces in which the hyperbolas are.

Cor. 2. The asymptotes G P and G Q are parallel to V M and V N, the lines in which the planes V P M and V Q N touch the conic surfaces.

For the plane V P M cuts the plane of the hyperbolas and the plane V M N (which are parallel planes) in the lines G P and V M; and the plane V N Q cuts the same planes in the lines G Q and V N.

Cor. 3. If a line be drawn parallel to one of the asymptotes through a point in one of the hyperbolas, that line does not meet the same hyperbola, nor the opposite one, again in another point.

For a line parallel to one of the asymptotes is parallel to one of the lines V M and V N in the conic surface; therefore it does not meet either of the conic surfaces again in another point, Pr. 3.

Cor. 4. A straight line in the plane of the hyperbolas, as F H, drawn through the centre of the hyperbolas within the angle contained by the asymptotes, will meet both the hyperbolas.

Because the asymptotes are parallel to V M and V N, therefore, if V O be drawn parallel to F H, it will be within the angle M V N; and it is plain that F H, parallel to V O, meets both the conic surfaces.

Lemma VII. Fig. 31.

Let A B and A C be two right lines that meet one another, then if B C, drawn through D, and terminated by A B and A C, be bisected in D, no other straight line, terminated by A B and A C, and drawn through D, will be bisected in that point.

Draw G H through D, and E F parallel to A C; because B D = D C, therefore A E = E B, 2, 6, E. Therefore A E and E G are not equal to one another: and, consequentially, G D and D H are not equal.

Prop. XXI. Fig. 32.

If a straight line, terminated by the asymptotes, as K L or S T, touch either of the hyperbolas, it is bisected in the point of contact: and if the middle point of a straight line, as K L or S T, terminated by the asymptotes be in either of the hyperbolas, that line is a tangent of the curve. Draw the diameter F H and let a b be ordinately applied to it, Pr. 17; also draw d e, between M V and V N, parallel to a b. Conceive a plane to be drawn through V G and F H, and let this plane cut the plane M V N in the line V O. It is manifest that V O is parallel to the diameter F H, 16, 11, E. And because a plane drawn through V G bisects a b, the same plane will bisect all right lines in either of the opposite cones that are parallel to a b, Cor. 9; therefore it will bisect d e; that is, d o = o e. Because K L is a tangent, it is parallel to a b, Cor. 1, Pr. 16, and, consequently, to d e. And because the asymptotes are parallel to V M and V N, Cor. 2. Def. XV., and F H is parallel to V O, and d e to K L, it is plain that K L and d e are similarly divided in H and O; therefore K H = H L.

Again, if K L meets the hyperbola in H, and is bisected there, it is a tangent. For, if not, then, a line being drawn between the asymptotes to touch the hyperbola in H, it would likewise be bisected in H as has already been shown: which is absurd. Lem. 7. Therefore K L is a tangent.

Prop. XXII. Fig. 32. Plate V.

If a right line, that cuts an hyperbola or opposite hyperbolas, likewise cuts both the asymptotes; the segments between the hyperbola, or hyperbolas, and the asymptotes, will be equal.

Let the right line D E cut a hyperbola in S and P, and the asymptotes in D and E: draw the transverse diameter F H to bisect S P, and let K L be drawn to touch the hyperbola in H, because F H bisects S P, therefore S P is parallel to the tangent K L, Cor. 1, Pr. 16, but K L is bisected in G.
CONIC SECTIONS.

in H, Pr. 21: therefore D E, parallel to K L, is bisected in Q, and because D E and S P are both bisected in Q, therefore D S and S E are respectively equal to S P and P D.

Next let S R cut the two opposite hyperbolas in S and T; and the asymptotes in N and I; draw G T through the centre to bisect S R; and draw the transverse diameter F H parallel to S R, and let K L touch one of the hyperbolas at H, and draw K M parallel to S R; because G T bisects S R parallel to G H, therefore G T is parallel to K L, Pr. 20; because K M and F H are both parallel to S R, therefore they are parallel to one another: but K L is bisected at H, Pr. 21, therefore L M is bisected at H, and K M is bisected at O, 2. 6. E; therefore N I, parallel to K M, is bisected at T. And, because S R and N L are both bisected at T, therefore the segments S N and N R are respectively equal to the segments R I and I S.

Prop. XXIII. Fig. 32.

The curve of an hyperbola approaches the nearer to the asymptote the farther it is continued; and, if continued far enough, the distance of the curve from the asymptote will become less than any assigned distance how small soever.

Assume any point, as A in the hyperbola, and draw A X parallel to the asymptote G C; then A X does not meet the hyperbola again, Cor. 3. Def. XV: through A draw any line B C to a point, as Z in the curve, and let B C meet the asymptotes in B and C, and draw B X perpendicular to A X, and Z Y perpendicular to the asymptote G C: because A B = Z C, Pr. 21, it is plain that B X = Z Y; now the more distant the point Z is, the nearer is the line A B to the line A X, and the less is B X, or Z Y the distance of the curve from the asymptote. And because A B may be drawn so as to make B X less than any assigned line, therefore a point of the curve may be found that shall be nearer to the asymptote than any assigned distance.

Definitions.

Fig. 30. Plate IV. XVI. If a straight line be drawn through the centre of opposite hyperbolas parallel to the tangents S T and K L at the vertices of a transverse diameter F H, and a part of that line bisected in the centre, as 1 R, be taken equal to the segments S T and K L (it is plain that S T = K L) of the tangents terminated by the asymptotes; then 1 R is called a second diameter of the hyperbolas, and the extremities of it are called the vertices of the second diameter.

But the word diameter is often used to signify a straight line drawn through the centre of an ellipse or opposite hyperbolas, without regard to the magnitude of such line.

XVII. A straight line, terminated by two opposite hyperbolas and bisected by a second diameter, is said to be ordinarily applied to that diameter; or it is called a double or conjugate diameter, and the half of it, an ordinate.

XVIII. Two diameters of an ellipse, or of opposite hyperbolas, that are mutually parallel to the ordinates of one another, are called conjugate diameters, or they are said to be conjugate to one another.

Prop. XXIV.

If a diameter of an ellipse, or of opposite hyperbolas, be parallel to the ordinates of another diameter, these two are conjugate diameters.

The demonstration of this proposition, in the case of the hyperbola, is manifest from Prop. 20th; for the ordinates 1 of a transverse diameter of a hyperbola are parallel to a tangent at a vertex of the diameter, Cor. 1, Pr. 16.

Fig. 33. Plate V. In the ellipse, let the diameter E D be parallel to P Q. S an ordinate of the diameter F H; draw the diameter P R and joyn S R cutting E D in T. Because P Q = Q S, and PG = GR; therefore S R is parallel to F H. And because E D is parallel to P Q, and S P = PG = GR; therefore R T = T S. Therefore RS is an ordinate of the diameter E D, Def. XVIV, and it is parallel to F H; therefore E D, &c. F H are conjugate diameters, Def. XVIII.

Cor. If a diameter of an ellipse, as E D, be parallel to F O, a tangent at a vertex of another diameter F H; then F H is parallel to D I, a tangent at a vertex of E D.

For a tangent at a vertex of a diameter is parallel to the ordinates of that diameter.

Def. XIX. When a straight line drawn through a point, situated within or without a cone, meets one, or both, of the conic surfaces in two points, it is called a secant: and the two parts of such a line, between the point through which it is drawn and the conic surface or surfaces, are called the segments of the secant. And when a line, drawn from a point without a cone, touches one of the conic surfaces; that part of the line between the point from which it is drawn and the conic surface is denoted by the word tangent in the following propositions.

Prop. XXV. Fig. 34, 35, and 36.

If a straight line be drawn from the vertex of a cone to a point, as B, in the plane of the base, but not in the periphery of the base; and, through any point, as P, situated without or within the cone, another straight line, parallel to the former, be drawn to cut or touch the conic surface, or opposite surfaces; then the square of the line drawn from the vertex of the cone to the point B is to the rectangle under the segments of the secant, or to the square of the tangent, drawn from the point P, as the rectangle under the segments of any line drawn from B to cut the base of the cone, is to the rectangle under the segments of any line, parallel to the base of the cone, drawn through the point P, to cut the conic surface.

Fig. 34. Let the point B be without the base of the cone, and let Q R, drawn through P without or within the conic surface, be parallel to V B, and let it cut the conic surface in Q and R: through P and the line V B draw a plane cutting the conic surface in the lines V G and V H, and the plane of the base in the line B G H; and through P draw L K parallel to G H. Because V B and P Q R are parallel, therefore the plane P Q R is contained in the plane B V P; 7. 11. E; and the points Q and R are in the lines V H and V G, the common sections of the plane and the conic surface. Because Q P is parallel to V B and L K to G H, therefore the triangle Q P L is equiangular to the triangle V B H, and the triangle P K R to the triangle V G B: therefore 4. 6. E.

V B: F R :: B G : P K
V B: P Q :: B H : P L

Consequently, V B :: P R x P Q :: B G x B H :: P K x P L. 23. 6. E. But the rectangle B G x B H is equal to the rectangle under the segments of any other line drawn from B to cut the base of the cone, 35 and 36. 3. E; and the rectangle P K x L K is equal to the rectangle under the segments of any other line, parallel to the plane of the base, drawn from P to cut the conic surface, Cor. Pr. 5; and hence the proportion is manifest in this case.

Fig. 35. And if the point B be within the base of the cone, and a straight line (as P Q R), parallel to the line V B,
conic sections.

V B that joins the point B and the vertex of the cone, be
drawn to cut the opposite surfaces through a point P situ-
ated without or within the cone: the proposition may be
demonstrated in this case, in the very same words as in the
former case.

Fig. 36. And if the point P be without the cone as
well as the line V B, and P S, parallel to V B, be drawn
to touch the conic surface, instead of cutting it; then
the plane P V B will meet the conic surface in a line V S M;
and E M will touch the base of the cone, and P N, parallel
to B M, will touch the conic surface. And because the
two triangles S P N and V B M are equiangular, there-
fore,

V B : P S :: B M : P N
And V B : P S :: B M : P N²

But B M² is equal to the rectangle under the segments of
any line drawn from B to cut the base of the cone; and
P N² is equal to the rectangle under the segments of any
line, parallel to the base of the cone, drawn from P to cut
the conic surface; and hence the proposition is manifest in
this case also.

Prop. XXVI. Fig. 37.

If a point be assumed without or within a cone, and two
lines be drawn through it to meet a conic surface, or oppo-
site surfaces, and so as to be parallel to two straight lines
given by position; then the rectangle under the segments of
the focent, or the square of the tangent, parallel to one of
the lines given by position, has to the rectangle under the
segments of the focent, or to the square of the tangent, pa-
allel to the other line given by position, a ratio that is
constantly the same, wherever the point (from which the
lines are drawn) is assumed within or without the cone.

Fig. 37. Let V B and V C be two straight lines, drawn
from the vertex of a cone to the plane of the base, and given
by position (or parallel to lines given by position); and let
P Q and M N be two straight lines drawn through any
assumed point, as R, to cut the conic surface, and so as to
be respectively parallel to C V and V B: and as C V² is
to the rectangle C K × C L (contained by the segments of
any line drawn from C to cut the base of the cone), so let
D, any assumed line, or magnitude, be to E; and as
C V² is to B G × B H (the rectangle contained by the segments of any line drawn from B to cut the base of the cone), so let F be to E; and draw S T parallel to the base
of the cone through the point R; then, Pr. 24.

(C V² : C K × K L, or) D : E :: P R × R Q : S R
× R T, and B V² : B G × G H; or) F : E :: M R ×
R N : S R × R T.

Therefore inverting and ex æquo,

D : F :: P R × R Q : M R × R N.

And, as the same reasoning applies wherever the point
R is assumed, therefore the ratio of the rectangles P R × R Q,
and M R × R N is the same with, or equal to, the conical
ratio of D to F, wherever the point R is assumed.

And, in like manner, may the proposition be demon-
strated in all other cases, or in all positions of the lines P Q,
and M N, whether they cut, or touch, the same or oppo-
site surfaces.

Prop. XXVII. Fig. 38.

If a point be assumed in the curve of an hyperbola, and
a straight line be drawn through it to cut both the asymp-
totes; the rectangle, contained by the segments intercepted
between the point in the curve and the asymptotes, will be
equal to the square of the semidiameter to which the straight
line is parallel.

First, let the straight line E M N, drawn through E in
the curve of a hyperbola and cutting the asymptotes in M
and N, be parallel to the transverse diameter, G H; join
H E, and produce it to meet the asymptotes in R and S: it
is obvious that the triangle R G H is equiangular to the
triangle R E N, and the triangle G H S to the triangle
S H E; therefore, 4. 6. E.

NE : E R :: G H : H R
S H : G H :: S E : E M

And, because S H = E R, and S E = H R, Pr. 22.

therefore,

ex æquo NE : E R :: G H : E M
consequently, M E × E N = G H², 17. 6 E.

Next, when the line is parallel to a second diameter. And
if it touch the curve at the point H through which it is
drawn, as K L; then the two segments, K H, and H L, are
equal to one another, Pr. 13, and to the semidiameter G P,
which K L is parallel, Def. XVI: whence the proposition
is manifest. But if a line, as D F, drawn through the point
of the curve, E, parallel to the second diameter G P, do
not touch the hyperbola, let K L, parallel to G P, touch
the hyperbola in H, and join H E, cutting the asymptotes
in R and S. Because K L and D F are parallel (be-
ing, both, parallel to G P), therefore the triangles, R H L,
and K H S, are respectively equiangular to the triangles
R E F and D E S; therefore,

F E : E R :: H L : H R
S H : H R :: S E : E D

And, because S H = E R and S E = H R, therefore,

ex æquo F E : H K :: H L : E D

Cor. If any number of straight lines, all parallel to one
another, meet the two asymptotes and the hyperbola or op-
posite hyperbolas; the rectangles contained by the segments
of the parallels, intercepted between the asymptotes and
the curve, will be all equal to one another.

For each of the rectangles is equal to the square of the
semidiameter drawn parallel to the lines.

Prop. XXVIII. Fig. 38.

If a point be assumed without or within a conic section,
and two straight lines be drawn through it to cut or touch
the section or opposite sections, and so as to be parallel
to two lines given by position; then the rectangle under the
segments of the section, or the square of the tangent, pa-
allel to one of the lines given by position, will have to the
rectangle under the segments of the section, or to the square
of the tangents parallel to the other line given by position,
a ratio that is always the same, wherever the point (through
which the lines are drawn), is assumed within or without the
section. And in the ellipse and hyperbola, or opposite
hyperbolas, the conical ratio is equal to that of the squares
of the diameters drawn parallel to the lines given by po-

For sections and tangents of a conic section are sections
and tangents of a conic surface, and thus the first part
of this proposition is included in proposition 25.

And because the diameters of an ellipse intersect in the
centre, and are bisected there; Pr. 14; therefore the ratio of
the rectangles under the segments of the sections, is, in this
case, the same with the ratio of the squares of the semi-
diameters, or the same with the ratio of the squares of the diam-

eters themselves: and thus the second part of the propo-
sition, in as much as it regards the ellipse, is manifest from
the first part.

It remains to demonstrate the second part of the propor-
tion in the case of the hyperbola. Assume any point, as F,
(fig. 28.), in one of the asymptotes, and through F draw

B I
B 1 and C E (terminated by the hyperbola, or opposite hyperbolas), parallel to the semidiameters G P and G H; and let B 1, and C E, or these lines produced, cut the other asymptote in D and A. Because B A = F I, Pr. 22; therefore B F \times F I = B F \times B A = G H^2; and, in like manner, E F \times F C = D C \times C F = G P^2, Pr. 27. Therefore the ratio of the squares of the semidiameters G H and G P, or the ratio of the squares of the diameters themselves, is equal to the ratio of the rectangles E F \times F I and E F \times F C.

And because the ratio of the rectangle B F \times F I to the rectangle E F \times F C is equal to the ratio of the rectangles under the segments of any lines terminated by the curve or curves that intersect one another, and are parallel to B F and F C (the squares of the tangents being taken when the lines touch the curve instead of cutting it), therefore, in the case of the hyperbola also, the second part of the proposition is manifest from the first part.

Cor. 1. If two tangents be drawn to an ellipse, or a hyperbola, or opposite hyperbolas, from the same point, then these tangents are proportional to the diameters, or semidiameters, drawn parallel to the tangents.

For the squares of the tangents are proportional to the squares of the diameters.

Cor. 2. If a right line be ordinately applied to a diameter of an ellipse, or to a transverse diameter of a hyperbola; then the square of the diameter is to the square of the conjugate diameter, so is the rectangle contained by the abscissae of the diameter, between the vertices and ordinate, to the square of the ordinate.

For the double-ordinate is bisected by the diameter, and it is parallel to the conjugate diameter.

Prop. XXIX. Fig. 39.

If an ordinate be drawn to a second diameter of opposite hyperbolas; the square of this second diameter is to the square of the conjugate diameter, as the sum of the squares of the second diameter, and of the part of it between the centre and the ordinate, is to the square of the ordinate.

Let P Q (fig. 39.) be a second diameter of two opposite hyperbolas, and F H the diameter conjugate to it, and let M O be an ordinate to P Q; draw M N parallel to P Q; then M N will be an ordinate of the diameter F H; Def. XX.

Therefore, G H^2 : G P^2 :: F N \times N H, or G N^2 - G H^2 : M N^2, Cor. 2. Pr. 27;

therefore G H^2 : G P^2 :: G N^2, or M O^2;

G P^2 + M N^2 :: M O^2.

Prop. XXX. Fig. 40.

If a right line, as P T, drawn through a point P in the surface of a cone so as to be parallel to a right line V B contained in the cone, and S be the point in the plane of the base in line B A; and, through R and S, draw M N and H G parallel to A B. Because P T is parallel to V B and R N to S G, therefore R N G S is a parallelogram; and R N is = G S. It is obvious that the triangles P M R and P H S are equiangular: therefore P R is to P S as M R is to H S, 4. 6. E, or as M R \times R N is to H S \times S G, 1. 6. E. But M R \times R N and H S \times S G are respectively equal to the rectangles contained by the segements of any two lines, parallel to the base of the cone, drawn through R and S to cut the conic surface, Cor. Pr. 5; and hence the proposition is manifest, when P T meets two lines parallel to the plane of the base.

And if P T meet two parallel lines D E and I K, not parallel to the plane of the base; then, let the same construction be made as before; and because D E is parallel to I K, and M N to G H; therefore, DR \times RE : MR \times RN :: IS \times SK :: HS \times SG;

Alternando, DR \times RE :: IS \times SK :: MR \times RN :: HS \times SG. Therefore, as is obvious from what has already been shown,

P R : P S :: DR \times RE :: IS \times SK.

And if S be without the cone and the line drawn through it touch the conic surface instead of cutting it, the reasoning is still the same, when the square of the tangent is taken in place of the rectangle under the segments of the fectant.

Prop. XXXI.

If two points be assumed in the diameter of a parabola, or in a right line drawn through a point in the curve of an hyperbola parallel to one of the asymptotes, and two parallel lines be drawn from these points to cut, or touch, the curve or opposite curves; then, as the rectangle under the segments of the fectant or the square of the tangent, drawn from one of the assumed points, is to the rectangle under the segments of the fectant, or to the square of the tangent, drawn from the other assumed point, so is the segment of the diameter of the parabola, or of the line parallel to the asymptote, between the first assumed point and the curve, to the segment of the same line between the second assumed point and the curve.

Because all the diameters of a parabola, Def. XIII. and all the straight lines drawn parallel to an asymptote of a hyperbola, Cor. 2. Def. XV. are parallel to a right line contained in the conic surface; and because fectants, and tangents of a parabola, or a hyperbola, are fectants and tangents of a conic surface; therefore it is manifest that this proposition is included in the last proposition.

Cor. The squares of the ordinates drawn to a diameter of a parabola are proportional to the abscissae of the diameter between the ordinates and the vertex.

Fig. 43. For the double ordinates of a diameter of a parabola, as G F D and L K E are parallel to one another; Cor. Def. XVII. therefore, by this proposition.

G F \times F D, or G F^2 :: L K \times K E, or L K^2 :: A F : A K.

Prop. XXXII. Fig. 41, 42, and 43.

If an ordinate be drawn to a diameter of a conic section, which is not a second diameter of a hyperbola: then, in the ellipse, the square of the ordinate is equal to a rectangle contained by an abscissa of the diameter and a constant line, deficient by a rectangle similar to that contained by the constant line and the diameter; and, in the hyperbola, the square of the ordinate is equal to a rectangle contained by an abscissa of the diameter and a constant line, exceeding by a rectangle similar to that contained by the constant line and the diameter: and in the parabola, the square of the ordinate is equal to a rectangle contained by the abscissa of the diameter and a constant line.

Let A B (fig. 41 and 42.) be a diameter of an ellipse, or a transverse diameter of a hyperbola, F G an ordinate of it, and D E the conjugate diameter; draw A H perpendicular to A B and equal to a third proportional to A B and D E.
and join BH: draw FL parallel to AH, and complete the parallelograms AK, FN and AM. It is obvious that BA is to AH as BF is to FL, 4. 6. E., or as BF \times FA is to FL \times FA or the rectangle FN, 1. 6. E. And because AH is a third proportional to BA and ED, therefore, 

\[ B : A : H :: B^* : D^2, \] 

Cor. 2. Pr. 28.

Therefore, 

\[ AF \times FB : FG^* :: AF \times FB : rect. FN, 14. 5. E. \]

And, FG \^2 = rect. FN. Now, in the ellipse, the rectangle FN is deficient from the rectangle AM, contained by the absciss AF and the line AH (which is the same for all the ordinates) by the rectangle NM, similar to the rectangle AK, contained by AH and AB; and, in the hyperbola, the rectangle FN exceeds the rectangle AM by the rectangle NM, similar to the rectangle AK.

In the parabola, let one ordinate of a diameter be pitched upon, as \( LK \), and take AH, a third proportional to the absciss AK and the ordinate \( LK \); then, if \( FG \) be any other ordinate, 

\[ LK^2 : FG^2 :: AK : AF, (Cor. Pr. 31) :: AK \times AH : AF \times AH. \]

And because \( LK^2 = AK \times AH \), therefore \( FG^2 = AF \times AH \), the rectangle contained by the absciss \( AF \) and the line \( AH \), which is the same for all the ordinates of the diameter.

Def. XX. The conical line \( AH \) is called the parameter of the diameter \( AB \); and, in the ellipse and hyperbola, it is a third proportional to the diameter \( AB \), and the conjugate diameter \( DE \); but, in the parabola, it is a third proportional to the absciss of any ordinate of a diameter, and the ordinate itself.

Scholium.

The phrases "deficient" and "exceeding by a rectangle similar to another rectangle," occur in Euclid's Elements, 27 and 28. 6. E., although they are now generally diffused by geometers; and, it must be confessed, they are far from expressing the meaning they are intended to convey, in a simple and perspicuous manner. These expressions have been used in enunciating this proposition, with the view of drawing the attention to the distinguishing circumstances from which the several conic sections derive their names. For Apollonius gave the name of the ellipse to one of these curves, on account of the defect of the square of the ordinate from the rectangle contained by the absciss and the parameter; and he called another of them a hyperbola, from the excess of the square above the same rectangle; and the third a parabola, on account of the exact equality of the same two spaces.

Prop. XXXIII. Fig. 44. Plate VI.

Let a scalicene cone be cut by a plane perpendicular to the plane of the base, making the triangular section \( VAB \); and let \( IE \) be the line found in the last proposition; also, let the cone be cut by a plane, making an elliptical section, \( P : F \); \( Q \); \( H \), the determining line of which, \( MN \), is parallel to the line \( IE \); and let \( FH \) be the diameter of the section that is parallel to \( MN \). Then, if \( MN \) fall between the base of the cone and \( IE \), \( FH \) is the least diameter of the section; and, if \( MN \) fall upon \( IE \), all the diameters of the section are equal to \( FH \) and to one another; and if \( FH \) fall on the opposite side of \( IE \) to the base of the cone, \( FH \) is the greatest diameter of the section.

Let \( RS \) be any diameter of the section different from \( FH \), and draw \( VK \) (meeting \( MN \) in \( K \)) parallel to \( RS \); and let \( KL \) cut the base of the cone. Because \( RS \) and \( FH \) are bisected in the centre \( G \), therefore, 

\[ RG^2 : HG^2 :: VK^2 : KL \times KT, Pr. 25. \]

Now, if \( MN \) fall between the base of the cone and \( IE \), then \( VK^2 \) is greater than \( KT \times KQ, Pr. 33 \); therefore \( RG \) is greater than \( HG \); and, in this case, \( FH \) is the least diameter of the section.

And, if \( MN \) fall upon \( IE \), then \( VK^2 = KT \times KL \); therefore \( KG = HG \); and, in this case, the section is a circle.

And, lastly, if \( MN \) be on the other side of \( IE \) to the base, then \( VK^2 \) is less than \( KT \times KL \); therefore \( RG \) is less than \( HG \); and, in this case, \( FH \) is the greatest diameter of the section.

Cor. 1. If a section of a cone, not parallel to the plane of the base, be a circle, then \( IE \), the line found in Prop. 32, is the determining line of that section.

For \( RG^2 : HG^2 :: VK^2 : KT \times KL. \)

And,
And, because the section is a circle, therefore $RG = HG$; therefore $KV = KT \times KL$; therefore $K$ is a point in the line $IE$, Cor. Pr. 32. And, in like manner, it may be shown that every point of the determining line of the section is in the line $IE$.

Cor. 2. Let $PQ$ be the common section of the plane $VAB$, and the plane of the ellipse; then $PQ$ is a diameter of the ellipse. It is manifest that $MN$ is perpendicular to the plane $VAB$; therefore $FH$, parallel to $MN$, is perpendicular to the same plane and to $PQ$. Also $PQ$ and $FH$ are conjugate diameters, Pr. 17. Therefore, when the plane $VAB$ is perpendicular to the plane of the base, $FB$, the diameter of the ellipse, parallel to the base of the cone, cuts its conjugate diameter, $FP$, at right angles.

**Scholium.**

If $FPQH$ be a section of the cone, of which $IE$ is the determining line, it is plain that $PQ$ is parallel to $VD$; therefore, the angle $VQP = angle VBD = angle VAB$. Therefore, the triangle $PVO$ is similar to the triangle $BAV$; but the angles at the base of the one triangle have a sub-contrary position to the equal angles at the base of the other triangle. For this reason a section of a cone that has the line $IE$ (found as in Prop. 32.) for its determining line, is called a sub-contrary section.

The word ellipse has hitherto been used to denote, generally, those sections of a cone which have their determining lines without the base of the cone; but, as it has been shown that the conic section is a circle in one particular case (viz. the sub-contrary section) included in this general definition, precision requires that the term ellipse be hereafter restricted in its signification, so as to exclude that particular case.

**Prop. XXXV. Fig. 46.**

An ellipse being given, it is required to draw a diameter of it that shall be equal to $FH$, the diameter which is parallel to the base of the cone; but the plane $VAB$, drawn through the vertex of the cone, and that diameter of the base which is perpendicular to the determining line of the ellipse, must not be perpendicular to the plane of the base of the cone.

Draw the line $IE$, as in proposition 32. And because $IE$ and $MN$ are perpendicular to two different diameters of the base of the cone, they are not parallel; let them meet in $K$, and draw $VK$, and the diameter $RS$ parallel to $VK$; then $FH = RS$. For, because $RS$ and $FH$ are bisected in the centre $G$, therefore $V^2 = KT \times KL$; $FG^2 = RG^2$, Pr. 24. But $V^2 = KT \times KL$; therefore, $FG = RG$.

Cor. Only one diameter can be drawn that shall be equal to $FH$.

For, if $FH = RS$, then $V^2 = KT \times KL$; therefore, $K$ is in the line $IE$; and $IE$ can meet $MN$ only in one point.

**Def. XXI.** A diameter of a conic section, that cuts its ordinates at right angles, is called an axis.

Cor. Because two conjugate diameters of an ellipse, and opposite hyperbolas, cut the ordinates in the same angles, Pr. 24.; therefore, if these become axes of these curves, there will necessarily be two; and these will be conjugate diameters, and they will cut one another at right angles.

**Prop. XXXVI. Fig. 47 and 48.**

An ellipse has only two axes.

Let $FH$ (fig. 17.) be the diameter of the ellipse drawn parallel to the base of the cone; and, first, let $FH$ be the greatest or the least diameter of the ellipse, Pr. 34.; then, it has already been shown, that $FH$ cuts its conjugate $PQ$ at right angles, Cor. 2, Pr. 34.; and, therefore, $FH$ and $PQ$ are axes of the ellipse, Cor. Def. XXI. Also they are the only axes of the ellipse.

For, let $XY$ be any other diameter, then $XY$ is not perpendicular to $FI$; draw $FZO$, cutting the ellipse again in $O$ perpendicular to $XY$, and draw $GO$. Because $FH$ is the greatest or least diameter of the ellipse; therefore, $FG$ is not equal to $GO$; therefore, $FZ$ is not equal to $ZO, 47.1. E$. Therefore $FO$, perpendicular to $XY$, is not an ordinate of $XY$; therefore, $XY$ is not an axis.

Secondly, when $FH$ is not the greatest or least diameter of the ellipse, draw the diameter $RS$ equal to $FH, Pr. 35.$; and draw the diameter $LK$ and $DE$ to bisect the angles contained by $FH$ and $RS$; join $FS$. And, because $LK$ bisects the angle at the vertex of the isosceles triangle $FGS$, it will bisect the base $FS$, and will cut it at right angles. And because $LK$ cuts $FS$, one of its ordinates at right angles, therefore $LK$ is an axis; and, it is plain, that $DE$, parallel to $FS$, is another axis and the conjugate of $LK$. Also, $LK$ and $DE$ are the only axes of the ellipse.

For, let $XY$ be any other diameter; then $XY$ is not perpendicular both to $FH$ and to $RS$; let it be not perpendicular to $FH$, and draw $FZO$ (cutting the ellipse again in $O$) perpendicular to $XY$, and join $GO$. Because $RS$ is the only diameter of the ellipse that is equal to $FH$, Cor. Pr. 35.; therefore $FG$ is not equal to $GO$; therefore $FZ$ is not equal to $ZO$. And because $FO$, perpendicular to $XY$, is not an ordinate of $XY$, therefore $XY$ is not an axis.

**Prop. XXXVII. Fig. 49.**

A hyperbola has only two axes.

Let $GF$ and $GK$ be the asymptotes of the hyperbola, and draw the transverse diameter $GA$ to bisect the angle of the asymptotes, and the second diameter $DE$ to bisect the adjacent angle; let $FK$, drawn between the asymptotes, be perpendicular to $GA$, and meet the hyperbola in $M$ and $N$. Because $FK$ is perpendicular to $GL$, and the angle $FGL = angle KGK$, therefore $FL = 26.1. E$. But $FM = NK, Pr. 22.$; therefore $ML = LN$. Therefore, $MN$ perpendicular to $GA$, is an ordinate of $GA$; therefore, $GA$ is an axis; and $DE$, parallel to $MN$, is the conjugate of $GA$, and another axis, Pr. 54.

And if $GA$ do not bisect the angle $FAG$, then $FK$, perpendicular to $GA$, will not be bisected in $L$; therefore $ML$ will not be equal to $LN$; therefore, in this case, $MN$, perpendicular to $GA$, is not an ordinate of $GA$. Therefore, the hyperbola has no axes besides $GA$ and $DE$.

**Prop. XXXVIII. Fig. 50.**

A parabola has only one axis.

Let $OS$, terminated by the curve, be perpendicular to any diameter, and draw the diameter $PQ$ to bisect $OS$; and, because all the diameters of the curve are parallel, therefore, $PQ$ is perpendicular to $OS$, and an axis of the curve, Def. XXI. And because $OS$ can be an ordinate of only one diameter, therefore there is only one axis.

**Prop. XXXIX. Fig. 51 and 52.**

The two axes of an ellipse are always unequal; and the greater axis is the greatest diameter, and the least the least diameter of the curve. And that axis of a hyperbola, which is a transverse diameter, is the least of all the transverse diameters.
CONIC SECTIONS.

Let A B and D E (fig. 51) be the two axes of an ellipse, C the centre, and C H any semidiameter; draw H P perpendicular to A B, and H Q perpendicular to D E. Because A B and D E are conjugate diameters; and H P an ordinate to A B, and H Q an ordinate to D E; therefore,

A B' = D E' = A P × P B = H P, Cor. 2. Pr. 28.

Now, if A B be supposed to be equal to D E, it will follow that A P × P B = H P²; therefore, A P × P B + C P² = H P² + C P², or A C = C H. Therefore, A C = C H; and the ellipse will be a circle, which is not the case, Cor. 1. Pr. 33. Therefore, A B and D E are unequal; let A B be supposed to be greater than D E.

Because A B' is greater than D E', therefore A P × P B is greater than H P²; and A P × P B + C P², or A C, is greater than H P² + C P², or C H'. Therefore the semi-axis A C is greater than any other semi-diameter H C.

In like manner,

D E' = A B' = D Q × Q E = H Q².
Therefore D Q × Q E is less than H Q²; and D Q × Q E + C Q², or C D', is less than H Q² + C Q², or C H'. Therefore the semi-axis D C is less than any other semi-diameter C H.

Fig. 52. In the hyperbola, a tangent of the curve drawn from the extremity of the axis C A, as A T, falls between the centre and the curve; and because C A, the semi-axis, is less than any other line drawn from C to A T, much more is it less than a semi-diameter C H drawn from C to the curve on the other side of A T.

Definition XXII.

The greater axis of an ellipse is called the transverse axis; and the lesser, the conjugate axis; and, in the hyperbola, that one is the transverse axis which is a transverse diameter, and the other is the conjugate axis.

Prop. XL. Fig. 51 and 52.

A diameter of an ellipse nearer the transverse axis is greater than one more remote; and a transverse diameter of the hyperbola nearer the transverse axis is less than one more remote.

Let C K and C H be two semi-diameters of an ellipse; join H K, and draw A G parallel to H K; join C G and draw C I to bisect H K. Because C I bisects H K, it will likewise bisect A G, Pr. 15. And because A M = M G, and A C is greater than C G, therefore the angle A M C is greater than the angle G M C, 25. 1. E.; that is, the angle K L C is greater than the angle H L C. And because H L = L K, therefore K C, nearer to C A, is greater than H C more remote from C A, 24. 1. E.

In the hyperbola, the same construction be made, because A C is less than C G, therefore the angle A M C, or K L C, is less than the angle G M C, or H L C. Therefore C K is less than C H.

Definitions. Fig. 53, 54, and 55.

XXIII. Let A B (fig. 53 and 54.) be the transverse axis, D E the conjugate axis, and C the centre of an ellipse, or hyperbola, or opposite hyperbolas; and let C F and C F' be taken in the transverse axis, such that C F² and C F'² are equal to C A² − C D² in the ellipse, and to C A'² + C D'² in the hyperbola; then the two points F and F' are called the foci of the ellipse, hyperbola, or opposite hyperbolas.

Fig. 55. But the focus of a parabola is a point F in the axis, within the curve, and distant from the vertex by a line equal to one fourth part of the parameter of the axis.

Cor. The distance of each of the foci from either extremity of the conjugate axis is equal to half the transverse axis; and the distance of either of the foci of a hyperbola from the centre is equal to the distance between the extremities of the transverse and conjugate axes.

XXIV. If F (fig. 53 and 54.) be a focus of an ellipse, or hyperbola, or opposite hyperbolas, and A G be taken in the transverse axis (on the opposite side of the vertex to the focus F), such that A F is to A G as C F is to C A; then a line, as H K, drawn through G perpendicular to the transverse axis, is called a director of the ellipse, or hyperbola, or opposite hyperbolas.

Fig. 55. But the director of a parabola is a line, as H K, perpendicular to the axis, drawn through a point G as far distant from the vertex of the axis on the one side as the focus is on the other side.

Cor. An ellipse, hyperbola, or opposite hyperbolas, have two directors; one corresponding to each focus. For the same construction that is made for one focus, may be made for the other focus.

Prop. XLI. Fig. 53 and 54.

Let A B be the transverse, and D E the conjugate, axis of an ellipse, or hyperbola, or opposite hyperbolas; from any point in the curve, or opposite curves, as M, let M C be drawn to the centre, and M P perpendicular to the transverse axis, and take C O, in the same axis, such that C O² may be equal to M C² − C D² in the ellipse, and to M C'² + C D'² in the hyperbola; then as A C is to C F so is P C to C O.

For, because A B and D E are conjugate diameters, therefore,

A C : C D² :: A P × P B : M P², Cor. 2. Pr. 28, therefore, A C : A C + C D² :: A P × P B : A P × P B + M P². But in the ellipse A C − C D² = C F²; and A P × P B − M P² = A C − C D² = M P² = A C − M C = A C − C D² = C F² = C O²; and in the hyperbola, A C + C D² = C F²; and A P × P B + M P² = −PC = A C + M P² = M C − A C = C D² = C A² = C O² = C F². Therefore the last analogy becomes,

A C : C F² :: A C + C D² : C F² + C O²
Consequently A C : C F² : C P² : C O² 19. 5. E.
And A C : C F : C P : C O.

Prop. XLII. Fig. 53 and 54.

If M be a point in an ellipse or hyperbola, and M F and M f be drawn to the foci; then, in the ellipse, the sum of M F and M f is equal to the transverse axis; and, in the hyperbola, the difference of M F and M f is equal to the transverse axis.

Draw M P perpendicular to the transverse axis, and take C O as in the last proposition. And, because

A C : C F : C P : C O, Pr. 41.

Therefore A C × C O = C F × C P, and A C × C O = 4 C F × F O. But, because A B and P F are bisected in C, therefore 4 A C × C O = B O² − A O² = 8 E 2; and, 4 F C × C P = P f² − P F² = M F² − M P², 47. 1. E.; therefore B O² = A O² = M F².

Again, M F² + M f² = P F² + P F² = 2 F C² + 2 C F² + 2 M P² = 2 F C² + 2 M P² = 2 F C'² + 2 M P² = 2 C F'² = 2 C D'² + 2 C O² = 2 A C² + 2 C O² = B O² + A O².

And,
And, because \(BO^2 + AO^2 = FM^2 + MF^2\), and \(BO^2 = AO^2 = fM^2 - MP^2\); therefore, by adding the equals, \(2BO^2 = 2AO^2 = 2FM^2 = 2MP^2\). Therefore \(FM = BO\), and \(FM = AO\); whence the proposition is manifest.

**Prop. XLIII. Fig. 53, 54, and 55.**

A straight line drawn from any point in a conic section to a focus has to a perpendicular drawn to the corresponding direc-tix, a ratio that is constantly the same wherever the point is assumed in the curve; and, in the ellipse, the constant ratio is a ratio of minority (or of a less magnitude to a greater): in the hyperbola, the constant ratio is a ratio of majority (or of a greater magnitude to a less); and, in the parabola, the constant ratio is a ratio of equality.

Fig. 53 and 54. Let \(M\) be a point in an ellipse or hyperbola, and draw \(MF\) to a focus and \(MK\) perpendicular to the directrix \(HG\), which corresponds to that focus; draw \(MP\) perpendicular to the transverse axis and take \(CO\) as in Prop. 41. Then

\[
AC : CF :: CP : CO. Pr. 41.
\]

Invertendo, \(CF : CA :: CO : CP\).

Therefore \(CF : CA :: AO : AP, 15, 5, E\),

But, \(CF : CA :: AP : AG, Def. XXIV.\)

Therefore \(CF : CA :: AO : GP, 15, 5, E\).

But, as has been shown in the demonstration of the last proposition, \(AO = MF\), and \(GP = MK\); therefore

\[
CF : CA :: MF : MK.
\]

But the ratio of \(CF\) to \(CA\) is a constant ratio; and it is a ratio of minority in the ellipse, and a ratio of majority in the hyperbola.

**Fig. 55.** In the parabola, \(GA = AF\), and \(4AF \times AP = MP^2, Def. XXIII.\); but, \(4AF \times AP = GP^2 - PF^2\), 8, 2, \(E\); therefore \(MP^2 = GP^2 - PF^2\); and \(MP^2 + PF^2 = GP^2 = MK^2\). Therefore \(MF = MK\).

Most branches of human learning take their origin from a few detached truths, viewed at first without connexion, and which, in the progress of knowledge, are at length joined together in one body of science. But when a science has risen, by accumulated discoveries, to such a degree of importance as to interest the curiosity of mankind, it is often too late to retrace its history, and to delineate its rise and progress in an accurate and satisfactory manner. It generally happens that the authors of many of the subordinate discoveries have already fallen into oblivion; and that some important improvements are disputed, and ascribed to different inventors by different writers. In reviewing the history of the conic sections, we must add, to the canons which commonly obscure the origin of all the sciences, the very high antiquity of this branch of the mathematics, and the lofs of the early geometers who have written on it. No work of antiquity that professedly treats of the history of the conic sections has reached our time; and there is little to satisfy curiosity in this inquiry, excepting a few incidental notices collected from different authors.

The discovery of the curves, denominated the conic sections, is attributed to the philosophers of the school of Plato; and it is even ascribed, by some authors, to the founder, himself, of that celebrated sect. Other authors, grounding their opinion on a few words in an epigram of Eratosthenes, have given the honour of this discovery to Menæchmus, who lived a little posterior to the time of Plato. But the information derived from ancient writers is too scanty to enable us to decide concerning the original discove-
CONIC SECTIONS.

ten is eight books, and it was esteemed a work of so much merit by his contemporaries as to procure for its author the title of the great geometer. The purpose of the four first books, as we are informed in the preface epistle to Eudoxus, is to deliver the elements of the science: and, in this part of his work, Apollonius professes only to have collected and methodized what had already been published by former writers. One improvement introduced by him deserves to be particularly mentioned; as it is a curious instance of the progress of the mind in generalizing its first conceptions. The conic sections, according to the definitions now given of them, are such curves as are produced by the common section of a plane and a cone of whatever kind. But the first mathematicians who noticed these curves, did not define them in a way to general. They confined their attention to the right cone only; and, even in this kind of cone, they always supposed the cutting plane to be perpendicular to the slant line. In this view of the matter it is manifest, that the species of the curve would depend on the fort of cone by which it was produced. If the vertical angle of the cone were supposed to be an acute-angle, then the cutting plane, perpendicular to the slant line, would meet one of the conic surfaces only, and the line of common section would form the whole, and would be an ellipse. If the vertical angle of the cone were supposed to be a right-angle, then the cutting plane would still meet only one of the conic surfaces, but the line of common section, not embracing the whole contour of the solid, would, in this case, be a parabola; and, lastly, if the vertical angle of the cone were supposed to be obtuse, then the cutting plane would intersect both the opposite conic surfaces, and the curve produced would be a hyperbola. It is true that the curves, thus defined, were rightly denominated conic sections, considering them as parts of a class; but it did by no means follow that they comprehended all the species of the class. Even retaining the right cone, yet curves of a different nature might possibly be produced merely by varying the inclination of the cutting plane: and much more, if the species of the cone, and the position of the cutting plane, were both changed. To Apollonius belongs the honour of having generalized the ancient definitions of the conic sections, and of presenting the subject in the more perfect form in which it still continues to be taught; and the improvement is equivalent to the discovery that all the possible sections of any cone, are reducible to three distinct species and no more.

Before the time of Apollonius, the names of the several conic sections were likewise different from those that they now bear. In conformity to the ancient definitions of the curves, the ellipse was called the section of an acute-angled cone by the more early geometers: and, in like manner, the parabola, and hyperbola, were denominated the sections of a right-angled, and obtuse-angled, cone. The present names are commonly supposed to have been invented by Apollonius; and, in compliance with the generality of writers, we have noticed the properties from which he derived them. But the received opinion on this point is probably not well founded: for both the terms, parabola and ellipse, occur in the writings of Archimedes, which were prior to the time of Apollonius.

The four first books of the conics of Apollonius is the only part of that work that has come down to us in the original Greek. On the revival of learning, the lovers of the mathematicies had long to regret the loss of the original of the latter part of this important treatise. In the year 1658, Borelli, passing through Florence, found an Arabic manuscript in the library of the Medici family, which he judged to be a translation of all the eight books of the conics of Apollonius. Transported with joy, he had interceded enough to prevail on the Duke of Tuscary to extricate him with the manuscript, which he carried to Rome: and, having procured the assistance of Abraham Ecchederisi, a professor skilled in the Arabic tongue, he published a Latin translation of it in 1661. The manuscript, discovered by Borelli, was entitled, "Apollonii Pergami Libri Octo," and was supposed to be a complete translation of the work of the ancient geometer: but, on examination, it was found to contain the first seven books only. Two other Arabic translations of the conics of Apollonius have been discovered by the industry of learned men: but both of them have the same defect as that found at Florence. From the circumstance of all the three manuscripts agreeing in the want of the eighth book, it is reasonable to suppose that this part of the treatise had already perished when the translations were written: and there is now no room to hope that the loss will ever be recovered. It is not easy to ascertain in what age the original of Apollonius's work disappeared; but we know that the whole of it was extant in the time of Pappus Alexandrinus. In the "Collectiones Mathematicae," this author has given a facsimile account of the contents of all the eight books, and has added the lemmas required for the demonstrations of the propositions they contain: and this circumstance enabled Dr. Halley to annex, to the complete edition of the conics of Apollonius, which he published in 1710, a restoration of the eighth book executed with so much ability as to leave little room to regret the want of the original.

In the four last books of his treatise, Apollonius, as he informs us in the preface epistle, delivers the higher and more abstruse parts of the theory of the conic sections. He here claims the merit of originality, and professes to develop the results of his own researches. And it must be confessed that the genius, invention, and geometrical skill, displayed in this part of his work, are such as fully to justify the honourable appellation bestowed on him by his contemporaries. This treatise must be allowed, even in the present times, to contain a very extensive, if not a complete, theory of the conic sections. This branch of the mathematicies has, perhaps, been more cultivated than any other, since the revival of learning; but the industry of modern mathematicians has discovered few properties of their curves, of which some traces are not to be found in the work of the great geometer. Montucla thus delivers his opinion of the treatise of Apollonius: "Pour donner enfin de l'ouvrage d'Apollonius l'idée qu'il mérite, je remarquerais le grand nombre de son, et qui est un précieux trésor, qui pour le besace de la génération des mathématiciens. Among the number we find the name of the learned Hypatia, the daughter of Theon: and we still possess the lemmas of Pappus Alexandrinus for all the eight books, and the commentary of Eutocius on the four last books. Since the revival of learning, the theory of the conic sections has been much cultivated, and is the subject of a great variety of ingenious works.

3 II 2
There is a relation subsisting between all the parts of human knowledge, which frequently connects speculations the most abstracted, and fome of the most barren, with inquiries that are highly interesting to us, and most fertile in useful consequences. In studying the properties of the conic sections, the followers of Plato sought merely to gratify a contemplative turn of mind. Their researches were chiefly undertaken with the view of resolvering speculative problems; they were directed to no immediate object of practical utility. It excites some degree of admiration, when we reflect that enquiries, purely intellectual, and apparently so little connected with external things, have, in modern times, been employed to explain many of the most remarkable phenomena of the material world. The doctrine of the conic sections is equally useful in the science of optics, and in determining the path of a projectile body. Above all, this branch of mathematics derives its chief importance from the applications that are made of it in modern astronomy.

The uses of the conic sections in physical science have, as it is natural to conjecture, led modern mathematicians to consider these curves under particular points of view suited to their purposes. It is for this reason that the properties of these remarkable points, called foci, have been investigated with so much care in latter times. In optics, these points are almost exclusively the subjects of consideration when the conic sections are concerned; and, in astronomy, the fun invariably occupies one of the foci of the elliptical orbits which the planets and comets describe round him. These points did not entirely escape the penetration of the ancient geometers. Apollonius has anticipated the moderns here, as well as in other parts of this science. He has unfolded many of the most curious properties of the foci, in the ellipse and hyperbola. He treats of them under the appellation of "Puncta ex applicationi facta," which signifies that they are points formed by cutting the transverse axis in the ellipse, and the transverse axis produced in the hyperbola, into two segments containing a right angle equal to the square of half the foci axis; and the phrase is thus equivalent to the modern definitions of the same points. The focus of the parabola is not noticed by Apollonius, nor by any other ancient author; unless, indeed (as has been pointed out to the writer of this article by a friend,) we except a proposition (Theor. 222, Prop. 238.) in the seventh book of the "Collectiones Mathematicae," where Pappus delivers, in the form of a Locus, that beautiful property of the focus, and the corresponding directrix of any conic section, which some modern writers, considering it as characteristical, have made the basis of a definition of the curves in plane. Mydorgius, contemporary with Des Cartes, is the first who treated generally of the foci, of all the conic sections. Since his time the properties of these points have been gradually and fully developed.

Before Dr. Wallis, all the writers on conic sections followed the ancient geometers in making the cone the common origin and foundation of their theorems. That mathematician first entertained the idea of using the conic as little as possible in delivering the elements of the conic geometry; and this plan is pursued in his treatise, published at Oxford in 1655. In support of this innovation, Dr. Wallis urges the probability of Apollonius's work, and the difficulty and perplexed nature of the demonstrations. On the old plan, many propositions respecting the generating of the cone, and the properties of that solid, are to be previously gone through; and the diagrams are rendered confounded by many lines drawn in different planes. On these accounts, he ascertains, that the study of the conic sections was generally neglected: "unde et simile neglecta sibi (conicorum doctrinae), tenuus infacebooki difficilem perspectiva." It must be allowed that the objections of Dr. Wallis are not without foundation. On the other hand, it has been the opinion of some later mathematicians, that the defects of the treatise of Apollonius arise, not from his having made too much use of the cone, but from his having availed himself too little of the assistance to be derived from that solid. They contend that the most general and characteristic properties are first to be sought for in the cone itself; whence they are to be transferred to its sections, as particular cases of more general propositions. The latter, and more approved writers, who have adopted this opinion, are Dr. Hamilton and professor Robison of Oxford. Although Dr. Wallis proposed to introduce the cone as little as possible in delivering the elements of the conic geometry; yet it is to be remarked that he did imitate his predecessors in deriving, from that solid, the fundamental property which he afterwards made the basis of all his reasoning. But the idea, which he introduced, was soon carried further; and treatises on the conic sections were written, in which the cone was entirely laid aside, and the curves were derived from descriptions in their. De la Hire, in his "Nouveaux Elemens des Sections Coniques," published at Paris in 1679, is the first author who successfully treated on the conic sections in this new view of the subject. He derives the description of the parabola from the equality that subsists between two lines meeting in any point of the curve, one of which is drawn to the focus, and the other is perpendicular to the directrix; and he describes the ellipse and hyperbola from the analogous properties, that, in the one, the sum of two lines drawn from any point in the curve to the two foci, and, in the other, the difference of two such lines, are equal to the transverse axes. In these fundamental points De la Hire is followed by most of the later writers, who have treated of the conic sections independently of the cone; and, in particular, by Dr. Simson of Glasgow, who has published an extensive and accurate treatise on this subject. Besides the method of De la Hire, another way of defining the curves in plane has been proposed. It is founded on that general property of the directrix first given by Pappus Alexandria, as we have already noticed above. The learned abbé Bosovich, an excellent Italian mathematician, has drawn his definitions of the curves from this fundamental property in the ingenious treatise on conic sections, published in his "Elementa Mathematica Universelle" and we have two works in our own language, which are founded on the same primary definitions; that of Mr. Newton of Cambridge, and that of Mr. Walker of Nottingham. The doctrine of the conic sections is of great use in physical and geometrical astronomy, and the physico-mathematical sciences. This doctrine has been much cultivated by geometers ancient and modern: and we have many good treatises on the subject; but that published by Mr. Simson, professor of mathematics at Glasgow, deserves to be particularly mentioned, not only for its elegance, but for its geometrical accuracy, which, as he justly remarks in his preface, has not always been so well observed in treatises of this kind, as is ought to be. See also Gregorii a St. Vincenti Opus de Quadratura Circuli, &c. Sectionum Coni; Mydorgius de Sectionibus Conicis; De la Hire de Sectionibus Conicis; Trevigari Elen. Section. Con.; Hamilton's Tract. Geom. de Section. Con.; de l'Hospital's Anal. Treat. of Conic Sections; Muller's Treatise, &c.; Hutton's; and Hallay's edition of Apollonius, &c. Oxon. 1719. fol.

To the properties of the conic sections, mentioned above
above, it may be proper to add the properties of their osculatory circles, or circles of curvature. See **Curvature**.

**Conic sections, similar.** See *Similar.*

**Conic Form of Mountains and Hills.** Too many naturalists have fallen into the mistake, of denouncing mountains or hills which have a conical top, to be of volcanic origin; because, granite sometimes, as Achelous mountain in the Hartz, assumes a conic form, Lopus 17; and porphyry frequently takes this shape. In some rare instances, the rupture of the strata has produced conical hills. See **Elevation of Strata and Volcano**.

**Conica, in Ancient Geography, a town of Aia, in Paphlagonia. Telomy.**

**Conics, that part of the higher geometry, or geometry of curves, which considers the cone, and the several curve lines arising from the sections thereof.**

**Conichthyodontes, or Plectonitis, in Natural History,** one of the three names by which the fossil teeth of fish are known; so called, from their supposed resemblance to the spurs of a fighting cock.

Though authors assure us that there are the teeth of a fish, the jaws have been found with these bodies in them; yet they do not pretend to know to what fish they belong. They are generally of an oblong conic figure, broad at the base, and narrow at the point, where they are usually a little crooked; they are halted at the root, and are from the tenth of an inch to two inches long, commonly of a chestnut colour, and are found in the strata of clay, but most usually in those of flint; and are seen more frequently in England than in any other part of the world. Hill's *Historia*, p. 64:

**Conjecture, in the Philosophy of the Mind, expresses a degree of belief founded upon slight evidence. In some cases, a disposition to conjecture, inconsiderably indulged, may be productive of many extravagancies. It may prompt us to build favourite hypotheses on very weak foundations, and to ascribe the conduct of others to wrong motives, according to our prejudices or against them. When indulged with discretion, a conjecture affords some relief to the mind from the inquietude of ignorance and uncertainty. It provides a temporary substitute for knowledge; and it frequently suggests ideas which lead to the discovery of truth.**

Conjectural criticism, and consequent emendations of ancient authors, classical and scriptural, should be exercised with great caution; otherwise, the imagination will be apt to mislead persons most eminent for their genius and learning.

It is one of the most important, and at the same time one of the most disputed points in sound criticism, says Michaelis, whether what is called "conjectura critica," may be applied to the New Testament; or, in other words, whether in certain cases, and under certain restriction, provided we use all due care and caution, we may reject the readings of all the MSS., versions, and fathers, and merely on a probable supposition, admit a reading that is supported by no written authority; and whether, if we proceed on these principles, we have any reason to expect, that we shall ever arrive at the truth. Many learned men, dejectedly felled in criticism, are of opinion, that conjectures are as allowable at present in the New Testament, as in the classic authors. Yet, however, the majority of divines formerly considered them as presumptuous, if not impious; but those persons who are so frequently attached to the printed text, are not aware, as Wetstein observes, in his *Prolegomena*, that a very great number of readings, which they so zealously support, are merely conjectures, advanced either by the ancient fathers, or by the modern editors of the Greek Testament in the 16th and 17th centuries. These readings must, therefore, be immediately rejected, if critical conjecture is wholly inadmissible. As this question is purely critical, it should be argued, not on theological, but on critical grounds. The argument which is drawn from the hypothesis, that Divine Providence would not permit the true reading in any text of the New Testament to be lost, seems to be very extraordinary, when it is urged by persons who tacitly acknowledge that the same providence has not guarded against the receptivity of conjecture in the Old Testament. Besides, no man can assert, that, because the true reading of any passage is no longer to be found, it is therefore totally lost, since the number of MSS. of the Greek Testament (together with other original documents) which have been actually collated, are trifling in comparison with the whole number that have been written; and a reading, which is now supported only by probable conjecture, may, in process of time, be confirmed by good authority. Moreover, it is by no means diminishes the certainty of our faith, that some few passages of the New Testament have certain internal marks, which discover them to be not genuine, and which render it necessary to restore the true reading by critical conjecture. Our faith would only be in danger, if the number of these passages was so very great, as to render the whole New Testament impious; or, if the principal and distinguishing doctrines of Christianity must be either added to, or taken from, the sacred text, on other authority than that of mere conjecture. But it, we beg to affirm to ourselves the power of altering articles of religion, and confining our emendations to more matters of criticism, we alter some words or sentences, the grounds of our faith are by no means affected, nor need we apprehend any evil consequences. In ancient writings, of which only one copy is extant, critical conjecture is indispensable. The necessity remains the same, even where there are several MSS. if these MSS. are only copies of one and the same more ancient MS. If we have more than a single copy of any work, and those copies are transcripts of different and distinct MSS., the necessity of critical conjecture decreases in proportion to the number of copies; but it does not entirely vanish, unless the number of the MSS. is very considerable. We have, therefore, no reason for cenfuring the critics of the 16th century, if, in their editions of the Greek Testament, they have sometimes, departed from the reading of their MSS., and subliumated such as were agreeable to probable conjecture. The probability, however, that critical conjecture alone can restore the true reading, decreases in the same proportion, as our materials of criticism, or collections of various readings increase. And since so many MSS., works of the fathers, and ancient versions made in distant countries, and in different periods, have been carefully collated; and since also those very ancient Latin versions that vary so considerably from each other, and were translated from very different Greek MSS. have been made known to the public, we might even doubt whether critical conjecture ought not at present to be entirely rejected. It has, however, its learned and zealous advocates. It deferves to be considered, in reply to the plausible objection above fuggled, that we have not a single MS. now extant, that was written in the four first centuries, and that the ancient versions have not defended us without alterations. It is likewise evident, from the writings of the fathers, that many readings were in those times in the Greek MSS., which are not now found in any, or only in a few; having been altered either by accident, or because they appeared to the transcribers to be obscure, or exceptable,
 exceptionable. It is therefore not impossible, that other readings, which have not been preferred in the works of the fathers, or in the Greek MSS., may have been equally bad; and among them, perhaps, some that were requisite. Besides, it is not impossible that there are many important MSS. of which we have no knowledge; and that a collection of those MSS. might confirm the critical conjectures of the 18th century, in the same manner as many conjectures of the 17th century have been confirmed in the 18th, by the authority of MSS., and ancient versions. It might further be added, and it deserves consideration, that all our MSS., and versions of the New Testament, were probably taken, not from the first copies of the Gospels and Epistles, which proceeded from the hands of the Apostles themselves, but from the copies of the several parts of the New Testament. If, instead of 292 MSS. enumerated by Michaelis, we had above 1000, they would still be transcripts of one and the same copy; and if this copy had any errors, which it would be the highest presumption to deny, these errors must have been transmitted into every MS. of the Greek Testament, whatever; and these errors can be remedied only by the aid of critical conjecture. Upon the whole, it appears, that a collection of critical conjectures may be of great use in establishing the genuine text of the Greek Testament; and it is likewise attended with this particular advantage, that we are led by it to examine MSS., and other original documents, with greater accuracy, in order to see whether those readings, which had no other support than conjecture, may not be established by written authority. Such a collection has been published by Bowyer, a learned bookseller in London, the third edition of which, with improvements, was published in London in 1782. Of several hundred conjectures, which Bowyer has produced, there is hardly one, says Michaelis, which, after impartial examination, will not be found probable. On the other hand, it cannot be denied, that there are some few, which bear on them the marks of probability. Several of these are examined by Michaelis, and he has added a variety of his own conjectures, for which he must refer to his work, cited at the close of this article. Besides the critical conjectures already mentioned, there is another kind of conjecture, denominated by Michaelis "theological conjecture," which consists in altering the text of the sacred writings, according to the maxims adopted by any particular party, whether it be the ruling, or the persecuted party, in the church. Although it is allowable to venture a conjecture in matters relating to history, to dates, or to names, as in these cases the Bible is not our only "principium cognoscendi," yet whatever alters the text in subjects which relate to points of divinity, evidently presupposes a "principium cognoscendi," that is prior to the Bible itself; and this is frequently nothing more than a set of principles, which this or that particular person has thought proper to adopt. It has been urged by those who defend theological conjecture, that we ought never to lose sight of the "audio is sola," or analogy of faith. Thus, if two passages in the Bible contradicted each other in matters of faith, the one must be altered. But the question recurs, how shall we determine which of the two is to be altered? "In my opinion," says Michaelis, "we should alter neither, but reject the whole, as not coming from the Deity, if it be true that there are real contradictions, for it is upon this ground, that we condemn the Koran." But every apparent contradiction is not a contradiction in reality; and passages that are seemingly at variance may, with skill and patience, be reconciled. Such is the case with respect to Rom. iii. 28. and James, ii. 24. the whole contradiction vanishing, as soon as we reflect that St. Paul understands faith in Christ, St. James faith in the unity of the Godhead. For other observations on this subject, we refer to the author, Michaelis's Introduction to the New Testament by Michaelis, vol. ii. part. 1. See Criticism.

CONIFERÆ in Botany, the fifteen natural orders in the Philodina Botanica of Link and the fifty-first of the Predictions. In the Philodina Botanica the genera included in it are abies, pinus, cupressus, thuja, juniperus, taxus, sphenia. These are all retained in the Predictions, pines and abies being united, and equifich added with a mark of doubt, and an observation that it has the pollen of flix. The order derives its name from the cones or floribres in which the seeds are contained. The fruit of juniperus, indeed, seems to be a berry, but it is properly a florible, with pulpy scales, which do not open; for it has fix-flabile conneate scales, each containing a single seed. Taxus also apparently bears a berry; but this falle berry is only the flabile receptacle almost covering the seed. All the conifer yield a resin, which renders a mould of them; evergreen. The fruit in all is biennial, produced in the spring, but not ripening and dropping its seeds until the spring after.

The coniferous cones also one of the natural orders of Jafbus, the fifth of his fifteen classes, with the following character: "Flowers monocious or dioecious. Male most frequently in a catkin, or hapsed together upon a catkin, each furnished with a scale, with or without a calyx: the flamous attached either to the calyx, or to the stem. Stamen definite or indefinite in number: filaments sometimes distinct, sometimes united into a flaque or branched stipes. Females either solitary, or capitate, or disposed in a florible or cone, densely imbricated with scales that separate the flowers: furnished either with a calyx or with a scale discharging the office of a calyx. Cone superior, conical, either double or manifold, with as many fyles and frigmas, and either as many seeds, or as many one-seeded capsules. Corema cylindrical, central, in a flixy perigynium, two-lobed; the fyles sometimes, but rarely, divided or palmat, thence appearing many-lobed. Stem a tree or shrub. It contains the following genera: 1. With a flixy perigynium: Calyx, conus, hurus, taxus. II. With only a flixy perigynium, the true conifer: Juniperus, cupressus, thuja, araucaria (Dom. beya). Lannea, pinus, abies. Venetian has the same division and genera, except that he omits araucaria.

CONIGLIANO, in Geography, a small, but populous, town, in the district of Trevinc, in the territory of Venice, which now forms part of the kingdom of Italy.

CONIL, a small town of Spain, in the kingdom of Seville, in Andaluria, on a bay to which it gives name; 15 miles S.S.E. from Cadiz, with a strong castle. Its inhabitants suffice chiefly by fishing. N. lat. 39° 16'. W. long. 6° 8'.

CONIMBRIGA, or Conimbriga, in Ancient Geography, Coimbre, a town of Spain, in Lusitania, on the Monda.

CONIN, or Konin, in Geography, a town of Poland, in the palatinate of Kalis, 15 miles S.E. of Orlic.

CONJOINED, or Conjunct, in Heraldry, a term used for charges in arms when linked together.

CONJOINT, or Conjunctor, is applied in Ancient Muffs, in the same sense as confinant, to two or more founds heard at the same time. See Consonance.

Conjoint degree, two notes which immediately follow each other in the order of the scale; as ut and re.

Conjoint tetrachords, are two tetrachords, where the same chord is the highest of the one, and the lowest of the other.

CONIQUE.
CONIQUE, Fr. This term is applied to a piece of artillery, of which the bore is wider towards the muzzle than it is towards the breech.

CONIRA, in Botany, a name used by some authors for the *murphia*. G. E. Emac. 1d. 2.

CONISALUS, in Mythology, a god of the Athenians mentioned by Strabo, and supposed to be the same with Priapus.

CONISBERG, in Geography. See KONISBERG.

CONISC, in Ancient Geography, a people of Spain, who formed a part of the Cantabri, and in their dress resembled the Gauls, according to Strabo.

CONISIUM, a town of Alm, in Myrrha, according to Pliny. Hierocles calls it *Chionias*, and makes it an episcopal city in the province of the Hellespont.

CONISOR. See GONISOR.

CONISSALIS, in Natural History, the name of a class of fossil bodies; the word is derived from *kabalos*, powder; all the species of bodies of this class being found like common sand, in form of powder, have been usually confused together, under the common name of *fundo*. The conissals are defined to be fossils of a differently debased, crystalline, or sparry matter, but always found in form of small and divided particles, great numbers of which, being amassed together, form a kind of powder.

Of this class of bodies there are two distinct and large genera. 1. The sands properly so called, which are composed of particles all appearing to have a tendency to the same regular figures, transparent, vitrifiable by a strong fire, and not soluble in, or effusing with acids. 2. The *fimmaros*, or grits, of stone found loose; these are found in form of powder, the particles of which, in general, have no tendency to any particular figure, but appear to be rudely broken fragments of larger masses. Hill's Hist. of Foss. p. 543.

CONISTERIUM, a room in the ancient Gymnasia or Palestra, in which was kept the sand for the use of the wrestlers, who were accustomed, after anointing their bodies with oil, to sprinkle themselves with sand to afford a firmer grasp in their encounters.

CONISTON, in Geography, a village in the northern part of Lancashire, in the hundred of Lonsdale. Latitude about 54° 25' lat. and longitude 2° 44' w. It is situated on the steep ascent of a mountain of blue argillaceous schists, near the northern end of a romantic lake, of fix miles in length, and one in breadth, called after its name; near this town some copper-mines are worked, but to no considerable extent, and some veins of lead-ore; slate quarries are also to be found near this place. There is a torrent or mountain stream of water which precipitates itself into the lake near this place.

CONISTORS, in Ancient Geography, a town of Spain in Celtiberia. Strabo mentions it as a very famous town.

CONITZ, or CHONITZ, in Geography, a town of Prussia, in Pomoricia; 40 miles S. of Dantizick.

CONJUGAL RIGHTS, in Law. The suit for "restitution of conjugal rights" is one species of matrimonial causes; which is brought whenever the husband or wife is guilty of "infradiction," or lives separate from the other without any sufficient reason: in which case the ecclesiastical jurisdiction will compel them to come together again, if either of them be weak enough to define it, contrary to the inclination of the other.

CONJUGATE Ant., G. in Conics. See Conic Sections.

CONJUGATE Point, in Geometry. See Point.

CONJUGATES, in Rhetoric, denote words deduced from the same origin with that of the subject: e.g. *he who does justly, is just*.

CONJUGATION, in Anatomy, a term applied by the older anatomists to the nerves coming from the brain, in the same sense that we employ the expression, pair of nerves.

Conjugation, in Grammar, an orderly distribution of the several parts or inflexions of verbs, in their different moods and tenses, to distinguish them from each other; or, the manner in which the personal terminations of verbs are changed to express the several moods and tenses.

The Latins have four conjugations distinguished by the terminations of the infinitive, *are*, *ir*, *ere*, *ire*, and most of the French grammarians reduce the conjugations of their language to the same number, ending in *er*, *ir*, and *oir*. So we have added a fifth Latin conjugation called the *mixt*, because it is composed of the third and fourth, as *architects, accius*.

The Greeks have three kinds of verbs; the first called *baryons*, because the last syllable is pronounced with a grave accent; (see *Barytonum*); such as *tau*, *tend*, and *pias*, verbs; the second are circumflex verbs, which admit a contraction in their termination, and are then marked with a circumflex accent; such as *apta*, *apta*, *amo*: the third kind comprehends the verbs in *&i*, as *mu*, *fim*. Of the first sort there are six conjugations; divided according to their characteristic, i. e. the letter preceding the termination. Accordingly verbs having the labials *u*, *o*, or *e*., form the first conjugation of barytons; those having the gutturals *k*, *g*, *x*, or *x*., the second; those having the dentals *d*, *d*, or *d*., form the third; verbs in *g*, *g*, or *g*, comprehend the fourth conjugation; the liquids *r*, *l*, or *l*, mark the fifth; while those in *a*, *a*, *a*, and *a*, distinguish the sixth conjugation. Of the second there are three, viz.: those in *a*, *e*, *o*, and those in *a*, *e*, *o*, *a*, *u*, *e*, *a*, or *o*, *u*, *o*: all the and the barytonous verbs are conjugated, that is, are varied in the same way to express mood, time, number, and person. Of the third, there are four. But Meffrs. de Port Royal reduce these 13 conjugations to two: viz., one in *a*, comprehending the barytons and circumflex verbs; and the other in *a*.

Mr. I. Jones, in his "Grammar of the Greek Tongue," on a new and improved Plan," has judiciously rejected the fore-mentioned distinctions as unnecessary, because they are useless and unmeaning: and distributed the Greek conjugations into four; viz. the active *a*, its passive *e*, the active *a*, and its passive *e*.

In the Hebrew language there are four conjugations, viz. *kal* with its passive *kipha*, *pela* with its passive *pela*, to which also may be referred *pela*, *pela* with its passive *bela*, and *bela*. The third person singular masculine of the first conjugation is the preterite of the theme; the second conjugation has a *deget* forte in the second radical; the third has the prefix letter *a*; and the fourth, the syllable *a*. In English, where the verbs have scarce any natural inflexions, but derive all their variations from additional particles, pronouns, &c. we have hardly any such thing as strict conjugations.

Some grammarians, however, distinguish English verbs into three conjugations, or classes, distinguished from one another by a peculiar formation in some principal parts belonging to each; and they observe that the three different terminations of the participles, viz. *ed*, of its contraction, *ed*, *ed*, and *ed*, may be considered as the characteristics of the conjugations.
conjugations. But as the verbs of the first conjugation would so greatly exceed in number those of the others; and as those of the third conjugation are so various in their form, and incapable of being reduced to one rule; it seems better in practice, as bishop Lowth judiciously observes, to consider the first in ed as the regular form, and the others as deviations from it: after the example of the Saxon and German grammarians. Lowth's Intro. to English Grammar, p. 124, 1772. Murray's Eng. Gram. p. 90. ed. S. Others again distinguish them by the different inflexion of the first tense in each root, and thus make four conjugations in the active voice: the first has three radicals alike: as I do read, I read; i.e. yesterday; I have read, i.e. just now. The second has the first and third radical alike: as I run, I ran, I have run. The third conjugation has the second and third radical alike: as I esteem, I esteemed, I have esteemed. The fourth has the three radicals different: as I write, I wrote, I have written or erit. The passive voice, being made up of the third radical and the auxiliary verb am, admits of no difference of conjugations. Ward's Essays on the English Language, p. 87.

Conium, in Botany, (conium); Theophrast. Diope. derived by Henry Stephens from conium, the cone of the mathematicians, a name given also, on account of its form, to that well-known children's toy, a top. From this latter sense came the verb conium, which Hefchius explains by πηχευω, implying a capacity to produce a whirling motion; and thence the poisonous herb employed by the Greeks as the means of inducing a capital punishment, was called conium, because it occasioned a fermentation of giddines in the fuller. Linnaeus unaccountably derives the word from conio, disf). Lam. Gen. 136. Schreb. 409. Willd. 52. (Cicuta. Town. 162. Hall. 766. Gart. 117. Lam. Ill. 533. Juif. 223. Vent. 3. 28. Gigl. Lam. Enc.) Cifas and order, penicandria digynia. Nat. Ord. Umbellata; Linn. Umbelliferae; Juif. Vent.

Gen. Ch. Umbel partial, and universal with many spreading rays. involucro universalis, three or many-leaved, short, unequal, membranous towards the base: partial with about three leaves, only half enclosing the pedicels. Cal. feebly perceptible. Cor. Petals five, flexed, heart-shaped, unequal. Stam. Filaments five, about the length of the petals; anthers roundish. Fil. Germ inferior; styles two, short, reflexed; stigma obsolete. Peric. none. Fruit nearly globular, with five crenate ridges; composed of two seeds, which are convex, almost hemispherical, fringed on one side, flat on the other, separating as they become ripe.

Eff. Ch. Partial involucre only on one side, about three-leaved. Fruit nearly globular, with five crenate ridges.

"Seeds striated." Linn. "Stem spotted at the base; furrows of the seeds crenate." Lam. "Seeds without prickles; stem much branched, shining, striated." Dr. Smith. Root biennial, spindle-shaped, often branched, white, fleshy. Stem three or four feet high, ereft, cylindrical, hollow, folowed, smooth, shining, marked with purple spots, much branched, especially towards the top, leafy. Leaves supra decumant, or several times pinnated; bottom ones very large, sometimes two feet long; leaflets oblong, acutely notched, dark green above, pale underneath. Rays of the umbel from ten to twelve; of the umbellule fifteen or sixteen. General involucre commonly many-leaved, deftexed. Petals white, heart-shaped, infefted, nearly equal. The whole plant is narcotic, with a disagreeable smell and nauseous taste. Very different opinions have been entertained with respect to its active qualities, but it may be doubted whether authors have always intended the same plant. Haler was inclined to think, that the plant which was fatal to Socrates and Phocion, was not that now before us, but the cicuta virosa of Linnaeus, which the French writers have called cicutaria. La Marse, on the other hand, believeth that the conium maculatum of Linnaeus, his cicuta magna, is the cicuta of ancient authors, the very plant by which Socrates was poisoned; and forcefully enunciates Linnaeus for changing its name to conium. But if this great botanist had looked into the Greek authors, he would have found that Linnaeus only restored the most ancient name, and that the word cicuta is entirely of Latin origin, unknown to the Greek language. Whether Linnaeus would not have done better, if he had retained the term cicuta, which had been adopted by all the modern botanists before him, is a question to which an affirmative answer may perhaps be given. His cicuta virosa might then, in concurrence with Haler's opinion, have been called conium. But when the change was made and had, through the extensive circulation of the works of Linnaeus, obtained general currency, a revival of the ancient name, instead of removing, has, in fact, increased the confusion. Whatever may have been the plant by which Socrates was judicially murdered, our conium maculatum unquestionably possesses deleterious qualities; but, as Dr. Smith observes, it is happily too nauseous to be incunabally swallowed in any dangerous quantity. See Cicuta in the Materia Medica, where it should have been observed that Plato does not call the plant, by which Socrates perished, cicuta, a word which he had never heard; nor does he give it any Greek name peculiar to it; but constantly uses the very general term Κοινον, which denotes a strong poison either poisonous or medicinal. 2. C. rugosum. Willd. 2. Thum. prod. 50. (C. fullirificum; Berg. cap. 77.) "Seeds wrinkled." Stem somewhat flabby. A native of the Cape of Good Hope. 3. C. rigens. Linn. Mant. 56. Lam. 2. Lam. 2. Willd. 2. Thum. prod. 50. "Seeds somewhat muricate; peduncles furrowed; leaflets channelled, obtuse." Root perennial. Stem purplish, rigid, striated, creft, diffuse, branched. Leaves twice-winged, somewhat feftthy, dented, obtus, crenulate, hard, the colour of ruf; petioles longitudinally channelled. Florus all fertile, white; leaflets of the general involucre five, shorter than the rays of the umbel; one or two divided; those of the little umbels few; a few of them crenate, petiole equal, lanceolate, rolled inwards. Seeds reddish, striated and somewhat muricate. A native of the Cape of Good Hope, on the coast, introduced into England in 1787, by Mr. Aiton. 4. C. africana. Linn. Sp. Ph. 2. Mart. 2. Willd. 4. Juc. Hort. tab. 102. (Cicuta africana; Linn. 3. Ill. tab. 105. fig. 2. Canavilla africana; Boerh. Lugd. h. 1. tab. 62. Capnophyllum; Gart. tab. 85. fig. 6.) "Seeds prickly." Linn. "Seeds muricate; pedioles and peduncles even-surfaced." Willd. "Leaves twice winged, glaucous; petioles and peduncles even-surfaced; seeds tooth-muricate." Lam. Root annual. Sp. three or four inches long, herbaceous, cylindrical, smooth, glaucous; with a few leaves, and one or two short axillary branches. Root-leaves almost as long as the stem; leaflets flat, not channelled, small, gashed. Flowers white, almost regular, in small terminal umbels; leaflets of the general involucre from three to five, membranous towards the base.
Eclipses of the sun never happen, but when there is a conjunction of the sun and moon in or near the nodes of the eclipse.

Conjunction, in Grammar, a particle which expresses a relation or dependence between words and phrases; thus called, because it serves to join or connect the parts or members of a discourse, which is its common use, and also to connect words; so as to shew the relations which those words so united have to other parts of the sentence.

Conjunctions, however, often unite sentences, when they appear to unite only words: e.g. "Durli and interred for bid vicious indulgences," which form of expression contains in reality two sentences. See Murray's Eng. Gram. p. 105, ed. 8.

Mr. Harris defines a conjunction to be a part of speech, void of signification itself, but so formed as to help signification, by making two or more significant sentences to be one significant sentence; and he distributes them into such as connect sentences and their meaning, and such as connect the sentences whist they do join the fence. The former are conjunctive, and are either copulative or connective, the former joining all sentences, however incongruous in signification, and the latter joining only those which have a natural connection; and the latter disjunctive some of which are simple, as either it is day or it is night, and adversative-as, it is not day but it is night. Harris, p. 240, &c. See Adversative a d Consecutive.

Mr. Horne Tooke, in his "Diversions of Purley," has made some remarks, in his usual manner, on the definition of a conjunction given by Mr. Harris, charging the author not only with self-contradiction, but with great want of peculiarity. Accordingly he thus rates Mr. Harris's definition: "A sound significant devoid of signification, (referring to Mr. Harris's definition of a word,) having at the same time a kind of obscure signification; and yet having neither signification nor no signification; but a middle something between signification and no signification, shewing the attributes both of signification and no signification; and linking signification and no signification together." This acute and ingenious writer denies conjunctions to be a separate fort of words or parts of speech by themselves. For they have not a separate manner of signification; although they are not devoid of signification. And the particular signification of each must be fought for from amongst the other parts of speech, by the help of the particular etymology of each respective language. By such means alone can we clear away the obscurity and errors in which grammarians and philosophers have been involved by the corruption of some common words, and the utilful abbreviations of construction. (See Abbreviation.) And, at the same time, we shall get rid of that farrago of uleels dilutions into conjunctive, adjective, disjunctive, fubdisjunctive, copulative, negative copulative, connective, &c. &c. &c., which explain nothing; and (as most other technical terms are abounded) serve only to throw a veil over the ignorance of those who employ them. In disfounding conjunctions from the rank which they have long held as distinct parts of speech, Mr. Tooke cites several authorities; and among others, bishop Wilkins, who, in his "Effay towards a real Character and a philosophical Language," (part iii. c. 4. p. 312), says, "According to the true philosophy of speech, I cannot conceive this kind of words" (speaking of adverbs and conjunctions) "to be properly a distinct part of speech, as they are commonly called. But until they can be distributed into their proper places, I have so far compiled with the grammars of milti- lated languages as to place them here together." Mr. Locke, who was much indebted to Wilkins, expresses his dissatisfaction...
difficult to deal with all the accounts of language which he had seen. Some judgments were made particularly from the number of these mysterious conjunctions, though he left it amongst them: and Servius, Scioppius, C. J. Veslius, Perizionius, and others, have explained and displaced many other suppositious adverbs and conjunctions. "In short," says the author whom we are now citing, "there is not such a thing as a conjunction in any language, which may not, by a skilful herald, be traced home to its own family and origin; without having recourse to contradiction and mythology with Mr. Harris; or, with Mr. Locke, eluding the head of man, to give it such a birth as Minerva's from the brain of Jupiter."

The author's scheme is fully developed in the following table, and the several conjunctions which it exhibits: and he says that

<table>
<thead>
<tr>
<th>If the past participle</th>
<th>and the participle of Seon, To See.</th>
</tr>
</thead>
<tbody>
<tr>
<td>An</td>
<td>or</td>
</tr>
<tr>
<td>Son</td>
<td>or</td>
</tr>
<tr>
<td>Sin</td>
<td>or</td>
</tr>
<tr>
<td>Sis</td>
<td>or</td>
</tr>
</tbody>
</table>

For a farther and ample illustration and proof of the etymologies above given, and several others, we must refer to Tooke's Elia Philothea, or Diversions of Purley, part i. p. 125—287, ed. 2.

The conjunction, according to the long-established classification, is the sixth of the eight vulgar parts of speech. See Speech.

Conjunctions render the discourse more smooth and fluent; and serve very good purposes in the argumentative and narrative style; but they must ever be omitted where a person speaks with emotion, as only serving to weaken and enervate it. Boileau observes, that nothing gives more warmth and life to a discourse than to drop the conjunctions or copulative; a passion, adds he, embarrased with conjunctions and useless particles, loses all the fire and vehemence it would require in its progress.

Conjunctions are of various kinds.

Conjunctions copulative, or conjunctive, are those which express a relation of union or comparison between things; and serve to connect or continue a sentence, as, and, only, as much as, in the same manner as, neither more nor less, insomuch as, not only, but also.

Conjunctions adversative, those which express a restriction, or contrariety; as, but, nevertheless, although, for from. See Adversative.

Conjunctions causal, those which show that the reason of something is alleged: as, for, because, seeing, the rather since, insomuch as.

Conjunctions cunctive, those which denote a consequence drawn: as, for which reason, but then, of consequence, so that, &c.

Conjunctions conditional, are those which import a condition: as, if, if not, on condition that, provided that, in case of. See Conditional.

Conjunctions continuative, those which express a succession, or continuation of the discourse: as, in effect, even, whatever it be. See Consecutive.

Conjunctions disjunctive, those which express a relation of separation or division, or which serve not only to connect and continue the sentence, but also to express opposition of meaning in different degrees: as, neither, whether, or, though, yet, but, &c.

Conjunctions dubitative, those which express some doubt, or tisension of opinion: as, if, that is to say, &c.

Conjunctions exceptive, are, if it be not, unless that, &c.

Conjunctiva Tunicus, in Anatomy, is the membrane which connects the front of the eyelid to the posterior surface of the eyeball. See Eye.

Conjurati Fratres. See Fratres.

Conjuration, in Antiquity, denotes an oath; and conjuratus the name with conjurator, viz. one who is bound by the same oath. Conjurare is used when several persons affirm a thing by oath. Mon. Ang. 7. p. 207.

Conjuration, in Law, signifies the plot or conspiracy, made by persons combining together by oath or promise, to do some public harm. But it was more particularly used, formerly, for having a personal conference with the devil, or some evil spirit, to know any secret, or to effect any purpose. Anno 5 Eliz. c. 16.

It is laid in some of our law books, that the difference between conjuration and witchcraft is, that the former endea- (continued)
there are but medicines and ceremonial forms of words (commonly called charm) without appurition. Covel.

Hawkins, in his "Pleas of the Crown," (l. i. c. 3) says, that conjurers are those, who, by force of certain magic words, endeavour to raise the devil, and obliges him to execute their commands. Witches are such who, by way of conference, bargain with an evil spirit, to do what they desire of him; and forcers are those who, by the use of certain superstitious words, or by the means of images, &c. are said to produce strange effects, above the ordinary course of nature. All these were anciently punished in the same manner as bewitch, by the writ "de Jure et cum beneficio," after a sentence in the ecclesiastical court; and they might be condemned to the pillory, &c. as an indictment at common law, 2 Inst. 44. H. P. C. 32. The president Montesquieu also (Sp. Laws, b. xii. c. 5) marks forcery and hereby together; laying it down, at the same time, as an important maxim, that we ought to be very circumspect in the prosecution of magic and hereby; because the most unexceptionable conduct, the purest morals, and the constant practice of every duty in life, are not a sufficient security against the suspicion of crimes like these. See Witch-craft.

Our fore-fathers were stronger believers in the ridiculous stories that have been generally told concerning witchcraft and forcery than any who live in these more enlightened times, when they enacted by stat. 33 Hen. VIII. c. 8. all witchcraft and forcery to be felony without benefit of clergy; and again by stat. 1 Jac. 1. c. 12. that all persons invoking any evil spirit, or confounding, coveting and with, entertaining, employing, feeding, or rewarding any evil spirit; or taking up dead bodies from their graves to be used in any witchcraft, forcery, charm, or incantation; or killing or otherwise hurting any person by such infernal acts; should be guilty of felony without benefit of clergy, and suffer death. And if any person should attempt by forcery to discover hidden treasure, or to restore stolen goods, or to provoke unlawful love, or to hurt any man or beast, though the fame were not effected, he or she should suffer imprisonment and pillory for the first offence, and death for the second. These acts continued in force till lately, to the terror of all ancient females in the kingdom; and many poor wretches were thus sacrificed to the prejudice of their neighbours, and their own illusions: not a few having, by fame means or other, confessed the fact at the galleries. But though some of the tales that led to these penal statutes still exist among the uninformed vulgar, as the triumph of impotence over credulity, and as bugbear to children, inexcusably employed for this purpose; all executions for this dubious crime are now at an end:—our legislature having at length followed the wise example of Louis XIV. in France, who thought proper by an edict to retrain the tribunals of justice from receiving informations of witchcraft. (See Voltaire's Age of Lewis XIV. c. 29. Mor. Un. H. R. vol. xxv. p. 245.) Yet Voughan's (De Droit Criminal, 351-450.) still reckon up forcery and witchcraft among the crimes punishable in France. With us the above recited statutes against conjuration and witchcraft are repealed; and no prosecution shall be carried on for the future against any person for conjuration, witchcraft, forcery, or incantation: but where persons pretend to exercise any kind of witchcraft or conjuration, &c. or undertake to tell fortunes, or from their skill in any occult science, to discover where goods stolen or lost may be found, they shall be taken upon conviction be imprisoned a year, and stand in the pillory once in every quarter, in some market-town, and may be ordered to give security for their good behaviour, by stat. 9 G. I. II. c. 5.

CONKAIL, in Geography, a town of Hindostan, in the province of Berar, situated between a high rocky hill and the south bank of the Mahanondice river, which riffs at a place called Sowahow, about 7 miles S. of Corkair. The rajah of Corkair has built a fortress on the summit of the hill, and mounted it with two guns.

CONKERE, a port of Shickan Tartary. N. lat. 44° 54'.

CONLIE, a small town of France, in the department of Jura, and chief place of a canton in the district of Long le Saulnier, with 1201 inhabitants. The canton itself reckons 20 communes and 9935 inhabitants upon a territorial extent of 220 kilometres.

CONLIE, a small town of France, in the department of Jura, and chief place of a canton in the district of Long le Saulnier, with 1201 inhabitants. The canton itself reckons 20 communes and 9935 inhabitants upon an extent of 1421 kilometres.

CONLOBONGI, a town of the island of Borneo; 120 miles N. of Banjier-Maffing.

CONN, in Sea Language. See Cond.

CONN, Lough, in Geography, a lake of the county of Mayo, Ireland, which is at the foot of mount Neptune, and extends 9 miles in length, but not more than two in breadth. There is a great number of islands in this lake, some of which are well planted, and being very fertile in fine grass, serve for pastures to sheep and other cattle. That kind of trout called Gilleara, is also found here in abundance. Dr. Shaw observes of these, that they do not appear to be specifically different from the common trout, but by living much on shell-fish, and swallowing small bones at the same time, their homasacquire a much greater degree of thickness, and a kind of muscular appearance, so as to resemble a sort of gizzard. Lough Conn stretches from N. to S. between the Kilbella and Coblefar.

CONNA, in Botany, Rheed. See Cassia Fisfalla.

CONNA, in Ancient Geography, a town of Asia Minor, in the Greater Phrygia. Prolemy. The 6th council of Constantinople places it in Pamphylia.

CONNAC, denotes in Arabia, Palefinne, Barbary, &c. the place, whether covered or not, where travellers or caravans halt or break off their journey for a time, in order to rest and refresh themselves and their beasts of burden. Similar to this was the "malon," or inn (Gen. xii. 27. xliii. 21. &c.) where the sons of Jacob opened their facks to give their fives provender. The appellation Connac in the East corresponds with the παραχων and καταχωμιa in the Old or New Testament, which are rendered inns or hospita. But excepting the caravansaries which may in some measure answer to the παραχων and καταχωμια, there are, properly speaking, no houses of entertainment in Barbary; at least, in the sense usually applied to inns or hospita, i.e. where travellers can be provided with lodgings, provisions, and other necessaries for the night.

CONNAMARA, the name of a district, in the county of Galway, Ireland, noted for the woolen stockings knitted there, and for the wild state of the country. It is in the barony of Bullinahich, and an account of it will be found under that name. See Ballinahich.

Gen. Ch. Cal. one-leaved, with five segments; or five-leaved. Cor. petals five, lanceolate, erect, equal. Stam. filaments ten, awl-shaped, connected at the base, (in pairs, Lam.), alternately larger and smaller; anthers roundish. Pf. germ fingle (except in one species), oblong, villous; style cylindrical; stigma obtuse. Peric. capsule gibbous, one-celled, either two-valved or dithecious on one side. Seel. fingle, large.

Species, I. C. aficanus. Ceylon Sumach. Wildl. 2. (C. monoecarpus). Linn. Mart. 1. Rhus zealyanicus trifoliatus pha- seolus racemus, floribus cyprium (sic); Burm. Zeyl. 196. tab. 89. Phaeseolus arborezens zealyanicus monoecarpus; Rai. Symb. 438. "Leaves ternate; leaves roundish, egg-shaped, one-nerved, veined." A tree. Leaves alternate, petioled; leaves acuminate, quite entire, smooth, equal, petiolated. Raceme erect, terminal. A native of the East Indies. 2. C. pentaphylus. Lam. 1. Wildl. 3. (Cavan. Diff. 7. 376. tab. 225.) "Leaves ternate; leaves roundish, egg-shaped, three-nerved; flowers pentagamous." A tree. Branches cylindrical, smooth, leafy. Leaves alternate, acute, entire, smooth, somewhat coriaceous, finely veined underneath. Flowers small, numerous, in axillary and terminal spikes, forming a kind of paniculate, sessile villous on the outside. Illicium, three to five, villous, short, appearing united at the base; styles shorter than the stamens; stigmas flat or truncate. Described by La Marec from dried epimecia without fruit, communicated by Sonnerat. A native of Madagascar and Guinea. 3. C. africana. Mart. 2. Lam. 3. Wildl. 1. Vahl. Symb. 3. 86. Cavan. Diff. 7. 375. tab. 221. (Omphalobium indicum; Gart. vol. i. 253. tab. 46. fig. 2, and vol. ii. praef. p. 33.) "Leaves ternate; leaves oblong, veined, acuminate." Wildl. "Leaves ternate, leaves egg-shaped, acute at both ends, veined underneath; flowers paniculate, stamens monogyne." Lam. A shrub. Branches cylindrical, smooth. Leaves alternate, petiolated; leaves four or five inches long, smooth, even-surfaced above, veined and veined underneath. Flowers small, numerous; panicle compound, oblong, terminal. Capsule oblong, almost cylindrical, gibbous on one side, pointed at both ends, pedicelled, two-valved. Lam. Capsule valves, dentate on the gibbous or outer side. Seed large, somewhat kidney-shaped, smooth, shining, dark brown-coloured, with an oblong pit on each side; aril incommnen. Filaments, slender, variously lobed, so as to appear curled, its on one side, and the exterior part of the seed. Gart. 4. C. pinnatus. Lam. 2. I1liff. tab. 572. Wildl. 5. Cavan. Diff. 7. 375. tab. 222. (Pericymeigil; Rheed. Mal. 6. 43. tab. 44.) "Leaves ternate and pinnate; leaves oblong, veined; petals with two bristles at the base." Wildl. A tree. Root perennial. Leaves of the fame configuration, and finely veined with those of C. pentagynus. Flowers white, in terminal and axillary panicles; calyx villous on the outside; petals lanceolate, with two remarkable bristles a little above the base, one on each side, pointing downwards, acute and somewhat divaricate; germ fingle, villous. Capsules oblong, gibbous on one side, suddenly narrowed at the base, ending rather abruptly in a point, one-celled. Seed one. A native of the East Indies; described from specimens communicated to La Marec by Sonnerat. 5. C. Santaloides. Mart. 3. Wildl. 4. Vahl. Symb. 3. 87. (Santaloides; Flor. Zey. 428.) "Leaves pinnate; leaves egg-shaped, acuminate; pedicels alternately, aggregate; flowers in racemes. A tree. Branches branch off from the top. Leaves unequally pinnate, scattered, remote, petiolate; leaves sometimes an inch and half long, quite entire, perfectly smooth; shining above; re-

ticularly veined underneath, on very short channelled per-
tioles. Peduncles from four to six together, half the length of the leaf, smooth; partially once, scattered with three or four pedicelled flowers towards the top. A native of the East Indies. 6. C. miniflora. Mart. 4. Wildl. 7. Vahl. Symb. 387. "Leaves pinnate; leaves about twenty-one, oval-oblong, emarginate; racemes axillary." A tree. Branches cylindrical, villous towards the top. Leaves growing near the ends of the branches, alternate, approximating, on slightly villous petioles; leaves opposite or alter-
tate, on very short petioles, inner ones smaller, obtuse, smooth, finely veined on the upper surface, paler underneath. Peduncles axillary, usually three together, the length of the leaves, slightly hoary; pedicels scattered, filiform, the lowest commonly two-flowered. Flowers small, with a minute bracte at the base of each pedicel. A native of the islands of Nicobar.

Connaurus decumbens; Wildl. Vahl. See Hermannia triphylla.

Propagation and Culture. C. aficanus is usually propagated in this country by laying down the young branches, which, if tongue in the manner practiced for carnations, and duly watered, will put out roots in twelve months. They may then be cut off from the old plants, and planted in separate small pots which should be filled with light fresh earth and plunged into a moderate hot-bed. They should afterwards be placed in a dry loft; but for about three months in summer they will bear the open air in a sheltered situation. The cuttings of this plant will sometimes take root, but without great care seldom succeed.

Connata folia. See leaf.

Connaught, in Geography, the name of the western province of Ireland, which contains the counties of Galway, Mayo, Sligo, Leitrim, and Roscommon. At the time of Strong-

bow’s invasion, it was a distinct kingdom, and its king was monarch of Ireland. This dignity continued until the reign of Henry III. after which time, the province was divided amongst petty chiefains, some of whom were of English extraction, until the reign of queen Elizabeth, when the earl of Suffolk, lord deputy, divided it into counties, A. D. 1503.; and Sir H. Sidney, lord deputy, established a lord president of Connaught, A. D. 1517. In 1604, Sir Arthur Chichele, lord deputy, established a circuit for judges of assize in Connaught. At present, the distinction of pro-

vinces is not attended to in any public acts; and indeed, as calculated to keep up a provincial spirit, which has often led to bitter animosities, it ought to be as much as possible disconsolenced.

Connaught Warm. See Warm.

Connaux, in Geography, a town of France, in the department of the Gard, and district of Uzes; three leagues N.E. of Uzes.

Conn, Cone, or Cow, in Geography, the county of Down, Ireland. See Strangford.

Connaught, and also Ashlada, are small rivers of America, in the state of Ohio, which form good harbours for boats and small craft on the borders of Lake Erie.

Connecticut, one of the United States of America, called by the ancient nations Squamicut, lying between 41° and 43° 2' N. lat., and between 71° 20' and 73° 15' W. long.; extending in its greatest length 100 miles, and great-

eth breadth 72 miles; and comprehending about 4074 miles, or about 2,640,000 acres. It is bounded on the north by Massachusetts; on the south by Rhode Island; and on the south by the Sound, which separates it from Long Island; and on the west by the state of New York. Connecticut is divided into eight counties, viz. Fairfield, the chief towns of which are
are Fairfield and Danbury; New Haven, with a capital of the
same name; Middlesex, the chief towns of which are
Middleton and Haddam; and New London, the chief towns
of which are New London and Norwich; which four coun-
ties extend along the Sound from W. to E.: Litchfield,
Hartford, Tolland, and Windham, each having a capital of
the same name respectively, which four counties extend
in the same direction with the border of the State of
Massachusetts. The first counties contain about 100 towns-
ships, which are subdivided into parishes, each of which has
one or more places of public worship, school-houses at con-
venient distances, and a college at New Haven. See Col-
lege. Each township is a corporation, invested with suffi-
cient powers for its own regulation. The number of repre-
sentatives is sometimes 180; but more commonly about 160.
The principal rivers in this State are Connecticut, Housat-
nick, and the Thames, with their branches; which see
respectively. The whole sea-coast is inhabited with harbours,
which are safe and commodious; but the principal are those
of New Haven and New London. This State lends seven
representatives to Congress. The inhabitants are almost
wholly of English descent, besides whom they have no
Dutch, French, or Germans, and few Scots or Irish. The
original stock, from which have sprung all the present occu-
piers of Connecticut, and the numerous emigrants from
hence to every part of the United States, consist of 3000
persons, who settled in the towns of Hartford, New Haven,
Windorf, Guilford, Milford, and Weathersfield, about the
year 1635 and 1636. In 1756 the population amounted to
120,611 persons; in 1774 to 197,856; in 1782 to
202,877 whites, and 6273 Indians and negroes; in 1790 to
237,946, of whom 27,662 were slaves; and by the census in
1800, to 251,002, of whom 121,113 were free white males,
123,528 free white females, 5300 free persons, except In-
dians, not taxed, and 951 slaves.

Connecticut, notwithstanding the changes of temperature
to which it is subjected, is very healthful. The surface of
the country exhibits mountains, hills, and valleys; and though
it is very well watered, some small parts of it are barren.
Its chief productions are Indian corn, rye, wheat, oats,
barley, and buck-wheat; flesh in abundance, some hemp,
potatoes of several kinds, pumpkins, turnips, peas, beans,
&c., together with fruits of all kinds which are com-
mon to the climate. The soil is well adapted for pasture
and moving, so that the farmers are enabled to feed a great
number of neat cattle and horses. This State carries on its
chief trade with the West Indies, in vessels from 60 to
140 tons. Its exports consist of horses, miles, oxen, oak-
leaves, hoops, pine-boards, oak-panks, beans, Indian corn,
fish, beef, pork, &c.; and a large number of coalings ves-
fels is employed in carrying the produce of Connecticut to
the other States; from which they receive in return, rice,
d pronounce, and money. But as New York is nearer, much
of its produce, particularly that of the western parts, is carried
thither; such as pot and pearl-ashes, flax-seed, beef, pork,
cheese, and butter, in large quantities. The value of the
whole exported produce and commodities from this State,
before the year 1774, was then estimated at about 200,000,
lawful money, annually. In the year ending September
30, 1791, the amount of foreign exports was 710,340 dol-
ars, besides articles carried to different parts of the United
States to a great amount; in 1792 it was 740,925 dollars;
in 1793, 770,239 dollars; in 1794, 806,746 dollars; and in
1804, 1,516,110 dollars, comprehending 1,486,882 domes-
tic and 29,228 foreign. This State owns and employs in
the foreign and coating trade more than 33,597 tons of
shipping. The farmers in Connecticut are generally clothed
in plain, decent, homespun cloth; and both their linens and
woollens are domestic manufactures, strong though coarse;
and many of their cloths are fine and handsome. This State
has large orchards of mulberry trees, and silk-worms have
been reared with such success, that they promise a supply of
silk, not only to the inhabitants, but also for exportation.
New Haven has linen and button manufactories; they have
established a woolen manufactory at Hartford, besides glis
tones, a flax and powder mill, iron works, and a filleting
mill. Iron works are also established at Salisbury and Nor-
wich, and in other parts of the State. Stafford has a furn-
ace, at which are made large quantities of hollow ware,
and other ironmongery, sufficient for the supply of the
whole State. Paper is manufactured at Norwich, Hartford,
New Haven, and in Litchfield county. Ironmongery, hats,
candles, leather, shoes and boots are manufactured in this
State.

Connecticut is laid out in small farms, from 50 to 300
and 400 acres each, which are held by the farmers in fee-
simple, and are generally well cultivated. The State is
chequered with innumerable roads or highways, crossing
each other in every direction; nor can a traveller pass more
than two or three miles, even in the most unfrequented parts,
without finding a house, or cottage, and a farm in such a
condition of improvement as to afford necessities for the sup-
port of a family. The whole State, it is said, refines a well-cultivated garden, which by industry produces the ne-
cessaries and conveniences of life in great plenty, without its
luxuries. To the agricultural mode of life prevailing in this
State with which a comfortable subsistence may be obtained,
so encouraging to early marriage, and also to the religious
liberty that is maintained, we may ascribe the rapid ad-
vance of this State in population. Luxury has not yet found
its way into this State, nor contaminated the manners of
the people. The common mode of travelling, both for men
and women, is on horseback; in this State there are few
coaches, but many chaises and whiskeys. In the winter is
used the sleigh, which is a vehicle drawn by two horses, and
carrying six persons in its box, which hangs on four poles
standing on two feet riders, or large skates. Dancing,
shifting, hunting, skating, and riding in sleighs on the ice,
are the chief amusements in this State. The men, in gen-
eral, throughout this province, are tall, stout, and robust;
the women are fair, handsome, and genteel; strictly virtuous,
and well-informed. We may observe, in general, that there
is no part of the world in which the education of all ranks
of people is more an object of attention than in this State.
Almost every town is divided into districts, each of which
has a public school kept in a manner a great part of the
year. Somewhat more than one-third of the money arising
from a tax on the polls and rateable estate of the inhab-
its, is appropriated to the support of schools in the several
towns, for the education of children and youth. The law
enjoins that a grammar-school shall be kept in every county-
town throughout the State. A certain gravity and serious-
ness of deportment, accompanied with a degree of stately
and reserve, appear in the full intercourse of the inhabitants
with strangers; but after a short acquaintance, they become
very familiar and inquisitive. Their hospitality is exemplary
and laudable. In their character there is a certain trait,
which renders them lefts amiable; and that is their fondness
for settling their trivial disputes "according to law;" and the
prevailence of this litigious spirit affords employment for
a numerous body of lawyers. This party spirit is,
however, subduing; their public proceedings are conducted
with calmness and candour; and as they are well informed
with
with regard to their rights, and judicious in the methods they adopt for securing them, the state enjoys a great share of political tranquility. Another circumstance, favourable to internal peace and harmony, is the abatement of that rage for theological disputations which formerly prevailed. The religion, or at least the church government and discipline, of this state, is such as favors to be peculiarly adapted to a republican government. Each church has a separate jurisdiction, and claims authority to chuse its own minister, to exercise judgment, and to enjoy religious institutions, within itself. The churches, however, amounting, feys Morse, to about 250, of the congregational denomination, in which are about 25,000 communicants and 175 pastors, are not strictly independent of each other; they associate for mutual convenience and benefit. The associations have power to license candidates for the ministry, to consult for the general welfare, and to recommend the adoption of measures by the churches, but have no authority to enforce them. Of these associations there are eleven in the state, and they meet twice in a year. All these are combined in one general association formed in 1709, consisting of delegates from the several associations which meet annually. All forms of religion that are consistent with the peace of society are tolerated in Connecticut; and a spirit of liberality and catholicism is said to be increasing. In this state there are few religious sects; the majority of the people consist of congrutationalists. But of these, there are episcopalians and baptists; the episcopal church is recent and by the superintendence of a bishop.

The constitution of Connecticut is founded on its charter, which was granted by Charles II. in 1662, and on a law of the state. Agreeably to this charter, the supreme legislative authority of the state is vested in a governor, deputy-governor, 12 councilors or councillors, and the representatives of the people, styled the General Assembly. The governor, expected-governor, and councilors, are annually chosen by the freemen in the month of May. The representatives (whole number not to exceed two from each town) are chosen by the freemen twice in a year, to attend the two annual sessions, on the second Tuesday of May and October. The general assembly is divided into two branches, called the upper and lower houses: the former is composed of the governor, deputy-governor, and councilors; and the latter consists of the representatives of the people. No law can pass without the concurrence of both houses. They have several law courts, of which the superior consists of five judges. The general assembly only have power to grant pardons and reprieves; to declare commissions of bankruptcies; or to protect the persons and estates of unfortunate debtors. The feudal system of sequestrations was never adopted in this state: the whole real estate of intestates is divided equally among the children, males and females; and all estates given in tail must be given to some person then in being, or to their immediate issue, and shall become fee-simple estates to the issue of the first donee in tail. The widow of an intestate is entitled to a third part of the personal estate for ever, and to her dower, or third part of the houses and lands belonging to the intestate at the time of his death, during her life. Attorneys are admitted and qualified by the county courts. Before their admission to the bar, they must study two years with a practising attorney in the state, if they have had a college education, and three years if they have not: their morals must be unblemished, and they must be examined by the attorneys of the court of the county where they are admitted, and be by them recommended to the court. There are, upon an average, about 13 attorneys to each county, and 150 in the whole state.

The American revolution, which so essentially affected the government of most of the colonies, produced no very perceptible alteration in the government of Connecticut. While under the jurisdiction of Great Britain, they elected their own governors, and all subordinate civil officers, and made their own laws, in the same manner, and with as little control, as they now do.

The present territory of Connecticut, at the time of the first arrival of the English, was peopled by the Pequots, the Mohegans, Podunk, and many other smaller tribes of Indians. The Pequots were numerous and warlike; and their country extended along the south coast from Pauktuck to Connecticut river; and about the year 1632, this powerful tribe extended its conquests over a considerable part of Connecticut, Long Island, and a part of Narragansett, the ancient Indian name of New London; the seat of the sovereignty of the whole nation was Pequot. The Mohegans were numerous, and their territory extensive; it comprehended most of New London county, almost the whole county of Windham, and a part of the counties of Tolland and Hartford. The Podunk inhabited East Hartford, and the adjacent country. In 1774 there remained of the descendants of the ancient nations on the 1603 persons; most of whom lived at Mohegon, between Norwich and New London. From the rapid decrease of the Indians, it is concluded that their number in this state does not now exceed 400.

The first government of Connecticut was made by the Plymouth council to the Earl of Warwick in 1632; and, in the following year, he assigned this grant to lord Say or Seal, lord Brook, and others. In 1652, an attempt was made on the English settlements by a number of Indian traders, who settled at Windsor. In the same year, a little before the arrival of the English, some Dutch traders settled at Hartford, the remains of whose settlements are still visible on the banks of Connecticut river. In 1634, lord Say and Seal, &c. sent over a small number of persons, who built a fort at Sibbybrook, and made a treaty with the Pequot Indians for the lands on Connecticut river. A number of adventurers afterwards settled in this province; and in 1634, they purchased of the agent of lord Say and Seal, and lord Brook, their right in the colony of Connecticut for 1600/. Connecticut and New Haven continued two distinct governments for many years; they extended their territories and rapidly increased. At length, John Winthrop, esq., who had been chosen governor of Connecticut, was employed to solicit a charter, which was obtained from Charles II. in 1662. Some jealousy was excited for a little while between this colony and that of New Haven; but 1665, these two colonies formed an union, which has ever since amicably subsisted; and the charter of king Charles continues to be the basis of their government. At the close of the revolution, Connecticut ceded all her charter claims west of Pennsylvania to Congress, referring only a tract of land as wide as the state of Connecticut, and 120 miles in length; bounded east on the western line of Pennsylvania, and north by lake Erie, containing nearly four millions of acres. The cession was accepted by Congress, which cedes to Connecticut her title to these lands. Morse's Geog.

Connecticut, the most considerable river in the eastern part of the United States, which rises in the highlands which separate the states of Vermont and New Hampshire from Lower Canada. This river has been surveyed about 25 miles beyond the 45th degree of latitude to the head spring of its northern branch; from which to its mouth it is upwards of 300 miles, pursuing its course through a settled country, and having on its banks a great number of the most flourishing and pleasant towns in the United States.
It is from 80 to 100 rods wide, at the distance of 130 miles from its mouth. Its course between Vermont and New Hampshire is generally S.S.W., and also through Massachusetts, and part of Connecticut, until it reaches the city of Middleton; after which it runs in a S.S.E. direction to its mouth, fertilizing the lands through which it flows, though its navigation is much obstructed by a great variety of falls. At its mouth also is a bar of sand, which very much impedes its navigation; however this river is navigable to Hartford city, upwards of 50 miles from its mouth; and the produce of the country for 200 miles above it, is brought thither in boats, which are flat bottomed, long and narrow, and so light as to be portable in cars. Before the construction of locks and canals on this river, they were taken out at three different carrying places, all of which made 15 miles; but these obstructions will, probably, be soon wholly removed. Sturgeon, salmon, and shad, are caught in plenty in their feaon, from the mouth of the river upwards, excepting angler, which do not ascend the upper falls; besides a variety of small fish, such as pike, carp, perch, &c.

Connecticut is also the name of a stream in Long Island, in the state of New York, which falls into a bay at the S. side of the island.

Connecting Oil. See Oil.

Connection, cr Connexion, a relation whereby one thing adheres to, or depends on another.

Eucild's propositions have such a connection among themselves, that the latter cannot subsist without the former.

Connection, or continuity, in the Drama, consists in the joining of the several scenes together.

When the scenes of an act succeed one another immediately, and are so joined as that the stage is never left empty, the connection is said to be observed.

Connectives, in Grammar, one of the four species under which, according to Mr. Harris, all words may be included. They are of two kinds, and as they connect sentences or words, are called by the different names of Conjunctives and Prepositions. Hermes, p. 311, and 237.

Connectsville, in Geography, a town of America, in the county of Washington and state of Pennsylvania, pleasantly situated on the Ohioginay, settled about ten years, and containing about 80 houses and 400 inhabitants.

Conner, A. See Ale-Conner.

Connere, in Geography, a town of France, in the department of the Sarthe; 4 leagues E.N.E. of Le Mans.

Connectable or Connétable de France, contable of France. In the origin of this title, the connetable, who succeeded the grand seigneur of France, was considered as one of the first demesnes of the French kings, in short as master of the hawks. Afterwards he became the first officer of the crown, chief and conductor of the armies, first ferjeant of the king for executing his orders and commands; for laying hands on the grandees, imprisoning them, and representing them in justice. This employment became by degrees so eminent, that the marshals of France were only lieutenants. This office was abolished in the reign of Louis XIII. Anne de Montmorency, who lost his head on a scaffold, was the last who filled it.

Connétable de France. This was a particular corps under the orders of the seigneors marshals of France, and consisted of 48 guards on horseback.

Connie, in Geography, a small river of France, in the department of Eure and Loir, remarkable for being so completely dried up in winter, that the fish are obliged to hide themselves in the cavities where there is a little water remaining; in summer, on the contrary, its stream is always copious.

Conneventes Valvule, in Anatomy, are folds of the internal, or villous coat, of the small intestine. See Intestine.

Connoie Bay, in Geography, a bay on the S. coast of Newfoundland, 50 miles E. of Cape Bay.

Connoisseur, a French term, of late use in English; it literally denotes a person well verfed in anything; being formed of the verb connaitre, to know, understand. Hence it comes to be used in our language as a term, or person who is a thorough judge, or master in any way, particularly in matters of painting and sculpture.

Connon, in Geography, a river of France, called also Aa, which runs into the Beuvron, six miles S.E. of Beuvron.

Connor, Bernard, in Biography, a native of Dublin, in Ireland, where he was born in 1666, received his education at an academy in France, and at a proper age was sent to Montpelier, where he was made doctor in medicine in the year 1690. He was soon after engaged to superintend the education of two young Polish noblemen, with whom, after residing some time at Paris, he travelled over Italy, and the island of Sicily, and then went to Poland, where he was appointed physician to the king. This did not, however, detain him long in Poland, as we find him practising in London, and made fellow of the College of Physicians, and of the Royal Society, in the year 1696. He had published, the preceding year, "Diferentiarum Medicop-Physicarum de Antiquis lecitarns, de Montis Vefuvii incendio, de lupendo offium coelain,. OXONI, 1696." He had seen, while in Italy, an eruption of Mount Vesuvius, and had visited the Grotto del Cano, of both which he gives descriptions, and of a skeleton, in which the vertebrae, ribs, and osa innominata, were all firmly united. "Tentamen Epistolare de Secretione Animalium," in which he attempts to account for the difference in the colour, taste, and other sensible qualities of the humours, secreeted from the blood. "Evangelium Medicum, feu Medicina MyFFica de sufpenfis Naiure legisb, Lond. 1697, 8vo." and in 1698, in the latter part of which year he died, "A Compendious Plan of the Body of Physic," apparently a text-book, from which he had given, or had proposed giving, a course of lectures. To this work he added, a short, but entertaining, account of Poland. Haller. Bib. Med. Eloy. Dict. Hum.

Connor, in Geography, a village in the county of Antrim, Ireland, that gives name to a bishopric which was united to that of Down in 1454, and which extends over most of the county of Antrim. It contains 395,000 Irish acres, which are divided into 76 parishes; but from unions, there are only 40 benefices and 45 churches. The church of Limalburn, was, by letters patent of James I, made the cathedral, that of Connor is in ruins. Connor is 67 Irish miles N. from Dublin, and 17 N. from Belfast. Beamont.

Connor, a river of the island of Jamaica, which runs into the sea, between Rocky point, and port Morant.

Connthal. See Caverium.

Cono, in Commerce, a Florence wine measure of 10 barrels, each barrel being about 12 gallons.

Conobea, in Botany, Abbr. See Conopea.

Conocarpedendor. See Protea and Pius.

The text appears to be a natural reading of a botanical description. It includes descriptions of flowers, leaves, fruit, and distribution. The text is relatively self-contained, discussing the characteristics of a particular plant species. The language used is formal and technical, typical of botanical literature. The text mentions features such as flowers, leaves, fruit, and distribution, providing a detailed description of the plant in question.
their common intersection being $AC$; let $GH$ be any other line meeting the generating section in $G$ and $H$, and intersecting $AC$ in $E$; and erect $EF$ perpendicular to the plane $ABC$ and meeting the proposed plane in $F$. Then, if $AC$ and $GH$ be conceived to move continually to themselves, the rectangle $AE \times EC$ be to the rectangle $GE \times EH$, always in a constant ratio; but if $GH$ be perpendicular to $BD$, the points $G$, $E$, $H$ will be in the circumference of a circle whose diameter is $GH$, so that $GE \times EH = EF^2$; consequently, $AE \times EC$ will be to $EF^2$; always in a constant ratio; and therefore $ACF$ is a conic section, and every section parallel to $AFC$ will be of the same kind with, and similar to it.

Hence.

1. The above constant ratio, which $AE \times EC$ has to $EF^2$, is that of $K\mathfrak{t}$ to $L\mathfrak{t}$, the squares of the diameters of the generating section respectively parallel to $AC$, $GH$; that is, the ratio of the square of the diameter parallel to the section to the square of the revolving axis of the generating plane. This will appear, by conceiving $AC$ and $GH$ to be moved into the positions $KL$, $MN$, intersecting in $I$, the centre of the generating section.

2. It appears also that the axis $AC$ and $2EF$ of the section, supposing $E$ now to be the middle of $AC$, will be to each other, as the diameter $KL$ is to the diameter $MN$ of the generating section.

3. If the section of the solid return into itself, it will evidently be an ellipse. This always happens in the spheroid, except when it is perpendicular to the axis; which position is also to be excepted in the other solids, the section being always a circle; in the paraboloid, the section is always an ellipse, excepting when it is parallel to the axis; and in the hyperboloid, the section is always an ellipse, when its axis makes with the axis of the solid an angle greater than that which the said axis of the solid makes with the asymptote of the generating hyperboloid: the section being an hyperbola in all other cases, except when those angles are equal, and then it is a parabola.

4. If the section be parallel to the fixed axis $BD$, it will be of the same kind with, and similar to, the generating plane $ABC$; that is, the section parallel to the axis, in a spheroid, is an ellipse similar to the generating ellipse; in the paraboloid, the section is a parabola similar to the generating parabola; and in an hyperboloid, it is a hyperbola similar to the generating hyperboloid of the solid.

5. In the spheroid, the section through the axis is the greatest of the parallel sections; in the hyperboloid, it is the least; and in the paraboloid, all the sections parallel to the axis are equal to one another. For the axis is the greatest parallel chord line in the ellipse, but the least in the opposite hyperbolas, and all the diameters are equal in a parabola.

6. If the extremities of the diameters, $K$, $L$, $M$, $N$, be joined by the line $KN$, and $AO$ be drawn parallel to $KN$, and meeting $GEH$ in $O$, $E$ being the middle of $AC$, or $AE$ the semi-axis, and $GH$ parallel to $MN$; then will $EO$ be equal to $EF$, the other semi-axis of the section. For, by similar triangles, $K:1 = IN::AE:EO$. Or, upon $GH$ as a diameter describe a circle meeting $E$, perpendicular to $GH$, in $Q$; and $EQ$ is evidently equal to the semi-diameter $EF$.

7. If $AP$ be drawn parallel to the axis $BD$ of the solid, and meet the perpendicular $GH$ in $P$, it will be evident that, in the spheroid, the semi-axis $EF = EO$ will be greater than $EP$; but in the hyperboloid, the semi-axis $EF = EO$ of the elliptic section, will be less than $EP$.
pay; the general hastened to the court of Persia, but was not followed to approach the sovereign, unless he submitted to a species of adoration very strange to a noble and dignified mind; this he resisted, and though denied an audience with his majesty, his remonstrances produced the desired effect, and he was allowed to nominate his own treasurer to the fleet. Conon refused his command, attacked the Spartan admiral Pheidon, whom he killed with his own hand; the Spartans were defeated with the loss of fifty ships, and the rest were glad to seek shelter in one of their own ports.

Conon, having thus obtained the dominion of the sea, returned to Athens with plans for restoring his country to its former honours. Scarcely had he begun his operations when he was accused of a misapplication of the royal money, and was apprehended for that and other crimes, for which there appears to have been little or no foundation. He did not, however, survive the accusation; but the manner and particular time of his death are not known, though it was suspected that he was safely murdered in prison.

Plutarch. Univ. Hist.

Conon, a mathematician of considerable celebrity at Samos, flourished about three centuries, and died about the year 223 B.C. He was a contemporary and friend of Archimedes, to whom he communicated his writings, and solved some problems, which Archimedes received with approbation, willing them to be published during the lifetime of his author, in order that from them they might receive a just demonstration. Conon made many observations on the eclipses of the sun and moon, and gave the name to the constellation called Coma-Berineses. His death happened during the period when Archimedes flourished, whose eulogium for his friend has come down to the present times: speaking of his great genius, he asks: "How many theorems in geometry, which to others seemed impossible, would, had Conon lived, have been brought to perfection?" Conon invented a spiral, the properties of which having been demonstrated by Archimedes, it has obtained the name of Archimedes's spiral. He is referred to with respect in the writings of Propertius and Virgil. Hutton. Moreri. See Conic Sections.

Conon, Porz, was by birth a Thracian, and educated in Spain, from which place, where he was ordained presbyter. Upon the death of pope John V., the disputes respecting a fiscullor ran so high, that for three months the papacy was vacant: the clergy espousing the interests of one candidate, and the army declaring for another. At length Conon was fixed upon, who proved acceptable to all those in whom the appointment was vested. He ascended the pontifical throne in the year 686, and died in about a year, but left behind him a character rarely attained by those who have filled that high station. His piety, learning, integrity, and fluavity of manners, were exemplary, and justly celebrated. There was also a cardinal of this name, a native of Germany, and advanced to his high rank in the church by pope Pafcal II. He was the avowed and intrepid defender of the high claims of the Roman see, and, on this account, fetected as a proper person to preside at the council of Jerusalem, in which Henry V., emperor of Germany, was excommunicated, for not submitting to the pope's allured right to the interdicture of bishops and abbots. He was afterwards legate at the council of Soissons, in the year 1141, when the death of the celebrated Adlard, on the Unity of God, was so wrung as to be burnt. Conon, it is believed, might have been elected to the popedom on the death of Gelarius, an honour which he declined for motives not now known. His own vote and interest he gave to Guy, archbishop of Vienne, who was elected pope, and assumed the name Callistus II. Moreri.

CONONIS A.R., in Ancient Geography, a place of Ethiopia, upon the Arabian gulf, according to Strabo; near port Main.

CONONITIS, in Ecclesiastical History, the followers of Conon of Alexandria in the sixth century, resembling in their opinions the Armenian, Thodosiani, and Triphians.

CONOPA, in Ancient Geography, a lake of Greece, in Etolia, afterwards called Gynea — Allo, a town of Greece, in Acarnania, according to Steph. Byz. and Polybius. Strabo says, that the town of Allo was, which he places in Etoia, had in former times been called Conopa.

CONOPEA, in Botany, (esp. in sect. a.) a seed, or to keep off gnats), Mart. (Conobea; Wild. Jull. 97. Abrl. Guian. 2. 630. tab. 257.) Clafs and order, didynamia angustiformia. Nat. Ord. Leguminosae, Jull.

Gen. Ch. Cal. perianth one-leafed, five-angled, permanently five-cleft; segments somewhat egg-shaped, acuminate, erect. Cor. one-petalled, ringent; tube oblong, gradually widening; border two lipped; upper lip erect, emarginate; lower lip trident, the middle segment larger, concave. Stam. filaments four, attached at the bottom, to the tube of the corolla; anthers arrow-shaped, Fl. Germ. roundish; style filiform, hairy; Stigma two-lobed. Peric. Capsule roundish, one-celled, four-valved. Seeds numerous, small, fixed to a roundish receptacle.

Species. C. aquatica, a creeping plant, growing naturally near water, spreading over its surface, and the grains near the banks, throwing out small fibrous roots from the joints. Stems and branches square, each angle bordered by a very sharp ring. Leaves at each joint, opposite, embracing the stem, kidney-shaped, plated at the nerves, undulated at the edge. Flowers blue, axillary, either solitary or in pairs; peduncle an inch long, slender; calyx with two long, narrow, pointed leaves at the base. Capsule with four grooves, partly enclosed by the calyx. A native of Guiana.

CONOPAEUM, in Antiquity, a sort of canopy of network, which hung above beds, and was designed to keep away gnats or flies; it comes from Κονόπα, a fly. A piece of furniture of this kind is now used in the East; and Mr. Harmer (Obs. on Scripture, vol. iv. p. 405.) figures, that if it obtained there at so early a period as the time of Saul, it may serve to illustrate a passage of Scripture, ver. 1 Sam. xix. 12—17. This writer supposes that the word translated "a pillow of goats-hair," meant a conopeum or guard against gnats. It is in one place translated a "thick cloth," and in another a "veil." Mr. Harmer observes, that a cloth of a nature fit to be used as a veil, is just such a thing as a conopeum, or fine net-work or gauze-like cloth. It appeared to be something relating to the head; but a conopeum relates to the head as well as a pillow, being a canopy suspended over the whole bed, or at least so far as to surround the head, and such upper part of the body as might be uncovered. That this kind of defence against gnats is now used in the East, Mr. Harmer has shewn, from the testimony of Maillet (Descrip. de l'Egypte, lett. iv. p. 37.) The word occurs probably in the same sense in 2 Kings, viii. 15.

CONOPAEUM, in Ancient Geography, a marsh of A sia, near the mouth of the river Halys, according to Arrian—Allo, a particular part of the Palus Maeotis. Steph. Byz. CONOPHORUS,
CONOPHORUS, in Botany, Petiv. Rai. See Protea Nana.

CONOPOLI, in Geography, a town of European Turkey, in the province of Livadia, 10 miles N.E. of Lepanto.

CONOPS, in Entomology, a genus of dipterous insects, the mouth of which is furnished with a projecting geniculate probosces, and the antenna elevated and pointed at the end.

The insects of this genus are remarkably active, and are found in gardens, where they feed on the nectaraceous juices of flowers; their larvae are unknown. In the true conops, the head is large and nearly hemispherical; the eyes large, and almost oval, and the antenna formed of three articulations, the middle one of which is long and cylindrical, the last joint terminating in a little point.

The genus conops is divided in the Linnaean system into two families; the first of which includes those species which have the sheath of the suckor single-valved, abbreviated, and inclining a single bristle; the other those with the sheath consisting of two equal valves, and which is genculated both at the base and in the middle. The latter are those of Fabricius. In the Fabrician Suppl. Ent. Syll. the Linnaean conops subcocleatus is decribed under the new genus, thereva.

Species.

* First Section.

** Vesicularis.** Blackish; hind head veicular, abdomen yellow with a black base. Fabr. Geoffr. Inhabits woods in Europe.

** Macrockapha.** Black; four of the abdominal segments edged with yellow; antennae and legs rufous. Linn. Like the last inhabits Europe, and is found in woods.

** Rufipes.** Deep-black; abdomen at the base ferruginous; segments edged with white; legs ferruginous. Fabr.

This species is a native of Germany. The rib of the wing, and the antennae are fuscous, front and posterior yellow.

** Aculeata.** Deep-black; inciures of the abdomen yellow; thorax with two yellow dots on the anterior part. Linn. Fr. Suec. A native of the northern parts of Europe.

** Flavipes.** Glossy-black; abdomen cylindrical; three of the segments edged with yellow. Linn. Fr. Suec. This inhabits Europe, and has the legs fasciated with yellow, whence its name.

** Picta.** Ferruginous; thorax black, varied with yellow, rib of the wing ferruginous. Fabr.

A native of the American islands, described from the cabinet of Smith.

** Vitata.** Abdomen cylindrical, hooked, and varied with ferruginous; an abbreviated sub-marginal black spot on the wings. Fabr. Inhabits Sicily.

** Second Section.

** Ferruginea.** Ferruginous; abdomen cylindrical and incurved; front yellowish. Linn. Sicus ferrugineus, Scop. Inhabits woods of Europe.

** Petiolaris.** Antennae black, the club red; head yellow; abdomen petiolate. Fabr. A native of Siberia.

** Astomaria.** Grey; abdomen ovate; wings fuscos, with crowded dots of white. Gmel. An European species.

** Testacea.** Ferruginous; thorax black on the back. Fabr. Stromaexides, Schaff. Found in Germany.

** Atea.** Abdomen cylindrical and incurved; body black. Fabr. Inhabits woods of Denmark.

** Cincta.** Tereteous; abdomen hooked and fasciculated with white. Fabr. A native of the East Indies. Koenig.

** Bucata.** Ferruginous; abdomen hooked, grey; face veicular and white; wings clouded. Linn. Fr. Suec. Sicus bucatus, Scopoli. Inhabits woods of Europe.

** Anulata.** Thorax black; abdomen cylindrical, varied with yellow and black; base of the wings ferruginous; legs ferruginous and annulated with brown. Linn. A native of Europe.

** Flava.** Thorax black; base of the abdomen black on the back, with a black mark each side, and the two next segments with an oblique black spot in the middle and at the sides. Linn. An European species.

** Cinerca.** Ferruginous; mouth veicular and white; tail black. Fabr. Described from a specimen in the cabinet of Dr. Aliomi. It is a native of Italy.

** Dorsalis.** Ferruginous; thorax fuscous on the back; abdomen cylindrical and hooked; margin of the segments white. Fabr. Myopia fuscata, Mant. Inf. Inhabits Germany. Smidt.

CONOPONDIA BASSIS, in Ancient Geography, a name given by Philip to an island at the mouth of the Danube, which the ancients called Pheidolema.

** Gen. Ch. Cal. one-leaved, deeply five-cleft; segments lanceolate, acute. Cor. Petals five, ovate-oblong, erect, doubled, forming a tube, acute, expanding or reflexed at their summit, attached to the receptacle of the pilli; accompanied by five interior, smaller, erect, lanceolate, concape, petal-like bodies placed opposite to them. (Nectaries?) Stam. Filaments five, very short, attached to the base of the petal-like bodies; anthers erect, oblong. Pfl. Germ superius, roundish; style slender; stigma capitate. Pericarp unknown. Sp. C. flaveum. Aubl. Guian. tab. 95. A shrub, three or four feet high, with numerous, scattered, knotty, compound branches near the top. Leaves opposite, on short petioles, egg-shaped, acute, entire, smooth, green above, reddish underneath, the largest of them six inches long, and near three inches broad. Flowers yellowish, alte nata, in spikes terminating the branches, and surmounted with scales at the base; peduncles with two, small, opposite scales about the middle. A native of woods in Guiana.

Gen. Char. Cal. none. Cor. monopetalous, ringent, four-cleft; tube swelling; upper lip vaulted, undivided; lower, in three equal, spreading segments. Stam. four. Anthers selle, fingle-celled, two in the hollow of the upper lip; two, which often seem abortive, at the base of the lower, remote from each other. Pfl. German superius, inversely conical, bearded at the summit. Style linear, bent, shorter than the corolla. Stigma obtuse, curved. Seed solitary, naked, inversely conical, its upper edge fringed with numerous, spreading, filaments; about its own length.

Ell. Char. Calyx none. Cor. of one petal, ringent, bearing the flamen; its upper lip vaulted; under three-cleft. Stigma obtuse. Seed one, naked, crowned with bristles.

Observ. Considering the irregularity of the flower, and the inequality of position of the anthers, perhaps this genus might be placed in didynamia gymnospermia, in which order...
it would add one to the very few genera that have left no
four seeds; but it has no affinity to any already chiled
there, being nearly allied to that tribe of 
"praise" whose flowers are simple, not aggregate; and as the authors are
all really wild, it could not literally accord with the definition of the 14th clus.
"Leaves linear, inclined to oblong, entire, smooth, with
a marginal nerve, and numerous transverse veins. Sm. Stem
thorzy, rigid, branched, about three feet high, with round
leafy branches, which are filky when young. Leaves alter-
nate, several inches long, entire, smooth, varying in breadth
from a linear to a narrow oblong figure, tipped with a small
point, and tapering at the base, into a longish slender foot-
stalk. Their margin is marked with a fine nerve, connected
by transverse veins with the midrib. Stipules none. Flower-
fucks about the tops of the branches, axillary, much exceed-
ing the leaves in length, each bearing a large bracteated
downy corymbus, of white or bluish-coloured, filifie, clus-
tered flowers. Bractae membraneous, wedge-shaped, pointed
fringed. Corolla about a quarter of an inch long, externally
downy. Seeds inerably conical, or top-shaped, brown, downy,
crowned with a marginal row of spreading redshin bristles,
and altogether resembling a antique. A native of New
South Wales, and other parts of New Holland; not yet
brought to Europe. The flowers are generally seen in the
aspect of the whole shrub not ingetent. 2. C. ellipticum.
"Leaves elliptical, rough, edged." Sm. MSS. A mere
humble and divaricate shrub than the former. Branches
hairly when young, thickly clothed with leaves, which are
about three quarters of an inch long, crowded, nearly fel-
ife, elliptical, obtuse, entire, thick, and apparently succu-
cent when fresh, concave when dry, single-rubbed, veined,
roughish underneath, especially at the edges, tipped with
a minute point. Flower-stalks situated as in the foregoing,
but shorter, and more crowded; very downy, as is likewise
the outside of the corolla. Seed rather smaller than the last.
Sect from New South Wales by John White, M.D. 3. C.
taxifolium. "Leaves linear-lanceolate, oblique, somewhat
downy." Sm. MSS. Branches long and wand-like, very
leafy, filky. Leaves imbricated, scattered, filifie, nearly an
inch long, linear-lanceolate, inclining to oblong, oblique,
narrow, rigid, pointed, single-rubbed, veined, thick-edged,
entire, for the most part clothed with short filky hairs
rarely smooth. Flowers situated as in the two species pre-
ceeding, in a dense leafy corymbus at the end of each branch, but their filkis are left compound. In general
aspect and structure they areem, as well as the food, to agree
precisely with those of C. ellipticum. Gathered also at New
South Wales by Dr. White. 4. C. crieffolium. "Leaves awl-
shaped, keeled, smooth." Sm. MSS. This has very much
the habit of the last, and their flowers and seeds exactly ac-
cord. Both seem to be rather herbaceous than shrubby,
though they have the hard rigid texture so frequent in New
Holland plants. This is the smaller of the two. Its leaves
are fearcely more than half an inch long, imbricated, awl-
shaped, obtuse, keeled, and somewhat triangular, tipped as
in the last with a small point, roughish occasionally to the
touch, but, as far as we can discover, always defluent of
pubeference, though the branches are filky. Gathered at
New South Wales by Dr. White. 5. C. reticulatum.
"Leaves wedge-shaped, jagged, reticulated on both sides." Sm. MSS. The fibres appear to be herbaceous and pro-
cumbent, leafy, hairy, a few inches in length. Leaves about
three inches long, alternate, erect, wedge-shaped, entire at
the sides, dilated and jagged at the extremity, veiny, beau-
tifully reticulated on both sides, tapering down at the base
into rigid, furrowed, hairy footstalks, about their own
length, whose bases are dilated, and bordered with a mem-
broaneous sheathing lipula. Flower-stalk terminal, two or
three together, hairy, erect, scarcely in falt as the leaves,
each bearing a loole, bracteated, single spike of downy,
apparently white, flowers, whose segments are more ob-
tulate than in the other species. The most remarkable char-
acter of C. reticulatum consists in the exquisitely reticulated
veins, prominent on both sides of the leaf, branching off
from the main ribs and veins, and forming a fine regular
uniform net-work over the whole surface, whose interfaces
are commonly pentagonal, and not more in diameter than
grains of common sand. The veins themselves are finely
hairy. For dried specimens of this most beautiful species
we are indebted to Mr. A. Menzies, who discovered it at
King George's Sound, on the west coast of New Holland,
at. 35. Its fruit we have not seen, but there can be no
doubt of its genus.

CONOSTEIN-Engers, or Engers, in Geography, a town of
Germany, in the circle of the Lower Rhine, and elec-
torate of Treves; 4 miles N. of Coblenz.

CONOTHATON, in Ancient Geography, an episcopal see
of Alsia, under the metropolis of Biiriat. CONON, in Geography,
a town of Persia, in the province of Luristan, on the coast of the Persian gulf; 66 miles E.S.W. of Lar.

CONOVITUM, in Ancient Geography, a town of the isle
of Albion, on the route from Segontium or Caernarvon
to Deva or Chester, according to Antonine's Itinerary.
It was distant 24 miles from Caernarvon, and is now called
Caer-Rhyn.

CONQUASSATION, in Pharmacy, a species of comminu-
tion, or a particular operation, by which moist concreted
substances, such as recent vegetables, their roots, lactescent
seeds, and the softer parts of animals, are contused and agi-
tated in a mortar, until partly by their proper succulence,
or the affusion of some liquor, they are reduced to a soft
pulp. Metallic instruments are not to be used for this pur-
pose, because not only the manifest, but also the latent
faits of the substances, subjected to this operation, acting on
the instruments, may derive an adventitious virulent quality from
them, which will not only render such substancess unfit for
the intended purpofes, but also nauseous and hurtful when
exhibited as medicament by incer.

CONQUERORS, in French Conquerant. A captain or
commander who has subdued several cities or entire countries
by force of arms. Alexander the Great, Julius Caesar,
Tamerlane, Mahomet II., &c. were conquerors.

CONQUES, in Geography, a small town of France, in
the department of Aude, and chief place of a canton in the
district of Carcassonne, with a population of 1591 inhabit-
ants. That of the canton amounts to 565, in 10 com-
munes, upon an extent of one hundred kilometres.—Alfo,
a small town of France, in the department of Aveyron,
in the district of Rhodos, with 805 inhabitants, 15 miles N. from
Rhodes. The canton, of which it is the chief place, has
13 communes, with 6597 inhabitants, and measures 187 ki-
nometres and a half.

CONQUEST, in French Conquête, the acquisition of a
place, province, or entire country, by a superiority of
arms, which compels the conquered to submit to the con-
queror.

CONQUEST, in Civil Jurisprudence, is the acquisition
of property in common by a number of persons.
In some countries, they confound acquisition with conquest;
but, according to the most general acceptance, acquisi-
tion is the gaining of unappropriated goods before the efla-
ishment
CONQUEST.

blishment of a community; whereas, by the term conquifit, is ordinarily intended whatever is acquired by a number of persons in community; or by some one for all the others.

As it is more especially in the union of persons by marriage, that a community of property takes place; it is in reference to them that we frequently use the word conquifit. There are, nevertheless, conquests also among other persons who are in a tacit community or society; such as obtain by particular local customs.

According to the sense of the word, it has been contended by several, that William I. claimed this kingdom; that is, not by right of arms, but by right of conquest or acquifit; under promise of succession made by Edward the Confessor, and a contract entered into by Harold, to support his pretensions to that succession; and by old writers, conquestus, acquifitio, and perquisitio, are frequently used as synonymous terms.

In consequence of the prodigious slaughter of the English nobility at the battle of Hastings, and the fruitless insurrections of those who survived, such numerous forfeitures had accrued, that king William was able to reward his Norman followers with very large and extensive poffiffions; which circumstance led the monkifh historians, and such as have implicitly followed them, to represent him as having, by right of the sword, feized on all the lands of England, and distributed them among his own favourites. This supposition is grounded upon a mistaken sense of the word "conquifit," which, in its feudal acceptation, signifies no more than "acquisition"; and hence many party writers have been led into a strange historical mistake, and one, says judge Blackstone, which upon the slightest examination, will be found to be most untrue. See Feudal Tenure.

What we call "purchafe," perquisitio, the feudalists called "conquifit," conquifitio, or conquifitio; both denoting any means of acquiring an estate out of the common course of inheritance. This is still the proper phrase in the law of Scotland; as it was among the Norman jurifths, who fyled the fitst purchaser (that is, the person who brought the estate into the family, which at present owns it) the conqueror or conquifeur. This is all that seems to have been meant by the appellation that was given to William the Norman, when his manner of acceding the throne of England was in his own charter, and in that of his successors; and after by the historians of the times, entitled conquifitio, and himself conquifeur or conquifeur; signifying that he was the fitst of his family who acquired the crown of England, and from whom, therefore, all future claims by descent must be derived; though now, from our difufe of the feudal sense of the word, together with the reflection on his forcible method of acquisition, we are apt to annex the idea of "victory" to this name of "conquifeur," or "conquifitio," a title which, however just with regard to the crown, the conqueror never pretended with regard to the realm of England; nor, in fact, ever had. See PURCHASE.

William the Norman, as we have already observed, and as some have maintained, claimed the crown by virtue of a pretended grant from king Edward the Confeflor; a grant which, if real, was in itself utterly invalid; because it was made, as Harold well observed, in his reply to William's demand, oblique generis featus, et populi conveniunt et edito; and this alto very plainly implies, that it was then generally understood, that the king, with content of the general council, might dispose of the crown and change the line of succession. William's title, however, was altogether as good as Harold's, who was a mere private subject, and an utter stranger to the royal blood. The conquest, then, by William of Normandy, was, like that of Canute before, a forcible transfer of the crown of England into a new family; but, the crown being so transferred, all the inherent properties of the crown were also transferred with it. For, the victory obtained at Hastings not being a victory over the nation collectively, but only over the person of Harold, the only right which the conqueror could pretend to acquire thereby, was the right to pilfer the crown of England, not to alter the nature of the government. And, therefore, as the English laws still remained in force, he must necessarily take the crown subject to those laws, and with all its inherent properties; the fin and essence of which was its indefinability. See Right of Crown.

Some writers have represented William's conquest as more extensive and complete than it has been above stated. Scarcely any of those revolutions, it is said, which, both in history and in common language, have been always denominated conquests, appear equally violent, or were attended with so sudden an alteration of power and property. The Roman state, which spread its dominion over Europe, left the rights of individuals in a great measure untouched; and those civilized conquerors, while they made their own country the seat of empire, found that they could derive the greatest advantage from the subjugated provinces, by securing to the natives the free enjoyment of their own laws, and of their private possessions. The barbarians who subjugated the Roman empire, though they settled in the conquered countries, yet being accustomed to a rude uncultivated life, found a part only of the land sufficient to supply all their wants; and they were not tempted to seize extensive possessions, which they knew how neither to cultivate nor to enjoy. But the Normans came from foreigners, who followed the standard of William, were far advanced in the arts as to know the value of a large property; and therefore having made the vanquished kingdom the seat of government, and having totally subjugated the natives, they pushed the rights of conquest, for the gratification both of their avarice and ambition, to the utmost extremity. Except the former conquest of England by the Saxons themselves, who were induced, by peculiar circumstances, to proceed even to the extermination of the natives, it would be difficult to find, in all history, a revolution more destructive, or attended with a more complete subjection of the ancient inhabitants. In the conduct of their conquerors, continually was blended with oppression; and the natives were universally reduced to such a state of meanness and poverty, that the English name became a term of reproach, and several generations elapsed before one family of Saxon pedigree was raised to any considerable honours, or could so much as attain the rank of baron of the realm. "These facts," says Mr. Hume (Hist. vol. i. p. 287, 5th ed.) "are so apparent from the whole tenor of the English history, that none would have been tempted to deny or clade them, while they were not heated by the controversies of faction; while one party was absurdly afraid of those absurd confquences, which they feared the other party inclined to draw from this event. But it is evident that the present rights and privileges of the people, who are a mixture of English and Normans, can never be affected by a transact which passed 700 years ago; and as all ancient authors, who lived nearest the time, and best knew the state of the country, unanimously speak of the Norman dominion as a conquest by war and arms, no reasonable man, from the fear of imaginary consequences, will even be tempted to reject their concurrence and united testimony."
The Norman invasion, and conquest, as it has been usually denominated, were important events in the history of this country; and produced as great an alteration in our laws, as it did in our ancient line of kings:—and though the alteration of the former was effected rather by the consent of the people, than by any right of conquest, yet that consent seems to have been partly extorted by fear, and partly given without any apprehension of the consequences which afterwards ensued. The alterations in our laws which then took place are enumerated by judge Blackstone; and we shall here subjoin a summary of them. The fall of these was the separation of the ecclesiastical courts from the king, which was effected in order to gratify the new king with the support of the clergy, who had been for some time endeavoured, in every part of Europe, to exempt themselves from the feudal power. This was the more easily accomplished, because the dispoal of all the episcopal fees being then in the breach of the king, he had taken care to fill them with Italian and Norman prelates. The second alteration of the English constitution was more violent, and confined in the depopulation of whole countries, for the purposes of the king's royal diversions; and subjecting both them, and all the ancient fiefs of the king, to the unreasonable severities of the laws imposed from the continent, by which the slaughter of a beast was made almost as penal as the death of a man. (See Forest and Game.) A third alteration in the English law was effected by narrowing the remedial influence of the county courts, the great feats of Saxon justice, and extending the original jurisdiction of all the king's judges to all kinds of cases arising in all parts of the kingdom. (See Acta regia.) Hence all proceedings in the king's courts were ordained to be carried on in the Norman, instead of the English language; a badge of slavery as evident and signal as ever was imposed upon a conquered people, which lasted till King Edward III. obtained a double victory, over the armies of France in their own country, and their language in our courts here at home. A fourth innovation was the introduction of the trial by combat, for the decision of all civil and criminal questions of fact in the last resort. (See Combat.) The last and most important alteration, both in our civil and military polity, was the enfranchising all landed estates, a few only excepted, the fiction of feudal tenure; which drew after it a numerous and oppressive train of servile fruits and appendages; aids, reliefs, primer feines, wardships, marriages, ecchates, and fines for alienation; the genuine consequences of the maxim then adopted, that all the lands in England were derived from, and held, mediately or immediately, of, the crown. See each article respectively, and Feudal Tenure.

"The nation at this period," says judge Blackstone, "seems to have groaned under as absolute a slavery as was in the power of a warlike, ambitious, and a politic prince to create. The confinences of men were enslaved by four ecclesiastics, devoted to a foreign power, and unconnected with the civil state under which they lived:—who now imported from Rome for the first time the whole fury of superstition, and Norman conquest; such as transubstantiation, purgatory, communion in one kind, and the worship of saints and images; not forgetting the universal supremacy and dogmatical infallibility of the holy see. The laws too, as well as the prayers, were administered in an unknown tongue. The ancient trial by jury gave way to the impatient decision by battle. The forest laws totally re-framed all rural pleasures and manly recreations. And in cities and towns the cafe was no better; all company being obliged to disperse, and fire and candle to be extinguished by eight at night, at the found of the melancholy curfew. The ultimate property of all lands, and a considerable share of the prent profits, were vested in the king, or by him granted to his Norman favourites; who, by a gradual progression of slavery, were absolute vassals to the crown, and as absolute tyrants to the commons. Unheard of forfeitures, tallages, aids, and fines, were arbitrarily exacted from the pillaged landholders, in pursuance of the new system of tenure. And to crown all, the consequence of the tenure by knight-service, the king had always ready at his command an army of 60,000 knights, or militia; who were bound, upon pain of confiscating their estates, to attend him in time of invasion, or to quell any domestic insurrection. Trade, or foreign merchandise, such as it then was, was carried on by the Jews and Lombards; and the very name of an English fleet, which king Edgar had rendered so formidable, was utterly unknown to Europe; the nation confiding wholly of the clergy, who were also the lawyers; the barons, or great lords of the land; the knights, or vassals, who were the subordinate land-holders; and the burghers, or inferior tradesmen, who from their insignificance, happily retained, in their foage and burgage tenure, some points of their ancient freedom. All the rest were vassals or bondmen."

"From so complete and well-concerted a scheme of servility, it has been the work of generations for our ancestors, to redeem themselves and their posterity into that state of liberty, which we now enjoy:—and which therefore is not to be looked upon as confining of mere encroachments on the crown, and infringements on the prerogatives, as some dulvish and narrow-minded writers in the last century endeavored to maintain:—but as, in general, a gradual reformation of that ancient constitution, whereof our Saxon forefathers had been unjustly deprived, partly by the policy, and partly by the force, of the Norman." Blackl. Com. Book iv. See Constitution.

Conquest, in the Law of Nations, is the acquisition of sovereignty by force of arms, by some foreign prince; who reduces the vanquished under his empire. The right of conquest is derived from the laws of war; and when a people is subjected, the conduct of the conqueror is regulated by four kinds of law. First, the law of nature, which dictates whatever tends to self-preservation; secondly, the reason, which teaches us to use others, as we would be treated ourselves; thirdly, the laws of political society, to which nature has not assigned any precez boundary; lastly, the law which is derived from the particular circumstances attending the conquest. Thus, a state conquered by another will be treated in one of the four methods following: Either the conqueror will continue it under its own laws, and will only claim the exercise of civil and ecclesiastical sovereignty; or he will impose a new form of government; or he will destroy the frame of their society, and incorporate the inhabitants with others; or he will exterminate them. Ancient and modern history will supply numerous instances of these different modes of treatment. See Colony and Plantation.

The right of conquest is allowed by the law of nations, if not by that of nature; but in reason and civil policy it can mean nothing more than that, in order to terminate hostilities, a compact is either expressly or tacitly made between the conqueror and the conquered, that if they will acknowledge the victor for their master, he will treat them for the future as subjects, and not as enemies. Puffin. Ls. of Nat. viii. b. 24.
CONQUET, L., in Geography, a pretty, rich, small town of France, in the department of Finlere, with a noble history, and excellent roads; 15 miles west from Brest. It is one of the 84 maritime quarters into which modern France is divided, and the residence of a maritime faction who desist from this place, besides Argenton, Lor- spered, and Oeufant.

CONQUER, or CONQUERED, a name of Holland, who was born about 1620. The works of this artist, for the greater part, con- of portraits, many of which are from his own drawings, of prints very much rembale to those of L. Voller- mance. Amongst his belt works the following may be enumerated: "Christopher Love," A. Conrad, fol, in fol.; "Jacob Triglande, Professor of Theology to the University of Leyden," Ab. Conradus, feit, in fol.; "The Proclamation and the Crucifixion of Christ," two plates in folio, from Ab. Van Driekenbeek. Huber, Manuel des Arts.

CONRAD I., emperor of Germany, was, previously to his attaining that high honour, duke of Franconia and Hesse. On the death of Louis IV., king of Germany, A.D. 912, the nobility of the realm assembled at Worms, for the pur- pose of choosing a successor. They offered the crown to Otho, duke of Saxony, by whom, on account of his great age, it was not accepted. He requested them to turn their thoughts to the duke of Franconia, who was highly esteemed for his great talents and excellent character. Upon this re- commendation he was called to the vacant throne, though not with that unanimity which is calculated to secure gen- eral homage. The people of Lorrain were attached to Charles the Simple, whom they wished to proclaim as their sovereign; Conrad marched thither with great expedition, and by his presence conciliated those who were disposed to refit his authority. While he was thus engaged, Henry, duke of Saxony, occupied the city of Worms, and raised the rebellion. This, after sur- mounting several difficulties, he crushed, and gained a com- plete victory over his enemies. The Hungarians now made a dreadful irruption into his dominions, and, after marking their progreswith fire and sword, compelled him to pur- chase a peace on very disgraceful terms: but, notwithstanding all the exertions of his enemies, he retained the sceptre, and conducted the affairs of the empire with con- siderable prudence till the time of his death. His constitut- tion being broken by the fatigues to which he had been ex- posed, and his health being much injured in consequence of a wound which he had received in battle, he assembled the princes and states of the empire, and firmly exhorted them to raise Henry, duke of Saxony, who had been his enemy, to the imperial throne. This is a rare instance, on the rec- ords of history, of a prince sacrificing his private resent- ment to the public good. He sent the crown, sceptre, and other regalia to his intended successor; and after an active and respectable reign of seven years, he died, A.D. 918, in peace, in one of the situations of quitting life under the influence of Christian principles.

CONRAD II., emperor of Germany, was likewise duke of Franconia; he was surnamed the Salic, on account of his having been born on the banks of the river Sala, and was unanimously invested with supreme authority. He succeeded Henry II., and was crowned, according to ancient usage, at Thoma. During the first two years of his reign, Conrad was chiefly employed in regulating the police, and other affairs of administration; but in the third, receiving intelligence that the Lombards had shaken off their allegiance, he was obliged to march into Italy. The rebels were soon reduced to obedience, and the king pro- ceeded to Rome, where he was solemnly crowned by pope John, in presence of Carute, king of England and Den- mark, and Rodolphus, king of Burgandy. He was re- called to Germany, on account of an insurrection, raised by the dukes of Swabia, Carinthia, and Worms, which he readily suppressed, and brought the offenders to the lowest state of subjection. By a decree of the empire, they were deprived of their dominions. The seven succeeding years were occupied by wars between the emperor, Poland, Bohemia, and Hungary: the details of these would be un- interesting to our readers. The imperial arms were in general successful; and on the demise of Rodolphus, Conrad ac- quired the peaceable possession of the sovereignty of Bur- gundy. A general war, however, broke out between Germany and Austria, which was planned in Italy, and fomented by many leading persons: the emperor passed suddenly into that country, and feizing some of the principal mainsprings, sent thither mon- etor to Germany. He besieged Milan, but without suc- cess; and severely chastised Parma. Being urged by the monks of Calzino to protect them against the violence and oppression of Pandolph, prince of Capua, he marched to that place, expelled the prince, and feized his country. Returning to Germany, he was feized with the gout in his legs, and died suddenly at Utrecht, in 1039, in the fifteenth year of his reign. He was universally revered as a just and magnificent prince; and all those who distinguished themselves in his service had no reason to be dissatisfied with the remunerations which they obtained. Among many in- instances of his munificence, it is said that one of his attend- anti, who had lost his leg in battle, received a boot full of gold, which the emperor observed might defray the expense of his care. He was interred in the cathedral church of Spira, which he had formerly founded. To III., another younger duke of Franconia and emperor of Germany, was nephew of the emperor Henry V., and elected to the imperial throne at Coblenz in 1035-9, as successor to Lothair II. This measure was warmly con- tented by Henry, duke of Bavaria, who positively refused to surrender the regalia, which had been deposited in his hands by Lotharius. He was, however, at length compelled to submit, with the loss of his own dominions; and the disappoin- tement and chagrin which he suffered on the occasion brought him to an early grave. Upon the death of this prince, his brother Guelph, with the assistance of the king of Sicily, made vigorous efforts for the recovery of the confiscated dukedoms: a war ensued, and, after several inde- cissive engagements, the duke was closely besieged by the emperor in the castle of Weinsberg, celebrated for the con- jugal fidelity and affection of the ladies; who, being per- missioned to leave the place with whatever they could carry, marched out, each with her husband on her back. This in- stance of kindness and regard so much affected the emperor, thnady, he readily came into terms with Guelph and his partizans.

In this war we must look for the origin of the dis- unities of the Guelphs and Ghibellines, which are so often referred to on the page of history. The troubles in Ger- many were immediately succeeded by a revolt of several of the
the town of Italy, which threw off the sovereignty of the empire, and formed themselves into independent republics. Conrad was now prevailed on to join a crusade against the Saracens, and took the cross from the hands of Bernard. He accordingly set out for Palestine, at the head of sixty thousand men. Under his banners a troop of females rode in the attire and armour of men; and the chief of these Amazons, from her boot spurs and buckles, obtained the epithet of the "golden-booted dame." This expedition proved unfortunate: one half of his troops perished by sickness, occasioned, it is believed, through unworthy provisions, furnish by the treachery of the Greek emperor, Manuel Comnenus. Conrad, with the remainder, joined Louis VII. king of France, in the siege of Damascus, exhibiting great provails, but without any success. The siege was raised, and the emperor returned to Germany, where he was overwhelmed with public calamity and private affliction, by another revolt of Guelph, and by the death of his eldest son. This last event preyed on his mind, and evidently affected his health. Aware of his approaching end, he was anxious to provide for the succession, and recommended his nephew, Frederic Barbarossa, to the flates of the empire, as a prince of known courage and tried talents. His recommendation was approved, and Conrad died in a short time after, at Bamberg, in the 14th year of his reign. He left one son by his empress Gertrude, whose tender age precluded him from taking any share in the government.

CONRAD IV., the last emperor of Germany of this name, was duke of Suabia, and son of the emperor Frederic II. He was declared successor to his father in 1250, but pope Innocent IV. refused to confirm the election. Conrad, notwithstanding the denunciations of the pontiff, marched into Italy, in order to take possession of the kingdom of the two Sicilies, which had been bequeathed to him by his father. He took the city of Naples after an eight months' siege; afterwards Capua and Aquino opened their gates to him. He did not long enjoy his success: in 1254, he fell sick, and died in the flower of youth, leaving one son, named Conradin, who, at the age of fourteen, was beheaded by the orders of Charles of Anjou; and in his place, his elder brother, the line of Suabia, Moreri, Unver. Hist. Gibbon's Rom. Empire.

CONRAD is a name distinguished in literary history, as well as among the princes of the earth; but as none of that appellation have become very illustrious by their works, we shall briefly notice them and their writings in a single paragraph. The first was a German abbot of the Benedictine order, about the commencement of the tenth century: he wrote "A Continuation of the History of France;" and on that account has, by some biographical writers, been supposed a Frenchman; by others, he has been confounded with Conrad of Cologne, who was author of the life of St. Wolphlinus. Towards the conclusion of the eleventh century, Conrad, bishop of Utrecht, flourished, to which office he had been raised by his pupil, the emperor Henry. He is chiefly known by a work, entitled, "Apologia de Unitate Ecclesie confervanda, et Schismate inter Henricum IV. Imp. ac Greg. VIII. Pont. Max." He wrote also a spirited defence of the imperial right on the subject of investitures. The bishop was assassinated in his palace, A. D. 1109, by a Friedland archbishop, in revenge for having instructed him in the method of erecting mally buildings on a swampy foil, and afterwards employing a rival in constructing the collegiate church of which the bishop was founder.—Conrad of Sieturn, a German monk, lived in the thirteenth century, and was author of "A Chronicle," and of more than fifty volumes on different subjects, chiefly left in writing of which John of Aventine made much use in composing part of his annals. By his various writings, this monk obtained the honourable epithet of "philosopher."—Conrad of Lichtenau, abbot of Uerberg, in the thirteenth century, was author of "A chronological History," extending from Belus, king of Assyria, to the year 1449, which was afterwards continued, by an anonymous writer, to the reign of Charles V. It was originally printed at Strasburg, in 1527, and afterwards, with the continuation, in 1590, at Boul. It created enemies, by some reflections on the wars carried on between the German emperors and the popes. The same author is said to have written the lives of the saints, in 12 books; but they have not come down to us, and probably were never published.—Conrad of Mentz flourished in the thirteenth century, and is known by a work, entitled, "Chronicon Reim Moguntianum," from the year 1140 to 1250, which was first printed in 1535, and has undergone several different impressions.—About the same period lived Conrad of Marburg, who was the first person of Germany that received the laudable commission of inquisitor from the papal see; an office which he executed with so much cruelty, that at length he fell a sacriifice to the indignation of popular clamour. He wrote "The Life of the Princess Elizabeth of Thuringia," who has obtained a place among the saints.—Conrad is the name of two Dominican monks, natives of Saxony, in the fourteenth century. One was a member of the chapter of his order in that province, and the other appointed by the pope vicar-general of Saxony, in the year 1350. The former published, among many other things, "A Commentary on the Book of Job;" "A Concordance to the Bible;" "The Student's Dream;" and "A common-place Book of the Life of Preachers."—Conrad of Alli, a Pietemonde Dominican monk, was author of "Commentaria in Jos Canonicum," and other pieces. He died in the year 1470.—In the sixteenth century appeared Conrad Lontinus, a learned German Cistercian monk, who appears to have been well acquainted with the best writers in profane and sacred literature, and to have maintained an intimate correspondence with the most learned men of his time. He published, in the year 1587, at Boul, "Nicholas de Lyra's Commentary on the Bible, with marginal Notes."—There were several others of this name, but it is needless to mention them all. Conrad of Mur, son of the church of Zurich, lived in the thirteenth century, and is known for his treatise on the sacraments, and the lives of the popes: and Conrad of Saxony wrote "A Chronicle," and some historical works, to which no date is assigned. Moreri. CONRI, Florence, a Franciscan friar, was born in the province of Connaught, about the year 1560, and was sent at an early age into Spain, as a student in theology and the philosophy of the times. When he had finished his studies, he travelled into the Low Countries, where he acquired great reputation among the Catholics, by his industry and zeal in illustrating and defending the doctrines of St. Augustine. He was author of several tracts on theological subjects, among which were "The Mirror of the Christian Life," "A Mem. of Catechism," printed at Louvain, in 1625; and "Treatises de Sacra of General "Baptism deedest ex hac Vita," Lovani, 1624. As a politician, he was fixed on to conciliate his countrymen to the measures of the court of Spain, when Philip III. attempted the conquest of Ireland, during the reign of Elizabeth. On the failure of that enterprise he escaped from
the country, and spent the remainder of his life in the Low Countries, and at Madrid, supported by a pension from Spain, in recompense for the services which he intended, but which proved ineffectual. He died at Madrid, in the year 1630. Moreri.

**CONRINGIUS, Herman, a philogopher of great talents, and almost universal learning, born at Norder in East Friesland in November, 1666, received his education at Heimhadt, where he was made doctor in medicine in 1636, and soon after advanced to the chair of professor in that science. He was also, in succession, appointed professor in physics, law, and politics. For his profound knowledge in the laws of nations and politics, he was consulted, and made physician and aile counsellor to Carliina, queen of Sweden, to the king of Denmark, and to several of the German princes and electors. Of his capacity for these employments abundant proof may be found in his numerous works in philosophy, medicine, and history, which were long held in great repute, though now referred rather from curiosity than for their utility. In all of them, however, there is a wonderful display of learning. In his philosophy he was a follower of the school of Aristotle, as he proclaims in the first of his publications, viz., "De Calido inato, de Morte, et Vita, et de Origine Formarum, libri, omnia ad Aristotelis Sententias elaborata." Lug. Bat. 1631, 8vo., republished with additions in 1640, 43, and 46; "De Germanicorum Corporum Habitibus antiqui et novi Canis, Differtatio," Helm. 1645, 4to. This has been frequently reprinted. The author has some ingenious conjectures on the canons of the diminished stature, and altered complexion, and habit of body, of the Germans, which he draws from indisputable documents which have taken place among these people. The ancient Germans were fair, with blue eyes, and abundant yellow hair, "Robulitis nato parentibus, sero venere deudente, inque conjugio caelos vicissuius, et fess vires conservasse integritates, et pinnorum filius impressibile, &c. &c. An entire change in the mode of living, the use of fows, of tobacco, &c., he conceives to have gradually undermined their constitutions, and to have produced the changes he states to have taken place. An edition of this work was printed at Frankfort, with notes, by Philip Burghaw, 8vo. 1727. "De Hermetica Aegyptiorum vetere, et Paracellica nova Medicina," Helm. 1648, 4to.; reprinted, with additions, 1669: a work abounding with ingenious and learned speculations, but little now attended to. "Introductio in universam Artem Medicam, ejusque singulas Partes," 1654; re-edited by Schelhammer, 1687; and again by Hoffman, 1726, 4to.; containing an history and bib. medica, with observations on the principal facts and writers in medicine, besides numerous disquisitions on particular diseases, as dropsy, pleurisy, &c. Conringius is said to have been remarkably diminutive in stature, but of great vivacity, and enjoying a strong memory. He retained the situation of fenis of the university of Heimhadt to the time of his death, which happened on the 12th of December, 1681. His character is contained in the following epitaph:

Hoc tumulo
Clauditur regum principumque consiliorum,
Juris naturales gentium publici doctor,
Philosophiæ omnium pedilium, præstite et theoretæ,
Philologus insignis, orator, poeta, historian, medicus,
Theologus.
Multas putas tuis conditionis.
Unus eft Hermanus Conringius, facculus miraculum,
Pohlit Henricus Medibomius.
Haller Bib. Eloy Dict. Hlst.
Vol. IX.
only to find a power of \(2\), the index of which is the number of degrees; \(\text{e.g.} \ 2^1, 2^{10}, 2^{14}, \text{etc.}\) will give the corresponding number respectively. Or, the number of ancestors at any even degree may be had by squaring the number of ancestors at half that number of degrees: thus \(16\), the number of ancestors at 4 degrees, is the square of \(4\), the number of ancestors at 2; \(256\) is the square of \(16\); \(65536\) of \(256\); and the number of ancestors at 40 degrees would be the square of \(1048576\), or upwards of a million of millions. These powers are easily found by means of logarithms. See Progression.

It is obvious that in this table the numbers in the progression increase much more rapidly than those of the former table; for though the first born is 1, the ratio of the progression is 4; that is, there is one kindred (a brother) in the first degree, who makes, together with A. B., the progenitor, as he is called, the two descendants from the first couple of ancestors; and in every other degree, the number of kindred must be quadruple of those in the degree which immediately precedes it. For, since each couple of ancestors has two descendants, who increase in a duplicate ratio, it will follow that the ratio in which all the descendants increase downwards must be double that in which the ancestors increase upwards; but the ancestors increase upwards in a duplicate ratio; therefore the descendants must increase downwards in a double duplicate; that is, in a quadruple ratio. This calculation may be formed by a more compendious process, viz. by squaring the number, or half the number of ancestors at any given degree, which will furnish the number of kindred who have in the same degree, at equal distance with ourselves from the common flock, besides those at unequal distances. Thus, in the 10th lineal degree, the number of ancestors is 1024; its half, or the couples, amount to 512; the number of kindred in the 10th collateral degree amounts, therefore, to 262144, or the square of 512. Or, it will be seen in the table that \(4^3 = 64\), the number of kindred in the 4th collateral degree; \(4^7 = 256\), the number in the 5th degree; \(4^{10} = 1024\), the number in the 6th degree, &c. and therefore if the number of degrees be denoted by \(n\), \(4^{n-1}\), will be the number of kindred in the degree expressed by \(n\); which is easily obtainable by the aid of logarithms in any degree, however remote. If any one will be at the trouble of recollecting the fate of the several families within his own knowledge, and of observing how far they agree with this account; that is, whether, on an average, every man has not one brother or sister, four first cousins, sixteen second cousins, and so on; he will find that the present calculation is very far from being overcharged.

From the records of scripture we learn, that there is one couple of ancestors belonging in common to us all, from whence the whole race of mankind is descended; and hence we deduce, as an obvious and undeniable consequence, that all men are in some degree, however remote, related to each other. For, indeed, if we only suppose each couple of our ancestors to have left one with another, two children; and each of those children on an average to have left two more; (and, without such a supposition, the human species must be daily diminishing) we shall find that all of us have now subliling nearly \(270\) millions of kindred in the 15th degree, at the same distance from the several common ancestors as we ourselves are; besides those that are one or two degrees nearer to or father from the common flock, who may amount to as many more. And, if this calculation should appear incompatible with the number of inhabitants on the earth, it is because, by intermarriages among the several descendants from the same ancestor, a hundred or a thousand modes of confusion may be consolidated in one person, or he may be related to us a hundred or a thousand different ways.

The method of computing these degrees in the canon law (Decretal. 4. 14. 3 & c.) which our law has adopted (Co. Litt. 23.) is as follows: We begin at the common ancestor, and reckon downwards; and in whatsoever degree the two persons, or the most remote of them, is distant from the common ancestor, that is the degree in which they are related to each other. Thus, Titius and his brother are related in the first degree; for, from the father to each of them is counted only one; Titius and his nephew are related in the second degree; for the nephew is two degrees removed from the common ancestor, viz. his own grandfather, the father of Titius. See Blackiz. Comm. ii. 261.

Marriage is prohibited by the church to the fourth degree of consanguinity inclusive; but, by the law of nature, consanguinity is no obstacle to marriage, except it be in the direct line. See Marriage.

Consanguinity terminates in the fifth and seventh degree, excepting in the succession to the crown; in which case, consanguinity is continued to infinity.

The civilians call frater consanguinis, those born of the same father; in opposition to frater utebris, who are only born of the same mother. See Descent.

According to the common opinion, those were not allowed to complain of an infidels meum testament, i.e. of being disinhérited without cause; excepting from the turpitude of the person appointed heir in their place. But Van Water endeavours to shew the contrary; and urges, that the consanguinis might plead insufficiency, even where the testament was not made in favour of a person incapable. See Kindred.

Consar, in Geography, a town of Persia, in the province of Irak; 52 miles N.W. of Ipahan.

Consarbruck, or Conz, a town of Germany, in the electorate of Treves, situated at the conflux of the Saar and the Moselle; 2 miles S. of Treves.

Consbach, a town of Sweden, in South Gothland; 32 miles N. of Wardberg.

Conscience, in Ethics, a secret testimony or judgment of the soul, or as some have defined it, a distinct faculty or power of the mind, by which it gives its approbation.
tion to things it does that are naturally good; and reproaches itself for those that are evil. Or, conscience is a dictate of the understanding power, concerning moral actions; considered as it has the knowledge of laws; and consequently as concerns of what is to be done, or not done, with regard to the legislator.

In the more popular sense of the word, conscience is a judgment, either true or false, whereby we pronounce a thing good or evil. This makes what we call the inner forum, or tribunal. Accordingly, it should be considered, not as a mere intellectual light, or informing faculty, a dictate of the practical understanding (as the schools call it), which directs, admonishes, and influences us, in what we are to do; but as it acts upon the soul by a reflection on what we have done; and is, by that means, the source and cause of all that joy, or dejection of mind, of those internal sensations of pleasure or pain, which attend the practice of great virtues or great vices.

Some divines maintain, that conscience is infallible; and hold it to be that immutable law whereby God will judge men: they deny that the understanding can be the source of errors, and lay them all at the door of the will. A man, say they, may secure himself from error, by forbearing to judge of things till he have a clear and distinct perception of them.

Some of the schoolmen distinguish between the conscience antecedent to an action, and that consequent to it: the first, called antecedent conscience, determines what is good, and what evil; and consequently prescribes what is to be done, and what avoided. Consequent conscience is a kind of secondary or reflex judgment, with regard to the goodnes, &c. of things, already done or committed.

The rule of conscience is the will of God, so far as it is made known to us, either by the light of nature, or by that of revelation. With respect to the knowledge of this rule, conscience is said to be rightly informed, or mistaken; firm, or wavering, or scrupulous, &c. With respect to the conformity of our actions to this rule when known, conscience is said to be good, or evil, &c.

In a moral view, it is of the greatest importance that the understanding be well informed, in order to render the judgment or verdict of conscience a safe directory of conduct, and a proper source of satisfaction. Otherwise, the judgment of conscience may be pleaded, and it has actually been pleaded, as an apology for very unwarrantable conduct. Many atrocious acts of perfecution have been perpetrated, and afterwards justified, under the sanction of an erroneous conscience. It is also of so small importance, that the facility of conscience be duly maintained and cherished; for want of which men have often been betrayed into criminal conduct without self-reproach, and have deluded themselves with false notions of their character and state.

Dr. Reid (See his “Essays on the active Powers of Man,” p. 252, &c.) has made the following observations on that power of the mind, which we call conscience. 1. Like all our other powers, it comes to maturity by infants degrees, and may be much aided in its strength and vigour by proper culture. 2. Conscience is peculiar to man. We see no velleity of it in brute animals; and it is therefore one of those prerogatives by which we are raised above them. Conscience is evidently intended by nature to be the immediate guide and director of our conduct, after we arrive at the years of understanding. Other principles may urge and impel; but this only authorizes. Other principles ought to be controlled by this: this may be, but never ought to be controlled by any other, and never can be with innocence. From these observations it evidently follows, that the moral faculty of conscience is both an active and an intellectual power of the mind. As an active principle, it sometimes concurs with other active principles, sometimes opposes them, and sometimes is the sole principle of action. As an intellectual principle, we have by it, and by it alone, the perceptions of right and wrong in human conduct, in their different degrees and different species. Philosophers in lieu of the word conscience, which seems appropriated to theological matters, frequently use that of consciousness; which see.

The power of conscience has been remarked in all ages of the world, and under all dispensations of religion; and history, both sacred and profane, furnishes innumerable examples, that are eminently instructive. One remarkable instance of this kind occurs in the history of Joseph and his brethren (see Gen. chap. xlili. and particularly v. 21.) Another is presented to us in the account which the evangelist Matthew has given us of the feelings and reflections of Herod the tyrant, when he heard of the name of Jesus, after he had occasioned the death of John the Baptist. (See Matt. xiv. 1, 2, 3.) Bishop Atterbury has admirably portrayed the state of Herod’s mind, in his excellent sermon on this subject. (Sermons, vol. iv. Serm. 4.) Many instances of a similar kind occur in profane history. We shall content ourselves with selecting one, and shall give it in the words of the elegant preacher already cited. “Tiberius, that complete pattern of wickedness and tyranny, had taken as much pains to conquer these fears (referring to the fears of futurity before deferred) as any man, and had as many helps and advantages towards it, from great splendour and power, and a perpetual succession of new buffoons, and new pleasures: and yet, as great a matter of dissatisfaction as he was, he could not dissemble the inward sense of his guilt, nor prevent the open eruptions of it upon very improper occasions. Witnesses that letter which he wrote to the senate from his impure retreat at Capræa. Tacitus has preserved the first lines of it; and there cannot be a livelier image of a mind filled with distraction and despair than they afford us: Quod, feribam volui, P. C. aut quomodo feribam, ut quid non moveo non feribam hoc tempore, Dei me Dercque pugis perdant, quam petere quisque fatis, si fatis! that is, ‘What, or how, at this time, I shall write to you, fathers of the senate, or what indeed I shall not write to you, may all the powers of heaven confound me yet worse than they have already done, if I know or can imagine!’ And his observation upon it is well worthy of ours, and very apposite to our present purpose: ‘In this manner (says he) was this emperor punished by a reflection on his own infamous life and guilt; nor was it in vain that the greatest matter of wifdom (he means Plato) affirmed, that were the hearts of tyrants once laid open to our view, we should see there nothing but ghastly wounds and bruises; the consciousness of their own cruelty, lewdness, and ill conduct, leaving as deep and bloody prints on their minds, as the strokes of the scourge do on the back of a slave. Tiberius (adds he) confessed as much, when he uttered these words; nor could his high station, or even privacy and retirement itself, hinder him from discovering to all the world the inward agoniés and torments under which he laboured.” Thus that excellent historian. We cannot forbear subjoining the following fact, related by Mr. Fordyce in his “Dialogues on Education” (vol. ii. p. 401), as a real occurrence which happened in a neighbouring state not many years ago. A jeweller, a man of good character and considerable wealth, leaving occasion, in the way of his business, to travel at some distance from the place of his abode, took along with him a servant, in order to take care of his portmanteau. He had with him some of the
bully jewels, and a large sum of money, to which his servant
was likewise privy. When the master had occasion to dis-
mount on the road, the servant, watching his opportunity,
took a pistol from his master's saddle and shot him dead on
the spot; he then rifed of his jewels and money, and
hanging a large stone to his neck, throw him into the nearest
canal. With this booty he made off to a distant part of the
country, where he had reafon to believe that neither he nor
his master were known. There he began to trade in a low
way at first, that his obfcurity might screen him from ob-
ervation, and in the course of feveral years seemed to rise,
by the natural progress of bufinefs, into wealth and con-
fraction; fo that his good fortune appeared at once the ef-
eft and reward of industry and virtue. Of this he con-
fronted the appearance fo well, that he grew into great credit,
mixed into a good family, and by laying out his hidden
fortunes as fcarcely as he could, and joining to all an
unfeveral affinity, he was admitted to a share in the govern-
ment of the town, and role from one poll to another, till at
length he was chosen chief magistrate. In this office he
maintained a fair character, and continued to fill it with no
small applause, both as a governor and a judge; till one day
as he sat on the bench with some of his brethren, a criminal
was brought before him who was accus'd of murdering his
master. The evidence came out full, the jury brought in
their verdict that the prisoner was guilty, and the whole as-
sembly waited the fentence of the prefident of the court (an
office which that day belonged to him), with great fufpence.
In the mean while he manifested an unfulfill disorder and agi-
tation of mind, and his colour often changed; at length he
arofe from his seat, and coming down from the bench, placed
himfelf juft by the unfortunate man at the bar. "You
fee before you (faid he, addressing himfelf to thofe who had
fat on the bench with him) a ftriking infufion of the juft
ration of heaven, which this day, after 30 years' conceal-
ment, presents to you a greeter criminal than the man juft
now found guilty." He then proceeded to make an ample
confifion of his guilt, and of all its aggravations. "Nor
am I felt (continued he) any relief from the agonies of an
awakened confcioufnefs, but by requiring that juftice be forth-
with done againft me in the moft public and solemn man-
ner." We may juftly fuppofe the amazement of the whole
assembly, and especially of his fellow-judges. However,
they proceeded, upon this confifion, to pass fentence upon
him, and he died with all the symptoms of a peafant
mind.

CONSCIENCE, Court of. See COURT.

CONSCIOUSNESS, in Logic and Metaphysics, is the
mind's perception of its own existence, facilities, and op-
erations; and, in this view of it, it is one of the fources of
judgment, and one species of evidence. Confeiionefls,
faith Dr. Reid, (Essays on the Intellectual Powers of Man,
p. 578.) is an operation of the understanding of its own
kind, and cannot be logically defined. The objects of it
are our prefent pains, our pleafures, our hopes, our fears,
our defires, our doubts, our thoughts of every kind in a
word, all the passions, and all the actions and operations of
our own minds, while they are prefent. We may remem-
ber them when they are past: we are confcioufs of them only
while they are prefent. It is, therefore, a firft princi-
ple that every thing exits of which we are confcioufs.
When a man is confcioufs of pain, he is certain of its exis-
tence; when he is confcioufs that he doubts, or believes, he
is certain of the effifence of fuch operations. And his
confcioufnes of the reality of fuch operations is not the ef-
eft of reafoning; it is immediate and intuitive. The effifence,
therefore, of the passions and operations of our minds, of
which we are confcioufs, is a firft principle, which reftores
requires us to believe upon her authority. Indeed, this is
the only principle of common fense, which has never been
directly called in quefion, and which retains its authority
with the greatest facility. Mr. Hume, after annihilating
body and mind, time and space, action and caufation,
and even his own mind, acknowledges the reality of the
thoughts, fentiments, and passions of which he is confcioufs.
From this fource of confcioufnes we derive all that we
know, and indeed all that we can know, of the ftructure,
and of the powers of our own minds: from which we may
conclude, that no branch of knowledge stands upon a ftronger
foundation; for surely no kind of evidence can go beyond
that of confcioufnes. Some have confounded confcioufnes
and reflection, though they are essentially diftinft. The
former is common to men at all times, but is insufficient
as to give us clear and diftinft notions of the operations of which
we are confcioufs, and of their mutual relations, and minute
differencies. The second, or attentive reflection upon
these operations, making them objeds of thought, for-
veying them attentively, and examining them on all fides, is
far from being common to all men, that it pertains to
very few.

Another firft principle, in relation to the fubject of this
article is, that the thoughts of which any one is confcioufs
are the thoughts of a being which he calls himfelf, his mind,
his perfon. "If any man asks a proof of this," fays Dr.
Reid, "I confefs I can give none; there is an evidence in
the propofition itfelf, which I am unable to refute. Shall I
think, that thought can ftand by itfelf without a thinking
being? or that ideas can feel pleafure or pain? My nature
dictates to me that it is impoffible. And that nature has
dictated the fame to all men, appears from the ftructure of
all languages; for in all languages men have expreffed
their ideas, by thinking, reafoning, feeling, loving, hating,
by personal verbs, which from their nature require a perfon who
thinks, feels, loves, hates. From which it appears,
that men have been taught by nature to believe that thought
requires a thinker, and reafon a reasoner, and love a lover."[
"Here," continues Dr. Reid, "we mtift leave Mr.
Hume, who conceives it to be a vulgar error, that besides
the thoughts we are confcioufs of, there is a mind which is
the fubject of thofe thoughts." If the mind be any thing
of more importance than impressions and ideas, it must be a word without
a meaning. The mind, therefore, according to this philo-
fer, is a word which signifies a bundle of perceptions; or
when he defines it more accurately, that it is the fufcifi-
fion of related ideas and impressions, of which we have an intimate
memory and confcioufnes. Whence it follows that, "I am,
faith our author, "that fucfiffion of related ideas and
impressions, of which I have the intimate memory and confci-
oufnes. But who is the I that has this memory and
confcioufnes of a fucfiffion of ideas and impressions? Why, it
is nothing but that fucfiffion itfelf."-Identity of confcioufnes, according to Mr. Locke,
constitutes identity of perfon. For a further difcufion of this
fubject, see IDENTITY.

CONSCRIPT, CONSCRIPTUS, a popular term in the
Roman history, used in speaking of feators, who were
called conscripts, fathers, patres conscripti; because their
names were written in the regifter, or catalogue of the
feators.

Livy, lib. i. cap. 1. tells us, that when Brutus filled
up the places of the feators cut off by Tarquin, with
others chosen out of the equeftrian order, those new
feators only had the appellation given them of patres
conscripti.

CONSCRIPTS
CONSCRIPTS also denote men raised to recruit the Imperial and French armies. All men capable of bearing arms in Hungary and Bohemia, have been usually enregistered and obliged to march wherever their services were called for. The conscripts in France, during the last and present war, have been raised on similar principles.

The militia of Great Britain comes likewise in some measure under this denomination or description, with this difference, that the men have been raised by ballot, and do not leave their native country, unless they voluntarily offer their services for that purpose.

Consecration, the act of converting or setting apart, any profane, or common thing, to a pious purpose; with certain ceremonies, prayers, benedictions, &c. appropriate to it.

Consecration is the return of sacrifice and profanation, which conflict in perverting a thing set apart for a pious purpose, to a profane and popular one.

The bishop consecrates a church, or a chalice; the pope consecrates medals, agnus dei's, &c. and grants indulgences to those who bear such about them with devotion. The consecration, or dedication, of a church is an episcopal ceremony, consisting in a great number of benedictions, with aspirations and invocations of chrism, &c. on the walls, both within and without. The form for consecrating churches, chapels, and church-yards, or places of burial, in England, may be seen in Wilkins's Concilia Magnae Britanniae, &c. vol. iv. p. 659. It directs that the bishop and clergy, of whom there are to be at least two, shall enter the church or chapel in their several habits, and, as they walk up from the well to the east end, repeat alternately the 24th Psalm; the bishop beginning, "The earth is the Lord's," &c. with the "Gloria patri." When they are come to the Lord's table, the bishop sitting in his chair shall have the instrument of dedication, donation, and endowment of the church or chapel, church-yard, or burial-place, presented to him by the founder, or some proper person, which he shall cause to be read by his registral, or other officer; and then the instrument shall be laid on the table, and he shall stand on the north side of it, and turning to the congregation, deliver an address to them, which is followed by suitable prayers. One of the priests then reads the service of the day, introducing proper psalms and litanies; after which, the bishop proceeds to the communion service, and instead of the collect of the day, utes one proper to the occasion. When the Epistle and Gospel are read, they are succeeded by the Nicene creed and the sermon; and then the bishop is to proceed with the service of the communion. When the service in the church is finished, the bishop and clergy with the people shall go into the church-yard, and make use of a prayer for the occasion. See uti jacta.

The custom of consecrating persons, temples, altars, vestments, utensils, &c. is very ancient; and all the ceremonies thereof are prescribed under the old law. When those consecrations relate to men, they are properly called ordinations; excepting those performed to bishops and kings, which full retain the name of consecration. Those which only consist in a ceremony instituted by the church, are more properly called benedictions. When they regard churches, altars, vessels, &c. they are properly called dedications.

In the trial of archbishop Laud, A.D. 1644, it was one of the charges alleged against him by the commons, that he had traitorously endeavoured and practised "to alter and subvert God's true religion by law established in this realm, and wished them to set up popish superstition and idolatry, and to reconcile us to the church of Rome." One branch of this charge was his introducing and practising certain popish innovations, and superstitious ceremonies, not warranted by law, nor agreeable to the practice of the church of England since the reformation. In proof of this charge, the managers, on the part of the commons, charged on his countenancing the setting up of images in churches, church-windows, and other places of religious worship. See Image.

Another popish innovation charged on the archbishop was, his superstitious manner of consecrating chapels, churches, and church-yards, such as had been practiced in Creed-church, and in the church of St. Giles's in the Fields. The managers objected further, his consecrating altars with all their furniture, as patterns, chalices, altar-cloths, &c. even to the knife that was used for cutting the sacramental bread; and his dedicating the churches to certain saints, together with his promoting annual revels, or feasts of dedication, on the Lord's day, in several parts of the country, by which that holy day was profaned, and the people encouraged in superstition and ignorance. With respect to the consecration of churches, the archbishop replied, that the practice was as ancient as Moses, who consecrated the tabernacle, with all its vessels and ornaments; that the temple was afterwards consecrated by Solomon; that as soon as Christian churches began to be built, in the reign of Constantine the Great, they were consecrated, as Eusebius testifies concerning the church of Tyre, (E.H. l.x. c. 3.), and so it has continued to the present time. Besides, if churches were not consecrated, they would not be holy, &c. &c. As to the manner of consecrating Creed-church, St. Giles's, &c. his grace confided that, when he came to the church-door, that passage in the Psalms was read, "Lift up your heads, O ye gates, even lift them up, ye everlasting doors, that the king of glory may come in;" that he knelled and bowed at his entrance into the church, as Moses and Aaron did at the door of the tabernacle; that he declared the place holy, and made use of a prayer like one in the Roman pontifical; that afterwards he pronounced divers curfes on such as should profane it, but denied his throwing dust into the air, in which he said, the witnesses had forsworn themselves; for the Roman pontifical does not prescribe throwing dust into the air, but ashes; and he conceived there was no harm, much less treason in it. As the consecrating of churches, and also dedicating them to God, has been of ancient usage, so has the consecration of altars and their furniture; and such consecrations are necessary, for else the Lord's table could not be called holy, nor the vessels belonging to it, as they usually are; yea, there is an holiness in the altar, which distinguishes the gift, which it could not do, unless itself was holy; if there be no dedication of these things to God, no separation of them from common use, then there can be no such thing as sacrifice, or difference between our holy table and a common one. And as to the form of consecrating the said things, the archbishop alleged, that he had it not from the Roman pontifical, but from bishop Andrews.

The managers for the commons replied, that if the temple was consecrated, it was by the king himself, and not by the high-priest; and if the tabernacle was consecrated, it was by Moses, the civil magistrate, and not by Aaron the high-priest; but we read, they said, of no other consecrating the tabernacle and its utensils, but anointing them with oil, for which Moses had an express command; nor of any other consecrating the temple, but of Solomon's making an excellent prayer in the outward court, not in the temple itself, and of his hallowing the middle court by offerings and peace-offerings; and it is observable, that the cloud and glory
CONSECRATION.

glory of the Lord filled the temple, so that the priests could not stand to minster before Solomon made his prayer, which some call his consecration. But if it should be allowed, that the temple was consecrated in an extraordinary manner, we have no mention either in Scripture, or in Jewish writers, of the consecration of their synagogues, to which our churches properly succeed. And, after all, it is no conclusive way of arguing, to derive a Christian institution from the practice of the Jewish church, because many of their ordinances were temporary, and abolished by the coming of Christ. Moreover, it is said, that from the beginning of Christianity, we have no credible authority for consecrating churches for 300 years. Eusebius, in his life of Constanine the Great, does indeed mention his consecrating a temple which he built over our Saviour's sepulchre at Jerusalem; but how?—with prayers, disputations, preaching, and exposition of scripture, as he expressly defines it (cap. 45.) Here were no proeessions, no knocking at the doors by the bishop, crying, "Open ye everlasting doors!" no calling duff or ashes into the air, and pronouncing the ground holy; no reverencing towards the altar, nor a great many other inventions of later ages. There were not known in the Christian church, till the very darkest times of popery; nay, in those very dark times, we are told by Otthe, the pope's legate, in his Ecclesiastical Conclusions, that in the reign of King Henry III., there were not only divers parish churches, but some cathedrals in England, which had been used for many years, and yet never consecrated by a bishop. But the archbishop's method of consecrating churches, it is said, evidently appears to be a modern popish invention; for it is agreed by Gratian, Pataia, the Centurinators, and others, that the popes Hyginus, Gelasius, Silvester, Felix and Gregory, were the first inventors and promoters of it; and it is nowhere to be found but in the Roman pontifical, published by command of pope Clement VIII. (De Ecclesiis dedicatione, p. 209, 286,) for which reason it was exploded and condemned by our first reformers, and particularly by bishop Pilkington, in his comment upon Haggai (ch. i. ver. 71, 81.) and archbishop Parker, who (in his Antiq. Brit. p. 87, 87,) expressly condemns the archbishop's method of consecration, as popish and superstitious. (See Altar.)

The archbishop, however, says, that if churches were not consecrated, they cannot be holy; whereas many places that were never consecrated are looked holy, as the most holy place, and the holy city Jerusalem; and our orthodox say, that the church is called holy, not of itself, but because God's people retaining thither come holy, and exercise themselves in holy things; and it is evident that sanctification, when applied to places, is nothing else but a separation of them from common use to a religious and sacred purpose, which may be done without the superstitious method above-mentioned; and though the archbishop avers, that he had not his form of consecration from the Roman pontifical, he acknowledges that he had it from bishop Andrews, who could have had it nowhere else.

As for the consecration of altars, pattens, chalices, altar-cloths, and other altar-furniture, its original is no higher than the Roman missal and pontifical, in both which there are particular chapters and set forms of prayer for this purpose; but to imagine that these vessels may not be reputed holy, though separated to an holy use, unless they are thus consecrated, is defective of foundation in reason or scripture, and contrary to the practice of the church of England, and the opinion of our first reformers. As to the practice of dedication, see Dedication. Neal's Hist. of the Puritans, vol. ii. ch. 5. 40.

CONSECRATION of the Pope, a ceremony which is particularly described by cardinal Raphson, in his book concerning the church of the Lateran, and which is also related by another Benedictine in his metallic history of that city; and by Lenfant, in his history of the council of Constance. "Before the usage of the concave was introduced by Gregory the tenth," says cardinal Raphson, "the cardinals, three days after the obsequies of the former pope, convened in the Lateran church, where, after the invocation of the Holy Spirit, and the celebration of mass, they proceed to the election of a pope. The election being made, the first cardinal deacon invected the pope elect in his pontifical habit, and announced the name which he chose to take;" for it has been the custom now, for several centuries, that the pope should assume a new name on being elected. "Afterwards, two cardinals, the most eminent in dignity, one on his right hand, the other on his left, conducted him to the altar, where he prostrated himself in adoration of God, whilst they sang the Te Deum. After the Te Deum, the cardinals seated the pope in a marble chair, which was behind the altar, under a fort of dome, or vault, where the pope, being set, admitted the cardinals, the bishops, and some others, to kiss his feet, and to receive the laves of peace. Then the pope rising, the cardinals conducted him through the portico to another chair, bordered like what is called in French, les portes. This chair was thence very properly named saceroraria, the saceroraria. It was formerly placed before the portico of the patriarchal basilica, and is now to be seen in the cloister of that basilica." The use of these chairs, however, was afterwards abolished by Leo the tenth, probably for this, amongst other reasons, because the perjured chair was become connected with the fabulous story of the female pope. That, however, is not a protestant fable, as some perfons ignorantly pretend, for it was current long before the days of Luther. But the continuance of the use of that chair preferred the memory of the story, and might appear to the credulous an evidence of its truth. Whilst the pope sat on the saceroraria, the choir sang these words of scripture: Sufciat de pulvere egenum, et de fercore erigit pauperem, ut fedest eum principibus, et folium gloriosum teneat. Psalm, exii. 7. The last clause is not in the psalm. He raiseth the poor out of the dust, and lifteth the needy off the dunghill, that he may set him with the princes of his people, and that he may poffess the throne of glory. The intention of this ceremony, it was said, was to iniminate to the pope the need there is of the virtue of humility, which ought to be the first step of his greatness. After remaining some time in this chair, the pope recumbeth himself in the hands of the chamberlain three dentors, which he throweth to the people, pronouncing these words: Silver and gold I have none for my pleasure, but what I have I give you. Afterwards, the prior of the Lateran basilica, and one of the cardinals, or one of the canons of that basilica, took the pope between them, and whilft they walked in the portico, fioots of esclamation were raised near the basilica, and the election was declared, with the name which the pope had taken. In this manner they conducted the pope to the basilica of St. Sylvester, where, being placed before this basilica in a chair of porphyry, the prior of the basilica put into his hands a ferula, in sign of correction and government, and the keys, to denote the power which God gave to St. Peter, prince of the apostles, of opening and shutting, of binding and loosing, and which paffes (according to our historian) efficaciously to all the Roman pontiffs. Thence the pope, carrying the ferula, and the keys, went to place himself in another chair, resembling the former; and after remaining there some time, refofed the ferula and the keys to the prior, who girt him with a girdle of red silk, giving him a move.
Consecration.

The word *consecration* is used in the liturgical and ecclesiastical context to denote the act of setting apart or dedicating something, usually for a religious purpose. This can involve the setting apart of a place, person, or object for a sacred purpose, often as part of a liturgical ceremony. In the context of the Church, consecration is an important act that sets apart a person or thing for God's use.

The text provided is a historical description of a consecration ceremony that took place in St. Peter's Basilica, Rome. The ceremony involved a number of symbolic actions, such as the anointing of the pope, the presentation of gifts, and the procession of the cardinals and clergy. The ceremony was performed as a way to sanctify the pope and the church, setting them apart for the holy work of ministry.

The ceremony was also performed as a way to celebrate the pope's ordination to the apostolic office, and to bless the pope and the church with the gifts of the Holy Spirit. The ceremony was a public display of the pope's holy office, and a way to celebrate the spiritual work of the church.

The text provides a detailed account of the ceremony, including the various actions performed, the symbolic significance of each action, and the historical context of the ceremony. The ceremony was performed as a way to sanctify the pope and the church, and to bless the people with the gifts of the Holy Spirit.
my body; this is my blood; which the Greeks maintain are
only necessary in the proofs of the consecration, as they
contam the history of the institution; not as they contribute
any thing to the change.

Consecration of various animals, was common among
the ancient Greeks and Romans. Suetonius mentions the
consecration of a great number of horses by Julius Cæsar,
when he passed the Rubicon; and Eustathius observes, that
it was common among the Greeks to consecrate whole-herds
of cattle, and several flocks of birds, especially geese and
peacocks, to their gods; giving such animals their liberty,
and forbidding all persons to touch or molest them. Atha
neus remarks, that they paid the same respect to fishes, par-
ticularly those bent adapted to the palate; and Pliny takes
notice, that the dolphin of Octavius Augustus had this fa-
vour conferred upon him. Aelian likewise relates, that they
sometimes put necklaces about the necks of thier fishes, and
then turned them loose to their proper element. The Ro-
mans also had their magical consecrations: it being cu-
tomary for their emperors to offer sacrifices, repeat charms,
dispel statues in certain places, imagining that such magi-
cal operations would hinder barbarians from entering their
domestions. Thus Marcus Antonius endeavoured to for-
ify himself against the invasion of the Marcomanni; and
some have thought that the palladium of Troy, and the
volcanic statue of Mammern, were of this kind. Macrobius
has given us a particular description of the consecration of
the Roman pontiffs, to the following purport: they dug a
pit in the earth, into which the perfon to be consecrated was
let down, dressed in priestly vestments, and the pit was
covered with a plank bored almost full of holes; a bull,
crowned with garlands of flowers, was placed on this plank,
and his throat being cut, the blood poured through the
plank on the priest, who received it on his head and face.
On ascending from the pit, covered with blood, he received
the salutation of Pontifex.

Consecration, among Magians, is the ceremony of the
apostasia of an emperor; or his translation into heaven,
and reception among the gods. See Apothesis.

On medals, the consecration is thus represented: on one
side is the emperor's head, crowned with laurel, sometimes
veiled; and the inscription gives him the title of divus: on
the reverse is a temple, a bull, an altar, or an eagle tak-
ing its flight towards heaven, either from off the altar, or
from a cippus; at other times the emperor is seen in the air,
borne up by the eagle; the inscription alway, conse-
crate.

These are the usual symbols: yet on the reverse of that
of Antoninus, is the Antonine column. In the apotheosis
of emperors, instead of an eagle there is a peacock. As to
the honours rendered these princes after death, they were
explained by the words consecratio, pater, divus, and deus.
Sometimes around the temple or altar are put, memoria felix,
or memoria eterna; for princesses, eternitas, and fidelitas
recepta; on the side of the head, deus, or Om. See Medal.

Consectary, a proposition that follows, or is de-
duced, from some preceding definition, lemmata, axioms,
conclusions, or the like. Some rather choose to call it a
consequence: and others a corollary, &c.

Consecutive Chords, in Music, are such as im-
meditately succeed each other in composition or performance.
See Music, Plate IV. Holder truly observes, when
speaking of the rule in composition, which follows a suc-
cession of octaves or fifths, except by contrary motion, that
in triads the name applies to all consecutively intervals what-
ever; but that the intermixture of major and minor thirds,
and major and minor-sixths in the scale, renders the oc-
urrence of consecutive major-thirds, major-sixths, minor-
thirds or minor-sixths, very rare and inoffensive in their cli-
ing effect upon the ear, compared with those of fourths,
fifths, or octaves, if care is not taken by the composer to
prevent the succession of the latter, except in contrary
motions.

Consecutively, consecutively, in the School Phi-
losophy, is sometimes used in opposition to successively, and
sometimes to effectively, or causally.

Thus, say the Schoolmen, the corruption of one thing
is the generation of another, not effectively, but consecutively:
that is, since matter cannot be without form, it is necessary,
that the generation of one thing follow upon the corruption
of another.

Consedia, in Ancient Geography, a piece of Gallia
Lyonnaesis, situated, according to the Itinerary of Antoninus,
between Comisae and Parium Marius.

Conseil de Guerre, Fr. Council of War. This is
composed of the general in chief, and the general officers
of the army, which he commands, whether it be held for
the purpose of deliberating among themselves on the mea-
sures they ought to pursue in a difficult conjuncture, of an
offensive or defensive nature or otherwise; or for some act
of military justice; or for accepting, regulating, stipulating,
or refusing articles of a proposed capitulation; or for es-
tablising rules and regulations for the police and discipline
of the troops; or, in fine, for judging of any military crime or
discharge.

Conseil de Guerre secrét, Fr. A secret council
of war. A secret council held by the king and his ministers
for deliberating on a defensive, offensive, or federative
war.

Consent of Parts, in the Animal Economy. See
Sympathy.

Consent of the Parties, in the Law of Succession.

Consentes, in Mythology, derived from the old
Latin consa, consel, denote twelve superior deitites among
the Romans, or the "di majorum gentium," who were ap-
prehended to belong to the council of Jupiter. They were
comprehended by Ennius in the following districts:

"Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars,Mercurius, Jovis, Neptunus, Vultanus, Apollo." Tho
ioe which were esteemed the superior deities, and were
the principal objects of the pagan worship, had been men,
according to Cicero (Tacl. Diu. lib. i. c. 12, 13); and
this was taught even in the mysteries. Varrus men-
tions twelve deities under the same denomination, who superin-
tended agriculture. Lib. i. De Re Rustica.

These confestes had a temple at Putei in Italy; and
they had their common altar at Athens, as Plutarch (in Nicia)
informs us. Aristophanes says, it was usual to swear by
them. In ancient inscriptions they are thus marked: J.O.M.
i. Jovis optima maxima, Catenis Di Consen-
tibus. They were also called "Dii magni," "caelestes,"
or "nobles," and are represented as occupying a different
part of heaven from the inferior gods, who are called "Plbs,"

Consentia were feasts instituted in honour of these
deities.

Consentia, in Ancient Geography, Cosenza, a town
of Italy and capital of the country of the vastis by whom it
was built. It was situated on the small river Crthus.
Alexander, king of Epirus, surpursed it in his expedition
into Italy. See Cosenza.

Consequent, in Logic, the conclusion of a rea-
oning, or argument.
Anciently there were appointed conservators of treaties of peace between princes; and these conservators became judges of the infractions made on a treaty, and were charged with procuring satisfaction to be made. They were usually the feudatories of the several powers. In lieu of conservators, princes now have recourse to other indifferent princes to guarantee their treaties. See Guarantee.

Conservator of the peace, in our Ancient Customs, was a person who had an especial charge, by virtue of his office, to see the king's peace kept.

Till the erection of justices of the peace by king Edward III., there were several persons who by common law were credited in keeping the peace; some having that charge as incident to other offices; by others simply, or of itself, called eybode, or conservators of the peace. Those that were so by virtue of their office still continue; but the latter are superseded by the modern justices.

The chamberlain of Chelft is still a conservator in that county; by virtue of his office. 4 Ind. 102.

Sheriffs of counties at common law are conservators of the peace; and constables, by the common law, were conservators, but some say they were only subordinate to the conservators of the peace, as they now are to the justices.

The king's majesty is, by his office and dignity royal, the principal conservator of the peace within all his dominions; and may give authority to any other to see the peace kept, and to punish such as break it: hence it is usually called "the king's peace." The lord chancellor, or keeper, the lord treasurer, the lord high steward of England, the lord marshal, the lord high constable of England, (when theSheriffs are in being,) and all the justices of the court of King's Bench (by virtue of their offices,) and the master of the rolls (by prescription) are general conservators of the peace throughout the whole kingdom, and may commit all the breakers of it, or bind them in recognizances to keep it. The other judges are only so in their own courts. The coroner is also a conservator of the peace within his own county; as also the sheriff; and both of them may take a recognizance or security for the peace. Constables, tithing-men, and such like, are also conservators of the peace within their own jurisdiction; and may apprehend all breakers of the peace, and commit them till they find sureties for their keeping it.

Those that were, without any office, simply and merely conservators of the peace, either claimed that power by prescription, or were bound to execute it by the tenure of their lands; or, lastly, were chosen by the freemen in full county court before the sheriff; the writ for their election directing them to be chosen "de probioribus et potentioribus comitatus sui in custodes pacis." But when queen Elizabeth, the wife of Edward II., had contrived to depose her husband by a forced resignation of the crown, and had set up his son Edward III., in his place, this being an unprecedented measure, caused an alarm; and, therefore, in order to prevent any insurrections, and disturbance of the peace, the new king sent writs to all the sheriffs of England, indicating the manner of his obtaining the crown, and commanding each sheriff to keep the peace throughout his bailiwick, on pain and peril of disfranchisement and loss of life and limb. Soon after it was ordained in parliament, that for the better maintaining and keeping of the peace in every county, good men and lawful, who were no maintainers of evil, or barreters in the country, should be affiliated to keep the peace. Thus, and at this time, the election of conservators of the peace was taken from the people, and given to the king; such affiliation being conformed to.

The two premises of a syllogism being granted, the consequence must also be granted.

In a more restrained signification, consequence is used for the relation or connexion between two propositions, whereas one follows, or is inferred, from the other. Thus: It is an animal, and therefore feels.

Consequent, the last proposition of an argument; being something deduced or gathered from a preceding argumentation. An ethymone only contains two propositions, the antecedent and consequent: if the antecedent be absurd, the consequent must be false too.

Consequent, in a more precise sense, is used for the proposition which contains the conclusion, considered in itself, and without any regard to the antecedent; in which sense, the consequent may be true, though the consequence be false.

Consequent of a ratio, in Arithmetic, the latter of the two terms of a ratio; or that to which the antecedent is referred. See Proportion.

Thus, in a : b, or a to b, b is the consequent, a the antecedent.

Consequents, in Rhetoric, are also used to signify such things as being allowed, necessarily, or very probably, infer their antecedents. Thus with respect to a substance, it is correlative, and therefore material.

Consequent, in the Italian Musici, is used to signify concords, or those intervals which accord pleasantly, be they either perfect, as the fifth and eighth, or imperfect, as the third, sixth, &c. See Octave.

Consequent, a motion in consequitans is a motion in the order of the signs of the zodiac.

Consequential Damages, in Law. See Damage.

Consequence, Ital. a term in Music, used by Zarlino and other old authors, instead of Fuga; but F. Martini makes it synonymous with Riposta, or reply to a subject given.

Conerans, or Conerans, in Geography, the name, before the revolution, of a country in France, in Gallesy, and the diocese of a bishop, who resided at St. Liger, the capital; it was bounded on the east by Foix, on the south by Catalonia, and on the north and west by Connings.

Conservation, in Ontology, denotes giving duration, or continuance in existence to all creatures; in contradistinction to creation, which gives existence to all created substances. Some of the ancient schoolmen have represented conservation as a continued creation; to which it has been objected that as God, whenever He creates a substance, must create it with all the properties, modes, and accidents which belong to it, it will follow, that be must at the same time create or give being to, all their final though s and inclinations, and even their most criminal and abominable actions; or, in the most complete sense of the term, be the author of sin. Wett's Philos. Eff. Eff. xii § 4.

Conservative Suture. See Suture.

Conservator, an officer established for the security and preservation of the privileges granted to some cities and communities; or, a person who has a commission to judge of, and decide, the differences arising among them. In most Catholic universities, there are two conservators; the conservator of royal privileges, or those granted by kings; and the conservator of apostolical privileges, or those granted by the pope. The first takes cognizance of personal and mixed causes between the regents, students, &c. and the latter of spiritual matters between ecclesiastics.

Vol. IX.
CONSERVATORIO, Ital. a title given in Italy to almost all charity-schoo?; but chiefly to those where children are taught music, and are otherwise educated with a view to that profession. The conservatorio in the city of Venice have been much celebrated by all travellers previous to the revolution; it had four of these schools: the Ospedale della Pietà, the Mendicanti, the Incurabili, and the Ospedale di S. Giovanni e Paolo, at each of which there was a performance every Saturday and Sunday evening, as well as on great festivals. At these, the performers, both vocal and instrumental, were all girls; the organ, violins, flutes, violoncellos, buffoons, and even double-basses, kettle drums, and French-horns, were supplied by females. Each of these establishments was a kind of founding hospital for natural children and orphans, under the protection of several nobles, citizens, and merchants, who, though the revenue is very great, yet contribute annually to its support. These girls are maintained here till they are married, and all those who have talents for music are taught by the best masters of Italy.

There were three conservatories in the city of Naples, for the education of boys who were intended for the profession of music, of the same kind with those of Venice, for girls. As the scholars in the Venetian conservatories have been chiefly celebrated for their talent and merits of execution, so those of Naples have long enjoyed the reputation of being the first contra-puntists, or composers in Europe. It is from these seminaries that Italy, and all Europe, have been delighted with the genius and talents of the two Scarlatti, Vinci, Leo, Pergolesi, Porpora, Farinelli, Cafarelli, Giazziello, Durante, Jonelli, Perez, Piccini, Trueta, Anfetti, Sacchini, Pacchierii, and innumerable others of the first eminence among composers and performers both vocal and instrumental.

CONSERVATORY, in Gardening, a place contrived somewhat in the manner of the green-hose, but more spacious and elevated, and finished in a neater and more perfect manner; being designed for containing and preserving the more rare and curious sorts of exotic plants, as well as for affording amusement by being provided with walks laid with some sort of neat material, according to the taste of the proprietor, in a serpentine or other irregular manner between the plants.

Houses of this nature should have dry and rather elevated situations, at a small distance from the residence, and be ranged in such a manner as to have the benefit of the sun as much as possible during the day. They must likewise be provided with fires for the purpose of communicating heat when it may be necessary, and also valves and other contrivances for the introduction of fresh air when wanted, and to afford due ventilation.

The sides, ends, and roofs, must be formed with glass, as in the green-house, in order to admit light freely, and at the same time protect the plants.

It has been generally considered as synonymous with green-hose; but its principle or essential difference consists in this, that in the latter the trees and plants are either in tubs or pots; and placed on beds or shelves through the winter, whereas in the former the ground is laid out in beds and borders made up of the finest compositions of soils or of earthy materials that can be procured, three or four feet in depth; in which the trees and plants, taken out of their tubs or pots, are regularly planted, in the same manner as hardy plants in the open air. And instead of taking out the plants in the summer, as in the green-house, the whole of the glass roof is taken off, and the plants exposed to the open air; when, on the approach of autumn, the lights are again put on, and remain so till the first frosts of the season shall fix such as that they can be removed without danger from cold.

In cases of necessity, it is evident however, that these buildings may also be used as green-houses by introducing stages instead of beds, in which case the glass roof should be fixed. Other conveniences may be attached to them, such as retiring rooms, bed rooms, aviaries, &c. Some buildings of this sort are, according to the editor of Miller's dictionary, formed so as to have one of the wings facing the south-east, and the other the south-west, so that from the time of the sun's first appearance upon any part of the building, until it goes off at night, it may be constantly reflected from one part to the other, and the cold winds be also kept off from the front of the centre building. In the area of the adjoining rooms or wings, many of the more tender exotic plants may be placed in the summer season; and in the spring before the plants can be let out. The beds and borders of this area may be full of amenities, ranunculuses, early tulips, &c. which will be part flowering, and the roots fit to take out of the ground, by the time the plants are taken out of the house. In the centre of this area may be a small basin of water, which will be very convenient for watering the plants, not only on account of its nearness, but because the water will be softened and warmed by the reflection from the glass. And the wing facing the south-east should always be preferred for the warmest, or bark-floe, because the sun, at its first appearance in the morning, shines directly upon the glass, and warming the air of the house, gives new life to the plants, after the long nights of the winter season.

It is also farther observed, that in these buildings, if there are not sheds running behind them their whole length, the walls should not be less than three bricks thick, and if they are even more it will be better, because where the walls are thin and exposed to the open air, the cold will penetrate; and when the fires are made the heat comes out through the walls, so that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the houses; and in general, the colder and better these houses are built, the less fuel will be required to warm them, so that the
CONSERVE, in Pharmacy, &c. a dry confect, or form of medicine, or food, contrived to preserve the flowers, leaves, roots, peels, or fruits of several simples, as near as possible to what they were when fresh-gathered; and to give them an agreeable taste.

Con verses are compositions of recent vegetable matters and sugar beaten together into an uniform mass. Vegetables whose virtues are lost by drying, may be preserved in this manner for a considerable time unimpaired, the sugar preventing the natural decomposition and moulding which would otherwise take place.

The preparation of the conserves is as simple as possible. The sugar is first ground to fine powder, and then mixed by long beating (not by solution) with the vegetable pulp or other material. No heat or other mode of preparation is employed, so that the vegetable matter remains as nearly as possible in the state in which it existed in the plant at the moment of gathering. The conserves directed by the London college are those of hips, roeses, floes, arum and squills. Of these the two last alone can be considered as active medicines; and the arum is exhibited with peculiar efficacy in this form, as its pungency to the palate is a little lessened, whilst its internal stimulating powers remain unaltered.

The conserve of arum, or cockow-pint, is a composition of arum bruised, half a pound, and double refined sugar, 1 pound, beaten together in a mortar. Those who hold in veneration the integrity and experience of Sydenham, will have no doubt of the effects of this medicine in rheumatic cases. This conserve may be given to adults in doves of a dram.

The conserve of the hip, or "conserve cynoblati," is formed by mixing one pound of hips with 20 ounces, by weight, of double refined sugar, powdered. This pulp should be separated with great care from the rough prickly matter including the seeds; a small quantity of which, retained in the conserve, is apt to occasion an unpleasing acrid to the stomach, a pruritus about the anus, and sometimes vomiting.

The conserve of the floes, "conserve pruni sylvetris," is prepared by putting the floes in water upon the fire, that they may soften, taking care that they do not burn; then taking them out of the water, prelling out the pulp, and mixing it with three times its weight of double refined sugar.

The conserve of squills, "conserve folliculi," is made by beating together in a mortar one ounce by weight of fresh squill with five ounces by weight of double refined sugar. This conserve is directed to be prepared in a small quantity, in order to guard against its variation in strength. It may be given to adults, from half a dram to two scruples, or more; especially when fresh.

For the conserve of fruit-wood, the outer rind of the Seville orange, sword-foresh, and of the red rose; pluck the leaves from the footstalks, and the unblown petals from the calyx, cutting off the heels: take off the outer rind of the oranges with a grater: when you have thus prepared them, bruise them with a wooden pelle in a marble mortar; and then beat them up with three times their weight of double-refined sugar, until they are mixed. The sugar should be powdered by itself, and passed through a sieve, before it is mixed with the vegetable mass; otherwise it cannot be properly incorporated. Rose buds, and some other vegetables, are usually prepared for mixing with sugar by a small wooden mill, contrived for that purpose. All the conserves are to be kept in close vessels, especially those of arum and squill.

With regard to fruits, as currants, &c. they are placed on the fire to make them yield their juice, then drain and strain them, and thicken what comes from them over the fire; and add to it the sugar. This last sort of conserve is particularly called a jelly; which see.

CONSERVES, Fr. in Military Language. See Counter-guard, or contre-garde, the names by which this work is usually and well known.

CONSETT Day, in Geography, a bay on the N.E. coast of the island of Barbadoes, N. of Consett's point, which is a cape, 10 miles N.E. of Bridge-town.

CONSETTI, Antonio, in Biography, an historical painter, native of Modena, where he enjoyed considerable reputation, in the last century. He was born in the year 1636, and is said to have been successively the disciple of his countrymen Francesco Stringis, and Donato Creti of Bologna, from whose precepts and example he acquired a correct style of drawing, and facility of composing. Unfortunately, however, his colouring is deficient of those charms of union and softness, which captivate the eye at first sight. The principal part of the life of this artist was spent in the state of Modena, where his pictures are by no means uncommon, and where he died in 1766. Lanzi. Storia Pittorica.

CONSIDERATIO curiæ, in Law, terms often occurring in law proceedings, and where matters are determined by the court. "Ideo consideratorium pro curia," i.e. therefore it is considered and adjudged by the court. Consideratio curiæ, &c. denotes the judgment of the court.

CONSIDERATION, the material cause, or quid pro quo, of any contract, and without which no contract is obligatory or binding.

This consideration is either expresse, as if a man bargain to give ten guineas for a horse, or to sell his land for a certain sum, or to grant it in exchange for other lands, &c.; or when a person agrees for a stipulated sum to do a thing; or implied, when the law itself enforces a consideration; as if a man coming into an inn, take meat, drink, and lodging for himself and horse, the law presumes he intends to pay for them, though there be no express contract between him and his host: and if he discharges not the house, the host may hoo his horse.

Considerations may be regarded either as pertaining to contracts generally, or to deals in particular. As to contracts, consideration may be defined to be the reason which moves the contracting party to enter into the contract. The citizens hold, that in all contracts, either express or implied, there must be something given in exchange, or something that is mutual or reciprocal. This thing, which is the price or motive of the contract, is called the consideration; and it must be a thing lawful in itself, or else the contract is void. A good consideration is that of blood or natural affection between near relations; the satisfaction accruing from which the law eleemos an equivalent for whatever benefit may move from one relation to another. (3 Rep. 83, 1 Inl. 271.) This consideration may sometimes, however, be lost aside, and the contract become void, when it tends in its consequences to defraud creditors or other third persons of their just rights. But a contract for any valuable consideration, as for marriage, for money for work done, or for other reciprocal considerations, can never be imputed
CON

peached at law; and, if it be of a sufficient adequate value, is never set aside in equity: for the person contracted with has then given an equivalent in recompense, and is therefore as much an owner, or a creditor, as any other person. These valuable considerations are divided by the civilians into four species. 1. Do, ut des; as when I give money or goods on a contract to receive in return money or goods: of this kind are all loans of money upon bond, or promise of repayment, and all fakes of goods, in which there is an express contract to pay so much for them, or else the law implies a contract to pay as much as they are worth. 2. Facio, ut facias; as when I agree with a man to do his work for him, provided that he will do mine for me; or if two persons agree to intermarry; or to do any other positive acts on both sides: or, to forbear on one side, on consideration of something done on the other, as that in consideration A, the tenant, will repair his house, B, the landlord, will not sue him for want; or, for mutual forbearance on both sides. 3. Facio, ut des; as when a man agrees to perform any thing for a price, either specifically mentioned, or left to the determination of the law to set a value on it. Thus, when a servant hires himself to his master for agreed wages, he contracts to serve his master for that specific sum: or, otherwise, if he be hired generally, he is under an implied contract to perform this service for its reasonable worth. 4. Do, ut facias; as, when I agree with a servant to give him such wages upon his performing such work, which is the last species inverted; for fereus facit, ut herus det, and herus dat, ut fereus faciat.

A consideration of some sort or other is so absolutely necessary to the forming of a contract, that a nudum pactum, or agreement to do or pay anything on one side, without any compensation on the other, is totally void in law; and a man cannot be compelled to perform it. (Dr. and Stud. l. 2, c. 24.) Thus, if one man promises to give another two l., nothing is contracted for or given on the one side, and therefore nothing is binding on the other. And, however a man may or may not be bound to perform it, in honour or conscience, which the municipal laws do not decide; those laws will certainly not compel the execution of what be had no visible inducement to engage for; and, therefore, our law has adopted the maxim of the civil law, that "ex nudo pacto non oritur actio." But any degree of reciprocity will prevent the pact from being null; nay, if even the thing be founded on a prior moral obligation (as a promise to pay a just debt, though barred by the statute of limitations), it is no longer nudum pactum. And as this rule was principally established to avoid the inconvenience that would arise from setting up mere verbal promises, for which no good reason could be assigned, it therefore does not hold in some cases, where such promise is authentically proved by written documents. For if a man enters into a voluntary bond, or gives a promissory note, he shall not be allowed to set up the want of a consideration in order to evade the payment; for every bond from the solemnity of the instrument, and every note from the subscription of the drawer, carries with it an internal evidence of a good consideration. Courts of justice will therefore support them both, as against the contractor himself; but not to the prejudice of creditors or strangers to the contract. Plowd. 308, 309. Hard. 4. 1 Ch. Rep. 157. Ld. Raym. 760. Fonsbanque, Treat. Eq. 334. n.) See Contract.

With regard to deeds, it may be observed, that they must be founded upon good and sufficient consideration; not upon an amiable contract (lat. 13 Eliz. c. 8.); nor upon fraud or collusion, either to deceive purchasers bona fide (lat. 27 Eliz. c. 4.); or just and lawful creditors (lat. 13 Eliz. c. 5.); any of which bad considerations will vacate the deeds, and subject such persons as put the same in use, to forfeitures, and often to imprisonment. A deed also, or other grant made without any consideration, is, as it were, of no effect; for it is construed to enure to, or to be effectual, only to the use of the grantor himself. (Park. § 533.) The consideration may be either a good or a valuable one. A good consideration is such as that of blood, or of natural love and affection, when a man grants an estate to a near relation; being founded on motives of generosity, prudence, and natural duty. A valuable consideration is such as money, marriage, or the like, which the law deems an equivalent given for the grant (3 Rep. 83.); and is therefore void, unless the consideration is sufficiently adequate. Deeds made upon good consideration only, are considered as merely voluntary, and are frequently set aside in favour of creditors, and bona fide purchasers. See Deed.

A mere voluntary curtesy will not be a good consideration of a promise; but the value and proportion of the consideration is not material for maintaining an action, whether it be a penny or 100 l.; but a jury will give damages proportionable to the loss. (Hob. 5. 10 Rep. 76.) A consideration that is void in part, is void in the whole; and if two considerations be alleged, and one of them is found to be a good consideration, the other consideration stands. (Hob. 126. Cro. Eliz. 848.) But if there be a double consideration for the grounding of a promise, for the breach of which an action is brought; though one of the considerations be not good, yet if the other be good, and the promise broken, the action will lie upon that breach; for one consideration is sufficient to support the promise. (1 Lill. 297.) A consideration must be lawful, to ground an affrumpet. (2 Lev. 161.) Where considerations are valuable, and consist of two or three, as a consideration of wages for the performance of every part, ought to be sworn. (Cro. Eliz. 579.) In case a deed of feoffment be made of lands, or a fine and recovery be passed, and no consideration is expressed in the deed, &c. for the doing thereof, it shall be intended by the law, that it was made for the use of the feoffor or conuor; for it shall be presumed he would not part with his land without a consideration; and yet the deed shall be construed to operate something, and that which is most reasonable. (4 Lill. Abr. 299.) Blackf. Com. vol. ii. Jacob's Law Dict. by Tomlins.

CONSIGLIONE, in Geography, a town of the island of Sicily, in the valley of Mazara; 19 miles S. of Palermo.

CONSIGNE, Fr. parole or counter-sign. When used in the masculine gender, it also means a person formerly paid by the French government for residing constantly in a garrisoned town in order to take cognizance of all persons that entered by the gates or went out of them. He had a place allotted to him, and regularly delivered a report to the governor or commandant of the place.

Consignee. A person who could not pass the post, or quit the house, to which the order of his superior had assigned him.

CONSIGNMENT, or Consignation, the depositing any sum of money, bills, papers or commodities, in sure hands; either by order of a court of justice, in order to their being delivered to the persons to whom they are adjudged; or voluntarily, in order to their being remitted to the persons they belong to, or sent to the places they are defined for.

Consignment of goods, is the delivering or making them over to another. Thus goods are said to be consigned to a factor,
factor, when they are sent to him to be sold, &c., or when a factor sends back goods to his principal, they are said to be confirmed to him.

CONSILNIUM, in Ancient Geography, a town of Italy, in a gulf between Brutium and Zephyrium, according to P. Mela. Frontinus says, that it was a Roman colony, and places it in Lucania.

CONSILNIUM, diei consilia, in Law, was a time allowed for the accused to make his defence, and to answer the charge of the accuser. It is now used for a speedy day appointed to argue a demurrer; which the court grants after a demurrer joined, on reading the record of the cause. See Imparlance.

CONSILI M Casu. See Casu.

CONSISTENT. See Consist.

CONSISTENCE, a state of rel, wherein things capable of growth or decrease, continue for some time at a stand, without either.

This term is particularly used with regard to trees, for the time, or age, beyond which they do not grow, and yet at which they do not decline.

Thus we distinguish three states or stages of a tree: its growth, confidence, and return: and these are common to all trees, even fruit trees.

The confidence of an oak is from fifty to a hundred and sixty years: some, however, hold, that their confidence only commences from a hundred years; affording that they grow till that time, and that they continue in that state of perfection to two hundred years of age.

Consistence, in Physic, is that state of a body wherein its component particles are so connected, or entangled among themselves, as not to separate or recede from each other.

Consistence only differs from continuity in this, that confidence implies a regard to motion or relf, which continuity does not; it being sufficient to denominate a thing continuous, that its parts are contiguous to each other.

When used relative to a disease, it imports the crisis or acme thereof: when applied to the humours, excrements, or excretions, it imports their state as to thicknes or thinnes.

Consistence is particularly used with regard to bodies considered as they are more soft, or more hard, more liquid, or more dry.

Forms of medicines, as electuaries, lambatives, boluses, syrups, ungues, &c. differ chiefly in confidence.

Not only the gratefulness, but also the operation, of medicines, depend in some measure on their confidence; for medicines of a thick confidence are taken into the stomach, and penetrate into the body with greater difficulty than such as are thin and liquid; and it requires more trouble to swallow a thick than a thin medicine: for this reason thick medicines are generally nauseous and ungrateful; and this is the reason why cathartic boluses are often dissolved in some agreeable liquor, since in this form they are more grateful than in any other: for this reason also apozems are generally clarified by whites of eggs, or a fraiser.

On the contrary, a thick confidence is on some occasions more to be desired; in ulcers of the aspera arteria, and esophagus, for instance, where we must give medicines made up with gum tragacanth, or other substances of a like nature, which by their viscidity fix the medicines, as it were, longer to the part affected.

CONSISTENT Bodies, is a term used by Mr. Boyle, for such as we ordinarily call firm, or fast bodies; in opposition to fluid ones.

That author has a particular essay on the atmosphere of consistent bodies; wherein he shews, that all, even solid, hard, ponderous and fixed bodies, do exhale or emit effluvia to a certain space all around them.

CONSISTENTES, in Church History, a kind of penitents who were allowed to assist at prayers, but could not be admitted to receive the sacrament.

CONSISTORIAL Advocate. See Advocate.

CONSISTORY, or Roman Consistory, denotes the college of cardinals; or the pope's senate, and council, before whom judicatory cauæs are pleaded.

De-Cange derives the word from consistorium; i.e. locus ubi consistoriis; used chiefly for a vestibule, gallery, or ante-chamber, where the courtiers wait for admittance; and called a consistorii multitudine.

The consistory is the first court, or tribunal of Rome: it never meets but when the pope pleases to convok it; the pope, præfides in it in person, mounted on a magnificent throne, and habited in his pontificals; on the right are the cardinal bishops and priests, and on the left the cardinals deacons.

The place where it is held, is a large hall in the apostolical palace, where princes and ambassadors of kings are received. The other prelates, prothonotaries, auditors of the rota, and other officers, are seated on the steps of the throne: the courtiers sit on the ground; ambassadors on the right, and consistorial and fiscal advocates behind the cardinals.

Besides the public consistory, there is also a private one, held in a retired chamber, called the chamber of papal-gayo; the pope's throne here being only raised two steps high.

Nobody is there admitted but the cardinals, whose opinions are collected, and called sentences. Here are first proposed and palled all bulls for bilipriacs, abbeys, &c. Hence bilipriacs, and abbeyes, are said to be consistorial benefices; in regard, they must be proposed in the consistory, the annates be paid to the pope, and his bulls taken.

Anciently they were elective; but by the concordat, which abolishes elections, they are appointed to be collated by the pope alone, on the nomination of the prince.

CONSISTORY was also the name of a court under Constantine, where he sat in person, and heard causes: the members of this court were called comites.

CONSISTORY is also used among the reformed, for a council or assembly of ministers and elders, to regulate their affairs, discipline, &c.

CONSISTORY, or Court Chrifian, in the English Law, is a council of ecclesiastical perons, or the place of justice in an ecclesiastical or spiritual court.

Every archbishop and bishop has a consistory-court, held, before his chancellor or commiffary, who is the judge, and supposed to be skilled in the civil and canon law, either in his cathedral, or in some other convenient place of his diocese, for ecclesiastical causes, arizing within their respective dioceses. In places of the diocese, far distant from the bishop's consistory, the bishop appoints a commiffary, commiffarius foracrorum, to judge in all causes within a certain district, and regifter to enter his decrees, &c. (2 Rol. Abr. 286. Seld. Hift. Tithes, 473, 444.) The spiritual court was anciently, in the time of the Saxons, joined with the county or hundred court; and the original of the consistory court,
court, as divided from those courts, is found in a law of the
Conqueror, quoted by Lord Coke.

From this court there lies an appeal to the archbishop of
each province respectively, by virtue of Stat. 24 Hen. VIII.

Consolation, one of the places in Rhetoric, where-
in the orator endeavours to abate and moderate the grief or
concern of another.

In consolation, a principal regard is to be had to the cir-
cumstances and relations of the parties. Scaliger considers
this exceeding well, De Arte Poetica. “The consoalator,
says he, is either a superior, an inferior, or an equal; with
regard, either to preferment, honour, wealth, wisdom, or
age. Livius is therefore to comfort Ovid, in a manner very
different from that wherein Ovid comforts Livius. Thus, as
to authority, a father and son, Cicero and Pompey, are to
conduct their consolations very differently: so in wealth,
as if a client should undertake to comfort Crassus: in wisdom;
as when Seneca comforts Polybius and his host: as to
age, there need no examples.”

“A superior may interpose his authority, and may even
chide; a wife may even dispute; sentences will become
him. An inferior is to shew respect and affection, and own
he had this from some wise or learned person: an equal
to appeal to their common friendship.”

Consolation, in Architecture, a bracket or projecting body
commonly in the shape of the letter S, which is used to sup-
port a cornice, vault, flat, statue, or even a column, as
in the barbarous architecture of the Diocletian palace at
Split.

Corbel is essentially the same thing as console, but
is generally confined to the description of Gothic building.

Consolation, in Bistry, Major; Baul. Pin. See
Symphoniurn officinale.

Consolatio medica; Baul. Pin. See Aegula.

Consolatio paliitris; Taber. See Seneo paliitris.

Consolatio regalis; Baul. Pin. Taber. Mon. See
Delphinium.

Consolation, in Law, the combining and unit-
ing of two benefits into one; Stat. 37 Hen. VIII. cap.
21. which union is to be by the allent of the ordinary, pa-
tron, incumbent, &c. and to be of small churches lying
near together.

The term is borrowed from the civil law; where it
properly signifies an union of the possession, or occupation,
with the property. Thus, if a man hath by legacy us-
fruitum fundi, and afterwards buys the property, or fee-im-
ple, of the heir: this is called a consolation.

Consolation, in Surgery, is the procès of nature, by
which a solution of continuity is united, either in a soft or
hard part of the body; and, as this procès was formerly
supposed to be within the control of surgeons, the remed-
dial applications employed for that purpose were denomi-
nated consolating medicins, or jarectics. Of this kind were
the different balsamic and refinous unguments, with all the
stimulating compositions containing turpentine. The sur-
genous may certainly vary the ingredients of his dressings in
such a manner to change the surface of a fore, and, in
many cases, so as to occasion a healing procès; but, after
all, he acts only as the hand-maid of nature, and is unable
to advance one step towards the consolation of a wound,
unless there be a previous tendency in the part to heal.

Warm stimulating applications will indeed cause a flow
of blood to the part wherein they are applied; and by ex-
citing the healthy action of blood-veffels, as well as by in-
creasing the sensibility of the skin or adjacent ulcerated sur-
face, they may promote suppuration, and even contribute to

Effect a cure, where it seemed unlikely before. In this
sense of the term, therefore, we may admit the existence of
consolating remedies.

Consonance, in Grammar, denotes a like cadence, or
close of words, periods, &c.

Consonances are ordinarily faults in discourse, especially in
English prose: though the ancients make a figure of them,
which they call quoniam. Too great a consonancy in the
rhymes has always an ill-effect.

Consonance, in Metre, signifies the union or agreement
of two sounds produced at the same time, and in this sense,
it includes all sorts of musical intervals, which naturally di-
vide themselves into three kinds, etc. The Concord, or such
sounds, as produce an agreeable and pleasing effect upon the ear,
see that article, 2d. Imperfect or tempered concords, which
are intervals nearly related to concords in respect to their
position in the scale, as explained when we were treating of
perfect concords, and also in partaking somewhat of the
pleasing effect of the concords to which they belong, when
not too much tempered; these are also further distinguished
by the phenomena of Brahs, see that article; and Imper-
fect Concord: and 3d. Discord, which are intervals that have
a grating or disagreeable jarring effect upon the ear, or
sometimes a fluttering roughness when nearly equal to an
imperfect concord, or to certain intervals in the scale, as
the notes major and minor, the tritone, semidiopt, and
other in effect, in defining consonance, “A passage of
several tunable sounds through the medium, frequently mix-
ing and uniting in their undulated motions, caufed by the
well proportioned commensurate vibrations of the resonous
bodies, and consequently arriving smooth and sweet, and
pleasing to the ear; as, on the contrary, diacutous, he main-
tains to arise from disproportionate motions of sounds, not
mixing, but jarring and clashing as they pass, and arriving in
the ear grating and offensive.”

This notion of a consonance exactly quadrates with that
we have already laid down for a concord. Accordingly, most
authors confound the two together; though some of the
more accurate dilhnguith with; making consonance to be
what the word implies, a mere concurrence of two or more
notes together, or in the same time; in contradistinction to
the motion of those touns in succession, or one after the
other.

In effect, the two notions coincide; for two notes, thus
played in consonance, constitute a concord; and two notes
that please the ear in consonance, will likewise please it in
succession. Notes in consonance constitute harmony, as notes
in succession constitute melody.

In the popular sense, consonances are either simple or
compound, &c. The most perfect consonance is unison; though
many, both among the ancients and moderns, differ it
from the number of consonances; as conceiving consonance
in agreeable mixture of different sounds, grave and acute;
not a repetition of the same found.

The second consonance is the othon; then the fifth, the
fourth, the thirds, and the sixths; the reil are multiples, or
repetitions of these.

Consonance is sometimes used by writers in the same
sense with concord; and thus, these are said to be variable,
and the term imperfect is prefixed when applied to intervals
which have a major and a minor of the same name, as thirds
and
and fithe, and perfect when applied to concords which never change their name, as the fifth, fourth, and octave; the absurdity of the use of the words perfect and imperfect is so apparent, that we wish to see them disused, and discontinue
theus in your books on music, in order that thes
terms may exclusively apply to intervals correctly tuned or perfect in respect of their accordance, or the reverse: there
was an impropriety in originally assigning one name to the
thirds and to the fifth, which naturally have no nearer relation
to each other, than the fourth and fifth, or octave and
unison, or even so much; but these being established in use,
may safely remain, without our continuing to confound and
reverse all ideas of perfection and imperfection, in con
sequence only of this defect in the musical nomenclature.

Consonants are said, by Dr. Smith, (Harmonics, p. 19.)
to be pure, where none of the equal times between the
pulses of the acuter found are subdivided by any intermediate pulse of
the graver; and interrupted when any of those equal times are interrupted by one or more pulses of the graver found.

See Cycls.

*CONSONANT, in Grammar, a letter which cannot be
perfectly founded by itself; but joined with a vowel, forms
an articulate sound, by a particular motion or contact of the
parts of the mouth: and hence the name consonant, q. d.
que sonant cum aliis.

A consonant, considering it philosophically, is nothing else but the modification of a sound, produced by means of the
organs of the voice, not a production of sound itself: thus,
commonly the sounds signified by the characters, a, r, t, o, u, &c. are differently modified when we say ah, than when
we say ae or au, ad or du; and these modifications are
called consonants.

Accordingly, Dr. Wilkins (Essay towards a real Char
acter, p. 72.) defines consonants to be those letters, in
the pronouncing of which the breath is intercepted, by
some collar or closure, among the instruments of speech:
and for this reason, he says, they are styled "clausa literarum,
"in contradistinction to vowels, which are "aperta." See
Vowel.

Consonants are divided into single, as b, m, q, &c. and
double, as x in auxiliary, corresponding to the κ of the
Greeks.

Consonants have been also divided into mutes and semivowels.
The mutes are such as cannot be found at all without a vowel, and all of which begin their sound with a
consonant; as b, d, g, k, p, f, t, and ch, being expressed
br, de, ge, &c. The semi-vowels have of themselves an
imperfect sound, and all begin with a vowel; as l, m, n, r, f,
t, &c. being found el, im, etm, &c. Four of these, viz.
l, m, n, r, are distinguished by the name of liquids, from
their readily uniting with other consonants, and flowing, as
it were, into their sounds. The mutes, as some writers
have described them, are those consonants whose sounds
cannot be protracted; and the semi-vowels are those whose
words can be continued at pleasure, partaking of the nature
of vowels, from which they derive their name. The mutes
may again be subdivided into pure, being those whose sounds
cannot be at all prolonged, as k, p, t, and impure, whose
sounds may be continued for a short time, as b, d, g. The
semi-vowels may be subdivided into vocal and aspirated: the former being formed by the voice, and the latter by the
breath. The vocal, which are eleven, are b, m, n, r, v, w, y, z, th flat, sh, ng; and the aspirated, five in number, are
f, h, j, wh, sharp, jh. The vocal semi-vowels may be subdivided
into pure, which are formed entirely by the voice, and
impure, which are such as have a mixture of breath with the
voice. Of the pure there are seven, viz. l, m, n, r, w, y,
and z; and four of the impure, viz. v, w, th flat, sh.

The popular writer, whose "Grammar" we are now citing, has
given the following list, exhibiting the sounds of the con
sonants, which are twenty-two in number.

Mr. Murray adds, that several letters marked in the Eng
lish alphabet, as consonants, are either spiratual, or re
present, not simple, but complex sounds. C, c, g, is super
fluous in both its sounds; the one being expressed by k,
and the other by g. In the soft pronunciation, is not a
simple but a complex sound; as age is pronounced age. J is
unnecessary, because its found, and that of the soft g, are
in our language the same. Q, with its attendant u, is either
complex, and reducible to ku, as in quality; or unnecessary,
because its found is the same with k, as in opaque. X is
compounded of gk, as in example, or of kt, as in respect.

See Murray's English Grammar, p. 4, &c. ed. 8.

Dr. Wilkins (ubi supr) disapproves of the common dis
vion of consonants into semi-vowels and mutes; and prefers
the distribution of them into three kinds, viz. spiratual or
breathed, semi-spiratual or half-breathed, and non-spiratual
or breathless. By the former he means such consonants as
require to the framing of them a more flory emission of the
breath, either through the nose or mouth; and he distin
guishes those that are formed by expiration through the nose
into sonorous, as m, n, ng, and mute, as bm, bn, and bg:
the sonorous being such as require some vocal sound for
framing them, and the mutes being other letters of the same
collection, pronounced by a flory emission of the breaths,
without any vocal sound. The spiratual consonants are
those that are formed by breathing through the mouth as all of two
kinds, viz. sonorous, as v, d, l, r, z, sh; and mute, as
f, th, bl, kr, f, and jh.

Semi-spiratual or half-breathed consonants are such as
are accompanied with some kind of vocal murmur, as b, d, g;
whereas those are denominated non-spiratual or breathless
which are wholly mute, as p, t, c. Thus, b and p are
framed when the breath is intercepted by the closure of the
lips; the first of them being more soft, with some kind of
murmur; the other more hard, and wholly mute. Again, a
and t are commonly framed by an appulse or collision of
the top of the tongue against the teeth or upper gums; the
first being more soft and gentle, with some kind of mur
mur; the other wholly mute. Moreover, g and e are
framed more inwardly, by an interception of the breath to
wards the throat by the middle or root of the tongue, with
such a kind of difference between them as subsists in the two former cases. The consonants already enumerated belong to the class of those that are simple; but those that are called compound are usually distinguished into such as are aspirated, and such as are double: the former seem to be blended with $b$, and are usually fo written; and the latter are compounded of some of the other letters, but for the sake of dispatch and brevity in writing, they are in several languages expressed by single characters, and reckoned in the alphabet as if they were distinct species of simple letters: such in the Latin alphabet are $q$ and $x$, and the double letter $ss$, whose power is the same as $ds$ or $ts$. The consonant $q$ is allowed to be a compound of $c$ and $u$; but what is the true original of $j$ consonant, and that power attributed to $e$ in the words charity, charity, &c. have not been completely determined. It is plain that neither of the letters $q$ or $x$ is a single letter, because in the pronunciation of them we do not end with the same sound with which we began: it seems, however, to be plain that $j$ consonant is a compound of $d$ and $zh$, and $eh$ of $t$ and $h$. As for the other three consonants that are reckoned in the common alphabet, $k$, $w$, and $y$. Dr. Wilkins thinks them unnecessary. If e, he says, be used always according to its proper power, $k$ must be superfluous; and therefore the Welch, who use $e$ for only one kind of sound, have no $k$. And as for the letters $w$ and $y$, their power is the same with that of the vowels $a$ and $i$, as will evidently appear when they are rapidly pronounced before any other vowel by way of diphthong, so as to make but one syllable, as in war, war; fan or twin, see or yes, soke or yoke. Upon the whole, Dr. Wilkins enumerates 34 simple letters, 8 of which are vowels, and 26 consonants, besides 24 diptonghs. See Letter.

According to some writers, the most natural division of consonants is that of the Hebrew grammarians; who have been imitated in this respect by the grammarians of all oriental languages; these divide the consonants into five classes; according to the five principal orders of the voice; which all contribute, it is true, but one more notably than the rest, to certain modifications, which make five general kinds of consonants. Each kind, or class, comprehends several consonants, which result from the different degrees of the same modification, or from the different motions of the same organs.

These organs are the throat, palate, tongue, teeth, and lips; whence the five classes of consonants are denominated guttural, palatal, lingual, dental, and labial.

We account fourteen consonants in the English alphabet, viz. $b$, $c$, $d$, $f$, $g$, $k$, $l$, $m$, $n$, $p$, $q$, $r$, $s$, $t$, $x$, $z$; to which there are three others to be added, viz. the $h$, and $j$ consonants, and $w$ consonant, which make the whole number of consonants nineteen: one whereof is guttural, viz. the aspirate $b$; five palatal, viz. $c$, as when pronounced before $a$, $o$, and $u$, as in cow, corn, curiosity; $g$, as in Gwen; $j$ consonant in jubil, $k$ in kernel; and $q$ in query. To these some have added $w$ and $y$, which are really consonants when they begin a word or syllable; although in every other situation they are called vowels. That they are consonants when used as initials seems to be evident, from their not admitting the article $a$ before them, and from their following a vowel without any hiatus or diffi ulty of utterance; that in other situations they are vowels appears from their regularly taking the sound of other vowels.

The four lingual consonants are $d$, $l$, $n$, $t$; the four dental are $r$, $s$, $x$, $z$; the three labial are $b$, $f$, $m$, $p$, and $w$ consonant.

With regard to which division it may be observed, that though the $g$ be modified in three different manners, as it comes before an $a$, an $o$, or an $u$; yet it is still a consonant of the palate; that the $j$ consonant differs in nothing but its figure from the $g$ before $e$ or $i$; that $h$ has the same pronunciation with the $e$; that $x$ comprehends the sound of two letters in its sound, viz. $e$ or $h$, and $j$ or another $e$, as in Alexander, and Alexis, which we pronounce as it wrote Alexander and Alexius; and that the $e$ before an $e$ or $i$, is no consonant of the palate, because in that case it loses its proper sound, and assumes the hissing sound of the $f$.

The abbot Dangeau thinks the nature of the division of the Hebrew grammarians to be very reasonable; but he does not acquiesce in the distribution they have made of them: to find a natural and full division of the consonants, he observes, no regard must be had to the characters that represent them; nor anything be considered but their sound, or the modification they give the sound.

On this principle, the same author finds in the French five labial consonants, $b$, $p$, $c$, $f$, and $m$; five palatal ones, $d$, $f$, $g$, $k$, $n$; four biffers, $j$, $w$, $y$, $h$; two liquids, $l$ and $r$; two that run into and mix with each other, as $ll$, and $nn$; which last, however, is peculiar to the French language; and the $h$ aspirate.

He adds, 1. That $m$ and $n$ are properly two nasal consonants: the $m$ a $b$ passed through the nofe, and the $n$ a $d$, in like manner, pronounced through the nofe; and, in effect, people with a cold pronounce barks for market, deed for need, &c.

2. That among the consonants, some are weak, others strong; their difference consisting in this, that the former are preceded with a small emission of the voice, which feizes them, which the latter have not. The weak are $b$, $c$, $d$, $g$, $j$, $l$; the strong, $p$, $f$, $t$, $k$, $s$, $x$, $z$.

It may be here observed, that when we speak of a person's talking through the nose, or of the red, only one organ is moved very strongly and sensibly, and the rest weakly.

It is hence also visible, that in all languages the aspirate, or guttural letters, are real consonants; since the throat modifies the sound as much as the palate, tongue, or lips.

Lastly, to find all the consonants that may be formed in any language, there needs nothing but to observe all the modifications that the sounds of speech will admit of, by which we shall have all the consonants practicable.

Dr. Hunter (Edinb. Trans. vol. ii.) in his investigation of the manner in which consonants are formed, distinguishes them in two different respects, viz. by the operation of the
CONSONANT.

the breath which is employed to make them audible. There
are free positions, he says, by which the vocal found is to
be articulated: the frf is formed by the close junction of
the lips, so that no breath is suffered to tranpire, and the
just modification of this position is that called oral, when
the passage of the breath or found by the nose is flapped,
and thus are formed the letters p and b; and the second
modification, termed the nasal, is formed by breaking the
communication, or exit, by the nose, and suffering the
found or breath to pass that way; in which case the letter
m is founded. The second position is formed by the appli-
cation of the under lip to the fore-teeth of the upper jaw,
which do not form an absolute interruption to the breath,
but suffer it to pass in an audible manner, by means of the
restraint with which it is made to pass: and then are pro-
duced the letters s and z. The third position is formed by a
similar application of the tongue to the fore-teeth, and a
similar expression of the breath; these producing the two
consonants b and rb. The fourth position is formed by the
application of the point or fore part of the tongue to the
root of the same teeth, or fore part of the palate, which
position may be variously modified; as by applying the tongue
closely to the palate, so as to form an absolute interruption
of the breath, in a manner similar to that of the frf position,
which may be called the mute modification, and which seems
to form the consonants t and d. 2. The tongue is not kept
closely fixed to the palate, but suffer, the breath to be ex-
pressed by an audible manner, similar to those of opening the
second and third positions: this may be termed the shi-bih
modification, and is that by which are expressed s and z. 3.
The passage of the breath between the point of the tongue and
the palate is opened alternately in a quick and tremulous
vibration: this may be denominated the vibratory modification,
and serves to form the letter r. 4. The passage of the breath
or found is not interrupted in any degree, but it is made to
pass in a very peculiar manner through the mouth; for
this purpose the tongue is closely applied to the fore part
of the palate, but it is retracted on each side so as to leave
an empty space, and then a passage is preferred for the breath,
which goes under the tongue and out of the mouth: this
may be termed the liquid modification, and serves to form
the sonorous letter l. 5. The lateral passages opened for the
breath in the lalt modification are shut, and the found at
the same time is suffered to escape by the nasal passage,
as in the second modification of the frf position: this may
be denominated the nasal modification, and produces the letter
n. The frfih position is formed in all respects like the
fourth, but only by a movement part of the tongue and palate,
and has the same number of modifications, which correspond
in their nature, and may be denominated in the same man-
ner. Thus, the letters b and g are formed in the mute modi-
fication; b and g in the shi-bih: the guttural or Northum-
brian r in the vibratory; the Spanish l, or the French l,
moiulé, in the liquid; and the guttural n or the English
ng in the nasal modification. Having thus explained the
several positions of the organ, with their different modific-
tions, Dr. Hutton proceeds to illustrate the formation of
the consonants, and articulations of voice, by the action of
the breath and found. In all the positions of the articulating
organ, he says, there is either employed the simple aspira-
tion of the breath, or a sound produced in the wind-pipe,
and modified in the articulating organ. Thus, in all the
positions, and in several of their modifications, there are
produced two distinct articulators, according either as sound
is emitted along with the articulation, or only the breath
employed without any other found. Hence proceeds the
distinction of mutes and consonants among the articulators
of voice.

But in each of these distinctions of mutes and consonants,
it is necessary to make a sub-distinction, according as the
articulator is either perfect or imperfect, whether as a mute
or as a consonant. Each of these, the author explains in
the following manner: The perfect mute can only take
place in those positions in which the breath is absolutely in-
terrupted by the close or impervious organ; which does not
happen in the second and third positions, and is the
result of the modifications of the fourth and fifth. This mute
articulator is formed, either by interrupting the vocal
found with the close position, in which case it is a final ar-
citulator; or by beginning to express the vocal found in this
close position, when it forms, upon opening the passage, an
initial articulator. Of this kind there are just three articu-
lators, corresponding to the three positions in which the
organ may be absolutely closed, in relation to the exit of
the breath: these are p in the frf position, t in the fourth:
and k in the frfih position. The imperfect mute is formed
by emitting a guttural sound, or that of the wind-pipe, in
these three positions of the mute articulator. The found
here is extremely limited; for it is necessarily restricted to
that quantity of breath which may be expelled through the
found wind-pipe in compressing the air, or distending the
cavity of the close organ. These short found articulators
may therefore be termed imperfect mutes. The b, d, and g,
are the three imperfect mutes, corresponding to the three
absolute mutes, p, t, and k; of the frfih, fourth and fifth
positions. In the labilating articulators of the second and third
positions, and of the second modification of the fourth and
frfih positions, the breath may be continually emitted, either
with the simple expiration, or attended with the guttural
found. This, then, forms two cases of articulation, differ-
ing from each other, and also from the other two cases of
mute articulation; seeing that in the present case, whether
the consonant be formed with a guttural found, or only
an audible aspiration, it is a continued thing, and is not ne-
cessarily terminated, as in the mutes, by the close position of
the organ. Now, as in the case of mutes, we have the dis-
tinction of perfect and imperfect, with regard to that species
of letter, so, in the case of consonants, we have a species
which is perfect, and one which is imperfect. The imper-
fect species of consonant-articulators is formed in the four
labilating positions and modifications just now mentioned,
e.g. the f in the second position, the b in the third position,
the / in the fourth position, and the b in the fifth position.
To perfect those four consonants, we have merely to add the
guttural found to the continued expiration, and we then produce of the frf, the frfih, the frfih, the
b, the b, of the g, and of the /, the t. We have now only remaining the nasal modification of the frfih
position, which gives the consonant m; the vibratory modification
of the frfih and fifth positions, which give two species
of the letter m; the liquid modifications, which give two species
of the letter l; and the nasal modifications of those two
lateral positions, which give two species of the letter n. In
\n\nnone of all these is formed a distinct articulator, by means
of the simple aspiration; consequently all these are perfect
consonants. Our author observes, that the letter h is a
general articulator, which is formed in many different posi-
tions of the vocal organ. Diphthongs and consonant-vowels,
or rather articulating vowels, are formed in the following
manner: the diphthong, by founding both vowels equally
in the time of one; the consonant-vowel again, by an un-
equal division of this time, or by sliding quickly from the po-

Vol. IX.
fitation of the two extreme vowels i and u, to the vocal sound which is to be thus articulated. See Vowel.

**Consonant.** is a term in **Majic,** which Dr. Calclott in his **Magical Grammar** applies to the concords, 2chave, 55th; 8th, thirds major and minor, and sixths major and minor. The consonant triads, or common chords, according to the same author are,

in the major mode \( \begin{align*}
\text{major} & : & \text{1} & \text{2} & \text{3} \\
\text{minor} & : & \text{3} & \text{1} & \text{2} \\
\text{1} & \text{2} & \text{3} & \text{1} & \text{2} \\
\text{2} & \text{3} & \text{1} & \text{2} & \text{3} \\
\text{3} & \text{1} & \text{2} & \text{3} & \text{1} \\
\text{1} & \text{2} & \text{3} & \text{1} & \text{2} \\
\end{align*} \) \( \text{See Triad.} \)

**Consort.** Queen. See Queen.

**Consonant.** in Botany. See Symphylum and Sollidago.

**Consound.** in Geography, a town of Poland, in the palatinate of Sandomierz; 28 miles S.E. of Radom.

**Conspiracy.** in Law, is taken for a combination or confederacy to do something evil, or illegal: though in the original sense of the word, and in its use in other languages, it signifies merely an agreement, whether for good, bad, or matters indifferent.

In our statutes and law books, conspiracy, in a general sense, is frequently confounded with maintenance, and chan- 

party.

**Conspiracy,** in its special signification, is used for a confederacy of two, at least, falsely to indict one, or procure him to be indicted of felony; who, after acquittal, shall have writ of conspiracy. See 52 Edw. 1. Stat. 2. 7 Hen. V. 18 Hen. VI. c. 12. The term is now commonly used for the unlawful combination of journeymen to raise their wages, or to refuse working, except on certain stipulated conditions; an offence particularly provided for by Stat. 2 & 3 Ed. VI. c. 15, revised, continued, and confirmed by Stat. 22 & 23 Car. II. c. 19 (now expired) which enables, among other things, that "if any artificers do conspire, that they shall not do their work but at a certain price, or shall not take upon them to do any other work, or shall do but a certain work in a day, or shall not work but at certain times, every person so confining shall forfeit for the first offence, 10l. or be imprisoned 20 days; for the second, 20l., or be pilloried; and for the third, 40l. or be pilloried, lose an ear, and become infamous." This statute appears to be yet in force, though it be not frequently referred to for remedy in this case; the proceeding being usually by indictment for conspiracy.

By the common law all conspirators wrongfully to prejudice a third person are highly criminal. 1 Hawk. P. C. c. 72. § 2. Stat. 5 Eliz. c. 4. Journeymen confederating and refusing to work unless for certain wages, may be indicted for a conspiracy, although the statutes which regulate their work and wages do not direct this mode of prosecution; for the offence culminates in the conspiring, and not in the refusal; and all conspiracies are illegal, though the subject-matter of them may be lawful. Thus also, a bare conspiracy to do a lawful act to an unlawful end is a crime, though no act be done in consequence of it. 8 Mod. 321. The fact of conspiring need not be proved on the trial, but may be collected by the jury from collateral circumstances. 1 Black. Rep. 592. Stra. 144. And if the parties concur in doing the act, although they were not previously acquainted with each other, it is conspiracy. 1 Hawk. P. C. c. 72. § 2. Writ of conspiracy lies for him that is indicted of a trespass, and acquitted, though it was not felony; also upon an indictment for a viti. 2 Mod. 326. 5 Mod. 465. Writ of conspiracy lies where a man is falsely indicted of any crime which may prejudice his fame or reputation; and though it doth not import fraud, if it endanger his liberty, or the indictment be injurious to his property, &c. 3 Salk. 97.

But though a conspiracy to charge falsely be indictable, yet the party ought to shew himself to be innocent; for the writ of conspiracy doth not lie without an acquittal. Mod. Ca. 127. 153. 156. Not only writ of conspiracy, which is a civil action at the suit of the party, but also action on the case in the nature of a writ of conspiracy, doth lie for a false and malicious accusation of any crime, whether capital or not capital, even of high treason; and this, though the bill of indictment be found ignoramus, or it doth not go so far as an indictment. And the same damages may be recovered in such action as in a writ of conspiracy, where the party is lawfully acquitted by verdict. 1 Rol. Abr. 111. 113. 9 Rep. 56. Gibb. Ca. 153. 19 Mod. 143. 212. Salk. 15. An action of the case is preferable, as it is more in use, and the proceedings more easy and not attended with such niceties as the writ of conspiracy.

If one falsely and maliciously procure another to be arrested, and bring before a justice of peace to be examined concerning a felony, &c. on purpose to vex and discourage him, and put him to charges and trouble, although he is not indicted for the same, yet he may have an "action on the case," in which he need not aver that he was lawfully acquitted, as he ought to do in a writ of conspiracy; but he may aver that the accusation was false et malitiose, which words are necessary in the declaration; and it must appear that there was no ground for it. And as an "action on the case" may be prosecuted against one person, where the writ of conspiracy or indictment doth not lie but against two, this action is most commonly brought. 1 Dauv. Abr. 258. 213. 2 Inf. 562. 638.

Conspirators may be indicted at the suit of the king, and at the common law, one may prefer an indictment against conspirators, though nothing be executed: however, the conspiracy ought to be declared by some act, or promise to stand by one another, &c. But a bare conspiracy will not maintain a writ of conspiracy, at the suit of the party, because he is not damaged by it, though it is a ground for an indictment. 9 Rep. 56; 2 Rol. Abr. 77. If the defendants can shew no foundation or probable cause of suspicion, they shall be discharged: and if a man hath good cause of suspicion, that a person is guilty of felony, and causes him to be indicted, in prosecution of justice, action of conspiracy will not lie; but it is otherwise if the prosecutor imposes the crime of felony, where no crime of felony was committed. 1 Rol. Abr. 115; 4 Rep. 438. Conspiracies ought to be out of court; for if a prosecution be ordered in a course of justice, and witnesses appear against a party, &c. there shall be no punishment; and if persons acted only as juries in a criminal matter, or judges in open court, there is no ground for prosecution. S. P. c. 173. 12 Rep. 24. If all the defendants but one are acquitted on indictment for conspiracy, this one must be also acquitted; because one person alone cannot be indicted for this crime: and husband and wife, being but one person, may not be indicted alone for a conspiracy. 2 Rol. Abr. 706. The acquittal of one person is the acquittal of another upon indictment of conspiracy (3 Mod. 220.) i.e., where only two are indicted, and it is not laid or proved that they conspired with others, unknown. However, where one is found guilty, according to the opinion of lord chief justice Hale, if the other doth not come in upon process, or if he dies...
CONSPIRATORS, in Mechanics, are all such as act in directions not opposite to one another. See Power, and Motion.

CONSPECIFIC. This appellation hath afforded ample matter of disquiet to learned antiquarians. History has traced it backwards from its introduction to England, through France, Germany, and Greece, to the imperial seat of Constantinople, in the days of Constantine the Great; and if we ascend farther towards the East, we shall find the term εἰδώλιον or εἰδωλαί in Palestine, which signifies in the times of the Old Testament, a flability, strength, or flay. Some trace of this word has been discoverable in the appellation of Laocoon at Troy, and particularly in that of Constantine, who was himself of oriental extraction, having sprung from Dardanus, a country of Upper Media, and from the former to have been descended from Dardanus and the Trojans. It is not improbable that this appellation of the emperor might have occasioned the adoption of the word into the Roman language about the same time. For it was at that period that the word contrariamente, obviously deduced from εἰδώλιον or εἰδωλαί, first became a name of dignity; and from thence was transmitted westwards, with some variation, according to the different genius of languages throughout the provinces. Amongst the Saxons the word was kæning or kæningas, from which, without doubt, we derive our word king. Moreover, the word flōle, flōla, flōhe, or flōbe, by an early transmutation of the several letters frequent in almost all languages, which seems to be the other confluence of the appellation contrariamente, is likewise common to the languages of the middle ages, and signifies a flammable place, division, or department, called by the Romans fiantio. According to this etymology, the word contrariamente signifies the flability or frailty of the place, or the strong man of the division. Those who derive it from the Saxon, discover contrariamente in kæning-præpel, denoting the support of the king. But others, as Sir Henry Spelman, and Dr. Cowl, considering that we borrow the name, as well as the office, from the French, deduce it, with greater probability, from that language; in which it is plainly derived from contrariamente, the matter of the flables, or perhaps of the horse, an officer well known in the empire; so called, because, like the great contrariamente of France, as well as the lord high contrariamente of England, he was to regulate all matters of chivalry, tilts, tournaments, and feats of arms, which were performed on horseback. Accordingly, they suppose, that the dignity, which at first was civil, in time became military, and the master of the flables was made general of the army.

CONSPIRATURE of England, Lord High, is an ancient officer of the crown, now disused in England, except on solemn occasions, as the king's coronation, and the like. The first contrariamente of England is said to have been created by the conqueror, who appointed Ralph de Mortimer, one of the principal commanders of his army; and the office continued till the reign of Henry VIII., A.D. 1521: when it became extinct, as the powers annexed to it removed to troubleshoot the king, by the attainer of the third duke of Buckingham, who derived it from the Bahamas, earls of Hereford, and in whom it was hereditary. Since this time there hath not been any permanent high contrariamente; but the office has been kept vacant, except on particular occasions. About a century after, viz. in 1677, it was also suppressed.
in France, by an edict of Louis XIII.; though the office has been exercised in the command of the marshals, by the first officer in the army. See Constable.

What authority and jurisdiction belonged to the constable, we may partly learn from a statute of the 13th of Richard II., in which it is said "that he ought to have cognizance of contracts touching debts of arms and of war out of the realm, and also of such things relating to arms or war within the realm, as could not be determined or discussed by the common law, with other usages and customs appertaining to the same matters, which other constables before that time had duly and reasonably used." Maxdor (Hist. Excheq. c. 11.) says, that he was a high officer, both in war and peace. As the duties enjoined on the constable and subconstable, as well in war as in peace, in home and in court, were munificent, honoured, and confidential; to the powers, privileges, authority, and pre-eminence of those officers, were extensive, judicial, executive, and respectable. The powers and functions of each of these high officers, when acting in their military capacities, were, in some instances, concurrent; in others, separate and independent. In the discharge of some official duties, they were upon an equal footing, and the marshal acted as coadjutor to the constable, but in others, the former was subordinate and servient to the latter. The functions of the constable, in his civil capacity, were few, and in a great measure restricted to certain personal attendances on the king in his court, on high feiths, and on occasions when such affairs were transacted as required pomp and solemnity. In his military capacity, the constable examined the number and qualifications of those who were lent by the military tenants, either into the field or garrison, and also of the dependents retained by the king, and gave them either their amittance or discharge. When the army took the field, and was commanded by a tought officer, the constable acted as his lieutenant, and was next to him in authority; but whenever the king was absent, the constable had the supreme and sole command of the forces. In both cases, the marshal was the substitute or vice-general of the constable. See Court of Chivalry, and Marshal.

From those mighty magistrates, the constables of England, are derived the inferior ones, since called the constables of hundred and frantiches: these were first ordained in the thirteenth year of Edward I. by the statute of Winchester (13 Ed. 1. flat. 2. c. 6.) which, for the contervation of the peace, and view of armour, and for preventing defaults of armour, and of the suits of towns and of highways, &c. appointed, that two constables should be chosen in every hundred and frantich. These are what we now call conslavarii capitaes, or high constables; because continuance of time, and increase of people, &c. have occasioned others of like nature, but inferior authority, in every town and parish, called petty constables, or sub-conslavarii, still instituted (as some say) about the reign of Edward III.

Although it has been a prevalent opinion, maintained by Coke, Hale, and others, that high constables are not more ancient than the statute of Winchester above cited; yet Hawkins concurs with others in maintaining, that both constables of hundreds, commonly high constables, and also constables of tythings, now denominated petty constables or tything-men, existed by the common law, and were not first ordained by the statute of Winton or Winchester; for that statute both not say, that such officers shall be constituted, but evidently seems to suppose that there were such before the making of it. 2 Hawk. 61. That the high constable was instituted long before the statute of Winton is a fact ascertained by a writ or mandate of Henry III., preferred in the Adversaria to Watts's edition of Matt. Paris, and from which chapters 4 and 6 of the statute of Winton are evidently taken. By this writ it is provided, that in every hundred there shall be constituted a chief constable, at whose mandate all those of his hundred, sworn to arms, should assemble and be obsequious to him, for the doing of those things which belong to the conservation of the king's peace. No mention of this officer, it is believed, can be anywhere found prior to the date of this instrument; which perhaps may no more determine the question as to his original creation than the statute of Winton. As for the "constable of the vii," or petty constable, as he is frequently called by way of distinction from the chief constable, this officer has been repeatedly acknowledged to be one of the most ancient officers in the realm, for the conservation of the peace (Poph. 13. 4. Inf. 265.). It must be confessed, however, that no mention of him by this identical name is anywhere found to occur anterior to the writ or mandate of King Henry III., already mentioned; by which it is also provided, that in every village or township there should be constituted a constable or two, according to the number of the inhabitants. But it is partly certain that lord Coke's idea is well founded, and that "this officer is actually owing to the institution of the frank-pledge, usually attributed to king Alfred," and was in fact originally the senior or chief pledge of the tything or decima. Hence it appears, that the ordinance of Henry III., far from instituting the office, merely enlarged the number of officers, placing them in towns and villages, instead of frantiches; hence it might frequently happen, that a manor of great extent had only a single constable for several townships; a case exactly similar sometimes occurring at this day, in which a township, comprehending several hundred, equally populous perhaps with itself, has only one constable for the whole. Upon the whole, it seems highly probable, that, at the common law, and before the mandate of Henry III., the constable of the hundred and the constable of the manor, were officers of the same nature and authority, originating at the same time and differing only as to the extent of their several districts; in short, that they bore to each other the same analogy as subsisted between the bailiff of the hundred and the bailiff of the manor. Hence it follows, that the constable of the hundred neither possessed nor could have exercised any more authority within the precinct of the latter, than the constable of one manor possessed or could have exercised in another; the manor being to all intents and purposes exempt from, and excluded out of the hundred.

High constables are chosen at the court leets of the frantich or hundred over which they preside, or, in default of that, by the justices at their quarter sessions, or by the greater number of the justices of the division: and they are sworn to the feiths, or by warrant from the feiths; which course hath often been allowed and conditioned by the justices of assize. Dall. c. 28. Salk. 170. And by Stat. 29 Geo. II. c. 25, 8. 9, in Welfinflur a high constable is to be elected annually by the dean or high eclewe, or his deputy at a court leet. But by 1 Geo. flat. 2. c. 13, high constables are required to take the oath of allegiance, supremacy, and submission, as other persons who qualify for offices; but they are not within the statute of the 25 C. II. c. 2, as to receiving the sacrament and subserbing the declaration against transubstantiation; and petty constables are exempted both from the one and from the other. The petty constables have two offices united in them; the one ancient, the other modern. Their ancient office is that of Headborough (which fey), tything-man, or...
or boritholder, who are as ancient as the time of Alfred; and
their more modern office is that of constable merely, which
was appointed (as it has been said) to lately as the reign of
Edward III., in order to afford the high constable. And, in
general, the ancient headboroughs, tything-men, and bor-
tholders, were made use of to serve as petty constables; though
not so generally, but that in many places they still continue
distinct officers from the constable.

The common law requires, that every constable should be
idoneus homi, i.e. apt and fit to execute the said office; and
in law he is said to be idoneus when he possesses three qualifi-
cations, viz. honesty, knowledge, and ability, (8 Rep. 4. b.)
And if one be elected constable, who is not idoneus, he by
the law may be discharged of his office, and another who is
idoneus appointed in his place. He must also be an inhabitant
of the place for which he is chosen, (12 Mod. 256.) nor
should he be the keeper of a public-house, (6 Mod. 42.)
which is made an express disqualification in Westminster, by
flat. 29 Geo. II. c. 25. Permits exempt from serving the
office of constable are aged persons, and in Westminster thos
63 years old are expressly exempted by flat. 31 Geo. II. c.
17, § 13;—aldermen of London;—the president, common
and fellows of the college of physicians in London, by 32
Hen. VIII. c. 40; but no other physicians, nor they else-
where:—apothecaries, practising in, or within five miles of
London, free of the company, or in the country having
twelve years, flat. 6 and 7 W. III. c. 41;—furgons, free of
the company of furgons in London, examined, approved,
and sworn, by flat. 5 Hen. VIII. c. 6: 32 Hen. VIII. c.
42: 18 Geo. II. c. 15; and by
custom all furgons (Com. Rep. 312.), and it seems by the
same flats. barbers free of that company in London;—attor-
nies of the courts of K. B. and C. P.;—practising barristers;
—diflancers, being teachers and preachers in a congregation,
tolerated by law, taking the oaths and making the required
declaration, but not others, by 1 W. c. 18. § 11:—foreign-
ers naturalized, who may rather be said to be incapacitated;
—militia-men, during the time of their service, by 26 Geo. III.
c. 107, § 130:—servants to members of parliament, but
doubtful;—prosecutors of felons to conviction; the original
proprietors, or first affiance of a certificate (commonly called
a tyburn-ticket), if a parish or ward office; within the parish
or ward where the felony happened, to be only once used, by
10 and 11 W. c. 23. § 231; but this is no exemption from
serving the office for a manor, nor, as it should seem, for
a vill or township; nor where the office is to be executed out
of the privileged district;—but matters of arts, judges of
peace in another county, officers of the guards, officers or
wardens and the Custum-house, tenants in ancient demesne,
and younger brothers of the trinity-house, cannot plead ex-
emption. If, however, a gentleman of quality, or a physician,
officer, &c. be chosen constable, where there are sufficient
persons besides, and no special custom exists; such persons, it
is said, may be relieved in B. R. 2 Hawk. P. C. 100. c. 10.
§ 41. A constable, whose office is ministerial, and not judi-
cial, may appoint a deputy; but the constable is answerable,
and his deputy ought to be sworn, though this is not in all
cases necessary; but if the deputy is allowed and sworn, the
principal is not responsible. Diflancers chosen to the office
of constable, &c. flealing to take the oaths, may execute the
office by deputy, who shall comply with the law in this behalf,
flat. 1 W. & M. c. 18. § 7. And by 31 Geo. III. c. 32.
the like privileges are given to Roman Catholics on their
taking and habening the oath and declaration therein spe-
cified. Constables may appoint a deputy to execute a war-
rant, when by reason of sickness, &c. they cannot do it
themselves. A woman made constable, by virtue of a cul-
tom, that the inhabitants of a town shall serve by turns, on
account of their eccles or houles, may procure another to
serve for her, and the custom is good.

Constables are chosen by the common law at the leet, or,
where there is no leet, at the town; sometimes by the
suitors, and sometimes by the reward, and now, in many
towns and parishes, by the parishioners: all according to
ancient and particular usage. But by whomsoever they
shall be chosen and appointed, they are to be sworn and
in their office by the lord, or his reward, or by the
sheriff respectively, as being judge in the matter. 2 Hawk.
62. If the constable be present when chosen, he is to take
the oath in court; if absent, he may be sworn before a
(single) justice of the peace: but in the latter case, he ought
to have special notice of his election, and a time and place
should be appointed for his taking the oath (well and truly
to serve the office). Every petty constable being a principal
peace officer, and it being necessary for the preservation of
the peace, that every vill should be furnished with one,
the justices of the peace have, ever since the institution of
their office, taken upon them, as conservators of the peace,
not only to swear the petty constables, who have been chosen
at a town or leet, but also to nominate and swear those who
have not been chosen at any such court, on the neglect of
the sheriffs or lords to hold their courts, or to take care that
such officers are appointed in them. And this power of
justices of the peace, having been confirmed by the unint-
terrupted usage of many ages, shall not now be disputed, but
shall be presumed to have been grounded on sufficient autho-
riety. Some have carried this point so far, as to allow the
justices, at their sefions, to swear one who was chosen at
the last, and unduly rejected by the reward, who had sworn
another in his place. 2 Hawk. 65. A constable has been
sworn by a single justice of the peace; and upon motion for
an information as not being duly sworn, the court held this
to be a good swearing. 2 Str. 14. It is certain that
justices of the peace had power to nominate and swear con-
stables, on the default of the town or leet, before the statute
of 13 & 14 C. I. c. 12; and therefore that they have such
authority in some cases not mentioned in that statute, which
enacts, that if a constable shall die, or go out of the parih,
any two justices may make and swear a new one, until the
lord shall hold a leet, or till the next quarter sessions, who
shall approve of the officer so made and sworn, or appoint
another; and if any officer shall continue above a year in his
office, the justices in their quarter sessions may discharge
him, and put in another, till the lord shall hold a court as
aforesaid. 2 Hawk. 65. 13 & 14 C. I. c. 12. § 15. It
seems to be clear at this day, that the King's Bench hath
power by mandamus to compel the court or judge to swear
a constable duly chosen. 2 Hawk. 65. And constables
lawfully chosen, if they shall refuse to be sworn, may be
bound over by a justice of the peace to the sheriff or sefions,
there to be indicted. Dalt. c. 28. 2 Str. 920. But it
seems that a justice hath no power to commit any person for
such refusal and no more, the proper mode being to indict
him upon his refusal; and if found against him, to affix a

Constables of London, which city is divided into 26 wards,
and every ward into precincts, in each of which is a constable,
are nominated by the inhabitants of each precinct on St.
Thomas's day, and confirmed, or otherwise, at the court of
wardment; and after they are confirmed, they are sworn in
to their office, at a court of aldermen, on the next Monday
after Twelfth-day. The oath of these constables is long and
particular, and comprehends a variety of duties, now seldom
performed, but regulated by articles of the Wardmote in-
quest,
CONSTABLE.

quell, which directs the conduct of the constable; who is a kind of superintendent of the morals of the inhabitants, and who ought to notice all new-comers, that these whole character is bad may be required to give security for their good behaviour, or be imprisoned. Catt. 130. 138. Every constable may execute warrants through the whole city. Such as are chosen into the office are obliged to place the king's arms, and the arms of the city, over their doors; and if they refuse in all cases, at the ends of such alleys, towards the streets, to signify that a constable lives there, and that they may be more easily found when wanted.

The general duty of all constables, both high and petty, is to keep the king's peace in their several districts; and for this purpose they are armed with very large powers, of arresting, and imprisoning; and of breaking open houses, and the like. One of their principal duties, arising from the statute of Winchester, which appoints them, is to keep watch and ward in their respective jurisdictions. See Ward and Watch.

If any one shall make an affray or assault upon another, in the presence of the constable, or shall threaten to kill, beat, or hurt another, or in a fury be ready to break the peace; the constable may commit him to the rocks, or other safe custody, and afterwards take him before a justice, or to a gaol, until he shall find surety for the peace; and if the party will not find surety to the constable, he may imprison the party till he shall find it, provided the offence be in his own view. Dalt. c. 1. Cru. Eliz. 375, 376. The duties of constables are so numerous and minute, in consequence of a variety of statutes, that the recital of them would extend this article beyond its due bounds. They will be found under several different heads or titles, that occur in this work.

If a constable neglect any duty incumbent on him either by common law or by statute, he may be indicted and fined by the justices of peace, to whom he is subordinate. If he will not return his warrant, or certify what he has done under it, he may be fined. If he wilfully lets a felon escape out of the rocks, and go at large, it is felony; and it seems generally agreed, that all voluntary escapes in the officer amount to the same crime as the offender was guilty of, whether treason or felony. 2 Hawk. P. C. c. 19. § 22, &c. It is a misdemeanor in him to discharge an offender, brought to the watch-house by a watchman in the night. In short, he is liable to various pecuniary, and sometimes personal, punishments, on neglecting the duty imposed on him by various statutes. As by his office he is subordinate to a justice of the peace, he is bound to execute his warrants; and therefore it hath been resolved, that where a statute authorizes a justice of the peace to convict a man of a crime, and to levy the penalty by warrant of distress, without paying to whom such warrant shall be directed, or by whom it shall be executed, the constable is the proper officer to serve such warrant, and inditcable for disobeying it. 2 Hawk. 262.

By 33 Geo. III. c. 55, two justices, at any special or petty se'ions, upon complaint upon oath, of any neglect of duty, or disobedience of any lawful warrant or order of any justice, by any constable, or other peace or parish officer, (such person being duly summoned to appear and answer to such charge,) may impove, upon conviction, any reasonable fine, not exceeding 40s., upon such constable, &c.; and if not paid, levy the same by distress and sale of the goods of such offender, to be applied to the poor of the parish or place where he resides; or for want of such distress, the offender shall be committed to the house of correction for any time not exceeding ten days. The officer executing such warrant, if required, shall draw the same to the perfon, whose goods and chattels are distrained, and suffer a copy of it to be taken. 27 Geo. III. c. 26.

On the other hand, the constable is protected by law, in the execution of his duty. By 7 & 9 Geo. I. c. 5, 27 & 28 Geo. II. c. 12. if any action is brought against a constable for any thing done by virtue of his office, he, and all who aid him, may plead the general issue, and give the special matter in evidence, and if he recovers, shall have double costs; but this must be certified on the record by the judge; and 19 Geo. II. c. 21. against profane swearing, gives treble costs. By 24 Geo. II. c. 41, no action shall be brought against any constable or others afflating him for any thing done in obedience to any warrant of a justice of peace, until demand of the perusal and copy of such warrant, and the facts have been refused or neglected for the space of six days, &c. &c. No action shall be brought against any constable but within six months after the act committed. For the charges of conveying malefactors to gaol, see COMMITMENT. By 27 Geo. II. c. 20, the constable executing a justice’s warrant, for levying a penalty or other sum of money directed by an act of parliament by distress, may deduct his own reasonable charges; and if any person shall be appointed to execute any warrant for felony, two justices may order by warrant under their hands a reasonable allowance to such special constable for his expenses and loss of time, to be paid by the treasurer out of the county rate. 41 Geo. III. c. 78. Two justices may in like manner order an allowance to be made to any high constable for extraordinary expenses incurred in the execution of his office, to be defrayed in the same manner. And by 28 Geo. II. c. 19, every constable, head-
to discharge a constable, the King's Bench may compel them by mandamus. 2 Hawk. 65. If a constable be discharged without just cause, the court of King's Bench will by rule of court order him to be referred to his place. Bull. 174.

**Constables of the Castles**, in Antiquity, were keepers or governors of the castles, or of great barons, who were frequently hereditary, or by feudal tenure; such were the constables of the Tower, the constable of London, or Baynard's castle, the constables of the castles of Dover, Windsor, Chelten, Caernarvon, and other castles in Wales; some of which offices, though not now hereditary, are remaining to this day. Their office seems to have been the same with that of the *castellani*, or governors of castles. These constables are those to whom Magna Charta (c. 17. 20.) refers; and who in the flat of Wefm. 1. (3 Ed. 1.) c. 15. are called constables of *fees*, and there considered as keepers of prisons; a distinct part indeed of all ancient castles. 2 Inst. 31. The statute of 5 Hen. IV. c. 10. reciting the oppressions of these constables, and enacting that none be imprisoned but in the common gaol, seems to have put an end to a race of tyrants, who, by their misdeeds, had rendered themselves odious to the people.

**Constable of France.** See *Constatel*.

**Constable, Provoost of the.** See *Provoost*.

**Constable**, in Biography, general of the Dominican order about the end of the sixteenth century, was born at Ferrara, to which city he was constituted inquisitor, and afterwards nominated master of the holy palace by pope Gregory XIII. In literary history he is known by a work entitled, "De canis in fatuo officio cognoscendis," which related to the history of the dreadful tribunal invented by the founder of his order. His own zeal in the duties of the office to which he had been chosen was exemplary; and to execute fatigue and over exertions occasioned in venting on foot the monasteries under his government, is to be ascribed an illness that terminated in his death, at Venice on 17th of Sept. 1582. Moreri.

**CONSTADT, or Konstadt**, in Geography, a small town of Prussia, situated in Lower Silezia, in the principality of Oeh.

**CONSTANCe, Costantcz, or Consteinitz, a considerable town of Wrtemberg, in the circle of Swabia, formerly a free imperial city, under the protection of Austria, delightfully situated at the north-western extremity of the lake of Constance, where the Rhine flows out of it again; or between the two lakes; 45 miles N.E. from Zurich. N. lat. 47° 40'. E. long. 9° 12'. The fort of Petershausen defends it on the left side of the Rhine. "I was much afflicted," says Mr. Coxe, who visited this place in 1776 (see Travels in Switzerland, vol. 1. p. 16.) "with the solitary appearance of a town once so flourishing in commerce, and so celebrated in the annals of history. A dead stillness reigns throughout; grass grows in the principal streets; in a word, it wears the melancholy aspect of being almost totally deserted, and secretly contains 3000 inhabitants. This city has endured a sad reverse of fortune; it was formerly in alliance with Zoric and Balle; and, supported by their affission, expelled the bishop, and embraced the reformation. But the Protestant cantons being worked in 1551; and the league of Smalcald, of which Constance was a member, being defeated by Charles V., the town was obliged to submit to the emperor;" (having been placed under the ban of the empire in the year 1548, for defeting the Roman Catholic religion), "and readmit the Catholic religion. From this period it lost its independence." In 1549 it was placed under the power of the house of Austria by Ferdinand I.; and though the estates of Swabia refused their assent, the subscription was ratified by the diet at Augsburg. Being neglected by the house of Austria, the town fell to decay. Constance once what revived, and afforded the prospect of becoming a commercial town, through the permission granted by the emperor Joseph, to the emigrants from Geneva, of settling and carrying on their trade and manufactures, with very considerable privileges; the principal of which were the following: viz. the right of purchasing or building houses; the free exercise of religion, entirely independent of the Catholic clergy; the power of erecting a tribunal for the purpose of deciding all affairs relative to their manufactures and commerce; exemption from serving in the militia and quartering soldiers, from all contributions during the space of 20 years, from duties on their tools and utensils; and the inevitable establishment of the standard of the gold and silver employed in their manufactures. "These favourable terms (says Mr. Coxe) signed on the 30th of June 1785, attracted to many fettlers to Constance, that in my second visit to this place, on the 25th of October 1757, the new colony of Genevans consisted of 70 families, comprising 350 persons; among these were 54 watch-makers, who had introduced the different branches of manufacture which belong to their trade. Four hundred watches were already finished, and above 1400 more were preparing. The emperor also has granted to Mr. Macaire the convent of Dominicans lately secularized, town, establishing a manufacture of coated linens and cloths. The refactory is appropriated for the chapel of the new colony. "This convent, which was once the asylum of monkish superlition, is now the seat of trade and industry; and it must suggest a pleasing reflection to a philosophic mind, that a successor of Sigismond, who violated his word," (as in the case of Hufs) "should have configned to a reformed establishment that very convent in which the Bohemian divines was imprisoned, and from which he was led to the stake; and that the most enlarged principles of toleration should be manifested in the same spot where persecution was inculcated by precept and example. It is the triumph of reason and religion over bigotry and intolerance." Since the period to which we have now referred, France has extended its revolutionary spirit and operations to the states of Switzerland; and time must develop their effects on the liberty and commerce, and consequent prosperity of the country. See *Helvetic Confederacy and Switzerland*. At present the manufactures and commerce of Constance are inconsiderable. Its celebrity is chiefly owing to a council held here from 1414 to 1418, which deposited three papas, viz. John XXIII., Gregory XII., and Benedict XIII., who had set up against each other; appointed Martin V. in their room, condemned the doctrine of Wickliff, and committed his works to the flames, in 1415; and caufed John Hufs and Jerome of Prague to be burnt, the former July 6, 1415, and the latter May 30, in 1416. At this council the assembled fathers on the 14th of June in 1415, passed the famous decree which took the cup from the laity in the celebration of the eucharist, ordered that the Lord's supper should be received by them only in one kind, i.e. the bread, and rigorously prohibited the communion in both kinds. The history of this council by L'Enfant is composied with great accuracy and elegance. A second edition of this work appeared at Amsterdam in the year 1728, in 2 vols. 4to.: the first was published in 1714. For an account of the treaty at Constance, A. D. 1183; see the article *City*.

**CONsTANCE, Lake of**, separates Switzerland from
that part of Germany hither called the circle of Swabia.

It is divided into three parts: the upper part, which is the broadest, is called Boden-See, the middle part Bodmer-See, and the lower part Zeller See.

The superior lake is about 15 leagues in length, and 6 in its greatest breadth. The borders consist of gently rising hills; on the left hand Swabia, and on the right Thurgau, with a variety of scattered towns, villages, and monasteries, and delightful villas, which afford several views to those who navigate the lake, that are truly enchanting. The form of the lake inclines to an oval, and the water is of a greenish hue. This lake, like all the other lakes of Switzerland, is considerably deeper in summer than in winter; a circumstance which is owing to the firm melting of the snow from the neighboring mountains. It abounds with all sorts of fish, and more particularly with the species of trout, called in its vicinity "Flank," and by Linnaeus *Salmo lacustris.*

A little above Stein, which is an independent town, under the protection of Zurzio; the Rhine widens considerably, and forms the inferior lake of Constance, or the Zeller-See, which is divided into two branches; from Stein to Constance is about 10 miles, and from the latter to Zell, its greatest breadth, about 10.

Near Merbourg the lake of Constance is fain to be 350 fathoms deep. This great depth is extremely advantageous to commerce, the lake being navigated by vessels of 100 tons and upwards. There are two islands in its middle, on one of which is the town of Lindau, formerly a free imperial city, but belonging now to the king of Bavaria, who, by the treaty of the confederation of the Rhine, has engaged to have it fortified and provided with artillery establishments. On the other island, about a mile in circumference, is the town of Meinau, which belonged to the knights of the Teutonic order, and whose situation is delightful.

The Rhine enters the lake of Constance at its south-eastern extremity, and issues out of it again at the north-west, not far from Stein. There is an ancient, and generally accredited tradition, that the Rhine, in crossing the lake in all its length, does not mix with its water. The fame is said of the Rhone, which runs through the lake of Geneva. Pliny the Elder, and Ammianus Marcellinus, are the authors of these fables. It is true that the two rivers are distinctly seen some time after their entrance into the lakes, but the difference of colour vanishes as soon as they have deposited the sand which they carry. Mr. Coxe, seated on a vessel on the lake, in vain attempted to distinguish the waters of the Rhine from those of the lake. The river, in its course from the superior lake, being exactly of the fame beautiful greenish colour as the inferior lake into which it flows; it is evident that the one can never be distinguished from the other. Probably, upon its first entrance into the superior lake it is troubled, and consequently, for some distance, its current may be easily traced; but it pursues itself by degrees, and becomes an indistinct part of the great body of water.

Of no better foundation is the report that the lake of Constance once froze. Wagner affirms that it was frozen in 1571 and 1596, when two inhabitants of Constance walked over the lake on the ice, measured it, and found it to be 7265 fathoms long, from Romizhorn to Bouchon, which is not its whole length.

**CONSTANCY, in a general sense, denotes immutability; but in ethics, or the philosophy of the human mind, the term implies resolution or steadiness, particularly under adverse trials and suffering. It was the saying of a heathen philosopher, that there cannot be imagined upon earth a spectacle more worthy of the regard of the creator, intent on his works, than a brave man superior to his sufferings. Nothing, indeed, can be more noble or honourable, than to imitate courage sufficient for executing the injunctions of reason and confidence; for maintaining the dignity of our nature, and the firmness which adheres to us; and for being so much unaffected by poverty, pain, and even death itself, as not to do anything that is reproachful or finful in order to avoid them. To imitate this temper, is to be great above title and fortune; and manifests a mind of heavenly extraction, and worthy of the offspring of the deity. Of this kind, many illustrious instances occur in history, and particularly in the history of the Christian church, and of the last moments of confessors and martyrs.**

**CONSTANS I., Flavius Julius, in Biography, third son of Constantine the Great, by Fausta, was born A.D. 320, and was created Caesar at six years of age. Upon the death of his father in 337, Constans succeeded to the sovereignty of Italy, Africa, and the western Illyricum, as his share of the empire. He had enjoyed his power but three years, when he was attacked by his brother Constantine, whom he defeated and slew.**

Constans, by this victory, became emperor of Gaul, Spain, and Britain; and in his turn, attacked the Franks, whom he humbled, and the Scots, which probably did not end much to his credit, as no notice is taken of the fact by his early biographers. Nevertheless, the prince was elated by the success of his arms, and assumed a degree of pride on the occasion, which would have ill become any man, and in him was rendered quite contemptible, owing to his want of talents and application. He was, moreover, a flave to his passions, and allowed himself in acts of voluptuousness, that drew down upon him the indignation of the people. Magnentius, an ambitious fable, encouraged by popular discontent, was resolved to avert the honour of the Roman name. A conspiracy was formed, and Marcellinus, count of the sacred laces, who had already supplied, with a liberal hand, the means of seduction, under pretence of celebrating his son's birthday, gave a splendid entertainment: the intemperance of the feast was artfully protracted till a late hour, and the unsuspecting guests were tempted to indulge themselves in a dangerous freedom of conversation. On a sudden, the doors were thrown open, and Magnentius, who had retired for a few moments, returned into the apartment invested with the diadem and purple. The conspirators instantly hailed him with the titles of Augustus and emperor. The guards immediately took the oath of fidelity, and ere the dawning of the day, Magnentius became master of the troops and treasure of the palace and city of Autun. Constans, who was pursuing his pleasure in an adjacent forest, being informed of the fact, threw off the imperial robes, and fled towards Spain; but before he could reach the sea-port, where he intended to embark, he was overtaken by a party of cavalry near Helena, at the foot of the Pyrenees, and put to death with a irong heart.**
been call headlong from the throne. Your majesty and wisdom have prevented the Roman state from degenerating into lawless tyranny. I therefore exhort and beseech you to stand forth as the counsellors and judges of the common safety." The senators were gratified by the respectful address of their sovereign; but Constanza was anxious to secure the crown that had suddenly devolved on him. He obliged his elder brother Theodosius to take holy orders, which rendered him incapable of civil government. The young emperor was not satisfied with this act, which was regarded as a profanation of the sacraments, but he caused Theodosius to be put to death. The act was scarcely perpetrated before the executions of his subjects, joined to the agonies of remorse, rendered life a burden. He could no longer bear to reside in the capital that had been the witness of a base and infamous fratricide. He became a voluntary and perpetual exile; and embarking for Grecia, displayed the hatred which he felt, and was conscious that he injured, by spitting against the walls of Constantinople as he left them. After passing the winter at Athens, he visited various parts of Italy, and concluded a pilgrimage of disgrace, by fixing his residence at Syracuse. Constantine easily fled from the imprecatory of an injured people, but he could not forget what he had done. The remorse of his conscience created a phantom that pursued him wherever he went: the image of his murdered brother was ever before his eyes, prefiguring to his lips a cup of blood, and saying, or seeming to say, "Drink, brother, drink!"—"a pure emblem," says the historian, "of the aggravation of his guilt, since he had received from the hands of the deacon, the mystic cup of the blood of Christ." Constantine, however, did not reign the cares of government. He took part in some wars carried on in Italy, and having been successful, entered the capital with great pomp, and was met by the pope and clergy at a distance from the city. In return for this mark of respect, he plundered Rome, and sent its wealth and ornaments to Constantinople. He then departed for Syracuse, where he resided five years, oppressing the people, and hated by those about him. Domestic treachery put an end to his life; he was assassinated while he was in the bath, in the year 668, after a miserable reign of 27 years. Gibbon, Univer. Hist.

**CONSTANT, DAVID**, was born at Lausanne, in Switzerland, in the year 1653, and became distinguished as a poetical divine, and professor of theology. He was indebted to his own country for the rudiments of useful knowledge, and was afterwards a student at Herborn in Germany, from which place he went to Groningen, Leyden, and Paris, for farther improvement. At Paris, he became acquainted with many very celebrated members of the reformed church, and having laid the foundation of solid learning, and formed a connection with several worthy characters, he returned to Switzerland in the year 1653, was ordained minister according to the Calvinistic form, and undertook the charge of a church at Copet. Here he cultivated a literary intimacy with Turretin, Tronchin, and other professors in the university of Geneva, and with Baille, the celebrated historian, but who at that time was tutor in the family of count de Donha, baron of Copet, the patron of David Constant. On a vacancy at the college of Lausanne, Constanza was appointed tutor to the first class, by the magistrates of Bern, and was afterwards elected professor of moral philosophy and the Greek language. The important duties of these stations he discharged with high honour to himself, and to the advantage of those placed under his instructions; his vacant hours were employed in editing some of the classics, original works. By his contemporaries he was much respected; they regarded him as a man of considerable literary acquirements, possessed of a fine judgment and a correct taste. In the year 1700, he was chosen professor of theology, a situation which he retained until he was eighty-nine years of age, when he resigned in favour of a successor, referring to himself, even then, the right of giving his advice and advice to the public in the most exalted degree. He died in 1733, having attained the venerable age of ninety-five. He published new editions of Eusebius; of Cicero’s smaller pieces, and of various other pieces adapted to the use of schools. His original writings were respectable; they were dissertations on various theological subjects. We have also "Styloma Ethico-theologicum," printed at Lausanne, 1695; a work "De Juramenti," and another "On Providence." — Moret. Constant quantity, in Geometry, that which remains the same, while others increase or decrease. Thus the semidiameter of a circle is a constant quantity; for while the absciss and semi-ordinates increase, it remains the same. Constant wind. See Wind.

**CONSTANTIA** in Ancient Geography, a town of Valeria, in the vicinity of the Danube. — Alfo, a town of Thrace, in the territory of Mount Rhodope. — Alfo, a town of Asia, in Mæopotamia; said by Ammianus Marcellinus to have been Amala, which was enlarged by the emperor Constantine, and adorned his name. — Alfo, a name given to Majumas, the port of Giza, after Constantine raised it to the rank of a town and gave it the name of his son. — Alfo, a name given to the town of Salamine. — Alfo, a name assigned by Constantine to the town of Arcata (Arles), according to Atanous, cited by Scaliger.

**CONSTANTIA GABRA**, a town of Gaul, in the second Lyconianus; now Courtance.

**CONSTANTIA, in Geography, a district of the Cape of Good Hope, a mile and a half from Alphen, close under the mountains, about midway between Table bay and False bay, consisting of two farms which produce the famous Cape or Constanitia wine, so remarkable for its peculiar rich flavour and sweetness. One of the farms where the white wine is made is called Little Constanitia; the other produces red. There are only from fifty to one hundred casks, of 154 gallons each, made annually of the genuine Constanitia wine. The grape is the muscadel, and the rich quality of the wine is owing partly to the situation and soil of the vineyards, and partly to the care taken in manufacturing the wine. No talk, and no fruit but such as is full ripe, are suffered to go under the press; precautions rarely taken by the other farmers of the Cape, who make annually about fix hundred 154-gallon casks of the common Cape wine, which, however, is frequently brought into the European markets, under the name of Constanitia wine. The muscadel grape grows at every farm; and at some farms in Drakenstein, the wine pressed from it is equally good, if not superior, to the Constanitia, though sold, on account of the name of the latter, at one fifth part of the price. This wine sells at the Cape for 50 or 80 rix-dollars for the half-case, which ought to contain 20 gallons; but the avaricious disposition of the proprietors, has led them to fabricate false cases, few of which come to England being found to measure more than 17 or 18 gallons, and many not above 16. When they find that the wine to be sent abroad, they adulterate it with some other wine. For, according to their own returns, the quantity exported and consumed in Cape Town, as in the case of Madeira wine, greatly exceeds the quantity manufactured.
The following table shows the quantity of Constantia wine exported in four successive years.

**CONSTANTINE**, or Constantine, the eastern province of the kingdom of Algiers, which see. This province, which is the largest and richest of the four provinces into which Algiers is commonly divided, (the three others being Mascara, the territory of the city of Algiers, and Titeri,) lies between the meridians of the rivers Boobarak and Zaine, which separates it from Tunis, and is bounded on the north by the Mediterranean, on the south by the Sahara, on the west by Blidgolger, and on the east, in its greatest extent, by the river Malva, or by the territory of Algiers, &c. It is nearly equal in extent to the two western and southern provinces, being, by Dr. Shaw's statement, 2,900 miles in length, and more than 100 in breadth; and far surpassing them in wealth and strength, as well as in the number and goodness of its cities. The tribute collected by the viceroy of this province, according to Dr. Shaw, is proportionably greater. For whilst the Titeri bey brings every year into the treasury of Algiers little more than 12,000 dollars, each being 32 and 42 or 62, and the Tlemcan bey from 40 to 50 thousand; the viceroy of Constantia never pays in less than 80, and sometimes 100 thousand. The sea-coast of this province, from the Boobarak to Boujjiah, and from thence almost entirely to Bona, is rocky and mountainous; and the whole tract which lies between the meridians of the rivers Boobarak and Zborre, from the sea-coast to the parallels of Sceef and Constantia, is, for the most part, a continued chain of exceedingly high mountains; few of whose inhabitants, from the ruggedness of their situation, pay any tribute to the Algerines. Near the parallels of Sceef and Constantia it is diversified with a beautiful inter-changing of hills and plains, which afterwards become less fit for tillage, till it terminates, upon the Saharan, in a long range of mountains, supposed by Dr. Shaw to be the Bazara of the ancients. The district of Zabib (which see) lies immediately under these mountains; and beyond Zabib, at a great distance in the Sahara, is Wadrey, another collection of villages. This part of the eastern province, including the parallel of Zabib, answers to the Mauritania Sitiffis, or the first Mauritania, as it was called in the middle age. The mountains are inhabited by free Arabian and Moorish tribes, which from time to time have proved formidable enemies to the power of Algiers. The most remarkable places are Boujjiah or Bugia, Culla, Bona, La Calle, the island of Tabarka, and Constantia; which see respectively.

**Constantina**, Constantina, formerly Cirta, is one of the most considerable cities of ancient Numidia, the capital of the above-deferred province, and the residence of the bey. Next to Algiers, it is the most populous city in the Algerine dominions. For a particular account of it, see Cirta.

**Constantina**, a town of Spain, in Andalusia; 50 miles S.W. of Cordova, and 42 N.E. of Seville.

**Constantina**, in Ancient Geography, a town of Phoenicia.—A so, a town of Alta, in Mesopotamia.

**CONSTANTINE I., Flavius Valerius Constantinus**, in Biography, the first Christian emperor, and transmitting the peace, was son of Constantius Chlorus by Helena. The situation to which this prince attained, has rendered posterity attentive to the most minute circumstances of his life and actions. The place of his birth, and the condition of his mother, have been subjects of warm, not to say violent, disputes. According to Mr. Gibbon, Helena was the daughter of an inn-keeper, and Naisius in Dacia was the birth place of her son, the subject of this article, about the year 274. In his youth he discovered little inclination to improve his mind by the acquisition of knowledge; but the combinaings of his figure, the dexterity which he exhibited in all manly exercises, and his known courage and affability, rendered him a favourite with the army and the people. He was about eighteen years of age when his father was promoted to the rank of Caesar; this event was attended with his mother's divorce, in order to make way for the second wife of Constantius, who could boast of an alliance with the imperial race. By this act the nobly-minded Constantine was reduced to a state of disgrace and humiliation. Indignant, probably, at the base conduct of his father, he remained in the service of Dioclesian, and signifying himself in the wars of Egypt and Persia, he was raised to the rank of tribune of the first order. The popularity of this young man rendered him an object of jealousy to Galerius, through whose interest he had already been denied the rank of Caesar. Endangered by the power and wiles of his opponent, and being kept for by Constantius, his father, whole health was daily declining, he secretly left Nicomedia, where he then was, and travelled with all expedition to Boulogne, and embarked with Constantius for Britain. The expedition was prosperous, and they easily obtained a victory over the Caledonians; but it was the last exploit of Constantine. He died at York, in the year 306, within little more than a year after he had received the title of Augustus. His death was immediately succeeded by the elevation of Constantine, who was proclaimed emperor by the army. The throne was the object of his ambition; and he knew too well the character of Galerius, the colleague of his late father, to hesitate as to the part he must take in this crisis. He was satisfied that if he wished to live, he must resolve to reign. At first he affected to refuse the choice of his people, and wrote a respectful letter to the emperor of the East, acquainting him with the event. The earliest emotions of Galerius were those of surprise, disappointment, and rage; he threatened to commit to the flames the letter, and him that brought it. Upon further deliberation, he resolved not to contest his succession to the sovereignty of the provinces beyond the Alps, but conferred on him the title of Caesar, referring that of Augustus to his favourite Severus. Constantine, who already possessed the substance, expected without impatience an opportunity of obtaining the honours, of supreme power; and accordingly employed himself some years in governing and securing the dominions fallen to his share. In defending his own rights, he was often betrayed into acts of cruelty, unworthy of a great mind. Contending with the Franks, he took two of their kings, whom he barbarously exposted to wild beasts in the amphitheatre of Trier: in some disturbances where he was victorious, he spared neither sex nor age; exhibiting a ferocity that freoms ill to accord with the general tenor of his character, to which he was probably
probably prompted by the supposition, that upon a bar-
barous foe all kinds of barbarity were allowable. In 307
he married Fausta, daughter of Maximian, who had re-
sumed the purple; but he took no part in the fortunes of
his father-in-law, who was ever engaged in warfare, till he
became himself Constatine's open enemy, and endeavoured
to drive him from his rightful authority. Under these cir-
stances he was delivered into the hands of his son-in-law,
who slew him at another favour than that of allowing him
the choice of the manner in which he would die: Maximian
strangled himself in the year 310.

Shortly after this event, which was little creditable to
the feelings of Constatine, or to the filial piety of Fausta,
who took no means to soften the resentment of her husband,
a civil war broke out. Maxentius, who had reigned in con-
junction with Constatine, now laid claim to the monarchy
of the whole West, and made preparations for an invasion of
Gaul. Constatine relying as well on his own talents, as on
the hatred borne to his rival, resolved to anticipate the attack,
and to carry the war into the heart of Italy. The armies of
Maxentius, amounted to one hundred and seventy thousand
foot, and eighteen thousand horse. The wealth of Italy
supplied the expenses of the war, and the adjacent provinces
were exhausted to form magazines of corn and other kinds of
provisions. The whole force of Constatine consisted of
ninety thousand foot, and eight thousand horse; a large part
of which was necessary to the defence of his other dominions.
At the head of forty thousand foot; he marched to en-
counter an enemy, whose numbers were at least four times
superior to his own. Constatine had been trained from his
earliest youth to war, to action, and to military command,
and his troops were in the highest state of discipline: these
he disposed with consummate skill, and for himself he chose
the point of honour and danger. Distinguished by the splen-
dor of his arms, he charged, in person, the cavalry of his rival,
and his irresistible attack determined the fortune of the day.
The victory was complete, and the dismayed followers of
Maxentius rushed by thousands into the Tyber. The em-
peror himself attempted to escape back into the city over
the Milvian bridge, but the crowds which pressed together
through that narrow passage, forced him into the river, where
he was immediately drowned by the weight of his armour.
His body which had sunk deep into the mud, was found the
next day; and the sight of his head, when it was exposed to
the eyes of the people, convinced them of their deliverance,
and led them to acknowledge as their sovereign Constatine,
who thus acquitted by his valor and high talents the most
splendid enterprise of his life. It was previous to this battle,
A.D. 312, that historians affign the date of Constatine's
conversion to Christianity, who had never before discovered
religious principles of any kind. A splendid miracle is men-
tioned as the immediate instrument of this change. Dr.
Lardner, indeed, offers some reasons why Constatine could
not well have remained through life without some religious
impressions; he is however willing to follow the account of
Eusebius, who says, that about the period of the war with
Maxentius, the emperor was led to consider that he had drawn
in need of more powerful assistance than military forces; he
therefore sought for a God that should be his helper. The his-
torians go on to say, that in part of his march, as the day was
decreasing, there appeared to the sight of Constatine, and to
that of all his army, a luminous cross above the sun, with the
inscription 

\[
\text{SALVAM} \text{nomen} \text{DOMINI} \text{EX} \text{VENETIS}.
\]

by this conquer; that the monarch not comprehending the meaning of this sign was further instructed, in the following night by a vision of Christ himself, bearing his cross, and directing him to take a similar standard, under
which he should march to victory. In the morning Con-

stantine communicated this wonderful circumstance to his
friends; and sending for ingenious workmen, he gave them a
description of the sign, and showed them how to make one like it
in gold and precious stones; which, says Eusebius, "we have
seen." Much has been said respecting this surprizing phe-
nomenon. By some the whole is regarded as a fiction, a fra-
tagem and political device of Constatine, yet it is related by
Eusebius a grave historian, who declares that he had it from
the emperor, who confirmed the narration by the narrators
elsewhere. By Fabricius, we are told, that the appearance in the heavens
was generally looked upon as a reality, and a miracle: but
for his own part, he is inclined to consider it as the result of
a natural phenomenon in a solar halo; he accordingly admits of the reality of the phenomenon, but does not suppose it to
be properly miraculous. Upon a full and candid review of
the evidence, Dr. Lardner, whom we have before quoted, and
than whom no one was a better judge of human testimony,
says inclined to doubt the relation given by the emperor,
upon whose sole credit the story is recorded, though it was
twenty years after the event, when Eusebius wrote his ac-
count, during which period he must have heard it frequently
from eye-witnesses, if the emperor's relation were accurate
that the appearance was visible to his whole army as well as to
himself. The oath of Constatine, on the occasion, with
Dr. Lardner, brings the fact into suspicion, and another
frightful circumstance is that Eusebius does not mention the
place where this wonderful fight appeared. Without, how-
ever, entering, at present, further into the discussion, which
we shall refer to the article Cross; we may observe, that
Eusebius has led us to the period, when the sign of the cross
began to be made use of by Constatine, among his armies,
and at his battles; this was probably the day before the last
battle with Maxentius, fought on the 27th of October, 312.
About this period, it is admitted, that Constatine became a
Christian, and continued to the remainder of his life, taking
care also to have his children educated in the same principles.
His conversion seems to have been partly owing to his own
reflection on the state of things, partly to conversation and
discourse with Christians, with whom, the son of Constatine,
their friend and favourer, must have been some time acquainted,
but perhaps, chiefly to the serious impressions of his early
years, which being once made can never be wholly obliterated.
Constatine was however a politician as well as a Christian,
and he probably hit upon this method to reconcile the minds
of his army, to the important change in their religious pro-
fection and habits, as well as making use of it as a mean of
favouring his designs against his enemies, for which purpose
he rightly judged, that the standard of the cross, and the
mark of it as a device on his soldier's shields, would be of no
small service.

We must now return to Constatine in the character of
a victorious general. After the battle, he entered the cap-
tal in triumph, wholly destroyed the family of his rival, but
refused to include among the victims, many whom the
Romans would gladly have sacrificed to their abhorrence of
the late tyranny. He disbanded and dispersed the pretorian
guards which had so often made and murdered emperors:
he recalled many who had been banished, and restored to
them their estates: he discouraged informers, and promoted
the welfare of the city. The senate immediately paid a
decrees, conferring on him the first rank among the three
Augusti, who then were masters of the world: Licinius
and Maximin were the other two. Africa readily followed
Italy in recognizing the sovereignty of the conqueror. To
Licinius, with whom he had an interview, he gave his sister
Constanitia in marriage, in order to strengthen his own
hands. From Milan, where the two emperors suffered an
edict under their joint authority, allowing a general toleration in religious matters within their dominions. Constantine was called by an attempt of the Franks to cross the Rhine. Once there he gained a complete victory, and made many prisoners, whom, as in former instances, he exposed to wild beasts. In the mean time a civil war arose between Maximin and Licinius, which terminated in the destruction of the former, and the expiration of his whole family.

Constantine and Licinius were now masters of the world, but they did not long continue united. A war broke out between them in the year 314, but the result of several battles was decided in favour of Constantine. Licinius sued for peace, which he obtained, and which continued eight years. In 323 another war was excited between the emperors. Licinius had long been hostile to the Christians, whose affection he had alienated, and who looked up to Constantine as their patron, and the head of their religion. Aware of this circumstance, and relying on his own superiority, as a military commander, Constantine began the quarrel. Under the banner of the cross, and accompanied by bishops and other ministers of their holy religion, he went out with 150,000 well-disciplined and well-armed soldiers to meet his rival, who waited his arrival in the vicinity of Adrianople. Constantine was again victorious: Licinius fled to Byzantium, and when he found that place no longer tenable against the power of his enemy, he withdrew to Chalcedon, and from thence, after hazarding another battle, in which he was also unsuccessful, to Nicomedia; where, by the intercession of his wife, he obtained a solemn promise of having his life spared, on the condition of his renouncing all claims to sovereignty. To the disgrace of Constantine imprisonment and death soon followed the humiliation of his rival. This deed has been justified on the plea that the fallen emperor had engaged in a treasonable correspondence against the reigning sovereign, but sufficient evidence of the fact was not added. The son of Licinius was also sacrificed to the jealousy of Constantine, who, by these atrocious means, delivered himself from all dread of opposition. An arbitrary prince seldom finds any difficulty in freeing himself from his enemies, but Constantine with all his powers, could neither foresee, nor prevent, those domestic calamities to which he shortly became the prey. Cripus, his son, by a former wife, was viewed, by his mother-in-law Fausta, as the chief obstacle to the future greatness of her own children. She introduced into the breach of Constantine suspicions of his son’s loyalty, and is said also to have brought a charge against him of having attempted her own chity. Cripus was examined, imprisoned, and put to death in the year 326. His grandmother Helena, convinced of his innocence, resolved to be revenged for his hard fate, and found means of convicting the empress of an adulterous connection with a flave of the palace, for which she was suffocated in the gream of a hot bath. From these circumstances, and from the contempt which he shewed for the pagan rites, the emperor became unpopular with the people and the senate. On his part there was no personal attachment to the ancient metropolis, and he was resolved to perpetuate his name by the foundation of a new city. After much deliberation he fixed on Byzantium, which he had once belied, as the imperial city that should, with future ages, give him celebrity and renown. See Constantinople.

In the year 331 Constantine was involved in a war with the Goths, who at first were successful against his power, but were, at length, defeated and compelled to agree on such terms as the victor thought proper to propose. Constantine, by challenging the pride of the Goth, and by accepting the homage of a suppliant nation, vindicated the majesty of the Roman empire; and ambassadors from Ethiopia, Persia, and the most remote countries of India, came to congratulate him on the peace and prosperity of his government; and he seems to have enjoyed an uninterrupted share of felicity, as a man situated as he was could reasonably expect. He attained to the thirteenth year of his reign, a period which none of his predecessors, since Augustus, had been permitted to celebrate. Constantine survived that solemn festival about ten months, and, at the age of sixty-four, after a short illness, he ended his memorable life at a palace in the suburbs of Nicomedia, whether he had retired for the benefit of the air, and with the hope of recruiting his exhausted strength by the use of the warm bath. The demonstrations of grief, or at least of mourning, purported whatever had been practised in any former occasion. The body of the deceased emperor was transported to the city which was destined to preserve the same and memory of its founder: there it was adorned with the symbols of greatness, and deposited on a golden bed in one of the apartments of the palace, which was splendidly illuminated and furnished for the purpose. Every day, at the appointed hours, the officers of state, approaching the porch of their sovereign, offered the same respectful homage to his dead body as they had been accustomed to present to him during his life, so that it has been said Constantine-alone, by the peculiar indulgence of heaven, reigned after his death.

It remains now to give a general estimate of the character of this great man, who was unquestionably the most splendid among the Roman emperors. It is no wonder that a prince who removed the seat of empire, and introduced such important changes into the civil and religious constitution of his country, should have fixed the attention, and divided the opinions of mankind. By certain classes of Christians he has been regarded as the deliverer and defender of the church, and has been decorated with every attribute of a hero, and even of a saint; by others, he has been considered as the real, though without any ill intentions on his part, enemy to the cause of true Christianity, by incorporating it with the civil government of the world: by contemporary historians who did not embrace the religion of Christ, Constantine was compared to the most abhorred of those tyrants, who, by their vices and weaknesses, dishonoured the imperial purple.

Constantine was, in person, remarkably tall, of a comely and majestic presence, and great bodily strength. The general tenor of his life proves that he was a prince of no mean capacity: the achievements and success of Constantine do not belong to men of weak and irreligious minds. His mind indeed was equal to his fortune, great as it was: his valour was tried and approved frequently in his youth, and was conspicuous on all proper occasions throughout his whole life: his chality, justice, and prudence, are commended by those of his biographers, who, on account of a difference in religion, were not disposed to flatter him: his many acts of bounty to the poor, and his just edicts are arguments of a merciful disposition, and a love of justice. According to Eusebius the palace of Constantine was converted into a church; and the emperor himself cheerfully led the way to those that assembled there with him. Taking the sacred books into his own hands, he attentively read and meditated upon the divine oracles; and then recited the usual prayers with those who were met together. Constantine besides prayed daily in private in his chamber. In time of war he had a chapel at a small distance from his camp for the performance of religious duties, especially before battle, seeking thereby the divine protection and blessing. He taught
taught even his heathen soldiery a form of prayer, in which they worshipped the one true God. Thence and many other influences of the Christian temper are ascribed to the emperor by Eusebius. By our own historian, the early part of his life is highly panegyrized: "He delighted," says Mr. Gibbon, "in the social intercourse of familiar conversation; and though he might sometimes indulge his disposition to rillery with less reserve than was required by the severe dignity of his station, the courtesy and liberality of his manners gained the hearts of all who approached him. The disadvantage of an illiterate education had not prevented him from forming a just estimate of the value of learning; and the arts and sciences derived some encouragement from the munificent protection of Constantine. In the dispatch of business, his diligence was indefatigable; and the acts of his mind were almost continually exercised in reading, writing, or meditating: in giving audience to ambassadors, and in examining the complaints of his subjects. Even those who confounded the propriety of his measures were compelled to acknowledge, that he poissfed magnanimity to conceive, and patience to execute, the most arduous designs, without being checked either by the prejudices of education, or by the clamours of the multitude. In the field, he invigorated his own intrepid spirit into the troops, whom he conducted with the talents of a consummate general; and to his abilities, rather than to his fortune, we may ascribe the signal victories which he obtained over the foreign and domestic foes of the republic. He loved glory, as the reward, perhaps as the motive, of his labours. The boundless ambition, which, from the moment of his accepting the purple at York, appears as the ruling passion of his soul, may be justified by the dangers of his own situation, by the character of his rivals, by the consciousness of superior merit, and by the prospect that his success would enable him to restore peace and order to the distracted empire." As he advanced in life, his character was less respectable, his actions less honourable. The ostentatious grandeur of his court, and his magnificent buildings, were supported by taxes which bore very heavily on the people, and in his old age he was charged with prodigality and rapacity. Eutropius says, that Constantine, "in the early parts of his reign, might be compared to the belles princes, in its conclusion to the indifferent ones." And Dr. Lardner, who took great pains to understand and appreciate the worth of this emperor, observes, with his usual candour, that "we should be willing to make allowances in favour of princes, and especially of long reigns. It is next to impossible for human wisdom and discretion, in the course of many years filled with action, not to be surprised into some injustice, through the bias of affection, or the specious suggestions of artful and designing people. Though, therefore, there may have been some transgressions in this reign which cannot be easily justified, and others that must be condemned, yet we are not to consider Constantine as a cruel prince or a bad man." Gibbon. Lardner. Jortin. Univer. Hill.

CONSTANTINE II., the eldest of the three sons of Constantine the Great, was born in the year 316, and, by the indulgence of his father, was admitted at a very tender age to share the administration of the empire. He and his brothers may be said to have studied the art of reigning at the expense of the people entrusted to their care. During his father's lifetime, the younger Constantiiæ was appointed to hold his court in Gaul: and upon his death in 377, he succeeded to the government of Gaul, Spain, and Britain; to him also was assigned the city of Constantinople, with a certain superintendence of rank above his brothers. During his short reign, he did little that has been deemed worthy of historical record. Dissatisfied with the share of empire allotted to him, he was driven to poise the provinces of Africa, which had been given to Constatine the Great; his solicitations were in vain: determining, therefore, to wail by force, what he could not obtain by argument, at the head of a tumultuary band, he invaded the dominions of Conslans, and laid waste many parts of the country. The measures of his brother were directed with more prudence; and Conslanctine, by too great eagerness, was betrayed into an ambuscade, which had been concealed in a wood, where he and his attendants were surrounded and slain, A.D. 342. His body was afterwards found in the obscure forest of Alis, and obtained a place in the imperial sepulchre; but his provinces transferred their allegiance to the conqueror. Contemporary historians speak of Constantine as a prince of great accomplishments; but his conduct towards his brother met with a punishment which neither merited nor obtained the pity of survivors.

CONSTANTINE III., the next emperor of this name, was the son of Heraclius by Eudoxia, and succeeded his father in 641. Of him more cannot be well said than that he reigned three months, and died in his 30th year, either by disease, or by poison, supposéd to have been administered by his mother-in-law.

CONSTANTINE IV. succeeded his father, Conslans II., in the year 665. Very soon after he came to the throne, he went to Sicily, with a view of punishing his father's murderers, and to depose the usurper whom they had established. His enterprise was successful; but upon his return to Constantinople, he was scarcely recognized, on account of the alteration in his beard; hence he obtained the appellation of the bearded. In this reign the Saracens invaded Africa, Sicily, and Cilicia, and at length laid siege to Constantia. Their attempts were completely baffled, and their losses in men was very considerable. The emperor, however, became tributary to the Bulgarians, who successfully invaded some of his territories. This prince, who died in the year 685, appears to have poissed a small share of talent, intermixed with cunning and cruelty. On his two brothers he had bestowed the empty title of Augustus, unconnected with truth or power. At their secret instigation, the troops of the Anatolian province approached the city on the Asiatic side, demanding for their royal brothers the partition or excretion of sovereignty, and supported their claims by a theological argument. "We are Christians," they said, "the sincere votaries of the holy and undivided Trinity; since there are three equal persons in heaven, there should be three equal persons on earth." The emperor invited them to a friendly conference, in which they might propose their arguments to the senate: they obeyed the summons; but the view of their bodies, hanging on the gibbet in the suburb of Galaten, reconciled their companions to the unity of the reign of Constantine. He pardoned his brothers; but on the repetition or suspension of a similar offence, the obnoxious princes were deprived of their titles and places, that the deformity might disqualify them from the empire. In the close of life, Constantine was anxious to establish the right of primogeniture; and the eldest son was exalted to the rank of Augustus, and the assurance of the empire.

CONSTANTINE V., son of the emperor Leo, was born in 719, and crowned in his infancy. He was consecrated Co-emp of his reign, from having polluted the baptismal font. During a long reign of 54 years, he ever exhibited an adherence of image-worship, which rendered him an object of hatred to the catholics, who had used every means in their power to tranquillize his name to pollute in the most disgraceful light.
light. Although he did not merit all the opprobria affixed to his character by ecclesiastical bigots, yet he undoubtedly exercised much cruelty towards the party which resisted his attempts for reform in the church. Some were put to death, others mutilated, and not a few underwent less severe punishments. As a general, he exhibited much prudence and courage. Soon after his accession he marched against the Saracens, who had made an irruption into Asia; and his brother-in-law, taking advantage of his absence, placed himself at the head of the orthodox faction, and was declared emperor. A civil war ensued, in which Constantine was victorious: the metropolis surrendered to its lawful sovereign, and the usurper and his son were deprived of their ill-gotten power, and of their eyes. When every thing at home was settled to his satisfaction, he made war again upon the Saracens, took their strong places, and destroyed their fleet. In the midst of his successes, a earthquake, and a pestilence among his own people, were calamities which excited in him the greatest consternation. After this he was attacked by the Bulgarians, by whom he was so completely defeated, that he was obliged to seek refuge in his capital: but in another attack, victory determined for Constantine, who cut off the invaders, with scarcely any loss. As he was proceeding on a new expedition against the same people, he was seized with a fever, which terminated his life in 775.

To the praise of this prince, his enemies admit that he restored the ancient aqueduct, a work of great importance to the inhabitants of Constantinople. He redeemed nearly three thousand captives: and under his reign, plenty was the characteristic of the times. Moreri. Gibbon. Univer. Hist.

Constantine VI., grandson of the preceding, was born in 770; and when only five years of age, he was associated with his father, Leo IV., in the government: but neither then, nor in 780, when he succeeded entirely to the throne, was he capable of efficient business. His mother Irene was appointed guardian to the young emperor; she, naturally ambitious, and impatient of control, was unwilling to resign the power over her own hands. The contests between the mother and her son were the most prominent features of this reign. During the childhood years of the emperor, nothing could be better administered than the government under Irene: but when he had attained the years of maturity, by the advice of his adherents, he would fain have rewarded his mother's services by perpetual banishment to the Isle of Sicily. Irene was too politic to be thus served: she retaliated upon her enemies, and obtained for herself almost an unlimited obedience. Her abuse of victory proved detrimental to her interests: Constantine ascended the throne sole sovereign, and his mother was dismissed to a life of solitude, to the enjoyment of which her mind was by no means adapted. She was recalled to court, and soon obtained a certain degree of authority. The emperor was attacked and defeated by the Bulgarians; and sullying an incursion in favour of Nicephorus, son of Constantine V. by a second marriage, he had him seized and his eyes put out, and the tongues of his four brothers were amputated. After this cruel punishment, they were doomed to perpetual imprisonment. Irene having submitted to their fate: an opportunity then offered, and they made their escape to the church of St. Sophia, displaying a pathetic spectacle to the people. "Countriesmen and Christians," exclaimed Nicephorus for himself and mute brethren, "behold the sons of your emperor, if you can recognize our features in this miserable state. A life, an imperfect life, is all that is spared: this is now threatened, and we appeal to your compassion." Their wretchedness affected the people, but the minislers of Constantine contrived to soothe their miseries, and draw them from public view. They were speedily embarked for Greece, and Athens allotted to them as a place of exile. Once more they escaped from the hands of their keepers, and appeared in parade at the gates of Constantinople. This was their last effort: in attempting to gain a crown, they lost their lives. Irene soon found an opportunity of exciting dissentions, with a view of depopulating her son. Suspecting his danger, he attempted to escape to the provinces, but was caught on the Asiatic shores, and carried prisoner to his own palace, where, in the very chamber in which he was born, the emblems of his unnatural and infamous mother affrighted him in his sleep, and plunged their daggers in his eyes. In this state he survived many years, to reflect on his own cruelty, and to learn the urgings of Irene.

Constantine VII. was son of the emperor Leo VI., and nephew to Alexander, whom he succeeded in 912, being but seven years of age. During his minority, Romanus Lecapenus, a successful general, got possession of the emperor's person, and prevailed on him to marry his daughter. He then assumed the royal purple himself, and associated his own three sons in the imperial authority, degrading the lawful emperor to the fifth rank among the titular princes. Much, however, to the honour of Romanus, he permitted him to live unmolested; and the time of Constantine was spent in the study and practice of the fine arts. The fall of Romanus was occasioned by the ambition of his own children, who effected the banishment of their father, and, contrary to their own expectations, elevated Constantine to his rightful throne. To prevent their future intrigues, the emperor's first act was to seize the conspirators, and banish them to the same island and monastery in which they had so lately confined their father. Romanus met them on the beach with a farcical smile, and, after a jilt reproach of their folly, ingratitude, and weakness, presented his imperial colleagues with an equal share of his water and edible diet. Constantine was now in possession of the eastern world, which he governed, or appeared to govern, fifteen years. He was, however, devoid of that energy of character which became the sovereign of so mighty an empire. The studies which had amused his life of comparative solitude, were not easily exchanged for the serious and important duties of a monarch. The reins of government he entrusted to his wife Helena, while he employed much of his time in the instruction of his son Romanus, and in drawing up a treatise for his immediate benefit, but of which he made folly a use, that he is suspected of having administered poison to his father, in order to succeed him in the empire. The death of Constantine was regretted by his subjects, who paid every demonstration of regret to his decafed corpse, which, according to usual custom, lay in state at the palace. Before the procession moved to the sepulchre, an herald proclaimed the awful admonition: "Arise, O king of the world, and obey the summons of the King of kings."—One of the deposed sons of Romanus had, during his short-lived authority, assumed the title of Constantine VIII.; of him therefore enough has been said; and we proceed to the reign of Constantine IX., who, in conjunction with his brother, Basil II., succeeded to the throne, on the death of John Zimricus, in the year 976. During the long life of Basil, Constantine had only the name of emperor: all emanated from his brother. After his decease, Constantine enjoyed, about three years, the power, or rather the pleasures, of royalty; and his chief care was the settlement of the succession. He had possessed sixty-five years, the title of Augustus; and the reign of the two brothers is the longest.
lager and most obscure of the Byzantine history. He ended his inglorious life in 1028, at the age of seventy.

Constantine X. was surmounted by Monomachus, the single combatant, which was probably expressive of his valour and victory in some public or private quarrel. He was a Greek noble extraction, and recalled from exile in Lesbos to succeed Michael V. He was at that time married to Zoe, the daughter of Constantine IX. With her, who had already been wife to two emperors, he was disdained, and took, as consuaine, a widow, to whom he gave the title of Augusta. This reign was disturbed by various revolts, in which the emperor was usually victorious. He was successful also against his foreign enemies; but his insolvency or avarice gave the Turks an opportunity of gaining a footing in Asia Minor. He died in 1054. The health of this emperor had, during the greater part of his life, been broken by the tortures of the gout, and his reign was spent in thealternatives of sickness and pleasure.

Constantine XI. surmounted Doucas, who was chosen by the emperor Isaac Comnenus, as the atteinder to succeed him, when he voluntarily laid down the crown in 1059. The beginning of his reign was affected by a conspiracy of his own people against him. Having quelled this, he began to turn his attention to government, for which he seems to have been very unequal. By the principles of avarice, he neglected the maintenance of his garrisons on the frontiers, and the Xians, a people of Scythia, taking advantage of this circumstance, paffed the Danube, and laid waste the country. They penetrated into Greece, and defeated the imperial generals, who had been sent against them. Constantine would have gladly purchased peace, on any terms; they, however, disdained to treat, and were finally flogged in their victorious career, by peltence, and the arms of the Bulgarians, circumstances which destroyed the greater part of the number, that in the outfl amounted to nearly half a million of souls. During this reign an earthquake did much damage to the empire. Constantine died at the age of 63 years, having previously secured the succession of his three sons. Of thefe one assumed the title of Constantine XII; but his glory was merely nominal, and lost in that of his elder brother Michael. Of the eleventh Constantine, historians say he was an orthodox and just prince, but the slave of avarice. The XIIIth prince of this name was son of the emperor Manuel Palaeologus, and succeeded his brother John in 1448, at a period when the whole empire scarcely extended beyond the limits of the capital. This sovereign having squandered the small remaining resources of his dominion in imperial ostentation, found himself threatened with the hostility of his potent neighbours, sultan Mahomet II., who erected a fortress on the Bosphorus, found occasion for a quarrel, and laid siege to the capital. Constantine determined to refit to the ball, and to share the fate of his people. He fought for succour among the Chilian princes of the West, but the aid he obtained was tardy, and insufficient to the great forces of the occasion. Constantinople was encompassed by Turkish arms, and the emperor, in this extremity, fulfilled the part of a hero. When the final assault was prepared, he took leave of his people in a moving harangue, received the sacrament in the church of St. Sophia, and then went to the walls. The numbers of the Turks without, exceeded those of the Christians within, the city, more than a hundred fold. Every hope of successful resistance was vanished; breaches had been made in the walls, and at length they and the towers were covered with flames of the assailants. Amidst these multitudes, the emperor, who nobly accomplished all the duties of a general, and lordly, was long seen, and finally lost; his mournful exclamation was heard, "Can there be found a Christian to cut off my head?" His last fear was that of falling alive into the hands of the infidels. He had thrown off the purple, and falling by an unknown hand, was buried under a mount of flour. The final catastrophe of the Greek empire, and emperor, happened May 29th, 1453, Constantinople having sustained a siege of 53 days. See Constantine XI. Morev. Gibbon. Univer. Hist.

Constantine, Flavius Julius, from a private soldier, in the legions of Britain, was raised to imperial honours, on account of his name, and in respect for the great Constantine. He had no sooner attained the high honour, than he passed over to Gaul with his troops, and made himself master of that country. With the assistance of his son Constans, he reduced Spain; and upon Comlans he conferred the title of Augustus. Constantin fixed his throne at Arles, and when the Goths under Alaric had taken pollution of Italy, he marched as far as the Po, on the pretence of effecting its deliverance, but probably with a view of sharing in the spoil. After passing through various scenes, in which he experienced by turns success and disaster, Constantine was befreed in his capital by Comlans, to whom he removed, on the promise of security for himself and his son. The terms were granted, but the engagement was not fulfilled. The fallen prince was sent to Italy, where he and his son Julian, in violation of a solemn promise, suffered death by the emperor's orders, Sept. the 18th, 411. Morev. Gibbon.

Constantine: there were two popes of this name: the one a native of Syria, raised to the Roman see in 708, characterized for his charity to the poor; and for his ambition, in engaging Julian to subjugate the independent see of Ravenna to the yoke of Rome; the other, from a laistan, was raised to the highest office in the church by the influence of his brother; an honour, however, that he did not long retain. An infurrection being excited against him, in the sixth year after his elevation, he was deposed, and, under the reign of the new pope, was subject to the insults and most cruel treatment of the people, deprived of his sight, and condemned to perpetual imprisonment. Morev.

Constantine is the name likewise of an abbot who flourished at Metz in the eleventh century, and who was author of "The Life of Adalbert II. bishop of that city: and of a monk distinguished for his writings in the thirteenth century, against Vecius, patriarch of Constantinople. Another of the same name was born at Florence, and became bishop of Orvieto. He acquired celebrity by his preaching talents, and after his elevation to the bishopric, he was appointed legate from pope Alexander IV. to Theodore Lalevis, the Grecian emperor, inquiring, by his perusals, to induce the emperor and his clergy to submit to the Roman see. He was author of the siege of St. Dominic, and other works. He died in the year 1257.

Constantine, surmounted the African, was born at Carthage, about the middle of the eleventh century. He reigned many years in Babylon, where he became celebrated for his knowledge in the Arabic, Chaldaic, Persian, and Egyptian languages. Among the sciences, medicine seems to have received the greatest share of his attention, as appears by two of his works, which were thought deserving of being printed several centuries after his death. In the first, which was published at Bale, in the year 1536, in folio, "De morborum cognitione, et curacione," he treats of affections of the stomach, hypochondria, and the diseases of women, &c. In the second, which was also published at Bale, three years after the former, he treats of fevers, of the elephasallia, of incantations, and of remedies taken
taken from parts of animals. The whole are however sup-
posed to have been principally translated from Arabic
writers.

After a residence of thirty nine years at Babylon,
he returned to Carthage, but soon fell into such disgrace
with his countrymen, whom he suspected of intending to
destroy him, that he went to Sardes. Though he was
there introduced to duke Robert, who wished to retain him
about his person, preferring a life of ease and retire-
ment, he entered into a monastery of the Benedictines, St. Agatha,
in Avera, where he died in 1087. Haller Bib. Med. Eloy
Dict. Hist.

CONSTANTINE, Robert, a native of Caen in Normandy,
was born, as it is said, about the year 1053. He was pro-
foundly versed in Greek, Latin, and oriental literature.
This procured him the intimacy of J. Caesar Scaliger (with
whom he resided several years), and of other great scholars,
but did not defend him against the facetiae of Joseph Scal-
ger, who attacked him with great ferocity. He took his de-
gree of doctor in medicine, but from the many learned works
he published, does not seem to have dedicated much of his
time to the practice of that art. His editions, with annota-
tions, of the works of Theophrastus, Dioscorides, Celsius,
and Quintus Serenus, gained him much credit. They were
published between the years 1554 and 1566, as was also
his "Nomenclator inquinum Scriptorum, quorum libri ex-
tant vel manuscripti, vel imprimunt," 1606. But the work
which established his name as a scholar, was his "Lexicon
Greco-Latinum," first published at Geneva, in 1572, in
two volumes folio, reprinted, much improved, in 1592. He
is said by De Thou to have lived to the great age of 103
years, preferring his faculties entire to the last. Other writers
say he died a centurion at the age of 75 years. Haller

CONSTANTINE, Antony, an eminent physician at Lyons,
published in 1597, in 8vo. "Brief traité de la Pharmacie
Provençale, et familière," in which he attempted to fowm
his countrymen, that they may find in their fields remedies
for their diseases, without having recourse to drugs imported
from foreign countries. Also "Opus Medico prophylac-
ico qui omnium symptomaticorum caufae et eventus expunctorat.
" 8vo. 1613. He died, far advanced in years, in 1616. Eloy
Dict. Hist.

CONSTANTINE, Order of, in Heraldy, otherwise the
order of the Golden Angel and St. George. Constan-
tine the Great is by some considered as the founder of this
order, after his memorable victory over the tyrant Max-
entius, A. C. 312. This is at present the second order of
the kingdom of Naples. Others affirm that the emperor
Iacus Angelus Commensus was the founder of it. The badge
of the order is a red cross, somewhat in the form of four
flares dehisced at the extremities, surrounded with a
border of gold, the entire embroidered the four letters I. H.
S. V., meaning, "In hoc signo vinces," being the words
displayed on the celestial meteor, or luminous cross, which
is said to have appeared to Constantine, and encouraged him
to attack Maxentius. In the badge of the cross is a
monogram, or cypher of our Saviour's name, expressed by
the letters X and P, and on each side are placed one of the
letters A and Ω (alpha and omega, or the fi and the laff
letters of the Greek alphabet.

The great collar of this order, worn over the mantle,
consists of fifteen enameled golden shields of an oval form,
and on each the letters X and P appear in the form of a
cypher. The middle shield is somewhat larger than the others,
and is surrounded with oak and laurel leaves entwined; and
from the lower part of it is suspended the effigy of St.

George, in complete armour, on horseback, and in the act
of slaying the dragon.

The council of this order is composed of 55 senators, who
are grand crossmen. When the grand master affixes in flate
therein, his device is as follows: the veil and small cloths
are of crimson velvet, embroidered with silver; above
the veil is worn a crook of silver, richly embroidered, with
wide sleeves, and reaching to the knees, festooned round
the waist with a girdle of scarlet velvet, embroidered with silver,
and about the neck with two rich cords of gold and scarlet
flok mixed, with tassels reaching to the ground. On the
left side of the mantle, the cross of the order is richly em-
brodered in gold. The cap is of crimson velvet, and on each
the cypher of our Saviour, as above described.

The grand crosses (in number 50) wear a blue veil and
small cloths, and over the same a white veil, which reaches
to the knees; their stockings and shoes are white; their
stuhl red, and their mantle of blue damask is lined with
white; they wear the great collar of the order, and their
cap, which is of blue satin, is turned up at the four fides,
and on each the cypher as before: the cap is also adorned
with a white ostrich feather.

The popes had conferred the grand mastership on the
house of Commenors for ever; but in 1669 Angelus Flavus
Commensus, the last of this house, resigned it to Francis
Fanalio, the then duke of Parma, to him and his successors
for ever; which was confirmed by a brief of pope Inno-
cent XII. dated 29th October, 1669. In 1725 the ducal
house of Farnese becoming extinct in the male line by the
death of Anthony the last duke, Don Carlos, the eldest
son of Philip V. king of Spain, and of Elizabeth Farnese, the
sole heiress of the family, succeeded to the dukedoms of Parma
and Placentia, and to the grand mastership of this order.
This prince was successively grand duke of Tuscany, and
king of Naples: upon his succession to the latter he declared
this order royal, and annexed it to the crown of Naples.

CONSTANTINOPLE, in Geography, the metropolis of
the Turkish empire, was built on the site and ruins of the an-
tique Byzantium in Thrace, by the Roman emperor Constan-
tine the Great, who, in the year of our Lord 330, removed
the seat of the empire from Rome to this new capital. The
reasons which induced Constantine to fix his residence here,
are not exactly known. The imperial court had in fact
been removed from Rome about thirty years before. Of
the subordinate emperors Diocletian and Maximian, the latter
removed from Nicomedia, and the latter mostly at Milan.
Ga-terius had his court at Nicea; Constanderius Chlorus at
York. It is supposed that Diocletian and Maximian, hav-
ing concerted a plan of admiration more systematically
depositive than that of any of the preceding emperors, and
being disposed of setting entirely aside the nominal authority
which the senate still possessed, had fixed their residence at a
distance from the ancient metropolis of the empire, in or-
der to avoid the republican remonstrances of that august
body. Constantine was probably actuated by the same
motive, for his administration was still more depopitive;
and after he had removed the seat of empire to Constantinople,
the senate could fearlessly be reckoned a conigrated order
in the state. Others attribute Constantine's choice of a
new capital to a dislike which he had conceived against
Rome, on account of the enthusiastic attachment of that
city to paganism. But whatever may have been Constan-
tine's motive, it cannot be denied that the situation of Con-
stantinople actually was preferable to that of Rome, both as
a check
CONSTANTINOPLE.

a check to the Persians, and as a barrier against the Goths, those terrible enemies of Rome, who, having once tasted the rich plunder of Greece and Asia Minor, seized every opportunity of making predatory incursions into all parts of the empire. Between the beautiful and picturesque arrangement of the land and water in the environs of Constantinople decided it to be preferred to Rome. It is situated on an elevated ground, consisting of gently swelling eminences, rising like terraces, one above another, without any of those deep valleys which separate the seven hills on which Rome is seated, and which, together with the marshes adjoining the Tyber, render the air unhealthy. It fills a triangle formed by the harbour, the Bosphorus and the Propontis, or sea of Marmora. Situated in the 41st degree of latitude, the imperial city commanded, from her seven hills, the opposite shores of Europe and Asia; the climate was healthy and temperate, and the soil fertile, and the approach on the side of the continent was small in extent, and easy of defence. The harbour on the north side is secure and spacious; it is five hundred yards wide at its entrance from the Bosphorus, and runs seven miles into the land. The Bosphorus and the Hellepont may be considered as the two gates of Constantinople; and the prince who possessed those important passages could always flout them against a naval enemy, and open them to the fleets of commerce when those gates were shut. The capital still enjoyed within their spacious enclosure every production which could supply the wants, or gratify the luxury, of its numerous inhabitants. In failing up the Propontis towards Constantinople the most enchanting prospects charm the eye of the navigator; from every part of that sea he may discover the high lands of either Thrace or Bithynia, and never leaves sight of Mount Olympus, till at last the city itself, rising from the Strand, attracts his view, and exhibits the most magnificent appearance. Constantinople also commands the commerce of the vast regions of the north, by means of the Euxine sea, and of the rivers Don and Dnieper, which discharge themselves into it. By the Strait of the Hellepont, which forms the communication between the Propontis and the Mediterranean sea, it is equally well situated for the trade of the south and west; and when Egypt is under its dominion its position is extremely advantageous with respect to the trade to India, and the eastern coasts of Africa.

Whatever rude commodities were collected in the forests of Germany and Scythia, as far as the sources of the Tanais and Borylhenes; whatever was manufactured by the skill of Europe or Asia; the corn of Egypt, and the gems and fábres of the farthest India, were brought by the varying winds into the ports of Constantinople, which for many ages attracted the commerce of the ancient world.

The prospect of beauty, of safety, and of wealth, united in a single spot, was sufficient to justify the choice of Constantinople. As prodigy and fable have, in every age, been supposed to reflect a becoming majesty on the origin of great cities, the emperor thought proper to avail himself of this circumstance; and in one of his laws he has taken care to inform posterity, that in obedience to the commands of God, he laid the everlasting foundation of Constantinople. The ingenuity of succeeding writers has led them to describe the nocturnal vision which appeared to the fancy of Constantinople as he slept within the walls of Byzantium. The tutelar genius of the city, a venerable matron, linking under the weight of years and infirmities, was suddenly transformed into a blooming maid, whom his own hands adorned with all the symbols of imperial great-

nefs. The monarch awoke, interpreted the auspicious omen, and, without hesitation, obeyed the will of heaven. In order deeply to impress the minds of the spectators, the emperor himself, on foot, with a lance in his hand, led the solemn procession, and directed the line, which was traced as the boundary of the defined capital, till the growing circumference was observed with allusion by the inhabitants, who, at length, ventured to observe that he had already exceeded the most ample measure of a great city. "I shall fill advance," replied Constantine, "till His, the invisible guide who marches before me, thinks proper to stop." In surveying the actual flate of the city, the palace and gardens of the fagade occupy the eastern promontory, the first of the seven hills, and cover about 150 acres of our measure. The new walls of Constantinople stretched from the port to the Propontis across the enlarged breadth of the triangle, at the distance of fifteen fladins from the ancient fortification; and with the city of Byzantium they enclosed fire of the seven hills, which, to the eyes of those who approach Constantinople, appear to rise above each other in beautiful order. About a century after the death of the founder, the new buildings, extending on one side up the harbour, and on the other along the Propontis, already covered the narrow ridge of the fifth, and the broad summit of the seventh hill. The incessant inroads of the Barbarians rendered it necessary for Theodorus the younger to surround his capital with an adequate and permanent enclosure of walls. The new wall of Theodosius was constructed in the year 413; and after having been thrown down by an earthquake in 447, it was rebuilt in three months by the diligence of the prefect Cyrus. The suburb of the Bocchermes was first taken into the city in the reign of Hærcius. From the eastern promontory to the golden gate, the extreme length of Constantinople was about three Roman miles; the circumference measured between ten and eleven; and the surface might be computed as equal to about 2000 English acres. The suburbs of Peræa and Galata, though distant beyond the harbour, may deserve to be considered as a part of the city; and this addition may perhaps authorize the measure of a Byzantine historian, who assigns sixteen Greek (about fourteen Roman) miles for the circumference of his native city. After all, Constantinople must yield to Babylon and Thebes, which filled the great but not incredible circumference of about 25 or 30 miles, to ancient Rome, to London, and even to Paris.

As to the expense incurred by the progress of the work, some estimate may be formed of it by the allowance of about two millions five hundred thousand pounds for the construction of the walls, the porticoes, and the aqueducts. The forests that overshadowed the shores of the Euxine, and the celebrated quarries of white marble, in the little island of Proconnesus, supplied an inexhaustible rock of materials ready to be conveyed, by the convenience of a short water-carriage, to the harbour of Byzantium. A multitude of labourers and artificers urged the termination of the work with unflagging zeal; but the impatience of Constantinople soon discovered that, in the decline of the arts, the skill, as well as the number of his architects, bore a very unequal proportion to the greatness of his design. However, the buildings of the new city were decorated by the hands of the most celebrated masters of the age of Pericles and Alexander. By the commands of the emperor, the cities of Greece and Asia were depoiled of their most valuable ornaments. The trophies of memorable wars, the objects of religious veneration, the most finished statues of the gods and heroes, of the fables and poets of ancient times, contributed to the splendid triumph of Constantinople; whence the historian Cedrenus took
occasion to observe, that nothing seemed wanting except the souls of the illustrious men, whom those admirable monuments were intended to represent. For an account of the principal buildings with which this imperial city was decorated, we must refer to the articles Forum, Hippodrome, &c. and the sequel of this article.

The baths of this city, which still retained the name of Zeuxippus, were enriched by the munificence of Constan-
tine with lofty columns, various marbles, and above thousand statues of bronze. In short, whatever could adorn the dignity of a great capital, or contribute to the benefit or pleasure of its numerous inhabitants, was contained within the walls of Constantinople. A particular description, composed about a century after its foundation, enumerated a capital or school of learning, a circus, two theatres, eight public, and fifteen private baths, 52 porticoes, five granaries, or storehouses for the meetings of the senate or courts of justice, 14 churches, 14 palaces, and 4388 houses, which, for their size and beauty, deferred to be distinguished from the multitude of Plebeian habitations. In order to furnish this favoured city with a population, corresponding to its extent and magnificence, Constan-
tine invited many opulent senators of Rome, and of the eastern provinces, to fix upon his chosen residence for their own habitation; and he devoted on his favourites the palaces which he had built in several quarters of the city, assigned them lands and pensions for the support of their dignity, and alienated the demesnes of Pontus and Asia, for the purpose of granting hereditary elates by the easy tenure of maintaining a house in the capital. By degrees, however, a variety of concurred circumstances contributed tofill the city with inhabitants. In less than a century, Constantinople disputed with Rome itself the pre-eminence of riches and numbers; and it became necessary to enlarge its extent by additional edifices, the foundations of which, on either side, were advanced into the sea, and which, of themselves, might have composed a very considerable city. The emperor also conferred, by way of additional allurement or encouragement to his plan of popula-
tion, several privileges on the settlers at Constantinople. He divided the city into fourteen regions or quarters, digni-
ified the public council with the appellation of senate, communicated to the citizens the privileges of Italy, and bellowed on the rising city the title of colony, the first and most favoured daughter of ancient Rome. The walls, porticoes, and principal edifices of the city, were com-
pleted, as some say, in a few years, or, according to others, in a few months; and the founder soon prepared to celebrate the dedication of his city, a ceremony which was attended with pompous games, and magnificent largesse. As often as the birth day of the city returned, the statue of Con-
tantine, framed by his order, of gilt wood, and bearing in its right hand a small image of the genius of the place, was enriched on a triumphal car. The guards, carrying white tapers, and clothed in their richest apparel, accompanied the solemn procession as it moved through the Hippodrome. When it was opposite to the throne of the reigning em-
peror, he rose from his seat, and with grateful reverence adored the memory of his predecessor. At the festival of dedication, an edict, engraved on a column of marble, be-
lowed the title of Second, or New Rome, on the city of Con-
stantine. But the name of Constantinople has prevailed over that honourable epithet, and, after the revolution of fourteen centuries, still perpetuates the fame of its author.

It has been conjectured, that the removal of the imperial residence from Rome, contributed to hasten the downfall of the empire: but it is certain, that the fixing of it at Constan-
tinople, put a heal period to the passage of the Barbarians, through the Bosphorus. They could never after force that immoveable barrier, and Greece, as well as Asia Minor, felt secure from their ravages, until Valens undis-
votedly suffered the Goths to pass the Danube, and received their armed bands into the heart of the empire.

Constantine the Great did not long enjoy his new refi-
dence. He died the 22d May, 337, and by his will divided his vast empire among his three sons, Conflantius, Con-
flans, and Conftantine. Within three years after their fa-
th, Conflans invaded the dominions of his brother Con-
flantius, who, being drawn into an ambush and slain, left Conflans in possession of two-thirds of the Roman em-
pire. But Magnentius revolting soon after against Conflans, surprized him hunting, and pursuing him in his flight, put him to death. Magnentius being in the next place defeated by Conflantius, terminated his life by suicide; and thus, by the diffatuated fate of his brothers, Conflantius became sole emperor in 333; and twenty years after the seat of the empire had been removed to Constantinople.

At the death of Conflantius, which happened in the year 361, Julian, commonly called the Apolite, son of Julius Conflantius, and nephew to Conflantine the Great, assumed the imperial purple. He marched soon after against the Perian, and was so infatuated by his expectations of con-
quest, as to destroy the fleet of boats which he had upon the Tigris. Allured by spies who pretended to be defter-
ers, he advanced far into an unknown country. His army found itself at last in the midst of fancy deferts, and felt the dreadful effects of famine. The guides suddenly disappeared, and the Perian monarch approaching, with the whole military force of his kingdom, wanted of provisions rendered a retreat necessary, in which the troops were continually ba-
ralled by the Perians, who carefully avoided any close en-
gagement. In spite of the incessant attacks of the Perian cavalry, the Romans succeeded in gaining the banks of the Tigris, but for want of their boats they could not pass the river. Exhausted with fatigue, and perishing with hunger, they still repulsed the attack which the Perian king made on their camp. In the confusion of the battle, Julian received a mortal wound, of which he died in a few hours, on the 20th of June, 363.

This emperor had conceived the project of extirpating the Christian religion; and if he had appointed, or if the army had elected an emperor equally averse to Christi,nity, his death could not have dispelled the storm that was gathering over Christendom. Fortunately, Jovian, a Christian officer, was chosen emperor. Forced to conclude a disadvantageous peace with Peria, he purchased a safe retreat by the cession of Mopota, and the strong cities of Nisibis and Singara.

Jovian dying in 364, soon after the conclusion of the peace with Peria, Valentinian, another Christian command-
er, was decorated with the imperial purple. He named his brother Valens his colleague in the empire, affixing him the eastern part, whilst he himself ruled the west. It was in this reign that the first step towards the subversion of the western empire took place. The Huns, a Tartar nation, being driven out of their own country, rushed like a torrent upon the Goths, on the north side of the Danube, who, seeing their possessions invaded, presented themselves in immense crowds on the banks of the river, and required an asylum in the Roman dominions. They delivered up their children, at least those of rank, as hostages; but were un-
fortunately suffered to retain their arms. The number of Goths who passed the Danube on the occasion, was computed at about 220,000 armed men, with their wives and children.
children along with them. A second army of Goths, coming to the banks of the Danube with the same result, was routed: but they passed without leaving, and being ill supplied with provisions, they joined their countrymen, and commenced a war against the empire. After various skirmishes, Valens, without waiting for his nephew Gratian, who was on his march to join him, gave battle to the Goths, in the plains of Adrianople, A.D. 378, and was totally defeated. The loss on the side of the Romans was so great, that this defeat was considered as the most severe since the battle of Cannae. Valens was never more seen. It is supposed that he was consumed in the flames of a cottage where he had taken refuge.

By the death of Valens, the empire fell into the hands of his nephew Gratian, who had done time before succeeding to Valentinian in the west. But at the end of the year 378, he declared Theodosius his partner in the empire, and committed the East to his care.

Theodosius was a native of Spain. In four years and a half he terminated the Gothic war. The Goths had lands assigned to them in the Roman provinces, and submitted to the Roman sceptre on condition of being governed by their own laws.

Theodosius was in every respect a second Constantine the Great. Like him he rendered the empire triumphant over all its enemies, extingushed intelline commotions, established Christianity upon a solid basis, and divided the empire between his two sons Arcadius and Honorius, assigning to the former the eastern, and to the latter the western part. From that period, the two monarchies, forming two separate and independent states, gradually became strangers to each other, and even regarded each other's prosperity with a jealous eye. Rome fell a prey to the Goths, whilst Constan tiople appeared totally unconcerned at the event. Theodosius died at Milan, the 17th of January 395, in the sixteenth year of his reign, and the fiftieth of his age.

After the death of Theodosius, the history of Constan tiople affords nothing remarkable, until the total destruction of the Roman empire in the west by the Goths. Towards that time Balilicus usurped the Eastern empire. Afflicted in his conspiracy by the empress Verina, his fitter, he drove out Zeno, the lawful emperor, who fled into Ifauria, whether he was pursued by Ilus and Trecondes, two of the usurper's generals, and forced to flit himself up in a caffle. But Balilicus having lost his popularity by his cruelty, his generals joined Zeno and restored him to the throne. Bais liucus perished in a dungeon in the year 457. He had reigned about twenty months. During his usurpation, a dreadful fire happened at Constan tiopol e; together with a considerable part of the city, it consumed the imperial library which is supposed to have contained 120,000 volumes.

Zeno had the good fortune to escape other conspiracies that were formed against him: but he was unsuccessful in the wars which he waged against the Ostrogoths, and purchased a short peace at the expense of the provinces of Lower Dacia and Moesia. Theodoric, king of the Ostrogoths, soon renewed his irritations into Thrace, and advanced with fifteen miles of Constan tiopol e, which he was expected to besiege, when he suddenly turned his arms against Odovacer, king of Italy, whom he subdued. Theodoric himself was proclaimed king of Italy in his room, two years after the death of Zeno, which happened in 491.

The administration of the following year was equally weak. Theodoric, however, reigned in Italy under the sanction of the imperial court of Constan tiopol e, and still acknowledged himself a vassal of the eastern emperor, but on his death the kingdom of Italy devolved upon his beautiful and accomplished daughter, Amalasonttha, and her dame, which happened in the year 535, the Goths of Italy refused to acknowledge the paramount authority of the imperial court, and renounced all dependence on the empire. Justinian was then reigning at Constan tiopol e. His uncle Justin, who ascended the throne in 518, after Athanarius, had named him his colleague in the year 527, and dying soon after, had left him sole master of the empire. He first turned his whole force against Chosroes, king of Persia, dispatched his general Belfarius against him, and after a severe defeat, forced him to sue for peace.

About this time, a great tumult happened at Constan tiopol e. It began among the different factions in the circus. Hypatius, nephew to Athanarius, was proclaimed emperor. To crush this faction, Justinian sacrificed two of his ministers who were most obnoxious to the people, but the multitude grew more outrageous, and several senators having joined the rebels, the emperor felt so much alarmed that he thought of abandoning the city, and making his escape by sea. Encouraged, however, by his empress Theodora, he resolved to defend himself to the last with the few senators who had not yet abandoned him. In the mean time, Hypatius was carried in triumph to the circus, where he was beholding the sports from the imperial throne, among the acclamations of the populace, when Bel farius on his return from Persia entered the city with a considerable body of troops. He immediately marched to the circus, fell sword in hand upon the disarmed multitude, and took Hypatius the usurper, and Pompey, another of the nephews of Athanarius, prisoners. They were both beheaded, and their elates, as well as those of the senators who had joined them, con fiscated.

Justinian next turned his arms against the Vandals in Africa, and the Goths in Italy. Bel farius entered Rome A.D. 536, where he was bejeweled by the Goths. His gallant defence, with only five thousand veterans, against a numerous army of Goths, commanded by Vitiges their king, during the space of a whole year, is deemed one of the most signal military exploits recorded in history. He made many successful forays. In one single assault the Goths are reported to have lost 30,000 men. They were obliged to raise the siege on the arrival of fresh troops from Constan tiopol e. At length the Gothic kingdom of Italy was completely subdued. Vitiges the king was sent to Constan tiopol e. Justinian assigned him for maintenance a rich estate in Aia Minor, and on his conforming to the Athanarian creed, conferred upon him the rank of Patrician and Senator, which still continued as an honorary title in the empire.

Gellimer, king of the Vandals, over whom Justinian had triumphed, had likewise an ample estate assigned to him, but could not enjoy any honorary title on account of his professing Arianism.

In the year 546, the Goths again revolted under the command of Totila, whom they had elected king. Bel farius a second time entered Italy, and retook Rome in 547, but at his recall it was again captured by the Goths. The command of the army of Italy was then conferred on Narces, an eunuch of great military skill and the most daring courage. This general defeated and slew Totila the Gothic king, and made himself master of Rome in 552. He likewise defeated and slew Ticius, who had succeeded Totila as king of the Goths, and made a prodigious slaughter of the Franks and Allemanni, who invaded Italy soon after. Italy was then made a province of the eastern or Byzantine empire, and a government established under the denomination of the Exarchate, of which Narces was the first exarch.
By the conquest of Italy and Africa, Justinian gave to the Eastern empire an augmentation which it had never before possessed. He displayed consummate political abilities, during a reign of thirty-eight years, and exhibited, during a life of eighty-three, a singular indulgence of long continued personal prosperity. He has left a noble monument of his legislative talents in his code of laws, and no less noble one of his skill in architecture, in the magnificent cathedral of St. Sophia at Constantinople, now a Mahometan mosque. His reign is also the important era of the transplantation of the Sclavonic from China to Constantinople. The brilliance of Justinian's reign was, however, in some degree clouded by great calamities of a physical nature. Tremendous earthquakes happened almost every year throughout the whole extent of the empire. A dreadful pestilence spread from Pelusium in Egypt, over the greater part of Asia, Africa, and Europe. During the space of three months, from five to ten thousand individuals died daily in Constantinople. Many cities in the East were almost depopulated, and in some parts of Italy, the harvest rotted on the ground. This cause, which began in the eleventh year of Justinian's reign, was not extinguished in less than fifty-two years.

Justinian died in the year 565. Soon after his death the Eastern empire began to decline. After the succesive reigns of Justin II, and of Tiberius, which filled up the interval, from the death of Justinian to the accession of Maurice in 582, a spirit of revolt manifested itself in Constantinople, and terminated in the deposition of Maurice, and election of Phocas the ceturion in 602. Phocas was in his turn deposed and put to death by Heraclius, A. D. 610, whose reign is remarkable for a most obstinate contest with Persia, to which country it proved finally fatal.

During a period of twelve years, from 610 to 622, the Eastern empire exhibited a scene of almost unexampled distress. From the Adriatic to the suburbs of Constantinople, the provinces were ravaged by the Chal. Avars, who had subdued the Huns and reigned in the royal village of Attila, in the great plain of Hungary, and a Persian army was encamped at Chalcedon, now Sutari, on the brink of the Bosphorus, directly opposite to Constantinople. The general consternation was so great that the emperor was about to leave the city, and transport himself with the treasures of the imperial palace to Carthage, when the patriarch of Constantinople led him to the altar of the church of St. Sophia, and made him take a solemn oath that he would live and die with his people. Heraclius having thus solemnly bound himself to the defence of his country, carried on the contest to the very centre of the Persians dominions. He every where defeated the numerous forces of Chosroes, whose continual disasters excited a general revolt of the Persians. Chosroes was deposed A. D. 628, and Siros his son proclaims king. The latter put to death his father and eighteen brothers, and then combines with Heraclius a treaty of peace, in consequence of which, the former boundaries of the Byzantine and Persian empires were restored.

The northern nations, which had overthrown the Roman empire in the West, were yet in an unsettled state, and Europe exhibited the most disquieting scene of barbarism and anarchy, whilst Constantinople was triumphing in the successful termination of a war, which had threatened the extinction of its empire. It was, however, soon to witness horrors similar to those with which the West had been famished for the space of two centuries. About the year 609, Mahomet, an Arabian, assumed the character of a prophet, and assembling together a determined and daring band, in whom he excited military enthusiasm by means of religious tenets, calculated to flatter their pious,
half of its possessions by the conquests of the Mahometan caliphs. Under Charlemagne, the whole world was divided into the Eastern, Saracen, and new Western empire. Of these the Saracen empire, under the caliphs, formed on the highest in literary attainments; Conantinople, though much declined, still held the second rank; and the rest of Europe was making some advances towards the restoration of learning, when Charlemagne, by dividing his new empire among his sons, rekindled it into barbarism.

In the ninth century, the Bulgarians, who had commenced their attacks towards the latter end of the tenth, and renewed their inroads at different periods, continued to be formidable enemies. They were completely subdued by Bascius II, towards the end of the tenth century. It was about the same time that the empire of the Saracens, being, like that of Charlemagne, split into a number of independent states, by the revolt of factious and ambitious chiefs, fell a prey to the Seljukian Turks and other barbarous nations of Asia.

This subversion of the caliphate was attended with the complete wreck of Arabian learning; and the Byzantine empire remained the sole depository of all that was worthy of notice in literature, commerce, and the arts and embellishments of civilized society. Thus the tenth century, which, in the western countries, was one of the darkest periods of Gothic ignorance, constituted the most flourishing era of the Byzantine learning, under the reigns of Leo the philosopher and his son Conantinople Porphyrogenitus.

About the year 1063 the emperor Conantinople XI. Ducas, at his death, the empire to his three sons, Michael, Andronicus, and Conantinople XII., and appointed the empress Eudocia regent during their minority, on condition that she should not marry again. But having been released from her engagement, through a stratagem practised upon the patriarch, who absolved her of the oath she had taken, Eudocia married an officer of great military merit, named Romanus Dogerizes, who was proclaimed emperor. After various successes against the Turks, who were continually encroaching upon all sides of the empire, Romanus was wounded in a desperate engagement, and taken a prisoner. Before his return to Constantinople, Eudocia was driven from the throne by John, the brother of Conantinople Ducas, and her eldest son, Michael Ducas, proclaimed emperor. Romanus was besieged in a strong castle, whither he had retired, and killed in the year 1067, after a reign of three years and eight months.

Immediately after the death of Romanus, the empire was again invaded by the Turks. In less than ten years they made themselves masters of all Media, Lycaonia, Cappadocia, and Bithynia. At last Alexius Commnenus, having wrested the empire from Nicephorus Botaniates, who had deposed Michael Ducas, prepared for war with so much vigour, that Solyma the Turkish Sultan made proposals of peace, to which Alexius acceded, in order to defend himself in the west against the Italians, under Robert Guichard, duke of Fuglia and Calabria, whom he defeated, with the assistance of the Venetian fleet. He also forced the Scythians, who had had walls great part of Thrace, to submit on his own terms.

The war with the Turks was renewed in 1083, and carried on with various success. But about the year 1095, a romantic scene of religious enthusiasm and military enterprise began to display itself; and though it threatened the utter ruin of the Turkish nation, proved finally fatal to Constantinople.

Under the polluted empire of the caliphs, the frequent pilgrimages of Christians to the holy sepulchre at Jerusalem had been encouraged; but the barbarians who had overthrown the caliphate oppressed the pilgrims with unreasonable impositions, and often added insult to injustice. Incensed at these outrages, Peter, a hermit, who had visited the holy sepulchre, preached a crusade for the recovery of the holy land from the infidels. The pope approved the project, and the princes and nobles of Europe readily entered into the measure.

This religious war was carried on, with some intervals, during the space of almost two hundred years, from the setting out of the first crusade in 1095, to the loss of Antioch and all Palestine in 1291. Innumerable armed bodies were collected out of England, France, Germany, the Netherlands, and Italy. Yet these tremendous efforts were not attended with effects of such permanency as might have been expected. But one of the most remarkable events which occurred in the course of the !udes, was the capture of the city of Conantinople by the Latin church.

The emperor, Isace Angelus, having been deposed and deprived of fight by his inhuman brother, his son, Alexius, who was only a youth, made his escape into Italy, and met with a number of the barons of France and Flanders, who were come to Venice to contract with the republic for the ships necessary to facilitate one of those crusading enterprises. He concluded with them a treaty, whereby they engaged to restore his father to the imperial throne of the East, and he promised to unite the Greek church to the Latin church. The French and Venetians, changing the destination of their armament, sailed for the Hellepont to Conantinople, broke the chain of the harbour, and assaulted the city. When they were almost ready to enter the town, the usurper made his escape. Isace Angelus and his son, the young Alexius, were proclaimed joint emperors. A cessation of arms took place: but as soon as the clergy under-fooed the terms of the treaty concluded by young Alexius, they reproved the idea of an union with the see of Rome, and cited the people to fly to arms. The insurrection was also fomented by Alexius Mourzouffe, of the family of Ducas, who assumed the purple, imprisoned the blind emperor Isace, and put young Alexius to death. The legal succession of the Greek empire being thus overturned, the French and Venetians recommenced the war. After a siege of more than three months, they assaulted the city from the harbour, and carried it by storm, eight hundred and eighty years after its foundation by Conantinople. The city being given up to pillage, the plunder was valued at 4,000,000 marks, nearly equivalent to 800,000. Berlin, the greatest sum ever found in any captured city previous to that period; and notwithstanding the penalties of excommunication, and even of death, denounced against any one who should secrete any part of the spoil, the secret plunder is supposed to have exceeded what was produced in public. Baldwin, earl of Flanders, was elected emperor, with one-fourth part of the empire for his share: the rest was divided among the barons and knights, into fiefs, held under the emperor.

The Greeks, after this disaster, established independent states at Nice, Trebifond, and Epirus. The Latins were not prosperous in their newly-acquired empire. The conquests which prevailed among the barons, laid their dominions open to the attacks of the Greeks. They continually gained ground. The Bulgarians also revolted, and the emperor, Baldwin of Flanders, being defeated and taken prisoner by them, died in captivity. He was succeeded by his brother Henry, who shewed himself of equal capacity for peace and war.

Henry checked the proceedings of the popish legate, in the pericution of the Greek schismatics. But after his death, which happened in 1216, the Latin empire of Conantinople rapidly declined: and so pressing were the exigencies of the state, that Baldwin II., the last emperor of
the Latin dynasty, pledge to the Venetians the crown of thorns pretended to have been worn by Chirl.

At last Michael Palaeologus, having usurped the Greek empire of Nice, his general, Alexius Strategopulos, with an inconsiderable force, surprized and recovered Constan
tinople in 1361: and thus, after a period of 57 years, that metropolis returned under the dominion of the Greeks. But a considerable part of the city had been destroyed in the three dreadful conflagrations which happened at the time of the siege and capture by the Latins: Constantinople never more regained that splendour which it had along main
tained. The imperial palace, which, during eleven cen
turies, had been the admiration of all who visited the East, was in ruins. It stood between the Hippodrome and the magnificent church of St. Sophia. Its superb gardens de
cended by several rows of terraces, to the shore of the Propontis. The primitive edifice, erected by Constantine, rivalled the palace of the Caesars on the Palantine Mount. The improvements made by his successors still added to its magnificence; and the emperors of the Comnenian dynasty had taken particular delight in embellishing this imperial resi
tence.

The invariable enmity of the clergy and people of Con
tinonople against the Latin church still subsisted. To avert a crusade, which the Latins were meditating against Constantinople, Michael Palaeologus negotiated with the pope, and concluded a concordat between the Greek and Latin churches; but at his death, in the year 1282, the union was dissolved. His son Andronicus, who succeeded him, restored the ancient Greek ceremonies, and by this imprudent step threw the empire into a new ferment.

In the mean time Constantinople was still worked upon by the Greeks, who continued their encroachments: but his valour rendered him conspicuous by the emperor. Con
tinople was transformed into a prison. On his removal from the army, the Turks in the famous Othoman murdered them
efelves masters of several places. Philanthropenus and Liba
darius, two officials of great merit, were sent to oppose them. The former gained some advantages over the ene
my: but elated with his success he caufiled himself to be proclaimed emperor. This rebellion however was soon sup
presse. Philanthropenus was betrayed by his own men: but the Turks taking advantage of these internecine commo
tions extended their dominions in Asia, conquered most of the island, and advanced into the Medi
cal plains of Greece. Andronicus, not trusting his subjects, hired the Maslakes to affright them; but they were defeated, turned their arms against him. He next applied to the Catalans who behaved in the same manner, and, in 1292, affailed the empire in conjunction with the Turks. This was their first appearance in Europe. Their enterprise this time proved unsuccessful.

New commotions having taken place in the empire, the Turks returned to the charge in 1327. The next year, however, Othoman, who may be styled the founder of the Turkish monarchy, being dead, the emperor recovered Nice and some other places, which were again lost the year fol
dowing; and, in 1330, a peace was concluded, which left the Turks in possession of their conquests.

This peace the Turks broke in 1357. Having reduced all Asia, they passed the Hellespont, and took a strong castle on the European side. Soon after Sultan Amurath, advancing still farther, made Adrianople the seat of his empire. He was slain by treachery, and succeeded by his son Bajazet, who levied a yearly tribute on the emperor of Constantinople, and commanded him to send his son Manuel to attend him in his military expeditions. This demand was complied with. But the emperor dying in 1392, Manuel hastened to Constantinople without taking leave of the sultan. This incensed Bajazet so highly, that he passed with great expedition into Thrace, ravaged the country adjoining Constantinople, and at last invaded the city both by sea and land. In this extremity, Manuel had recourse to the western princes, who sent him an army of 130,000 men, under the command of Sigismund, king of Hungary, and John count of Nevers. After a few sieges they were defeated with great slaughter by Bajazet, who returned the siege of the city, and would infallibly have accom
dplished the conquest of Constantinople had he not been obliged to turn his forces against Tamerlane the victorious Tartar, by whom he was overcome in battle, and confined in an iron cage against the bars of which he beat out his brains in the year 1399.

But as this relief could not be expected to be of long du
ration, Manuel Palaeologus felt the necessity for Venice, and from thence visited London and Paris in the year 1400. In the reign of Henry IV. of England and Charles VI. of France, with the view of procuring some assistance, which the circum
cstances of those countries did not permit them to grant. He also endeavoured to negotiate an union with the Latin church; but the negotiation broke off. His son John Palaeologus, who succeeded him, was more fortunate. He concluded a treaty at Florence with pope Eugenius IV.; but it was universally reprobated by the whole body of the clergy of Constantinople, and the emperor was obliged to renounce it. He did not long survive these unhappy disturb
ances, and, in 1448, left the empire now confined al
most within the walls of Constantinople to the last Con
stantine.

Upon the near prospect of being besieged in his capital by the Tartar Turks, Constantinople renewed the concordat with the Latin church. A cardinal legate from Rome was admitted at Constantinople; but after he had officiated in the cathedral of St. Sophia, the Greek clergy abandoned it as a polluted temple, and the whole city of Constantinople displayed every extreme of fanaticism and avarice against the Latin church. Though reduced to a narrow corner between the Propontis and the Bosphorus, the Byzantine empire continued the theatre of crimes and political as well as fanatical faction, until the 26th of May, 1453, when, after a siege of 53 days, Constantinople was taken by the Turks under Mahomet II. Whatever may have been the strength of the army which the Turks brought against that celebrated metropolis, the force, which the minister was able to enroll by the emperor's command for its defence, was inconsiderable. They were only 4970 volunteers, and including the Italian auxiliaries, the empe
nor's troops did not exceed 8000 men.

Constantine Palaeologus made a vigorous defence, and rashly refused advantageous terms of capitulation. When the city was at last carried by assault, he nobly fell in the breach by which the enemy entered Constantinople. A shocking scene now followed. The persons and property of the citizens were given up to the disposal of the conquer
ning army. The terrified people fled to the cathedral of St. Sophia and other asylums, from whence they were dragged forth, and without any distinction of sex or rank, chained together, driven through the streets like beaals, and more than sixty thousand of them sold into slavery. Mahomet, at the expiration of the three days allotted for pillage, made his triumphal entry into Constantinople, which he named the capital of the Ottoman empire, and which has ever since held that station. See Turks.

Such was the dreadful catastrophe of Constantinople, once the metropolis and long the sole exiling remnant of the
the Roman empire. It fell a prey to the Turks 1043 years after Rome was taken by Alaric, and 977 years after the entire subversion of the western empire. Gibbon's Hist. of the Decline and Fall of the Roman Empire, p. 756. Le Beau, Histoire du Bas Empire. Bigland's Letters on Ancient and Modern History.

Constantinople is called by the Turks Stamboul, Hfampol, or (according to Thornton's present State of Turkey, p. 729) Stamhpal, abounding in faith. It is situated at the eastern extremity of the province named Romania, or Romania, on the European side of the Bosphorus, or Straits of Constantinople, which separates Europe from Asia; in N. lat. 41° 10'. 330 miles S. E. of Vienna and 500 E. of Rome. It rises gradually from the shore in the form of an amphitheatre; but the streets are narrow, and the houses, in general, mean; the most spacious not exceeding two stories in height. The street called Adrianople is the longest and broadest in the city. The public buildings, such as the palaces, the mosques, bagnios, bazaars, and caravanserais or khans, for the entertainment of strangers, are many of them very magnificent. On one point of the triangle, on which the city is built, is the feraglio from whence there is a charming prospect of the delightful coast of Asia Minor. This inclosure of the Ottoman palace is separated from Constantinople by a wall thirty feet high with battlements, embrasures, and towers, in the style of ancient fortifications. Its circumference is above six miles. There are in it nine gates, but only two of them remarkable for their size and beauty. It is from one of these the Baba Hoamajun, or Sublime Porte, that the Ottoman court is supposed to have taken the name of the Porte, or Sublime Porte, in all public transactions and records. But Mr. Thornton, in his present State of Turkey, page 117, contends that the palace of the grand vizir, by a metaphor familiar to most of the Eastern languages, is called the Porte or King's gate, in Persian Dar, being, as it were, the door of communication between the sultan and his subj ects, and corresponding with the European appellation of a court which follows the person of the sovereign.

The feraglio is so extensive, that it is supposed to occupy the whole of the ground on which the ancient city of Byzan tium stood, and to contain 10,000 inhabitants. That wing of the feraglio which is exclusively appropriated to the ladies of the Grand Signor, is called the Harcum. Among the ancient monuments preserved in the feraglio, is the tomb of Conстантин the Great. Of the mosques, or Turk ish churches, the most celebrated is that of St. Sophia, which fronts the great gate of the feraglio, and is thought, in some respects, to exceed in grandeur and architecture St. Peter's at Rome. Round it are several chapels, which serve as burial-places for the imperial family. The other mosques of sultan Achem, sultan Mahomet, sultan Selim, sultan Solyman, and sultan Dajazet, are also very fine. These imperial mosques are founded chiefly by sultans, who have obtained victories, and devote the spoils of war, gained from the enemies of their religion, to the service of public worship, the instruction of youth, and the relief of the poor. Foundations of this kind are annexed to every mosque. There are in Constantinople 118 fæminaries of learning, and 1270 primary schools. The Greeks, besides their patriarchal church, dedicated to St. George, have 22 others. The palace of their patriarch is on a hill, about two hundred paces from the harbour. The Armenians have an archbishop and three churches; the Roman Catholics have fix convents, and the Jews several synagogues. There is also a Swedish Lutheran church.

The bazaars, or belligins, answer to our markets. They are squares enclosed within gates, where merchants meet for traffic, having generally two rows of shops built under piazzas. The market of female wares, Avarat Bazar, is a quadrangle, surrounded by a covered gallery, and ranges of small and separate apartments; but Mahometans only are admitted.

The bagnios, or public baths, are elegant and noble structures, built with hewn stones; the inner chambers are capacious, and paved with slabs of the rarest and most beautiful marble.

At the south end of the city, is the formidable flate prison of the seven towers, built of fine free-flour, and surrounded by a wall, with several smaller towers.

There are no theatres at Constantinople; the Ombres Chinoifes, which are sometimes exhibited in the streets, supply the want of dramatic exhibitions. Of other public amusements, the principal are wrestling, and throwing the javelin, on horseback, in the ancient Hippodrome, an oblong square, called by the Turks Ali-cdilim.

Constantinople counts 35 public libraries, some of which contain 10,000 volumes. That which was founded under Mustafa III. by the vizir Racub Pasha, is the most modern. A renegado, of the name of Ibrahim, encouraged by the grand vizir, Ibrahim Pasha, and the Mufti Abd'ullah Efendi, introduced the first printing-prets at Constantinople, in the year 1727. It was afterwards destroyed by some fanatics, but Abdul Hamid reforted it. Only the Koran, and books treating of the law and the doctrines of the prophet, are forbidden to be printed. These circulate in manuscripts, and afford a comfortable subsistence to 20,000 individuals who live by copying them.

The trade of Constantinople is chiefly in the hands of the Jews, Armenians, and Greeks; and its commerce is carried on by foreigners of all nations, who are confounded under the general name of Franks. No restrictions are laid on commerce, except in the articles necessary for the support of human life; the exportation of which is sometimes prohibited, especially from Constantinople, where alone the prohibition is rigorously enforced. Besides silk, cotton, wool, flax, drugs, coffee, sugar, wax, honey, fruits, hides, and tobacco, Constantinople exports its own printed muf lin, the foutain, silk Guffs, and velvets; of Brins and Alle ppo, the ferges and cameotts of Angora, the ripes and gauzes of Salonica, the sword-blades of Damasces, and the carpets of Smyrna. The harbour is spacious, and suppos ed capable of holding 1200 ships. Near it is Galata, a suburb chiefly inhabited by Greeks, Armenians, Jews, and Franks, who have their warehouses here. Beyond this is Pera, which may be considered as the suburb of Galata, where the foreign ambassadors reside. The air is uncommonly healthy, and the prospect delightful. Near Pera is the quarter called Topsham, from its cannon foundry.

According to Mr. Dallaway, the population of Constantinople, including its suburbs, does not exceed 400,000 souls, of whom 200,000 are Turks, 100,000 Greeks, and the remainder Jews, Armenians, and Franks, or strangers from all the European nations. Mr. W. Etton (in his Survey of the Turkis Empire, second edition, page 297.) brings it down to less than 300,000. But this computation is evidently too low. At the time of its capture by the Latins, Constantinople is supposed to Villehardouin to have contained 400,000 effective men; this, however, must be regarded as an exaggeration. Mr. Le Beau, in his Histoire du Bas Empire, supposes that it contained then about one million of inhabitants, and that its present population amounts to 400,000, which, by all accounts, is the most probable computation.

Constantinople is frequently visited by the plague, which, however, excites but little alarm, and Turkifh indifference.
counteracted all efforts to subdue this dreadful epidemic disorder. From the year 1783 to 1785, it swept away 100,000 children and young people. The city has also often been exposed to great conflagrations. In 1782 a fire consumed from 7 to 8,000 houses, among which were some belonging to the officer of the late. On the 5th of August, 1784, more than 10,000 buildings were laid in ashes, and towards the end of the same year, 1600 houses and mosques were burnt down. In 1788 there was so extensive a conflagration as to threaten the entire destruction of the city. They generally originate in the discontent of the Janizaries, or other military bodies. In the latter revolution, which they effected on the 28th of May, 1807, when they forced Selim III. to abdicate the throne, and proclaimed Mustapha IV. emperor, they contented themselves with cutting off the heads of a few ministers and military chiefs. But between the fifth and sixth day of August following, three great fires reduced several hundred houses to ashes, and are supposed to have proceeded from the strong dissatisfaction that prevailed in the mutinous army against the new grand vizier, for having refused an order to pay the troops on the 11th of the camp. In time of peace the Janizaries watch over and secure the public tranquillity, and execute all the functions of police officers. A foreigner, who would be inflicted if he were alone in the streets of Constantinople, may walk any where without the least molestation if accompanied by a Janizary. See Janizaries. (D'Osson’s Tableau General de l’Empire Ottoman. Eton’s Survey of the Turkish Empire. Thornton’s present State of Turkey.)

CONSTANTINOPLE, Patriarch of. See Greek Church.

CONSTANTIUS, Flavius Valerius, in Biography, surmamed Chlorus from the paleness of his complexion, was the son of Eutropius, a Dardanian noble, but his education did not correspond with the tyle of his birth. Under the emperors Aurelian and Probus, he had learned the military art, and by the emperor Carus, he was appointed governor of Dalmatia in the year 282. Ten years afterwards, in conjunction with Galerius, he was made Caesar, and associated with the emperors Diocletian and Maximian. To Constantinople were assigned the provinces of Gaul, Britain, and Spain. At this time Carausius, an ambitious general, had excited a revolt in Britain, and carried matters so far as to assume the imperial authority; he was also in possession of the port and fleet of Boulogne. To oppose the usurper, Constantius first attacked Boulogne, which surrendered to his arms, together with a great part of the naval strength of the place. After this, Constantius employed three years in preparing a fleet for the conquest of Britain; he scourged the coast of Gaul, invaded the country of the Franks, and deprived the usurper of the assistance of those allies. Before the preparations were finished, Carausus was deposed and murdered by his own servants. Allectus, his prime minister, succeeded to his power and to his danger. But he did not possess equal abilities, either to exercise the one or to repel the other. Constantius, under favour of a thick fog, cleared the British fleet, and landed in safety on the western coast, where an engagement took place, in which Allectus was slain; a single battle decided the fate of this great island, and when Constantius landed afterwards on the shores of Kent, he found them covered with obedient subjects. He now had occasion only to exert his talents in establishing a regular government; to which he appears to have been fully competent; he reigned with mildness, and was anxious not to oppress his subjects by heavy taxes; his court was distinguished by simplicity and great frugality, and he himself was a decided enemy to the perfections which disfigured the reigns of Diocletian and Maximian; but in which, as their superior, he was obliged occasionally to join. When, how-
the warrant, than he relented, and endeavoured to recall the bloody mandate; but that the second messenger entreated with the representative, was detained by the eminence, who dreaded the unforgiving temper of Gallus, and were likewise deems of reuniting to their empire the wealthy provinces of the East. Some time after the event, Syvanus, a Frang, who had been in the confidence of the emperor, and who had been of the utmost importance to him in his contests with Magnentius, was, by false accusations, driven into rebellion. He assembled an army at Cologne, but was affiliated before it could be properly organized. The barbarian tribes of Germany, resolving to be revenged for his death, burst into the province, destroyed many cities, and among the rest Cologne itself, and reduced the empire to the most alarming danger. Julian, the remaining nephew of the emperor, was sent against them, and returned victorious. In 357, Constans paid a visit to Rome, where he was received with the highest honours. He displayed his regard for the ancient capital, by adding to its ornaments an obelisk of granite in a single piece, brought from Egypt, and set up in the Circus Maximus. After this, he engaged in other wars, and was in general successful. His nephew Julian became now his rival; his high reputation in the army, induced the soldiery to proclaim him Augustus, but the emperor refused to acknowledge him as partner in the empire, and began to make preparations to assert his own rights over that of his adoption. Julian had imported him, and had already feized upon Illyricum; in pursuit of him there, Constans was feized with a fever, which at first threatened no serious consequences, but which terminated his life, and thus delivered the country from the horrors of a civil war. He died in November 361, having reigned twenty-four years. He obtained the character of a zealous Christian, and is applauded for having discouraged Pagan rites and ceremonies. He built many churches, and behaved with great respect towards the clergy; in matters of speculation and theological controversy, he considered himself an adept; was himself a favourer of the Arian party, and the persecutor of Athanasius, and of those who maintained his doctrines. It must be confessed that the genuine principles of Christianity were never understood by any of the Roman emperors; and their support of it, however laudable their motives might be, was highly injurious to its progress in the world. Gibbon. Unit. Hist.

CONSTANS, in Lutw., the name of a certificate, which the clerk of the pipe, and auditors of the eschequer, make at the requel of any person, who intends to plead or move in that court for the discharge of any thing; and the effect of it in, the certifying what (appears) certat. on record, touching the matter in question. 3 & 4 Edw. VI. cap 4. and 13 Eliz. cap. 6.

A certat is held to be superior to an ordinary certificate; because this may err or fail in its contents, that cannot, as certifying nothing but what is evident upon record. Also the exemplification under the great seal of the inrolment of any letters patent, is called a certat. Coke on Littl. 225.

CONSTELLATION, in Astrologny, an assemblage or system of several stars, expressed and represented under the name and figure of some animal, or other thing: this assemblage is by some called also an asterism. The ancients portioned out the firmament into several parts, or constellations; reducing a certain number of stars under the representation of certain images, in order to aid the imagination, and the memory, to conceive and retain their number, disposition, and even to distinguish the virtues, which astrologers attributed to them: in which sense a man is said to be born under a happy constellation, i.e. under a happy configuration of the heavenly bodies. The division of the heavens into constellations is very ancient, and probably, as old as astronomy itself; at least, it was known to the most ancient authors extant, whether fact or profane. In the book of Job, mention is made of the names of some of them; as in chap ix. 9. "Which maketh Arcturus, Orion, and Pleiades, and the chambers of the south." By the "chambers of the south," some have understood the constellations near the south pole, which are invisible to the inhabitants of the northern hemisphere. From the manner in which Job speaks of commerce, we may infer that he lived in a country frequented by merchants, who imported thither the rarities of the south. To this purpose Sir Isaac Newton suggests, (Chronology, p. 157.) that Job, who lived in Arabia Petraea, among the merchants, might have derived from them his knowledge of the constellations. And again, mention of them occurs in that sublime expolation, chap. xxxviii. 31, 32. "Canst thou refrain the sweet influence of the Pleiades, or loosed the bands of Orion? Canst thou bring forth Mazzaroth, (by which some understand the twelve signs, or zodiac,) or canst thou guide Arcturus with his fons?"

The first of the three constellations, mentioned by Job, is אטְרִיֵכְו, or אטְרִיֵכְו אטְרִיֵכְו, by which some have thought that he meant the constellation, now called the Great Bear. The root of אטְרִיֵכְו is אטְרִיֵכְו אוּחְיָה, which, in Hebrew, signifies, 'to gather together, or to assemblce;' and in Arabic, "to make a circuit, or to describe a circle." These two significations may very well be applied to the Great Bear, which is a group of stars making a remarkable circuit round the pole. "Canst thou guide (or feed) אטְרִיֵכְו with his fons?" (chap. xxxviii. v. 32.) is an expression which figuratively represents the stars that compose the Great Bear, collected together, like a flock which feeds in a meadow. In the same strain Virgil says, (Aen. 1. v. 611.) "Polus dum fidea pacent." It has been further observed, that אטְרִיֵכְו is the first star named in Job; and that ארָה, or the Great Bear, is the first constellation mentioned by Homer, in his description of the shield of Achilles. The second constellation or group of stars mentioned by Job is כֹּלָנָה כֹּלָנָה. From the different significations in which this term occurs, we may reasonably conclude, that it must be understood of some constellation remarkable for its relation to an agreeable season. God says to Job, "Canst thou bind the sweet influences of כֹּלָנָה? i.e. Canst thou bind up or refrain the fertility of the earth, for producing fruits and flowers, when כֹּלָנָה appears?" The different significations of this word, both in the Hebrew and Arabic; concur in pointing out the same sense of the term. כֹּלָנָה may be derived from כֹּלָנָה כֹּלָנָה, which, in Hebrew, signifies, "to defirc, or to rejoince." Of all the seasons the spring is the most dearable, and the most productive of delight and joy. If we deduce the word כֹּלָנָה from the Arabic root כֹּלָנָה, or כֹּלָנָה, this characterizes the spring as distinctly as the former. כֹּלָנָה, in Arabic, signifies, "inferior medicum," and "to become warm," Accordingly, the earth, at the approach of spring, begins to become warm, and to open its bosom; this is also the time when the females of most kinds of animals become pregnant. It remains only to know, what was the constellation which in the time of Job introduced the spring; and this, as we have sufficient reason for believing, was the Pleiades. כֹּלָנָה also signifies a "troop, number, or multitude;" and this etymology agrees perfectly well with the Pleiades, on account of the number of stars included in this collection, or in the constellation of the Bull.

The third constellation mentioned by Job is כֹּלָנָה כֹּלָנָה; the root of which word is כֹּלָנָה כֹּלָנָה, which, in Hebrew, signifies, "to be inconstant or changeable:" and in Arabic,
"to be benumbed, to be idle, to be cold." By Kefs, therefore, it is supposed that Job means the Scorpion. God says to Job, "Canst thou loose the bands of Kefal?" i.e. "Canst thou loose and open the earth, which is shut up and benumbed when Kefal appears? Canst thou then make it produce flowers and fruits?" Adverting to the interpretation already given of Kimah, we shall perceive, by the contrived characters which diftinguished them, that they are two constellations of the zodiac, pointing out two very opposite feasons. If by Kimah Job designed the Pleiades, it is not improbable that by Kefal he meant the Scorpion, a constellation opposed to Pleiades by almost one-half of the circuit of the heavens, and which then announced the approach of winter. Accordingly, Allen-Edward still it is now Kefal that star of the first magnitude, known by the name of the Scorpion's heart, or Antares. In his commentary on Job, he thus explains himself: "Kimah," says he, "is the northern stars, and Kefal is a southern star. Kimah produces fruits, which are the delight of man; and Kefal does the contrary. Kimah is a great star, called the Bull's eye, that is to say, Hyades; and Kefal is a great star, called the Scorpion's heart, that is to say, Antares." Rabbi Levi ben Gershom also, in his commentary on Job, that Kefal is one of the southern constellations; and that when the sun enters into the sign where this star is found, the trees can no longer bring forth fruit, on account of the cold which this star brings with it. Kefal has been suppos'd, by some learned commentators and critics, to denote the constellation Orion, which, at the time of its rise, portends clouds and tempests; and they derive it from Κήφας, Kefal, denoting inclemency. See Schultens's Commentary on Job, vol. i. p. 239, &c. vol. ii. p. 1586. Goguet's Origin of Laws, &c. vol. i. Dictt. 3.

In the prophecy of Amos, who is suppos'd to have lived 790 years B.C., we have the following animated exhortation (chap. v. 7, 8.): "Ye who turn judgment into wormwood, and leave off righteousness in the earth: seek him that maketh the seven stars and Orion, and turneth the shadow of death into the morning, and maketh the day dark with night; that calleth for the waters of the sea; and poureth them out upon the face of the earth: the Lord is his name." In this passage, the seven stars and Orion are mention'd as being well known, both by Amos, who was a herdsman of Tekoa, and the common people, to whom this exhortation was addressed; and we may hence infer, that the constellations had been invented for some time before that period. Some of the constellations are also occasionally mentioned by Hefiod and Homor, who flourished about 900 years before Christ; and Aratus of Tarus, the astronomical poet, who lived about 277 years B.C., in his "Phenomena," profec'dly treat'd of them all, except some few which were invent'd after his time; shewing how each constellation is situated with regard to those that are near it, what peculiarion it bears with respect to the principal circles of the sphere; and what other constellations rise or set with it. Hipparchus, the Bithynian, has shewn, that Aratus followed the descriptions of Eudoxus, who flourished about 366 years B.C.; and it is very probable that the Greek astronomers, who succeed'd him continu'd to use the same figures of the constellations till the time of Ptolemy, though not without some variations and additions. Ptolemy's Almagest (see Almagest) has been in such esteem among astronomers, that almost all who have written since his time have agreed in drawing the figures of the constellations, or supposing them to be drawn, so as to answer his description, as far as possible; and indeed this is necessary, in order to avoid confusion, when ancient and modern observations are compared.

The division of the ancients only took in the visible firmament, or so much as came under their notice; this they distributed into forty-eight constellations, those being reckoned ancient constellations which have been received from the Greeks, and particularly from Ptolemy; twelve of these took up the zodiac: the names they gave them are, Arias, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces; from whence the signs of the zodiac and zodiac take their names; though they have since lost their contiguity to the constellations which denominate them; e. g. the constellation Arias, about 2600 years ago, occupied the place of the first sign of the zodiac; but, on account of the precession of the equinoxes, it is now removed to the second, and so of the others. See Sign.

The other stars, on the northern side of the zodiac, were disposed into twenty-one constellations; viz. Ursa Major and Minor, Draco, Cepheus, Bootes, Corona Septentrionalis, Hercules, Lyra, Cygnus, Cepheus, Perseus, Andromeda, Triangulum, Auriga, Pegasi, Equuleus, Delphinus, Sagitta, Aquila, Ophiuchus or Serpentarius, and Serpens; to which we have since added Antinous, and Cuma Berenices, and some others.

The stars on the southern side of the zodiac were distributed into fifteen constellations: their names are, Cetus, Eridanus, Lepus, Orion, Canis major and minor, Argo, Hydra, Grater, Corvus, Centaurus, Lupus, Ara, Corona Meridinalis, and Piscis Australis; to which we have since added several others, viz. Phoenix, Grus, Indus, Pavo, Apus or Avis Indica, Apsis Mearer, Chamæleon, Trigunum Australis, Piscis volans, Tucan, Hydrus, Xiphias or Dorado, Columba Noctis, and Roros Caroahum, &c. &c. See each constellation under its proper head, Arias, Taurus, &c.

Thus other stars, not comprehended under these constellations, yet visible to the naked eye, the ancients called incolumes, or spies, some of which the modern astronomers have since reduced into new figures, or constellations.

Thus, Hevelius, v. gr. between Leo and Ursa major, makes Leo minor; and between Ursa minor, and Auriga, over Gemini, makes Lynx; under the tail of Ursa major, Comae venatici, Cerberus, Vulpecula, and Antier, Scutum Sobiek, Lacerta, Camelopardalis, Monoceros, and Sextans. See also Antinous, Berenice, and Cor Caroli.

In these constellations, the stars are ordinarily distinguisht by that part of the image wherein they are found. Bayer distinguishes them farther by the letters of the Greek alphabet; and many of them, again, have their peculiar names, as Arcturus, between the knees of Bootes; Gemina, or Lucida, in the Corona septentrionalis; Pollutum, or Aldebaran, in the Bull's eye, Pleiades in the neck, and Hyades in the forehead of the Bull; Castor and Pollux in the heads of Gemini; Capella, with the head; the shoulder of Auriga; Regulus, or Cor Leonis; Spica Virginis in the hand, and Vindemiatrix in the shoulder of Virgo; Aitares, or Cor Serpentis, in the mouth of Piscis; Regis, in the foot of Orion; Siris, in the mouth of Canis major; Ptolemy, in the back of Canis minor; and the Polestar, the last in the tail of Ursa minor.

The knowledge of the stars has become more extensive; the number of constellations has increased; and a greater number of stars has been introduced into each constellation; as their positions, by more accurate observations, have been ascertained.

The following tables exhibit the names of the constellations, and the number of stars in each, including all to the fifth magnitude; and also some of the most remarkable stars in each constellation.

There are several ways of delineating the constellations and stars, so that an observer may be able to distinguish them in the heavens. The most eligible method of all is to construct a hollow globe of such a large size as to admit the observer to stand on a frame near its centre; and then to paint the stars and constellations in its inner surface, in their proper situations with regard to one another. If such a globe be elevated according to the latitude, were made to turn on its poles, the observer near the centre would behold the motions and aspects of the stars as they really are in the heavens, and soon obtain a correct idea of the whole. A machine of this kind, however, could not be constructed without a very considerable expense as well as ingenuity. Large machines on this plan have been made at Gottorp, at the expence of Frederick III. duke of Holstein; and at Paris by the direction of cardinal d'Etrees; but these are far inferior in size to one erected at Pembroke college, in Cambridge, under the direction of Dr. Long. The description of this curious machine is here subjoined in the doctor's own words. "I have, in a room lately built in Pembroke hall, erected a sphere of 18 feet diameter, wherein 50 persons may sit conveniently: the entrance into it is on the south pole by six steps:—the frame of the sphere consists of a number of iron meridians, not complete semi-circles, the northern ends of which are screwed to a large round plate of brass with a hole in the centre of it; through this hole, from a beam in the ceiling, comes the north pole, a round iron rod about three feet long, and supports the upper parts of the sphere to its proper elevation for the latitude of Cambridge; the lower part of the sphere, so much of it as is invisible in England, is cut off: and the lower or southern ends of the meridians, or truncated semi-circles, terminate on, and are screwed down to a strong circle of oak, of about thirteen feet diameter, which, when the sphere is put into motion, runs upon large rollers of lignum vitae, in the manner that the tops of some wind-mills are made to turn round. Upon the iron meridians is fixed a zodiac of tin, painted blue, whereas the ecliptic and horizonitic orbits of the planets are drawn, and the constellations and stars traced:—the great and little bear, and Draco, are already painted in their places round the north pole; the rest of the constellations are proposed to follow: the whole is turned round with a small winch, with as little labour as it takes to wind up a jack, though the weight of the iron, tin, and wooden circle, is about a thousand pounds. When it is made use of, a planetarium will be placed in the middle thereof. The whole, with the floor, is well supported by a frame of large timbers." In 1758, the constellations and chief stars visible at Cambridge, were painted in their proper places upon plates of iron joined together, which form one concave surface. We here add with regret, that this curious machine has been much neglected and is so far decayed as to answer none of the purposes which the ingenious contriver proposed. The constellations and stars might also be drawn in two concave hemispheres, which would contain them all, or segments of spheres might be made of brass or plate board, of such dimensions that each segment should contain a single constellation upon its concave surface. Sometimes the constellations are drawn upon two planisphere projected upon a great circle, which give us the pictures of the two concave hemispheres in plane. The constellations and stars may also be depicted on a celestial globe. The first use of all these concave spheres, planispheres, and globes is, by comparing them with the originals, to know the stars in the heavens; but as the rotation of the earth round its axis causes the heaven and stars, &c. apparently to move the contrary way; and thus the sphere of the fixed stars is made to change its position, with respect to us, every moment of the natural day; it will be necessary, in order to compare the stars upon a concave hemisphere, globe, or planisphere, with the stars in the heaven, to place the globe, hemisphere, &c. in such a position as to correspond with the situation of the heavens at the time of observation. The method of rectifying the celestial globe for any hour of the night, or to place it that every star on the globe may point at the corresponding star in the heavens, will be found under the article Celestial Globe; and when this is done, the constellation may be known, by comparing the heavens and the globe with one another. E. G. if I would find a star called Arcturus in the heavens, the globe being rectified for the star Arcturus, then if I imagine a line to be drawn from the centre of the globe through that star, that line continued will point at Arcturus in the heavens. Suppose, on the other hand, I see some bright star in the heavens which I want to find upon the globe, I first rectify the globe for the hour of the night, and then if I imagine a line to be drawn from the star to the centre of the globe, it will point at the corresponding star on the surface of the globe. Maps of the concave surface of the heavens, especially such as take in only one constellation, with some parts of those which surround it, are very useful for the purpose of becoming acquainted with the stars. Of this sort are the figures given by Beyer in his "Uranometria," and those of Flamsteed, published after his death by Hodgson. See our Plates of Constellations. The manner of using these maps will be seen by the following example. If I would know the stars in the Great Bear, I turn the figure about, till the principal stars of it are in the same situation with regard to upper or under, right or left, as they appear in the heavens, at the time of making my observation; when this is done, it is easy to look for the stars on the heavens and then upon the map, to discover to what parts of the figure, whether to the eye, fountain, &c. the rest of the stars are to be referred.

It is very probable that the stars, and more especially some of the most remarkable collections of them, such as Charles's Wain, the Pleiades, Orion, &c. were formed into constellations.
 Constellation.

The Greeks, who learned astronomy of the Egyptians, retained several of their figures, as the ram, the bull, the lion, the dog, the triangle, &c.; but accommodated almost all of them to the fabulous history of their gods and heroes, whom they thus placed among the stars. According to the Greek and also the Roman poets, from the ancient theology, they had given us wild and romantic fables about the origin of the constellations, probably derived from the hieroglyphics of the Egyptians, and transmitted, with some alterations, from them to the Greeks; which may be seen in Hyginus’s Ptolemaic Almanac. and Ricciola’s Almagest, lib. vi. cap. 3, 4, 5; and Sertorius’s notes upon Manlius. Sir Isaac Newton observes, (see his Chronology, apud Oper. vol. v. p. 62.) that the Magnes, one of the Argonauts, was the first among the Greeks who made a sphere; and the sphere itself, he says, shews that it was delineated in the time of the Argonautic expedition; for that expedition is delineated in the Atlantis. Thus we have the golden Ram, the enigma of the veil in which Phryxus fled to Colchis; the Bull with broken hoofs tamed by Jason; and the twins, Castor and Pollux, two of the Argonauts, with the Swan of Leda their mother. We have also the ship Argo, and Hylas the watchful dragon: with Medea’s cup, and a Raven upon its carcase, the symbol of death. We have Chiron the master of Japhet, with his altar and sacrifice; the Argonaut Hercules with his dart and culture falling down, and the Dragon, Crab, and Lion, which he killed; and the Harp of the Argonaut Orpheus. All these, says sir Isaac, relate to the Argonauts. We have also Orion, the son of Neptune, or, as some say, the grandson of Minos, with his Dogs, and Hare, and River, and Scorpion. We have the story of Perseus in the constellations of Perseo, Andromeda, Cepheus, Cygnus, and Cetus; that of Calibos, and his son Arcas; that of Callisto, and her son Arcas; that of Icarus and his daughter Erigone in Bostis, Plutarch, and Virgo. Ursae minor relates to one of the nutres of Jupiter; Auriga to Erechtchous; Ophiuchus to Pherbas; Sagittarius to Caelus the son of the nurse of the Muses; Capricorn to Pan; and Aquarius to Gaumide. We have Ariadne’s Crown, Bellarophon’s Horse, Neptune’s Dolphin, Ganymede’s Eagle, Jupiter’s Goat, with her Kids; Bacchus’s Affer, the Fishes of Venus and Cupid, and their parent the South-fish. These with Delphin are the old constellations mentioned by Aratus; and they all relate, says Newton, to the Argonauts and their contemporaries, and to persons one or two generations older; and nothing later than that expedition was delineated there originally. Anthius and Coma Berenices are novel. Although it be true, as sir Isaac Newton affirms, that none of the figures on this sphere bear relation to any transtition of later date than the Argonautic expedition; yet the great disagreemant that fults among mythologists in their accounts of these figures shews them to be of greater antiquity, and that the constellations were received for some time among the Greeks, before their poets, according to their several fancies, applied them to different fables. See Long’s Astronomy, vol. i. p. 162.

As the stars grouped in our constellations are capable of being reduced to very different figures, those of the Chinese and Japanese are very different from ours; and some superstitious Arabsians, though they received their astronomy from the Greeks, have given some of their constellations different figures; because they thought it unlawful to draw any human figure; and therefore they changed all such on the celestial globe into some other form. Some Christian astronomers, displeased to see the heavens of the fixed stars occupied by the fabulous heathen deities and heroes have proposed,
proposed, from superstitious zeal but without a due regard to the science of astronomy, to introduce a reformation in this respect; and whilst they retained the ancient figures, to refer them to some scripture history. With this view they would have Arius, or the ram, to be a memorial of that which was offered instead of Isaac, Vlgo to represent the blessed Virgin, &c. Thus, venerable Bede, instead of the profane names and figures of the twelve constellations of the zodiac, substituted those of the twelve apostles; whose example being followed by Julius Schillerius, in 1627, he completed the reformation, and gave scripture names to all the constellations in the heavens. Thus, Arius, or the ram, became converted into St. Peter; Taurus, or the Bull, into St. Andrew; Andromeda into the pharmacy of Christ; Lyra into the manger of Christ; Hercules into the Magi coming from the East; Canis Major into David, &c. Weigheus, professor of mathematics in the university of Jena, made a new order of constellations; converting the firmament into a caulis heroidicum; and introducing the arms of all the princes in Europe, by way of constellations. Thus, Ursa Major, he transformed into the elephant of the kingdom of Denmark; the Scutum into the Ruta with arrows of the banner of Saxony; Opibuchus into the cats of Cologne; the Triangle into the comets, which he calls the symbol of artificers; and the Pléiades into the Moxus Pythagorizans, which he calls that of merchants, &c. However, the more intelligent among astronomers never approved of innovation; as leaving no purpose but to introduce confusion into astronomy. The old constellations, therefore, are still retained; both because better could not be introduced, and likewise to keep up the greater correspondence and uniformity between the old astronomy and the new. See Catalogue.

CONFIRMATION is defined by ethical writers to be an excess of horror, owing to the ill government of our admiration and fear; or such an immediate degree of fear as confounds the faculties, and incapacitates a person for confusion and execution. It denotes a strong foreboding of tremendous evils, that are likely to follow misfortunes which have already taken place.

CONSTIPATION, in Medicine, is synonymous with constipation of the bowels, or a retention of the motions beyond the usual period; which likewise implies, in general, a dry and hardened condition of the excrements, and some difficulty in discharging them.

The proximate cause of constipation of the bowels may consist in an unusual flow of the peristaltic motion, or in an obstruction to the passage of the feces, while the proper peristaltic motion continues to propel them. The natural motion of the bowels is considerably different in individuals of different constitutions, and even in the same individuals at different periods: so that it is not easy to say when the peristaltic motion can be considered as preternatural flow, while the general health continues good.

But it is probable that a stool should occur once in 24 hours, in most habits, although there are many persons who retain the feces much longer without inconvenience. Dr. Cullen affirms, that he is clearly of opinion, that every deviation from a diurnal stool is an approach to an unnatural state. The accumulation and induration of the feces in the large intestines not only often produces many diseases in the lower part of the canal, but even occasions disorders in different organs, and deranges the system in general.

The occasional causes of an inefficient peristaltic motion are various. A weakness of the muscular coat of the bowels appears to be, in some cases, the origin of colic, which is then accompanied with other marks of dilatation, and hence colic is not unfrequent in the female sex, who suffer considerable inconveniences from it. A cause of a contrary nature seems likewise to give rise to constipation, namely, a rigour and rigidity of the alimentary canal. In such cases there is necessarily a degree of immobility or torpor, so that the stimuli of the passing feces excites the intestines to less active motions, than in the more irritable habits; at the same time digestion is more perfectly performed, and a smaller proportion of feces therefore is produced: the absorption of the liquid parts too is more complete, and hence the feces are not only smaller, but dryer, and pass less easily. In rigid and robust persons therefore habitual constipation is not uncommon. And in those of hypochondriacal or melancholy habits, a similar torpor in the motions of the whole system, and particularly of the intestinal canal, produces a similar disposition to colic. Another cause of the flow of the peristaltic motion may be a deficiency of the in the intestines, which is considered as one of the principal stimuli in maintaining the motion of the canal downwards. It is not indeed always in our power to alter the occurrence of this phenomenon; but we know, that where the bile is withheld from the intestines, as in jaundice, there is common colic. It is not quite evident in what manner a regular and constant exercise of secretion, as in a carriage, or on the water, produces colic, rather than any considerable bodily activity, which is accompanied by much perspiration; Dr. Cullen is disposed to attribute it to the abstraction of the other intestinal fluids, secreted from the mucous glands and exhalent arteries. See Materia Med. vol. ii. p. 496.

The causes which may obstruct the passage of the fecal matter, occur either in the intestines themselves, or in the neighbouring parts. In the intestines, a mechanical impediment is sometimes occasioned by a thickening of the coats, which straitens the passage, or by chirrous tumours, especially near the lower extremity of the canal. Sometimes the cavity of the intestine is partly filled by calculous concretions. A temporary diminution of the caliber of the canal is also occasioned by spasmatic contractions in the coats, as occurs in coils, or by the occurrence of inflammation, as in enteritis and enteritis, in all of which the feces are retained. Tumours in the neighboring parts, comprizing the intestines, necessarily impede the passage of the contained feces. Hence obstinate constipation has sometimes been occasioned by a fistomatous tumour in the omentum; and a very frequent cause of colic is the compression of the dilated uterus upon the rectum, or lower gut, in pregnant women.

When, from neglect of evacuation, or other circumstances, an accumulation of feces to a considerable extent takes place in the rectum, or lower intestines, this collection of matter itself becomes a cause of a most painful and distressing constipation, attended with peculiar symptoms, and sometimes terminating fatally. This disorder was first described by an anonymous writer in the Medical Observations and Inquiries, vol. iv. p. 123, and other cases have since been recorded by other practitioners. (See Duncan's Medical Commentaries, vol. x. p. 255, and vol. xii. p. 282.) It is the more important to attend to this complaint, because it assumes the appearance of a diarrhœa, or rather a chronic dysenteric, and has been often mistaken for the former, and erroneously treated with astringents and opiates in consequence. The patient complains of severe pain about the lower region of the belly, retchting and again returning after frequent, but short intervals, and accompanied with a perpetual bearing down, and almost continual inclination to evacuate the contents of the intestines; but only a trifling quantity
CON

When a fresh spasmoidal effort succeeds, and with similar succeess, is considered as a kind of spontaneous emission of all the parts in, or connected with, the pelvis, for the exclusion of this irritating substance. When, from a previous collisence, from the acuteness of the pain and tenesmus (or bearing down), and the obstruction of formed and feculent flouts, this state of the rectum is to be suspected, the gut should be examined per anum, when the faces will be readily detected in general, and must be broken down and removed by the finger, or some other mechanical means. The accumulation, which thus takes place, is sometimes very great. The following account from an apothecary, is given by Dr. Warren of Taunton:—"the evening you left us, I extracted from our patient (a lady, aged 65, who had laboured under this disease for five months,) four large balls of hardened excrementitious matter, about the size of hen's eggs; the next morning the discharged near twenty, and has continued to pass more or less of them every day, until about a week ago, when she took a larger dose than ordinary of caustic oil, which evacuated 19 lumps of the same size as formerly; since that her flux has been natural, none of the balls having appeared." See Duncan's Med. Com. vol. x. p. 259. This disorder is peculiar to persons in advanced life, when a degree of atony often exists in the bowels; and it is more frequently observed in the female, than in the male sex. Whatever tends to lessen the peristaltic motion of the bowels, must induce a predispension to it; and it is said to have been frequently occasioned by a long continued use of bark, opium, and other astringent medicines.

The consequences of a constricted state of the bowels, however, though in a comparatively trivial degree, whether idiopathic, or as a concomitant of other diseases, are frequently extremely injurious to the constitution; producing, when it is idiopathic, a variety of disorders; and aggravating, when symptomatic, the diseases of which it is a symptom.

The stomach and intestines, being a continuation of the same canal, reciprocally affect each other, when diarrhoea. Hence, complaints of the stomach are frequent consequences of colicneses of the bowels; such as flatulence, stomach ache, or gastrodynia, heart-burn, indigestion, &c. Another affection of the canal is frequently produced by complication, namely, the appearance of hemorrhoidal tumours, or piles, at the lower extremity of the rectum, about the anus. See HEMORRHoids. Sometimes, from a sympathy of the head with the stomach, and sometimes probably from the pressure of the loaded intestines on the great veins, impeding the circulation of the blood downwards, and therefore determining it more copiously towards the head, a pain of the head is excited by a constricted condition of the bowels. This head-ache is various in different instances, but most commonly is confined to the forehead, or to the occiput, or nape of the neck: occasionally the hemicrania, or intermitting head-ache, appears to arise from complication. In those whole states predispose them to apoplectic, paralytic, or lethargic attacks, a loaded state of the bowels, by obstructing the circulation downwards, increases the predisposition, and occasionally even becomes the exciting cause of those diseases.

There are, besides, many disorders both acute and chronic, which, although they cannot be said to be produced by conification of the bowels, are nevertheless greatly aggravated by it; and the complication is frequently a leading symptom of these disorders. Thus in all acute febrile complaints, and particularly in idiopathic and eruptive fevers, such as the syphillis, or summer-fever, typhus, scarlet-fever, small-pox, &c. complication is liable to occur, and when occurring at any period of the fever, tends to aggravate its symptoms, and to prolong its duration: and if, on the contrary, the bowels are freely opened in the commencement of these disorders, their severity is mitigated, and their duration frequently abridged. This is more especially the case in syphilis and typhus, and in the febrile complaints of children. In a certain set of chronic diseases, which have heretofore been considered as unconnected with the condition of the bowels, such as many hysterical affections, chlorosis, and particularly chorea, or St. Vitus's dance, complication has lately been shown to be a source of much mischief, if not frequently the exciting cause. (Hamilton on Purges.) See CHOREA, and CATARRHES. In short, a constricted state of the bowels is at all times liable to produce injurious effects on the constitution; in health it is a common exciting cause of various complaints; and in all states of diseases, whether acute or chronic, it tends to aggravate the symptoms, and to prevent the beneficial operation of remedies.

The mode of obviating complication must be varied, according to the nature of the case, and the constitution of the patient. Where it is slight and accidental, any of the milder cathartics, such as magnesia vomita, or Epsom salt, or calomel, or (solem nitr.), rhubarb, or small doses of coloewel, will generally answer the purpose of removing it; if these fail, the more active purgatives must be resorted to, especially in strong habits, such as japa, aloes, extract of cocoynth, coloewel in larger doses, and combined with some of the preceding substances. Coloewel, or the other mild mercures, preparations, appear to be peculiarly useful, when the complication is occasioned by a torpor of the hepatic system, and a consequent deficiency, or morbid change in the quality of the bile, as they appear to stimulate more particularly the biliary ducts and vesicles. The colour and factor of the fluids should be noticed with care, since the quality and condition of the bile, which is the principal colouring matter of the faces, may be thus most clearly ascertained. In acute diseases this observation is more particularly important, as the sensible qualities of the faces frequently indicate a loaded and morbid condition of the alimentary canal, and the necessity of laxatives, when the number of motions does not appear to require such evacuations. See Hamilton: also Abernethy, Surgical Observations, vol. iii.

When complication is habitual, some gently stimulating or cooling laxative, according to circumstances, may be required to be given daily, until the habit be removed. Much may be done for the relief of this by diet; as by eating a large proportion of vegetables, or by the free use of fruits, even those which are dried, or preserved with sugar; and by avoiding such articles as manifestly tend to counteract the body. And the advice of Mr. Locke should be steadily followed; i.e. the patient should go regularly to stool at the same hour daily: for such is the periodical regularity of all the functions of the body, that they are more perfectly performed at the accustomed hours than at any other period. Thus sleep, and the appetite for food, often forsake us altogether, if we delay the gratification beyond the usual hour.

In states of extreme complication it is very common among the vulgar to refer to a medicine which appears to have been first employed from the most absurd and false notions of its powers, namely, crude mercury, or quicksilver. Whether it may have been supposed to open the bowels by some self-
moving power, or by its mechanical weight, the theory is equally absurd: and what is worse, the practice is not only useless, but dangerous. There are cases on record, in which the quicksilver, thus administered, had accumulated in the intestines, formed itself a sac by its weight, and at length produced death, by passing into the cavity of the abdomen, in consequence of the rupture of this sac. It is obvious, indeed, that the medicine could not ever force a passage by its weight, along the course of the bowels, since it must ascend occasionally, if the body is erect; and the whole passage must be nearly horizontal, if the patient be in a recumbent posture.

In the worst degrees of constipation, glibsters consisting of an infusion of tobacco, or the smoke of tobacco, have been thrown into the bowels with advantage. And when all other expeditious means fail, an affusion of quicksilver into the lower extremities, while the patient is placed with his feet on a cold hearth, has been found to excite the propulsion of the faces. See Cole. A glibster consisting of Venice turpentine, suspended in water by means of mucilage, or the yolk of an egg, was a favourite remedy with Dr. Cullen for severe constipation; and it is undoubtedly an efficacious expedient; more especially if administered a few hours after an active cathartic has been taken internally.

Where the constipation is occasioned by a mechanical ob-struction, it can of course be alleviated only by the removal of the obstruction. If it arises from the presence of tumours or concretions external to the bowels, it may be considered as incurable; and can only be alleviated by keeping the bowels lax, and the faces in as liquid a state as possible. Strictures of the lower intestine have been frequently relieved by the introduction of a bongie, mechanically enlarging the passage. An intelligent writer remarks, that "strictures take place in different situations; but they occur so frequently about the sigmoid flexure of the colon, near its termination in the rectum, that this part should be carefully examined in every case of a total obstruction of the bowels."

The infusion of an unyielding tallow candle, though often practised, has been generally found painful and inefficacious. It is requisite for the purpose to employ a bongie thirteen inches long, and of a proportionate strength; which should also be directed, with a nice hand, by a skilful surgeon. "I lately saw a lady," he adds, "thus relieved, who had been twenty-six days without any evacuation from the bowels, and who seemed nearly exhausted by violence of pain, and dilatation of the abdomen, hicoupa, cold sweat, &c. It is remarkable how long patients submit under these distressing circumstances. In one infance the time was twenty-nine days; in another patient thirty-three days. As the latter recovered after enduring every torture such a disorder could inflict, practitioners may be encouraged to persevere steadily in their attentions, and to retain some hopes even in the greatest extremity."

Wllian on Diffeces in London, page 185.

CONSTITUTENT Parts, in Chemy. The constituent parts of bodies are their diminutive parts, or principles, into which they may be resolved, by the rules of that art. They are thus called in distinction from the integrant parts of bodies, which are parts of the same nature and properties with the bodies themselves. Thus quicksilver, dissolved by aqua fortis, may be separated from the diluted menstruum, by means of a copper plate, in its own form; this therefore was only divided into its integrant parts; but cinnabar resolved by chemisty into sulphur and mercury, is divided into its constituent parts, neither of these, nor any particle of them, being cinnabar, or having its properties. Shaw's Lectures, p. 15.

CONSTITUTION, an establishment, ordinance, decision, regulation, or law, made by authority of a prince, or other superior, ecclesiastical or civil.

The constitutions of the Roman emperors make a part of the civil law. The constitutions of the church make a part of the canon law. Some of the papal constitutions are in form of bullis, others of briefs. See each article.

Constitutions of Clarendon. See CLARENDON.

Constitutions, Clementine. See CANON LAW.

Constitutions, Legitime, were ecclesiastical laws enacted in national synods, held under the cardinals Otho and Otho- bon, legates from pope Gregory IX. and pope Clement IV., in the reign of Henry III., about the years 1237 and 1260.

Cardinal Otho arrived in England, as a legate from the pope, in the year 1237, where he continued about three years, receiving many valuable presents from the bishops, monasteries, and clergy. This legate held a council at London, A.D. 1237, in which a great number of canons were framed, which were called "the Constitutions of Otho." These constitutions do not contain many things new or remarkable. By the second canon, the sacraments are declared to be seven in number; the fifteenth is against the clandestine marriages of the clergy; and the sixteenth against their keeping concubines publicly: both which practices were still very frequent in England. This legate convened two other assemblies of the clergy, with no other view but to make exorbitant demands of money. After the restoration of the royal authority, by the victory of Ewelham, the pope sent his legate Othobon into England, who held a national council, A.D. 1268, at St. Paul's in London. In this council many canons were made, much the fame in substance with those of the former council of London, in 1237, under the legate Otho.

Constitutions, Provincial, are principally the decrees of provincial synods, held under several archbishops of Canterbury, from Stephen Langton, in the reign of Henry III. to Henry Chicheley, in the reign of Henry V., and adopted also by the province of York in 1464, under Henry VI.

Constitutions of 1603. See Canon Law.

Constitutions, Apologetical, in Ecclesiastical History, denote a collection of regulations attributed to the apostles, and supposed to have been collected by St. Clement, whose name they likewise bear.

These are divided into eight books; consisting of a great number of rules and precepts, relating to the duties of Christians, and particularly to the ceremonies and discipline of the church.

Mr. Robert Turner, in his "Discourse of the pretended Apologetical Constitutions," maintains, that these eight books seem to have been made out of several doctrines, constitutions, canons, travels, and traditions, ascribed to the apostles, and out of some of the ancient liturgies, and the discipline and practice of the Greek church, only blended together, adulterated, and changed, by some ignorant Arian, in the fifth century. Bishop Pearson was of opinion, that the Apologetical Constitutions were formed out of several lesser works, called Doctrines and Constitutions, and it is to be written by Clement, Ignatius, Hippolytus, and others, but altered and interpolated by the author of this collection; and that the eight books of the Constitutions, as we now have them, were not composed and finishead till after the time of Epiphanius.

Authors, however, are divided about the genuineness of these Constitutions: the generality hold them spurious, and endeavour to prove them posterior to the apostolic age; maintaining they were unknown till the fourth century; 5 R which,
which, if this be the fact, shews, that St. Clement had no concern in them. It is certain, that no such book is quoted as Scripture by any Christian writer of the three first centuries. The first who citing a work under this title is Epiphanius, and yet he speaks of it as of doubtful authority; and some modern writers are of opinion, that the Constitutions quoted by Epiphanius were different from the present Constitutions. When he says, that it was "doubted by many," he himself intimates, that some suspected it to be the work of some heretic; in opposition to which he says, it ought not to be rejected, as, from its contents, it appeared to be the work of some honest, orthodox, or Catholic Christian.

It is not easy to say, what respect Epiphanius himself had for this work. He quotes things from it as ordinances of the apostles, and as the divine word or doctrine; but it is not mentioned in any of the passages, where he gives the catalogues of the books of Scripture. Besides, his expressions just taken notice of seem to imply no more, than that the book was an ecclesiastical or orthodox writing; and we may observe farther, either that his Constitutions were not the same as ours, or that he had no great regard for them. For in our Constitutions, several early heretics are named, and they are condemned and confuted; of which passages, nevertheless, Epiphanius has made no use in his history of those heretics, or in his arguments against them; which every one must think he would have done, if the Constitutions which we have had been then in being, and had been esteemed by him as of authority. Whatever might be his opinion concerning this work, we have no good reason for supposing that it was a book of sacred Scripture; because no such book is quoted as Scripture by Irenæus, Clement of Alexandria, Origen, Cyprian, Eusebius, or any other Christian writer of the first three centuries. It is more than probable that the eight books, as we have them, were not composed and finished till after the time of Epiphanius, towards the middle, or before the end, of the fifth century. Cotelarius (Ap. Pat. Apoll. t. r.) says, it is certain, that the work of the Apostolical Constitutions, in eight books, is apocryphal and pseudepigraphal, not composed by the apostles, nor by the apostolic Clement. Tülemont concours in opinion with Cotelarius. Dailé thinks, that the Constitutions were composed after the council of Nice, and before the end of the fifth century; and bishop Pecior supposes, that the eight books of the Constitutions, as we have them, were not composed and finished till after the time of Epiphanius. Le Clerc mentions some things in the Constitutions exceedingly unfitting to the character of the apostles of Christ; and says, that they well represent the ecclesiastical discipline of the fourth century, but not of earlier times. He thinks, they were composed by some Arian of the fourth century; and seems to imagine, there may be some probability in the conjecture of another learned man, viz. Thomas Bruno or Brown, that they are the work of Leontius, bishop of Tripoli in Lydia.

Mr. Whiston has ventured to oppose the general opinion; and with some reason, much learning, and more warmth, affented the Apostolical Constitutions to be one of the sacred writings, dictated by the apostles in their meetings, written down from their mouths by St. Clement, and intended as a supplement to the New Testament; or, rather, as a scheme and synod of Christian faith and polity. See his Essay on the "Apostolical Constitutions," and his historical preface; wherein the several steps he made in his fancied discovery are traced.

Dr. Lardner, after citing several opinions of learned men concerning this work, offers his own sentiments in his usual judicious and impartial manner. In his investigation of its contents and authority, he observes, that the whole of the work, and all the ordinances in it, from beginning to end, are delivered in the name of all Christ's apostles, and as from God himself; and moreover, that they assume not only the names of the apostles, but also their characters and actions. Hence, according to the whole tenor of the work, they are rightly termed "Apostolical." Dr. Lardner next proceeds to inquire, both from external testimony and internal evidence, how far the authority claimed by these constitutions, and by the advocates of their antiquity, is well founded. To this purpose he observes, that Dâlle, after having examined all the several ecclesiastical writers of the first three centuries. Barnabas, Clement of Rome, Justini Martyr, Athenagoras, Irenæus, Clement of Alexandria, Tertullian, Origens, Cyprian, Dioniynus, Peter of Alexandria, and some others, has shewn, with great probability, that the constitutions were unknown to all these writers. In this opinion Mr. Turner, already cited, concurs. Moreover, the constitutions contain a long history of Simon Magus, and an account of divers other heretics, such as Cleobinus, Dorotheus, the Ebionites, Cerinthus, Marc, Menander, Balsides, Saturninus, the Nicolaitans, and Heterobaptists. The evil of heresies is shewn; the canons of them are ascertained and enumerated; they are condemned and confuted. Neverthelesse, no notice is taken of all this by Irenæus, Tertullian, Clement of Alexandria, or Eusebius; nor even by Epiphanius; though it would have been much more to their purpose. In short, says Dr. Lardner, they could not have omitted it in their censures of the ancient heresies, or in their arguments against them, if they had been acquainted with it; for, certainly, the express authority of the apostles would have been of great advantage to them. As to Clement of Alexandria, though he quotes Clement of Rome, Barnabas, and other Christian authors, and had many occasions for quoting the constitutions, if he had been acquainted with them, yet he does not make the least notice of them. Besides, the constitutions absolutely forbid the reading of heathen authors; nevertheless, the fore-mentioned Clement, who was himself a man of extensive reading, and a great master of heathen learning, frequently cites in his works all sorts of authors, and has recommended the reading of heathen authors, and the study of philosophy; which he would not have done, if he had been acquainted with these constitutions, and had acknowledged them to be apostolical. Tertullian, Origen, and many more justify and recommend the reading of heathen compositions, which could not have been the case, if in doing this they would have violated an apostolical constitution. If, indeed, there had been a constitution of the Christian church, which forbade the reading of such books, the emperor Julian would have had no occasion to make the same prohibition. In the third century a dispute occurred about baptism; in which Cyprian and the African bishops maintained against Stephen bishop of Rome, that the baptism of heretics was null and void, and therefore that those who came over from them were to be re-baptized; this controversy is decided in the constitutions negatively to the judgment of Cyprian and his colleagues; and yet it was not appealed to at that time, because, probably, it was not then extant. Dionylius, who was bishop of Alexandria about the year 248, appears to have been altogether unconvinced with our apostolical constitutions. When a controversy occurred about the time of keeping Easter, which commenced in the second century, and lasted till the fitting of the council of Nice, no appeal was made to the constitutions, which would have served to decide the dispute, if they had actually existed or had been received as apostolical. If an appeal be made to the writers of the fourth and the former part of the fifth century, such as Gregory Nazianzen, Eust., Chrysto-
CONSTITUTION.

ton, the Cyril of Jerusalem and Alexandria, Jeron, Augustine, &c.; they give us no intelligence concerning the apotolical constitutions; having neither cited nor mentioned them in any of their writings. The first (Epiphanius excepted) who has mentioned them, as divided into several books, is the author of the imperfect work upon St. Matthew, probably a Latin writer, and plainly an Arian, who wrote some time after the reign of Theodosius the Great; probably not till after the end of the fifth century. Upon the whole, the constitutions are destitute of all external evidence, that should entitle them to the character of apostolical. As to the internal evidence, they evidently bear many marks of a later age than that of the apostles, and unsuitable to their character. Their manner of quoting the books of the New Testament does not suit the apostles, of which Dr. Lardner has given several instances; many things occur in these books, that refer to a later period than that of the apostles: e. g. they mention several heretics, as we have already observed, that did not appear before the end of the apotolical age; they also record various circumstances, which seem to shew, that the reign of heathenism in the Roman empire had terminated, and that Christians enjoyed ease and prosperity; and they write in a style, make use of terms and appellations, and refer to practices and observances, and offices of the church, which did not obtain till a much later period than the age of the apostles. Several things in the constitutions appear to be unworthy of the apostles of Christ; of which numerous instances are cited by Dr. Lardner, and also by Dr. Jortin, ubi infra. Moreover, this work is not free from incongruities, which are a disparagement to any writings, and they use a mode of expression that betrays a later time than is pretended. From a recital and ample illustration of the several particulars, above cursorily mentioned, by the two learned writers already named, and of others which our limits will not allow us to introduce, we may justly conclude, that the constitutions, in eight books, are not a work of the apostles, and since they bear their names without sufficient authority, they must be referred to the class of impostures. Although the exact time when this work was composed, cannot be determined, and learned men have offered various conjectures, Dr. Lardner inclines to the opinion of those, who think that it was composed in the latter part of the fourth, or the beginning of the fifth century. "The author," probably, says Dr. Lardner, "was a bishop of a proud and haughty spirit, who was fond of church-power, and loved pomp and ceremony in religious worship." To this purpose Dr. Jortin says, that the constitutions repeatedly assert, "that a bishop is a God, a God upon earth, and a king, and infinitely superior to a king, and ruling over rulers and kings. They command Christians to give him tribute as to a king, and to reverence him as a God, and to pay him tithes and first-fruits, according, say they, to God's command; and they strictly forbid Christians to make any inquiry, and to take any notice, whether he dispoe of these revenues well or ill." Sentiments thefe which seem to have been dictated at a time when there were Christian emperors.

Many learned moderns, says Dr. Lardner, "think the author was an Arian; but I do not concern myself about that: the palleges, which have been suppos'd to favour Arianism, make a very small, or no part of the preceding collections; I have no reason, therefore, to bring that point into the conclusion. But I presume, that none ever suspected the author to be a Homoufian." The author of this work, however he was, bears testimony to the feriptures; and appears to have received all these books of the New Testament, which were all along generally received by Christians. Lardner's works, vol. iv. part 2. ch. 35. p. 320—334. Jortin's Remarks on E. H. vol. i. p. 228—278.

CONSTITUTION, in a Physical Sense, is used to denote the general condition of the body, as evinced by the peculiarities in the performance of its functions: such are, the peculiar pre-disposition to certain diseases, or liability of particular organs to disease: the varieties in digestion, in muscular power and motion, in sleep, in the appetites, &c. &c. Some marked peculiarities of constitution are observed to be accompanied with certain external characters, such as a particular colour and texture of the skin, and of the hair, and also with a peculiarity of form and disposition of mind; all of which have been observed from the earliest times, and divided into classes, which have received names, during the prevalence of the humoral pathology, which they still retain, in consequence of the neglect of this important study by modern physicians. See Temperament.

CONSTITUTION, in Political Economy, is frequently used in common language as synonymous with government; but the constitution and the government of a country have different meanings, and are actually distinguished by accurate writers. "By constitution we mean," says lord Bolingbroke, in his "Disquisition on Parties" (Works, vol. ii. p. 130.), "whenever we speak with propriety and exactness, that amalgam of laws, institutions, and customs, derived from certain fixed principles of reason, directed to certain fixed objects of public good, that compose the general system, according to which the community hath agreed to be governed. Whereas by government we mean, whenever we speak in the same manner, that particular tenor of conduct which a chief magistrate, and inferior magistrates under his direction and influence, hold in the direction of public affairs." (See Government.) Constitution, says the same writer, in reference to our own country, is the rule by which our princes ought to govern at all times: government is that by which they actually do govern at any particular time. One may remain immutable; the other may, and as human nature is constituted, must vary. One is the criterion by which we are to try the other; for surely we have a right to do so, since, if we are to live in subjection to the government of our kings, our kings are to govern in subjection to the constitution; and the conformity or non-conformity of their government to it prescribes the measure of our submission to them, according to the principles of the revolution, and of our present settlement, in both of which, though some remote regard was had to blood, yet the preservation of the constitution manifestly determined the community to the choice then made of the persons who should govern. In order further to evince the difference between the constitution and the government of a country, lord Bolingbroke observes that "kings have may have preceded lawgivers, for ought I know, or have possibly been the first lawgivers, and government by will have been established before government by constitution. Theseus might reign at Athens, and Eurytion at Sparta, long before Solon gave laws to one, and Lycurgus to the other of these cities. Kings had governed Rome, we know, and confuls had preceded kings, long before the decemvirs compiled a body of law; and the Saxons had their monarchs before Edgar, though the Saxons laws went under his name." These examples plainly prove, "that however men might submit voluntarily in the primitive simplicity of early ages, or be subjected by conquest to a government without a constitution, yet they were never long in discovering, that (as Hooker observes, Eccle. Pol. i. § 10.) "to live by one man's will became the case of all men's misery," and therefore "they soon rejected the yoke."

or
or made it fit easy on their necks." By the constitution of a country, says archdeacon Paley (Princ. of Moral and Political Philos. vol. ii. chap. 7.), is meant so much of its law, as relates to the designation and form of the legislature; the rights and functions of the several parts of the legislative body; the construction, office, and jurisdiction of courts of justice. Accordingly, the constitution is one principal division; it is the title to the code of public laws; distinguished from the rest only by the inferior importance of the subject of which it treats: and therefore the terms constitutional and unconstitutional, mean legal and illegal. In England the system of public jurisprudence is made up of acts of parliament, of decisions of courts of law, and of immemorial usages: consequently, these are the principles of which the English constitution itself consists; the sources from which all our knowledge of its nature and limitations is to be deduced, and the authorities to which all appeal ought to be made, and by which every constitutional doubt and question can alone be decided. This plain and intelligible definition will serve to discover the error of those writers who absurdly confound what is constitutional with what is expedient, and what is unconstitutional with any measure which they may judge in any respect to be detrimental or dangerous; and also of others, who ascribe a kind of transcendent authority, or mysterious sanctity, to the constitution, as if it were founded in some higher original truth, which gives force and obligation to the ordinary laws and statutes of the realm, or were inviolable on any other account than its intrinsic utility. An act of parliament, in England, can never be unconstitutional, in the strict and proper acceptation of the term; but in a lower sense it may, viz. when it militates with the spirit, contradicts the analogy, or defeats the provision of other laws, made to regulate the form of government. Most of these, says our author, who treat of the British constitution, consider it as a scheme of government formerly planned and contrived by our ancestors, in some certain era of our national history, and as set up in pursuance of such regular plan and design. This is intimated in the expressions of those who speak of the "principles of the constitution," of bringing back the constitution to its "first principles," of referring it to its "original purity," or "primitive model." This, in his opinion, is an erroneous conception of the subject. No such plan was ever formed: consequently no such first principles, original model, or standard exit; that is, as he conceives, there never was a date, or point of original institution, at which the government of England was to be set up anew, and when it was referred to any single person, or assembly, or committee, to frame a charter for the future government of the country; or when a constitution, so prepared and digested, was by common consent received and established. The great charter, and the bill of rights, were wise and laborious efforts to obtain security against certain abuses of regal power; by which the subject had been formerly aggrieved; but these were, either of them, much too partial modifications of the constitution to give it a new original. The constitution of England, like that of most countries in Europe, hath grown out of occasion and emergency; from the fluctuating policy of different ages; from the contentions, successes, interludes, and opportunities of different orders and parties of men in the community. It resembles one of those old manor-houses, which, instead of being built all at once, after a regular plan, and according to the rules of architecture, at present established, has been reared in different ages of the art, has been altered from time to time, and has been continually receiving additions and repairs suited to the taste, fortune, or convenience of its successive proprietors; to such a building we look in vain for the elegance and proportion, for the just order and correspondence of parts, which we expect in a modern edifice; and which external symmetry, after all, contributes much more perhaps to the amusement of the beholder, than the matter of which the building is made.

Some of our approved historians, and political writers, have discovered, as they conceive, the origin of the British constitution in the government of the Anglo-Saxons, brought hither from Germany and the northern countries. To this purpose, it is alleged, that the government of the northern nations, which extinguished themselves on the ruins of Rome, was always extremely free; and that the free constitutions then introduced, however impaired by the encroachments of preceding princes, still preserve an air of independence and legal administration, which distinguish the European nations; and if this part of the globe maintains sentiments of liberty, honour, equity, and valour, superior to the rest of mankind, it is said to have owed these advantages chiefly to the seeds implanted by the generous barbarians of the north. The Saxons who subdued Britain in the 5th century, as they enjoyed great liberty in their own country, obstinately retained that invaluable possession in their new settlement; and they imported into this island the same principles of independence, which they had inherited from their ancestors. The Saxons, as they were early kings, and perhaps more properly than kings or princes, who commanded them in their military expeditions, still possessed a very limited authority; and as the Saxons exterminated, rather than subdued, the ancient inhabitants; they were indeed transplanted into a new territory, but preserved, without alteration, all their civil and military institutions. Their manners and customs were wholly German; and the same picture of a fierce and bold liberty, which is drawn by the masterly pencil of Tacitus, will suit those founders of the English government. The king, so far from being involved with arbitrary power, was only considered as the first among the citizens; and his authority depended more on his personal qualities, than on his station. The Anglo-Saxons, being an independent people, little restrained by law, and cultivated by science, were not very strict in maintaining a regular succession of their princes. Although they paid great regard to the royal family, and ascribed to it an undoubted superiority, they either had no rule, or none that was distinctly observed, in filling the vacant throne; and prefert convenience, in that emergency, was more attended to than form. In other words, however, to suppute, that the crown was considered as altogether elective; and that a regular plan was traced by the constitution for supplying, by the suffrages of the people, every vacancy made by the demise of the first magistrate. All the changes which occurred in the royal succession, and indeed the ordinary administration of government, required the express concurrence, or at least the tacit acquiescence of the people. *The Anglo-Saxon monarchies were not, strictly speaking, either elective or hereditary; and though the deification of a prince might often be followed in appointing his successor, they could not be regarded as wholly testamentary. The rites by which their succession might sometimes establish a sovereign; but they more frequently recognized the person whom they found established. Our knowledge of the Anglo-Saxon history is so imperfect, that it is not easy to ascertain all the prerogatives of the crown and privileges of the people, or to give an exact delineation of that government. It is probable, that the constitution might be somewhat different in the different kingdoms of the HEEPTARCHY, and some occurred, for example, during the course of six centuries, which elapsed from the first invasion of the Saxons, till the Norman conquest. It appears, however, that at all times,
times, and in all the kingdoms, there was a national council, called a wittenagemot, or assembly of the wise men, as the import of those words, and thus was required for enacting laws, and for ratifying the chief acts of public administration. The preambles to all the laws of Ethelbert, Ina, Alfred, Edward the Elder, Athelstan, Edmund, Edgar, Ethelred, and Edward the Confessor; even those to the laws of Canute, though of a kind of conqueror, supply unquestionable proofs every where of a limited and legal government. But who were the constituents, members of this wittenagemot, is a question that has not been determined, in the continuance of antiquity. (See WITTENAGEMOT.) Nevertheless, it is certain, that whatever we may determine concerning the wittenagemot, in whom, with the king, the legislature reposed, the Anglo-Saxon government, in the period preceding the Norman conquest, was become extremely aristocratical; the royal authority was very limited; and the people, even if admitted to that assembly, were deemed of little or no importance and consideration. Upon the whole, notwithstanding the seeming liberty, or rather licentiousness, of the Anglo-Saxons, the great body even of the free citizens, in those ages, really enjoyed much less true liberty, than where the execution of the laws is the most severe, and where subjects are reduced to the strictest subordination and dependence on the civil magistrate. But though the general strain of the Anglo-Saxon government seems to have become aristocratical, there were considerable remains of the ancient democracy, which, though insufficient to protect the lowest of the people, without the patronage of some great lord, might nevertheless give security, and some degree of dignity, to the gentry or inferior nobility. The administration of justice, in particular, by the courts of the deanery, the hundred, and the county, was well calculated to defend general liberty, and to restrain the power of the nobles. The county courts, in particular, where all the freeholders were admitted, formed a wide basis for the government, and furnished considerable checks on the aristocracy. However, the great influence of the lords over their slaves and tenants, the chivalry of theburghers, the total want of a middle class of men, the extent of the monarchy, the loose execution of the laws, and the continued disorders and convulsions of the state, sufficiently evince, that the Anglo-Saxon government became at last extremely aristocratical; and the events, during the period immediately preceding the conquest, confirm this inference or conjecture. If we direct our views to a period much more ancient than that of the establishment of the Anglo-Saxon government, and prior to the invasion of the Romans, we shall find that the governments of the Britons, who were divided into many small nations or tribes, though monarchical, were free, as well as those of all the Celtic nations; and the common people seem to have enjoyed more liberty among them, than among the nations of Gaul, from whom they were defended.

Other writers have maintained, that the government, established by the Anglo-Saxon princes, had little more affinity with the present constitution, than the general relation common indeed to all the governments founded by the northern nations, that of having a king and a body of nobility; and the ancient Saxons government is said to be "left us in flory," (according to the statement of Sir William Temple—Int. to the Hist. of England,) but like to many antique, broken, or defaced pictures, which may still represent something of the costume and fashions of those ages, though little of the true lines, proportions, or resemblance. According to these writers, it is at the era of the conquest, that we are to look for the real foundation of the English constitution. From that period, says Spelman, "novus feclorum nascitur ordo." William of Normandy, it is said, having defeated Harold, and made himself master of the crown, subverted the ancient fabric of the Saxon legislation; he extinguished, or expelled, the former occupiers of lands, in order to distribute their posessions among his followers, and established the feudal system of government, as better adapted to his situation, and indeed the only one of which he possessed a competent idea. A division, however, ought to be made between the government of William 1., which was very tyrannical, and the constitution established under him in the kingdome, which was no absolute monarchy, but an ingratiation of the feudal tenures and other customs of Normandy upon the ancient Saxon laws of Edward the Confessor. He more than once swore to maintain those laws, and in the 4th year of his reign, confirmed them in parliament; yet not without great alterations, to which the whole legislature agreed, by a more complete introduction of the strict feudal law, as it was practised in Normandy.

But that the liberty of the subject was not destroyed by these alterations to the degree which some writers have supposed, plainly appears, says lord Lyttelton, (Hist. Henry 11. vol. 1. p. 59,) by the very statutes which William enacted; in one of which we find an express declaration, "that all the freemen in his kingdom should hold and enjoy their lands and possessions free from all unjust exactions and from all tallage; so that nothing should be exacted or taken of them but their free service, which they by right owed to the crown, and were bound to perform." It is further said, "that this was ordained and granted to them as an hereditary right for ever, by the common council of the kingdom; which very remarkable statute is judically styled by a learned author (Nathaniel Bacon) the first Magna Charta of the Normans; and it extended no less to the English than to the Normans. But it was ill observed by William, who frequently acted as if his will had been the only law to both nations. It must be allowed, that by the interposition of many Mefhe Lords between the crown and the people, and by many offices of judicature and military command being rendered hereditary, which under the Saxons had been either elective, or granted for a short time, the constitution became more aristocratical than before, more unequally balanced, and, in some respects, more oppressive to the inferior orders of freemen. Nor was the condition of the nobles themselves to be envied. For there were certain burthens annexed to their system of fefts, which, as they naturally grew out of that policy, were imposed on the highest vassals as well as on the lowest, and were more grievous than any which the Saxons had borne under their constitution. In process of time the excessive power arrogated and exercised by the king contributed to establish and guard the freedom of the British constitution; because this excess gave rise to the spirit of unity and of concerted resistance. Possessed of extensive domains, the king found himself independent; and vested with the most formidable prerogatives, he cruised at pleasure the most powerful barons in the realm. It was, therefore, only by close and numerous confederacies that those barons could reftift the tyranny of the sovereign; and for this purpose they were constrained to associate the people with themselves, and to render them partakers of public liberty. As acts and inftances of tyranny on the part of the conqueror were multiplied, the confederacies of the barons and of their vassals became more general and more vigorous; and the people at large, instructed and inflamed by their leaders, riangled conditions for themselves, and insisted that, for the future, every individual should be intitled to the protection of the whole.
COnstitution.

The authors, with which the lords had prevailed, in order to oppose the tyranny of the crown, become a bulwark, which was, in time, to restrain their own. It was in the reign of Henry I., about forty years after the conquest, that the operation of these causes produced effect. As the nation had resolved to bfe the crown on a prince, who should acquire and hold it under no other claim than a contract with his people, the title of the king became thus a kind of security for the liberty of the subject. In order to give that liberty a more solid and lasting establishment, they demanded a charter; which Henry granted soon after his coronation, as he had sworn to do before he was crowned. By this he restored the Saxon laws which were in use under Edward the Confessor, with such alterations, or (as he styled them) conditions, as had been made in them by his father with the advice of his parliament; at the same time annulled all civil suffrages, and illegal sanctions, by which the realm had been unjustly oppressed. Some of these grievances were specified in the charter, and the redress of them was there expressly enacted. It also contained very considerable mitigations of those feudal rights claimed by the king over his tenants, and by them over theirs, which were either the most burdensome in their own nature, or had been made so by an abusive extension. In short, all the liberty, that could well be consistent with the safety and interest of the lord in his fief, was allowed to the vassal by this charter, and the profits due to the former were settled according to a determined and moderate rule of law. "This," says Sir Henry Spelman, "was the original of king John's Magna Charta, containing most of the articles of it, either particularly expressed or in general, under the confirmation it gives to the laws of Edward the Confessor." These are therefore much mistaken, who have supposed all the privileges granted in Magna Charta were innovations extorted by the arms of rebels from king John; a notion which seems to have been first taken up, not so much out of ignorance, as from a baseless abuse of adulation to some of our princes in later times, who, endeavouring to grasp at absolute power, were deftions of any pretension to consider those laws, which flowed in their way, as violent encroachments made by the barons on the ancient rights of the crown; whereas they were in reality restitutions and sanctions of ancient rights enjoyed by the nobility and people of England in former reigns; or limitations of powers which the king had illegitimately and arbitrarily stretched beyond their due bounds. In some respects, says Lord Lyttleton, this charter of Henry I. was more advantageous to liberty than Magna Charta itself. Henry II. in a parliament held in London, A.D. 1155, granted a charter of liberties confirming that of his grandfather, Henry I., already mentioned. In consequence of the legal rights established by his excellent prince and the mixture of Saxon customs, which mitigated and tempered the Norman institution, the constitution of England was the best feudal system subsisting at that time, in any part of the world. The honour of establishing in the English constitution itself several judges belongs to Henry II., by whom this institution was revived and regularly settled in the 22d year of his reign, with the advice and concurrence of his parliament held at Northampton. The extension of trials by juries to civil cases may also be well esteemed a principal glory of this reign. Although some vestiges of that method of trial appear among the Anglo-Saxons; yet Spelman says, that the use of trials by 12 men before the conqueror was rare, and did not prevail in any great degree, till the reign of Henry II. (See JURY and Grand Assize.) The debilitated reign of King John excited through the kingdom a general confluence against him and constrained him, A.D. 1215, to sign the famous deed, commonly called the great charter or Magna Charta, which either granted or secured very important liberties and privileges to every order of men in the kingdom; to the clergy, to the barons, and to the people. (See Magna Charta.) This charter, the rigour of the feudal laws was greatly mitigated in favour of the lords; and conditions were also stipulated in favour of the numerous body of the people, who had concurred to obtain it, and who claimed, with sword in hand, share in that security which it was designed to establish. This charter was confirmed in parliament by king Henry III., A.D. 1217, with the addition of some articles to prevent the oppressions by sheriffs; and also with an additional charter of forests. Accordingly, these famous charters have sufficed nearly in their original form, during many generations, as the peculiar favourites of the English nation; and they have been justly esteemed as the most sacred rampart to national liberty and independence. As they secured the rights of all orders of men, they were anxiously defended by all, and became the basis, in a manner, of the English constitution, and a kind of original contract, which both limited the authority of the king, and enforced the conditional allegiance of his subjects. King Edward I. who made it a rule in his own conduct to observe, except on extraordinary occasions, the privileges secured to the barons by the great charter, acquired a right to inflict upon their observance of the same charter towards their valets and inferiors. By the statute (25 Edw. I.) called Confirmatio Charteratum, (the confirmation of which was renewed eleven times in the course of his reign,) he directed the great charter to be allowed as the common law; all judgments contrary to it are declared void; copies of it are ordered to be sent to all cathedral churches, and read twice a year to the people; and mention of excommunication is directed to be as constantly denounced against all who by word, deed, or counsel act contrary to it, or in any degree infringe it. He also, in the statute De Tollagio non Concedendo, (24 Edw. I.) decreed, that no tax should be laid, nor impost levied, without the joint consent of the lords and commons. This important statute, in conjunction with Magna Charta, forms the basis of the English constitution. Under Edward II., the commons, feeling their importance, began to annex petitions to the bills by which they granted subsidies; and this was the dawn of their legislative authority. Under Edward III., they declared they would not, in future, acknowledge any law to which they had not expressly assented. Soon after this, they exercised a privilege, in which consists, at this time, one of the great balances of the constitution: they impeached, and procured to be condemned, some of the first ministers of state. Under Henry IV., they refused to grant subsidies before an answer had been given to their petitions. In a word, the fundamental articles of our free constitution have been affirmed and confirmed by a multitude of statutes, (for Coke is said to reckon thirty-two,) from Edward I. to Henry IV. Then, after a long interval, they were corroborated by the petition of right, which was a parliamentary declaration of the liberties of the people, assented to by king Charles I., in the beginning of his reign. This famous act was soon followed by the still more ample concession made by that unhappy prince to his parliament, before the fatal rupture between them; and by the many salutary laws, particularly the habeas corpus, passed under Charles II. To these succeeded the bill of rights, or declaration delivered by the lords and commons to the prince and princes of Orange, 13th February, 1688; and afterwards enacted in parliament,
CONSTITUTION.

ment, when they became king and queen; which declaration terminates with these remarkable words: 'And they do claim, demand, and inflict upon, all and singular, the premisses, as their undoubted right and liberties.' And the act of parliament itself (W. & M. it. 2. c. 2.) recognizes all and singular the rights and liberties, alleged and claimed in said declaration, to be the true, ancient, and indefeasible rights of the people of this kingdom. 'The Revolution of 1688 may, therefore, be justly deemed the third grand epoch in the history of the English constitution. The great charter had marked out the limits within which the royal authority ought to be confined; some outworks were raised in the reign of Edward I.; but it was at the Revolution that the circumvallation was completed. 'It was at this era,' says De Lomme, 'that the true principles of civil society were distinctly specified and fully established. By the expulsion of a king, who had violated his oath, the doctrine of Resistance, that ultimate resource of an oppressed people, was confirmed beyond a doubt. By the exclusion of a family, heretofore depotist, it was finally determined, that nations are not the property of kings. The principles of Passive Obedience, the divine and indefeasible right of kings; in a word, the whole seculifying of false and superstitious notions, by which the royal authority had till then been supported, fell to the ground; and in the room of it were substituted the more solid and durable foundations of the love of order, and a sense of the necessity of civil government among mankind.' The liberty of the press, the balance and guard of a free constitution, was properly speaking, established four years afterwards, in consequence of the refusal of the parliament to continue any longer the restrictions to which it had before been subject. Finally, the liberties of the British constitution were again asserted at the commencement of the last century, in the act of settlement, (12 & 13 W. III. c. 2.) by which the crown was limited to his present majesty's illustrious house; and some new provisions were added, at the same fortunate era, for better securing our law, religion, and liberties, which the statute declares to be 'the birth-right of the people of England,' according to the ancient doctrine of the common law.

The distinguishing excellence of the British constitution, which has been sometimes called a mixed government, and sometimes a limited monarchy, consists in its being formed by a combination of the three regular species of government, viz. the monarchy, refining in the King; the aristocracy, in the House of Lords; and the democracy or republic being represented by the House of Commons. To this purpose Cicero declares himself of opinion, (in his Fragments, de rep. l. 2.) 'esse optimi constitutum rempublicam, quae ex tribus generibus illis, regali, optimo, et populari, sit mollici confusa.' As the executive power of the laws, in the British constitution, is lodged in a single person, they have all the advantages of strength and dispatch; which are to be found in the most absolute monarchy: and as the legislature of the kingdom is entrusted to three distinct powers, entirely independent of each other; and as this aggregate body, actuated by different springs, and attentive to different interests, composes the British parliament, and has the supreme dispensation of every thing; no inconvenience can be attempted by either of the three branches, which will not, according to the theory of the constitution, be withstood by one of the other two: each branch being armed with a negative power, sufficient to repel any innovation which it shall think inexpedient or dangerous. Whereas, if the supreme power were lodged in any one of the branches separately, we must be expostulated to the inconveniences of either absolute monarchy, aristocracy, or democracy; and to want two of the three principal ingredients of good polity, either virtue, wisdom, or power. If it were lodged in any two of the branches, e. g. in the king and house of lords, our laws might be providently made, and well executed, but they might not have always the good of the people in view: if lodged in the king and commons, we should want that circumvolution and meditatory caution, which the wisdom of the peers is to afford: if the supreme rights of legislature were lodged in the two houses only, and the king had no negative on their proceedings, they might be tempted to encroach upon the royal prerogative, or perhaps to abolish the kingly office, and thereby weaken (if not totally destroy) the strength of the executive power. But the constitutional government of this island is so admirably tempered and compounded, that nothing can endanger or hurt it, but destroying the equilibrium of power between one branch of the legislature and the real. For if events should happen, that the independence of any one of the three should be lost, or that it should become insufficient to the views of the other two, there would soon be an end of our constitution. The legislature would be changed from that, which (upon the supposition of an original contract, either actual or implied) is presumed to have been originally set up, by the general consent and fundamental act of the society: and such a change, however effected, is, according to Mr. Locke, (on Government, part ii. § 212.) who, says judge Blacklem, perhaps carries his theory too far, at once into an entire dislocation of the bands of government; and the people thereby reduced to a state of anarchy, with liberty to constitute to themselves a new legislative power.

Archdeacon Paley, in his discussion of this subject, has flated the expedients by which the British constitution provides for the interest of its subjects, and for its own preservation. With a view to the first of these purposes, it promotes the establishment of salutary public laws, by rendering every citizen of the state capable of becoming a member of the senate, and by investing every senator with the right of the four patricians in the deliberation of the legislature whatever law he pleases. In order to the attainment of this object, it provides such representatives of the people, with respect to their rank, condition, and character, the mode of their election, as well as the publicity and utility of their parliamentary deliberations, as shall be most likely to answer the end of their appointment, and to satisfy their constituents. (See Commons and Parliament.) For preventing depriving the inhabitants of their property, the constitution has committed the executive government to the administration and limited authority of our hereditary king. (See King.) The British constitution has also guarded the safety of the people in the two articles of taxation and punishment by the most judicious precautions. With regard to taxation, this buisness is exclusively referred to the popular part of the constitution, who, it is presumed, will not tax themselves, nor their fellow-subjects, without being first convinced that the aids which they grant are necessary. The application of the public supplies is also watched with the same circumvolution as the affilection. The national expenditure is accounted for in the house of commons, and computations of the charge, appropriated to any particular purpose, are previously submitted to the same tribunal. In the infliction of punishment, the power of the crown, and of the magistrate appointed by the crown, is confined by the most precise limitations: the offender's guilt, being submitted to the judg-
ment of 12 men, of his own order, and the nature and
degree of the punishment being ascertained by fixed laws.
In order to prevent arbitrary or clandestine confinement,
with all its injurious consequences, the constitution has
now fixed every one of these following: The ancient writ of
habeas corpus; the habeas corpus act of Charles II., and
the practice and determinations of our sovereign courts
of justice founded upon these laws, afford a complete remedy
for every conceivable case of illegal imprisonments. (See
these articles; and see also Treason.) The constitution has
also provided for its own preservation, by securing each part
of the legislature in the exercise of the powers assigned to it,
from the encroachment of the other parts. This security is
sometimes called the balance of the constitution; and the
political equilibrium, which this phrase denotes, consists in
two contrivances—a balance of power, and a balance of
interest. By the former is meant, that one part of the
legislature possesses no power, the abuse, or excess of
which it is not checked by some antagonist power residing in
another part. Thus, the power of the two houses of parlia-
ment to frame laws, is checked by the king’s negative;
and, on the other hand, the application of this negative,
checked by the privilege which parliament possess of, refu-
sing supplies of money to the exigencies of the king’s
administration. The constitutional maxim that the king
can do no wrong, is balanced by another maxim, not less
constitutional, that the illegal commands of the king do
not justify those who assist, or concur, in carrying them into
execution; and also, that the acts of the crown acquire
not any legal force, until authenticated by the subscription
of some of its great officers.” In coincidence with this
maxim, we might mention the check which parliament holds
over the administration of public affairs, in the practice of ad-
ressing the king, for the purpose of knowing by whole
advice be resolved upon a particular measure, and of puniting
the authors of that advice for their pernicious counsel.
Again, the power of the crown to direct the military force
of the kingdom, is balanced by the annual necessity of re-
porting to parliament for the maintenance and government
of that force. The prerogative of the king, in declaring
war, is checked by the privilege which the house of commons
possesses, of granting or withholding supplies necessary to
carry it on. The king’s choice of his ministers, is controlled by
the obligation he is under of commanding those men to offices
in the state, who are found capable of managing the affairs
of his government, with the two houses of parliament.

By the balance of interest, which accompanies and gives effi-
cacy to the balance of power, is meant this, that the respective
interests of the three estates of the empire, are so disposed
and adjusted; that whichever of the three shall attempt
any encroachment, the other two shall unite in resisting it.
The exercise of arbitrary power, on the part of the king,
would corrupt the power and privileges of the commons,
deprive their dignity, and endanger their independence.
It would also be no less formidable to the grandeur of the
aristocracy than fatal to the liberty of the republic; as it
would reduce the nobility from their hereditary participation
in the national councils, which constitutes their true great-
ness, to the low and servile state of making a part of the
empty pageantry of a despotic court. On the other hand,
if the commons should entrench upon the crown, the house
of lords, attached to the monarchy which gives them their
distinction, would instantly receive an alarm from every
new extent of popular power. If the nobles themselves
should attempt to revive the superiority, which was exercised
by their ancestors under the feudal constitution, the king
and the people would alike remember how the one had been
insulted, and the other enslaved, by that barbarous tyranny.
And all it should be remembered, that there is a wide dif-
terence between the constitution, or the theory of govern-
ment, and the actual exercise of it, nor should those anoma-
lies, or irregularities, which occur in peculiar circumstances,
or periods of the public administration, be charged on the
constitution itself. It is a well-known, and often cited ob-
server of Montesquieu, in reference to the British con-
stitution, “as all things have an end, the state we are
speaking of (viz. England,) will lose its liberty, and perish.
Having not Rome, Sparta, and Carthage perished? It will
perish when the legislative powers shall be more corrupt than
the executive.” Lyttelton’s Hist. of Hen. ii. Hume’s Hist.
chap. 7. Rapin’s Hist. of Eng. vol. i. Montesqu. Spirit of
Laws, vol. i. b. xi. chap. 6.

CONSTRUCTION, compounded of con, together; and
stringers, to tie or close up; the act of binding, or drawing
the parts of a thing close together.

CONSTRICCTOR CUMNI, in Myology, a name applied
to the sphincter muscle of the vagina. See Generation,
organ of.

CONSTRICCTOR JUHNI SACIUM, one of the muscles be-
longing to the soft palate. See Deglutition.

CONSTRICCTOR NASI. See Compressor.

CONSTRICCTOR ORIS. See Oricularis Oris.

CONSTRUCTORES PHARYNGIS. See Deglu-
tition.

CONSTRUCTION, in Geometry, the art or manner of
drawing, or describing a figure, scheme, the lines of a
problem, or the like. The equality of the lines of such a
triangle, &c. is demonstrated from their construction.

Construction of equations, is the method of reducing
a known equation into lines and figures; whereby the truth
of the rule, canon, or equation, may be demonstrated geo-
metrically. Or, it is the method of finding the roots or
unknown quantities of an equation, by the geometrical
constructions of right lines or curves, according to the
order or rank of the equation. The roots of any equation
may be determined; that is, the equation may be con-
structed of the intersections of a right line with another
right line or curve of the same dimensions with those of the
equation to be constructed; for the roots of the equation are
the ordinates of the curve at the points of intersection with
the right line; and it is well known, that a curve may be cut
by a right line in as many points as its dimensions amount to.
Thus, a simple equation will be constructed by the intersec-
tion of one right line with another: a quadratic equation,
or an affected equation of the second rank, by the inter-
sections of a right line with a circle, or any of the conic
sections, which are lines of the second order, and which may
be cut by the right line in two points, which will give
the two roots of the quadratic equation. A cubic equation
may be constructed by the intersections of the right line with
a line of the third order, &c. &c. But if, instead of the
right line, some other line of a higher order be used; then
the second line, whose intersections with the former are to
determine the roots of the equation, may be taken as
many dimensions lower as the former is taken higher. And,
in general, an equation of any degree may be constructed by
the intersections of two lines whose dimensions, multiplied
together, produce the dimension of the given equation.
Thus, the intersections of a circle with the conic sections,
or of those with each other, will construct the biquadratic
equations or those of the fourth power, because
\[ \sqrt{2} \cdot 2 = 4 \];
and the intersections of the circle or conic sections with a
line
line of the third order, will construct the equations of the fifth and sixth powers, &c. &c. Hence it appears, that the method of constructing equations is different, according to the diversity of equations.

To construct a simple equation. The whole mystery consists in this, that the fractions, to which the unknown quantity is equal, be reduced into proportional terms: the method of which will be better shewn by examples than it can be taught by many rules.

1. Suppose \( x = \frac{ab}{c} \), or \( cx = ab \); then will \( e : a :: b : x \), to be determined by the method of finding a fourth proportional.

2. If \( x = \frac{b^2}{a} \), or \( ax = b' \); then \( a : b :: b : x \), a third proportional to \( a \) and \( b \).

3. Suppose \( x = \frac{a-bb}{b} \); let \( d : a :: b : \frac{a-bb}{b} \). This fourth proportional found, being called \( g \); \( x = \frac{g}{e} \), which is therefore found as in the first case.

4. Suppose \( x = \frac{ab-bb}{a} \), or \( cx = a^2 - b^2 \). Since \( a \) and \( b \); let \( f \) and \( \frac{a+b}{a} \) be \( \frac{ab-bb}{a} \); then will \( af + e = 2ab \); and therefore, \( \frac{a+b}{a} = \frac{ab-bb}{a} \).

Thus is the present case brought to the preceding one.

5. Suppose \( x = \frac{a^2 - b^2}{b} \). Find \( \frac{af}{b} \), and make \( \frac{af}{b} + e = 2b \);

then will \( af + e = 2b \). Hence, \( x = \frac{a^2 - b^2}{b} \).

Consequently, \( b \times x = a^2 - a \times d = a \times -d \); and \( b : a :: x : -d \).

6. Suppose \( x = \frac{a^2 + b^2}{b} \), or \( cx = a^2 + b^2 \). Contrafuct the triangle \( A BC \) (Plate I, Analysis, fig. 8) whose side \( A B = a, \), \( BC = b \), then \( AC = \sqrt{a^2 + b^2} \). Let \( AC = m \);

then will \( a^2 + b^2 = m^2 \). And therefore \( x = \frac{m^2}{c} \); consequently, \( c : m :: m : x \), a third proportional to \( c \) and \( m \).

7. Suppose \( x = \frac{a^2 - b^2}{c} \). On \( AB \) (fig. 9) \( = a \), describe a femicircle, and therein set \( AC = b \). Since the angle \( A C B \) is rectangular; \( CB = \sqrt{a^2 - b^2} \). Let \( CB = m \);

then will \( x = \frac{m^2}{c} \); consequently, \( c : m :: m : x \).

8. Suppose \( x = \frac{a^2 + b^2}{c} \), or \( cx = a^2 + b^2 \). Contrafuct the triangle \( A BC \) (Plate I, Analysis, fig. 8) whose side \( A B = a, \), \( BC = b \), then \( AC = \sqrt{a^2 + b^2} \). Let \( AC = m \);

then will \( a^2 + b^2 = m^2 \). And therefore \( x = \frac{m^2}{c} \); consequently, \( c : m :: m : x \).

9. Suppose \( x = \frac{a^2 - b^2}{c} \). On \( AB \) (fig. 9) \( = a \), describe a femicircle, and therein set \( AC = b \). Since the angle \( A C B \) is rectangular; \( CB = \sqrt{a^2 - b^2} \). Let \( CB = m \);

then will \( x = \frac{m^2}{c} \); consequently, \( c : m :: m : x \).

10. Suppose \( x = \frac{a^2 - b^2}{c} \). Say, \( b : a :: \frac{af}{b} \); and let \( \frac{af}{b} + e = bb \); then will \( b(e + af) = bb \). Hence, \( x = \frac{a^2 - b^2}{b} \).

Find between \( A C = c \) (fig. 10) and \( CB = d \).

Vol. IX.
ture of the parabola, \(y^2 = 2x\), and \(x^3 = \frac{y^4}{b^2} \); substituting therefor these values for \(x^3\) and \(x\), it will be
\[
\frac{y^4}{b^2} \pm \frac{2}{b} \frac{y^2}{b} + \frac{y^2}{b} \pm \frac{2}{b} \frac{d}{d^3} + d^3 - d^3 = 0.
\]
Multiplying by \(b^3\), \(y^4 \pm 2bc + b^2 \times y^2 \pm 2 d b \times y + c^2 + d^2 - d^2 \times b = 0\).
Which may represent any biquadratic equation that wants the second term; since such values may be found for \(a\), \(b\), \(c\), and \(d\), by comparing this with any proposed biquadratic, as to make them coincide. And then the ordinates from the points, \(P\), \(P\), \(P\), \(P\), on the axis will be equal to the roots of that proposed biquadratic. And this may be done, though the parameter of the parabola (viz. \(b\)) is given: that is, if you have a parabola already made up, or given by it alone you may resolve all biquadratic equations, and you will only need to vary the centre of your circle and its radius.

If the circle described from the centre, \(C\), pass through the vertex \(A\), \(\left(\frac{3}{2}, \frac{14}{11}\right)\) then \(CP = CA = CD = AD\), that is, \(a^2 = d^2 + e^2\); and the half term of the biquadratic \((c^2 + d^2 - a^2)\) will vanish; therefore, dividing the term by \(b\), there is the cubic, \(y^3 \pm 2 b c + b^2 \times y \pm 2 d b = 0\).
Let the cubic equation proposed to be resolved be \(y^3 \pm p y \pm q = 0\). Compare the terms of these two equations, and you will have \(p = 2 b c + b^2 = \pm p, \) and \(\pm 2 d b = \pm r, \) or, \(\pm e = \pm \frac{1}{2} \pm \frac{1}{2} b, \) and \(d = \pm \frac{1}{2} \pm \frac{1}{2} b'\).
If you have this construction of the cubic \(y^3 \pm p y \pm q = 0, \) by means of any given parabola \(A P E\).

From the point \(B\) take in the axis (forward, if the equation has \(+p, \) but backwards, if \(p\) is negative) the line \(BD = \frac{p}{b}\), then raise the perpendicular \(DC = \frac{r}{2 b}, \) and from \(C\) describe a circle passing through the vertex \(A,\) meeting the parabola in \(P,\) so that the ordinate \(PM\) be one of the roots of the cubic \(y^3 \pm p y \pm r = 0\).

The ordinates that stand on the same side of the axis with the centre \(C\) are negative or affirmative, according as the half term \(r\) is negative or affirmative; and those ordinates have always contrary signs that stand on different sides of the axis. The roots are found of the same value, only they have contrary signs, when \(r\) is positive as when it is negative; the second term of the equation being wanting.

A cubic equation, that has all its roots equal, may be constructed by a circle. Let the radius \(O B = \frac{1}{\sqrt{3}}\), the line \(EF = r, \) \(GH\) the line of the arc \(O B\) or \(3 B E\).

Then, by trigonometry, \(s \times -\frac{4 s^3}{3} = G H.\) Draw \(C D\) parallel to \(A B,\) and put \(SF = e, \) \(S E = x, \) \(G H = b;\) then \(e + x = r, \) whence \(3 \times e + x = \frac{4}{3} \times \epsilon + x = \frac{3}{2} e;\) and this reduced will give \(x^3 + 3 e x^2 + 3 e x \epsilon + e^3\)
\[-\frac{3}{2} RR + \frac{1}{2} b RR = 0.\]

Suppose this cubic equation to be given; viz. \(e^3 + p \times e^2 + q \times e + r = 0.\) Comparing this with the former, and equating the coefficients, we shall have \(p = 3 e, \) and \(e = \frac{1}{3} \rho, \) also \(q = 3 e \epsilon - \frac{3}{4} R R = \frac{1}{4} \rho p - \frac{3}{4} e R R;\) whence
\[R = \frac{2}{3} \sqrt{p^2 - 9 q}, \text{ and } r = e^2 + \frac{1}{4} b R R - \frac{3}{4} e R R,\] and \(b = \frac{6}{3} (p - q) + \frac{2}{3} p.\) Hence we obtain the following rule for the solution of the given equation \(x^3 + p x^2 + q x + r = 0.\) With the radius \(\frac{2}{3} \sqrt{p^2 - 3 q}\) describe the circle \(B G A K.\) (fig. 16.) Draw the diameter \(A B,\) and \(C D\) parallel to it at the distance of \(\frac{1}{3} \rho;\) above it, if it be \(+ p,\) but below it, if it be \(- p.\)

Draw also \(Z G\) parallel to \(A B,\) at the distance \(\frac{9}{3} \sqrt{p^2 - 3 q} + \frac{2}{3} p,\) above it, if it be affirmative, or below it, if negative. Let it cut the circle in \(G.\)

Take the arc \(B P = \frac{1}{3} \sqrt{G K}, \) and make \(P Q = Q K = K P.\)

From the points \(P, P, K,\) let fall perpendiculars upon the line \(C D,\) which will be the roots of the equation; the affirmative above the line, and the negative below it.

\(N. B.\) If \(p\) be greater than \(p,\) the equation is impossible; for in this case the equation has two impossible roots. Also, if \(p = 0,\) then the radius of the circle \(O B = 2 \sqrt[3]{-3 q}\), and \(C D\) coincides with \(A B;\) and the distance of \(Z G\) from \(A B\) is \(\frac{2}{3}.\)

And if \(q\) be affirmative, the equation is impossible.

These constructions are easy: e.g. 1. Let \(x^3 + 9 x^2 - 22 x = 120 = 0.\)

Here the radius \(O B = \frac{2}{3} \sqrt{p^2 - 3 q} = \frac{2}{3} \sqrt{81 + 66} = 5(3,29),\) and \(1 \rho = 3,\) the distance of \(C D\) above \(A B.\)

And \(\frac{9}{3} \sqrt{p^2 - 3 q} + \frac{2}{3} p = \frac{1}{3} \sqrt{76 + 66} + 2 \times 6 = -6 + 6 = 6 = c,\) the distance of \(G Z\) from \(A B,\) which therefore coincides with it; and the arc \(G B,\) and also its third part is \(c,\) and \(P\) falls on \(B;\) and making \(P Q = Q K = K P,\) and letting fall perpendiculars on \(C D,\) we shall have \(P S = -3,\) \(Q T = +4,\) and \(K T = -10,\) the three roots required.

\(E. G.\) 2. Suppose \(x^3 - 17 x^2 + 82 x - 120 = 0.\)

The radius \(O B = \frac{1}{3} \sqrt{289} - 24 = 4.37; \frac{1}{3} \rho = -5.66,\) the distance of \(C D\) below \(A B,\) and \(\frac{9}{3} \sqrt{p^2 - 3 q}\) \(\frac{p}{p} = 3.37 \sqrt{890 + 1394} - \frac{2}{3} \frac{76}{3} = -4.03,\) the distance of \(G Z\) below \(A B.\)

Take \(B P\) the third part of \(B G,\) and making \(P Q = Q K = K P,\) and measuring the perpendiculars upon \(C D,\) we have \(P S = +4,\) \(Q T = +10,\) and \(K V = +5,\) the roots of the equation.

\(E. G.\) 3. Let \(y^3 - 13 y^2 + 2 y + 13 = 0.\) In this example \(p = 0,\) and therefore \(C D = \frac{1}{3} \sqrt{289} - 24\) coincides with \(A B;\) and the radius \(O B = \frac{2}{3} \sqrt{3 q} = \frac{2}{3} \sqrt{39} = 4.18;\) and \(\frac{3}{3} \sqrt{q} = -36,\) the distance of \(Z G\) above \(A B.\)

Take the arc \(B P = \frac{1}{3} \sqrt{289} - 24,\) the distance of \(G B,\) and make \(P Q = Q K = K P,\) and let fall perpendiculars on \(A B,\) and \(P S = +1,\) \(Q T = +3,\) and \(K V = -4,\) will be the roots required.
CONSTRUCTION.

If the roots of a cubic equation, $x^3 + qx + r = c$, be possible, they may be found by means of a table of coines. Let $DAC$ (fig. 20) be an angle whose whole coine, to the radius $m$, is $x$; in $AD$ take $AB = m$; from $B$, as a centre, with the radius $BA$, describe a circle cutting $AM$ in $C$, and from $C$, with the same radius, describe a circle cutting $AD$ in $D$; join $BC$, $CD$, and draw $BK$, $DM$, at right angles to $AM$ and $CL$ at right angles to $AD$. Then, the triangles $BAC$ and $BDC$ being isosceles, the angles $BAC$ and $BCA$ are equal, as also $CBD$ and $CDB$; and the perpendiculars $BK$, $CL$, bisect the bases $AC$, $BD$. Also, the angle $DBC = BAC + BCA = 2BAC$, and the angle $DCM = CAD + CDA = CAD + CBD = CAD + 2CAD = 3CAD$. Let $CM$, the coine of the angle $DCM$ to the radius $m$, be called $e$; thence, from the similar triangles $ABK$, $ACL$, $AB : AK :: AC : AL$, or $m : x :: 2x^3 = \frac{2}{m}$.

$AI$; and $AL - AB = \frac{2x^3}{m} - m = BL$; hence $AD$, or $AL + BL = \frac{4x^3}{m} - m$.

Again, $AB : AK :: AD : AM$, or $m : x :: \frac{4x^3}{m} - m : \frac{4x^3 - m^2}{m} = \frac{4}{m}$.

Let $AM$, and $AM - AC = CM = 4x^3 - 3m^2 = c$; therefore $4x^3 - 3m^2 = m^2$, and $4x^1 = -3m^2 - m^2 = 0$.

Let the equation $4x^3 - 3m^2 - m^2 = 0$, or $x^3 - \frac{3m^2}{4} = x$ = be made to coincide with the equation $x^3 - q x + r = 0$; that is, let $\frac{3m^2}{4} = q$, and $\frac{m^2}{4} = -r$, or $m = \sqrt{\frac{4q}{3}}$, and $\epsilon = -\frac{3r}{q}$; then, from a table of

colines, find the angle whose whole coine is $\frac{3r}{q}$ to the radius

$\sqrt{\frac{4q}{3}}$, and the coine of one-third of this angle, to the same radius, is one value of $x$. Hence it follows, 1. That if $A$ be the arc whose coine is $x$, and $P$ the whole circumference, $x$ is also the coine of $A + P$, or $A + 2P$; therefore the coines of $\frac{A}{3}$, and $\frac{A}{3} + \frac{A}{2}$, are also values of $x$. 2. Since the radius is greater than the coine, $\sqrt{\frac{4q}{3}}$ is greater than $\frac{3r}{q}$; or $\frac{4q}{3}$ is greater than $\frac{9r^2}{4}$; that is, $\frac{q}{27}$ is greater than $\frac{r}{4}$; therefore this solution can only be applied when the roots of the cubic equations are possible.

Vieta, in his "Canonica Recensione affections geometricarum," and Ghetaldius, in his "Opus poëllumum de Refolutoine et Compositione Mathematica," and also Des Cartes, in his "Geometria," have shown how to construct simple and quadratic equations. Des Cartes has also shown how to construct cubic and biquadratic equations, by the interception of a circle and parallel; and the same has been done by Bcker in his "Chiva Geometrica," or "Geometrical Key." (See the artice Bcker.) But the genuine foundation of all their constructions was balb and explained by Shaffus in his "Molalabrum," page 2. This doctrine is also treated of by De la Hire, in a small treatise, entitled, "La Construction des Equations Analytiques," annexed to his "Conic Sections." Sir Hane Newton, at the end of his "Algebra," has given the construction of cubic and biquadratic equations mechanically; and also by the conchoid and cissoid, as well as the conic sections. See also Dr. Halley's construction of cubic and biquadratic equations, and Colson's in the Philosophical Transact.; the Marquis de l'Hospital "Tracte Analytique des Sections Cylindriques," lib. iv.; and Maclaurin's "Algebra," part ii. chap. 3. However, the intent of these geometrical constructions is more readily answered by the method of extracting roots by converging series and approximation; and therefore this mode of obtaining them is very much like the

CONSTRUCTION, or Syntax, in Grammar, denotes the arranging and connecting of the words of a sentence, according to the rules of the language. See Syntax.

The construction is generally more simple, easy, and direct, in the modern tongues than in the ancient: we have very few of those inversions which occasion so much embarrassment and obscurity in the Latin; our thoughts are usually delivered in the same order in which the imagination conceives them: the nominative case, for instance, always precedes the verb, and the verb goes before the oblique cases it governs.

The Greeks and Latins, M. St. Evremont observes, usually end their periods, where, in good sense and fiction, they should have begun them; and the elegance of their language conflicts, in some measure, in this capricious arrangement, or rather in this transposidal disorder of the words.

Construction is either simple or figurative. Simple, is that wherein all the terms, or parts of the discourse, are placed in their natural order.

Figurative construction, is that wherein we recede from this simplicity, and use certain expressions, shorter, and more elegant than nature affords.

The syntax, or construction of words, is distinguished into two parts, concord and government, or regimen.

Construction of deeds and wills, in Latin, is regulated by aforesaid rules and maxims, which have been laid down by courts of justice. These are, 1. That the construction be favourable, and as near the minds and apparent intents of the parties, as the rules of law will admit. For the maxims of law are, that "verba intentioni debent interire," and "benigne interpretans certat propter simpliciitatem laicorum." And therefore the construction must also be reasonable, and agreeable to common understanding.

2. That "quoties in verbis nulla est arbitriata; ibi nulla expostio contra verba fraudula est;" but that where the intention is clear, too minute a fire be not laid on the firest and precise signification of words: "nun qui heret in litteris, heret in cortice." Therefore, by a grant of a remainder a reversion may well pass, and be conveyed. Another maxim of law is, that "nulla grammarica non vivat chartam," neither false English nor false Latin will delivcr a deed. 3. That the construction be made upon the entire deed, and not merely upon disjointed parts of it. "Nan ex antecedentibus et consequentibus fit optimam interpretation." And therefore that every part of it be (if possible) made to effect, and no word but what may operate in some shape or other. "Nam verba debent intelligi eum effici; ut res magis valscat quam placeat." 4. That the deed be taken most strongly against him that is the agent or contractor, and in favour of the other party. "Verba furtiis accipiuntur contra proferentem." As, if tenant in fee-simple grants to any one an estate for life, generally, it shall be construed an estate for the life of the grantee. 5. That, if the words will bear two senses, one agreeable to, and another
other against law, that sense be preferred which is most agreeable to it. As, if tenant in tail lets a lease to have and to hold during life generally, it shall be construed to be a lease for his own life only, for that stands with the law; and not for the life of the lessee, which is beyond his power to grant. 6. That, if there be in a deed two clauses to totally repugnant to each other, that they cannot stand together, the first shall be received, and the latter rejected. In this respect it differs from a will: for there, of two such repugnant clauses the latter shall stand. In both cases, however, we should endeavour to reconcile them. 7. That a device be most favourably expounded, to pursue if possible the will of the devisor, who, for want of advice or learning, may have omitted the legal or proper phrasal. Hence the law often dispenses with the want of words in devises, that are absolutely requisite in all other instruments. Thus, a fee may be conveyed without words of inheritance; and an estate-tail without words of procreation. By a will also an estate may pass by mere implication, without any express words to direct its course. With regard to a will, in this respect, there is no distinction between the rules of law and of equity: for the will, being considered in both courts in the light of a limitation of uses, is construed in each with equal favour and benignity, and expounded rather on its own particular circumstances, than by any general rules of positive law. Blackltf. Comm. b. ii. ch. 23.

**Construction of Statutes.** Comprehends the following rules: 1. In the construction of remedial statutes there are three points which require consideration, viz. the old law, the mischief, and the remedy; that is, how the common law stood at the making of the act: what the mischief was, for which the common law did not provide; and what remedy the parliament hath provided to cure this mischief. And it is the business of the judge to construe the act, as to suppress the mischief and advance the remedy. An influence may be specified in the prefatory flat of 15 Eliz. c. 10. By the common law, ecclesiastical corporations might let as long leases as they thought proper; the mischief was, that they let long and unreasonable leases, to the impoverishment of their successors: the remedy applied by the statute was the making void all leases by ecclesiastical bodies for longer terms than three lives, or 21 years. In the construction of this statute, it is held, that leases, though for a longer term, if made by a bishop, are not void during the bishop's continuance in his see; or, if made by a dean and chapter, they are not void during the continuance of the dean: for the act was made for the benefit and protection of the successor. The mischief is, therefore, sufficiently suppressed, by vacating them after the determination of the interdict of the grantor; but the leases, during their continuance, being not within the mischief, are not within the remedy. 2. A statute, which treats of things or persons of an inferior rank, cannot, by any general words, be extended to those of a superior. Thus, a statute, treating of "deans, prebendaries, parsons, vicars, and others having spiritual promotion," is held not to extend to bishops, though they have spiritual promotion: deans being the highest persons named, and bishops being of a still higher order. 3. Penal statutes must be construed strictly. Thus, by the statute 14 Geo. II. c. 6, feeding sheep, or other cattle, was made felony, by benefit of clergy: but other cattle being considered as too loose an explication for creating a capital offence, the act was held to extend to nothing but mere sheep. In the next sessions it was therefore found necessary to make another statute, 15 Geo. II. c. 34, extending the former to bulls, calves, oxen, fers, bullocks, beavers, calves, and lambs, by name. 4. Statutes against frauds are to be liberally and beneficially expounded. 5. One part of a statute must be to confided by another, that the whole may (if possible) stand: "ut re magis valesit quam perceat." As if land be vested in the king and his heirs by act of parliament, saving the right of A.; and A. has at that time a lease of it for three years; here A. shall hold it for his term of three years, and afterwards it shall go to the king. 6. A saving, totally repugnant to the body of the act, is void. If, therefore, an act of parliament vests land in the king and his heirs, saving the right of all persons whomsoever, or vests the land in A. in the king, saving the right of A.: in either of these cases the saving is totally repugnant to the body of the statute, and (if good) would render the statute of no effect or operation; and therefore the saving is void, and the land vests absolutely in the king. 7. Where the common law and a statute differ, the common law gives place to the statute; and an old statute gives place to a new one: and this upon a general principle of universal law that "leges posteriores priores contrarias abrogant," by conformation to which it was laid down by a law of the Twelve Tables at Rome, that "quod populus peregrinum juit, id jus ronu efo." This is to be understood only when the latter statute is couched in negative terms, or where its matter is to clearly repugnant, that it necessarily implies a negative. But if both acts be merciful affirmative, and the substantive such that both may stand together, here the latter does not repeal the former, but they shall both have a concurrent efficacy. 8. If a statute, that repeals another, is itself afterwards repealed, the first statute is hereby revived, without any formal words for that purpose. 9. Acts of parliament, derogatory from the power of subsequent parliaments, bind not. 10. Acts of parliament, that are impossible to be performed, are of no validity; and if out of them arise collateral any absurd consequences, manifestly contradictory to common reason, they are, with regard to those collateral consequences, void. Some have laid down this rule more largely, alleging that acts of parliament, contrary to reason, are void. We may further observe, that equity is frequently called in to aid, to moderate, and to explain positive laws. Nevertheless, our courts of equity are only conversant in matters of property. For the freedom of our constitution will not allow, that in criminal cases a power should be lodged in any judge, to confute the law otherwise than according to the letter. This caution, while it admirably protects the public liberty, can never bear hard upon individuals. A man cannot suffer more punishment than the law assigns, but he may suffer less. The laws cannot be strained by partiality to inflict a penalty beyond what the letter will warrant; but in cases where the letter induces any apparent hardship, the crown has the power to pardon. Blackltf. Com. vol. i. Intro. § 3.

**Construction Military.** This term, in its general and unlimited acceptance, extends to the constructing of every sort of military work. But it is commonly and peculiarly applied to the constructing of the different parts of the various systems of fortification that have been delivered by writers on the subject in different nations and languages. And to this application of it we shall chiefly attend.

Fear and necessity must have first given rise to works of defence or fortification, of which the object originally was safety or security. And although there must have been quarrels ever since there have been men, we have every reason to suppose that the erection of works of defence, even of the simplest kind, were frequent to the fishing and hunting flate of society, and even in a great measure to that of the pastoral.
CONSTRUCTION.

The discovery of America, which exhibited men in a much simpler state of society than any that was recorded prior to that event in history, faced or prefaced, afforded to specimens or traces of such works among tribes who had not formed some sort of villages, and become partly, at least stationary, by paying some attention to agriculture. The form and structure of works of defence, varied gradually with the means and the modes of attacking them. At first, a simple row of pickets, or a ditch, with that addition, was deemed sufficient. Afterwards, in woody countries (and all countries have been more or less covered with woods) an enceinte or enclosure of solid timber was made use of. Sometimes the walls round towns were raised with beams, earth, and stones. This mode of erecting them appears to have prevailed among the Gauls, in the time of Julius Cæsar, who, in the 23d chapter or section of his seventh book, "De Bello Gallico," expresses himself on the subject in the following words:

"Maris autem omnibus Gallicis haec fere forma eft. Tabulas directe perpetuas in longitudinum, paribus intervallis, diftantes inter le binos pedes, in fabulo collonctrur. Exe revinctur introitus, et multum aggeri velituri. Ea autem, quae diximus intervala grandibus in fronte lexius efficurunt. Quæ collocantur et augmentantur, alius insuper erit ad niediam inter idem intervallum tertiam, neque inter fer tantum tabulas, sed paribus intermedia spatia singulae singuli facris, interjectis arte continue, neque deinceps omne opus constantur dum quæ muri alto, latitudine explicantur. Hoc quum in græce variatatem opus deformare non eft, alterius tabulæ aut facris, quæ recta lineæ suo ordine servent, tum ad utilitatem et defendentem urbium summam habet opportunitatem, quod et ab incendio laps, et ad ariete maliadavendi defendit, quæ perpetuos tabulæ pedes quadragesimos, per quam introitus revincta, neque purrumpi neque dilrabi potest."
CONSTRUCTION.

D B M, are each of them equal to a right one, or 90 degrees. The angles of the epaules or shoulders A C E, B D F, are also each of them equal to a right angle. The angle diminished A F G, or B E H, or the angle A B E, or B A F, formed by the exterior side, and either line of defence being equal to the difference between 60 and 45 degrees, is of course equal to 15 degrees. The angle C E F, or D F E of the flank, is equal to 75 degrees, and the flanking angle C N D, is equal to 150 degrees. But since the angle C A E, which is half the flanked angle, or angle of the battalion, is equal to 45 degrees, and is by construction bisected by the right line A E, each of the angles C A E, E A C is equal to 22° 30'. And the angle A E C, the complement of C A E to 90°, is consequently equal to 67° 30'. The angle A E G is therefore equal to 37° 30', the angle A E F to 142° 30', the angle A G F to 130 degrees, and the angle E A B to 37° 30'. Also the angle A E B is equal to 127° 30'.

Thus then all the necessary angles are known for calculating the different parts of the construction. For the exterior side A B being given, the line of defence A F or B E is easily found by means of the triangle A F B, or the triangle A E B, by the following analogies.

As the sine of the angle A F B

Is to the sine of the angle A B F,

So is the site A B

To the side A F.

As the sine of the angle A E B

Is to the sine of the angle B A E,

So is the exterior side A B

To the line of defence B E.

And the right line A E, or its equal B F, is found by the following analogy.

As the sine of the angle A E B

Is to the sine of the angle A B E,

So is the right line A E, or its equal B F

To the site A B.

And as the angle A C E is a right one, we get the face A C of the battalion, and the flank C E, by means of A E, and the following analogies.

As radius

Is to the sine of the angle A E C,

So is the right line A E, or its equal B F,

To A C, the face of the battalion, or its equal B D.

And

As radius

Is to the sine of the angle C A E,

So is the right line A E, or its equal B F,

To the flank C E, or its equal D F.

The perpendicular to the exterior side A B, or the rectilinear distance from the middle of it, to the point N, the intersection of the ravel lines, or lines of defence, is determined by this analogy.

As radius

Is to the tangent of the angle B A N, or A B N,

So is half the exterior A B

To the perpendicular distance from the middle thereof, to the point N.

By means of the flank, the curtain is found by the following analogy.

As radius

Is to the secant of the angle C E F, or D F E,

So is the flank C E, or D F,

To the curtain E F.

And the capital A G of the battalion is found by this analogy.

As the sine of the angle A C E

Is to the sine of the angle A E G,

So is the right line A E

To the capital A G of the battalion.

In like manner, the demi-gorge E G, or F H, is found by the following analogy.

As the sine of the angle A G E

Is to the sine of the angle A E G,

So is the right line A E, or its equal B F

To the demi-gorge G E, or its equal F H.

The calculation of these different parts will be similar when the flank is perpendicular to the curtain, instead of the lines of defence as in polygons above an octagon, which is effected by taking the right lines N C, N D, equal, respectively, to the lines N E, N F. The flanks then are longer and better.

This author affirms no reason drawn either from the nature of the polygons, or their capability of being embraced or defended for the length of his perpendicular or the magnitude of the angle formed by an exterior side, and a line of defence. And, as in all polygons, from the hexagon upwards, the flanked angle or flank of the battalion, is the same, or equal to 90 degrees; his construction in all polygons, above an octagon, gives this perpendicular or angle much greater than it ought to be. Thus, in a decagon, it gives this angle equal to \[\frac{180° - 126° - 90°}{2} = 27°\]; whereas, it ought but very little to exceed 25°. And this construction on part of a right line, which may be regarded as a polygon of an infinite or rather indefinite number of sides, gives this angle equal to 45 degrees, and the flanking angles formed by the intersections of the lines of defence, equal each to 100 degrees. The lines of defence in this case exactly correspond with Montalbant's construction in his "Fortification Perpendiculaire."

As in this construction the angle diminished, or the angle formed by an exterior side and a line of defence increases half in magnitude, as the number of the sides of the polygon increases, being in the decagon twice as great as it is in the hexagon, the lengths of the curtains decrease and the faces of the battlements increase greatly beyond their just proportions, which is a material defect; since the faces, which are the weakest parts, being defended respectively, only on one side by a single flank, are thereby augmented, and the curtains, which are the strongest, being defended each on both sides, or by two flanks, are diminished.

His mode of placing the flanks in figures up to the octagon inclusive at right angles to the lines of defence, and in other polygons perpendicular to the curtains, though it certainly secures them well against the enemies' batteries, and renders them fit for defending the gates and curtains, (which, however, by their nearness to the flanks, are naturally beink fired), does not enable them to discover the enemy's batteries sufficiently to defend the counterflaps, and prevent them from advancing their works to it, a circumstance which affords great advantage to the besiegers. And if orillons be made in flanks, so placed, the covered flanks would be so hid, that they could scarcely see the ditch throughout its whole width, and the merlons from their angles towards the field being very acute, would easily be ruined by the enemy's batteries and rendered useless. Flanks ought to be placed perpendicularly,
CONSTRUCTION.

pendicularly, or at least very nearly so to the lines of defence. For when an enemy once makes a lodgment on the counterfearp, he will discover them whether they be so placed or not. And if flanks be discovered, they also discover, and being either revetted or demi-reveted and formed of earth that is well fettled, they are by no means so easily ruined as the batteries of the besiegers, which are formed of gabions and newly raised earth.

Count Pagan's method of construction on a polygon, (fig. 2.) is widely different from that of Errard, and also much preferable. For instead of making the angle of the flank acute in the octagon and figures of a smaller number of sides, it is only equal to a right one in any polygon of a greater number of sides, as Errard does, he makes it obtuse and places his flanks perpendicularly to the lines of defence, in order that they may discover more ground, and the better rafe and defend the faces of the bastions, which are the most faulant and weakest parts of the body of the place and are first attacked, breaches being commonly made in them. This ingenious author makes his lines of defence like Errard's, always faulant, but does not like him make 90 degrees the maximum of his flanked angle, or angle of his baftion.

He delivers constructions for three sorts of fortifications, namely, the great, the mean, and the little. He fortifies or constructs inwards, and in the great fortification makes the exterior side equal to 200 toises, in the mean equal to 180 toises, and in the little equal to 160 toises. He allows 60 toises to each face of a baftion in the great, 55 in the mean, and 50 in the little, in all figures above a square. He makes the perpendicular to the exterior side in the great fortification in all figures, except the figure where it is 27 toises, equal to 30 toises; in the mean equal to 24 toises; and in the little equal to 21.

The dimensions of these principal lines in these three kinds of fortification, are contained in the following Table.

<table>
<thead>
<tr>
<th>Great Fortification.</th>
<th>Mean.</th>
<th>Little.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In all other Polygons.</td>
<td>In all other Polygons.</td>

<td>200</td>
<td>180</td>
</tr>
<tr>
<td>Perpendiculars</td>
<td>27</td>
<td>24</td>
</tr>
<tr>
<td>Faces of bastions</td>
<td>60</td>
<td>55</td>
</tr>
</tbody>
</table>

Supposing then the exterior side A B, (see the figure,) equal to 200 toises in the great, to 180 in the mean, and to 160 in the little, biffect it in the point C. In C, which is perpendicular to A B, take C D equal to 50 toises, in all regular figures of a greater number of sides than four. Through the point D, draw the lines of defence A D H, B D G, on which take A E and B F, each equal to 60 toises in the great fortification, to 55 in the mean, and to 50 in the little. Then draw the flanks E G, F H, perpendicularly to the raft lines or lines of defence B G, A H, and form the curtain by joining the points G, H. This is Count Pagan's construction, without orisons and retired flanks.

The figure is a regular hexagon, supposed to have each of its sides equal to 180 toises, as in his mean fortification. The angle A O B of the centre is therefore equal to 60 degrees, and the angle of the polygon to 120. A C, or B C, is equal to 90 toises, the perpendicular C D is equal to 30, and the face A E, or B F, to 55 by construction.

Now by means of these lines and angles, the others are eas-

fily found. And in the first place, the angle diminui C A D, or the angle formed by the exterior side A P, and the line of defence A H, is formed by the following analogy.

As A C, equal to 50 toises, is to C D, equal to 30 toises, 
So is radius 
To the tangent of the angle C A D = 18° 26' 6" very nearly. If this angle be taken from 60 degrees, half the angle of the polygon, we get the angle O A H, or M A E, equal to 41° 33' 54". But this is equal to half the Jallant angle of the baflion, wherefore the whole flanked angle or angle of the baflion is equal to 83° 7' 48". And the flanking angle A D B, being equal to the excess of 180 degrees above twice the angle diminui, is evidently equal to 143° 7' 48".

The tenaille A D, being equal to \(\sqrt{A C + C D} \), is = \(\sqrt{50 + 30} \approx 9.779798552 \), nearly. Or it is found by this analogy.

As radius 
Is to the tangent of the angle diminui C A D, 
So is A C, half the exterior side A B, 
To the tenaille A D.

If from this there be taken the face A E, which is equal by construction to 35 toises, we get the right line D E, and the following analogy for the flank E G.

As radius 
Is to the line of double the angle diminui C A D, 
So is the right line D E 
To the flank E G.

And as the angle E G of the epaule or shoulder is always, in regular construction, equal to twice the angle diminui C A D, and the angle E G B formed by the flank and line of defence, the angle D E G is known, and D G is ascertained by the following analogy.

As radius 
Is to the line of the angle D E G, 
So is the right line D E 
To the right line D G.

The angle E G H of the flank, is in this construction equal to 90 degrees, together with the angle diminui, or the angle formed by the exterior side, and one of the lines of defence.

The complement, D G, or D H, being thus found, the curtain G H is ascertained by the following analogy.

As the line of the angle diminui D G H 
Is to the line of double the said angle, 
So is the complement D G 
To the curtain G H.

The lengthened curtain M H, or G N, is determined by the following analogy.

As the line of half the angle of the polygon 
Is to the line of half the flanked angle, 
So is the raftant line, or line of defence A H, 
To the lengthened curtain M H. From which, and the curtain G H, the inward or interior side M N is immediately obtained.

And the capital A M is ascertained by this analogy.

As the line of half the angle of the polygon 
Is to the line of the angle diminui, 
So is the raftant line, or line of defence A H, 
To the capital A M of the baflion.

It is manifest from the foregoing table, that the perpendicular in this learned and judicious author's great fortification, subfends in the square an angle of about 15° 6' 54" nearly, and in all other regular figures of about 16° 41' 57" nearly; that in his mean fortification it subfends in the square an angle of about
CONSTRUCTION.

about 14° 15' 4", and in all other regular figures an angle of about 15° 27' 6'; and that in his late fortification, it subtended in the square an angle of about 14° 44' 30", and in all other regular figures about 15° 33' 22".

For his extremities or retired batteries and oriollons, he builds his flanks, leaving one-half of each adjoining the epaule or shoulder for the orillon. The first flanks or battery on the other half is retired five octaves behind the orillon, and is two octaves above the level of the ditch; the second is retired seven octaves within the flanks, and is four octaves above the level of the ditch; and the third is retired seven octaves behind the second, and is six octaves above the level of the ditch, being as high as the rampart, which is three octaves above the level of the field, or terre-plain of the place, as the bottom of the ditch is three octaves below it. These are formed by continuing the lines of defence into the bastions, and drawing lines parallel to these continuations from the points bisecting the flanks.

He makes within each of his bastions a sort of smaller ba- 

tion, or a cavalier in the form of one, having its faces parallel to those of the bastion and 13 octaves distant from them, which serves as a retrenchment. The great ditch is 16 octaves wide, and its counter-carp is parallel to the faces of the bastions or to the lines of defence. The capital of each of the ravelins, which he places on the re-entering angles of the counter-carp in such a manner as to be defended by the faces of the bastions and the counter-guards before them, is equal to 30 octaves, and its faces are drawn to the flanks. The demi-gorges of the redoubt within the ravelin are each equal to 15 octaves, and the faces of it are parallel to those of the ravelin itself. The ditch of the ravelin is 12 octaves wide, and that of the redoubt 6. The solutio angle of each counter-guard is 40 octaves distant from that of the bastion which it covers, and this work is from 9 to 10 octaves broad at its extremities. The ditch before it is 12 octaves wide. The covert-way is 4 octaves wide, and the faces of the places of arms are each 8 octaves long, and parallel to the opposite counter-carp.

The flanks, curtain, and other lines in this construction found above by means of lines, tangents, and secants, may be ascertained without any logarithmic table, in the following manner.

Since the tenaille A D is $= 10 \times 90$ toises $= 90 \times 10$ toises, and A C is $= 90$ toises, by hypothesis, and C D is $= 30$ toises, by construction, or $= \frac{1}{3}$, we have A D : A C :: $\sqrt{\frac{10}{3}} : 3$, and A D : C D :: $\sqrt{\frac{10}{3}} : 1$. But A D : A C :: A E (57 toises by construction) : the exciss of A C above one half of E F, which exciss is therefore equal to $\frac{1}{3} \times \frac{35}{\sqrt{10}}$ toises, and its double, which is the exciss of A B above E F, is of course equal to $\frac{320}{\sqrt{10}}$ toises, or to $32 \sqrt{10}$ toises; consequently E F is equal to $180 - 32 \sqrt{10}$ toises; but A D : C D :: E F : $\tilde{H}$ H, and A D : A C :: E F : E H; therefore the flank F H is equal to $180 - 32 \sqrt{10}$ toises $= 18\sqrt{10} - 33$ toises; and E H is equal to $\frac{540 - 99 \sqrt{10}}{\sqrt{10}}$ toises $= 54 \sqrt{10} - 99$ toises. And since E D is $= A D - A E = 30 \times 10 - 55$ toises; we get D H equal to $24 \sqrt{10} - 44$ toises. But A D : A B :: D H : G H, which is therefore equal to $\frac{144 \sqrt{10} - 264}{\sqrt{10}}$ toises; and D I, which is equal to a sixth part of G H is equal to $\frac{24 \sqrt{10} - 44}{\sqrt{10}}$ toises.

Consequently C I is equal to $\frac{54 \sqrt{10} - 44}{\sqrt{10}}$ toises. And C G

: C I :: O A : the capital A M of the bastion. Count Pagans's flank, in his mean fortification, being to the perpendicular, as $18 \times \frac{10}{10} = 30$, is upwards of 3 toises less than it, which is certainly too great a difference.

This learned and judicious author, whom the principal fortifiers since his time, particularly Vauban, have very much followed, considering that the flanks, ramparts, and ditches, were the works that contributed most powerfully towards the defence of the body of a place, and the retarding of the approaches of an enemy to it, made the demi-gorges of his bastions large, in order to have three flanks or batteries on each of them, sufficiently long for placing four pieces of cannon in, respectively. Three of these, in each of the said three flanks, are, by his construction, so well covered from the counter-batteries of the besiegers, that they cannot easily be damaged by them. And the besiegers, on approaching the breaches, and attempting to make lodgments in the ruins of them, must suffer greatly from the guns so covered in those retired flanks, as they are then fired on by them, de revers, or in the rear.

Though his division of fortification, into great, mean, and little, seems not to be of much use, or moment, he must certainly be allowed to be the first writer on the subject that gave the true position to his flanks, making them perpendicular to the lines of defence. His mean fortification appears to be preferable to the great, as it does not make the lines of defence too long for musquete-shot. The position of the flanks, and great length, he gives to the faces of his bastions, render his demi-gorges long enough to afford a sufficiency of room for his retired flanks.

The two ditches, with the two ramparts, that he makes, are well calculated for obstructing and retarding the enemies' passage of the ditch, for depriving them of the use of fourneaux, and for preventing them from lodging themselves on the ruins of the breaches. For when the besiegers have even passed the main ditch, and taken the first rampart, they will find themselves exposed in the second ditch to the besiegers's fire on all sides, and liable to be destroyed by shells, hand-grenades, fourneaux, mines, &c.

By giving one-half of his flank to the orillon, he covers his retired batteries extremely well. The ditch is very well defended from the flanks, which being perpendicular to the lines of defence, look fully along the faces of the opposite bastions.

It must be observed, however, that though the position of his flanks be good, they are too small, particularly in polygons of a considerable number of sides, being a good deal shorter than the perpendiculars to the exterior sides; whereas they should be equal, or nearly equal to them, as perpendiculars to the exterior sides of polygons were first introduced into construction for the sole purpose of obtaining flanking defences. This is in a great measure occasioned by his making the faces of his bastions too long, which he was probably led to do from a desire of obtaining three retired batteries in each flank. The face of the bastion is equal to the $\frac{1}{3}$th part of the exterior side, whereas it may with confidence be asserted, that it ought not to exceed a fourth. For the faces of the bastions are most fiant, and consequently the tenderest part of the body of the place. They are always first attacked, and in them the breaches are constantly made. But when they are very long, the besiegers

311
can make large breaches in them, which is a great advantage to them, and a no less disadvantage to the besieged.

The retrenched bastion, or redoubt in form, of one within the bastion, must inconvenience the expense at least one-third. The ditch before it is but ill defended, and as there are tenailles for that purpose. And as it is hollow or empty, it may be taken as easy as the main bastion, by means of a second mine, and thereby occasion the loss of the place, especially as no retrenchment can be raised within to enable the besieged to capitulate with more advantage.

His retired flanks, or batteries, appear to be too near to one another, being only seven toises distant from outline to outline. He makes no traverses. But this cannot be imputed to him as either an oversight or fault, as firing en ricochet was not known in his time. By giving the same length of perpendicular to the exterior sides of all figures of a greater number of sides than four, he makes the flanked angle, or angle of the baflion in a polygon of a considerable number of sides, very obtuse. This angle begins to become obtuse in the hexagon, and by his construction on part of a right line, it is no less an angle than one of 145° 4' 48'. He assigns no reason whatsoever for the length of his perpendicular, derived from the properties of different polygons, or their relative degree of importance and capability of defence, nor for giving the same perpendicular in all regular figures of a greater number of sides than four. His perpendiculars are mere arbitrary assumptions, like those of all other authors, who have written on fortification since his time. The truth however is, that every regular figure has a perpendicular of its own, which is different from that of any other, of a precise and determinate length, and bearing a given ratio to the exterior side.

Mr. Blondel's method of construction is as follows:

Like Count Pagan he fortifies inwards, but instead of the perpendicular he begins with the angle diminué, or the angle formed by an exterior side, and a line of defence. This angle is determined by taking a right angle, or 90 degrees from the angle of the polygon, and adding 15 degrees to a third part of the remainder. Thus, if \( n \) denote the number of the sides of a regular figure, the angle of the polygon, or the angle contained by two of its sides, will be equal to 180° - \( \frac{360°}{n} \), and his angle diminué will of course be equal to 30° - \( \frac{120°}{n} + 15° \) or 45° - \( \frac{120°}{n} \), which gives 15° for it in the square, 21° in the pentagon, 25° in a hexagon, and in his construction on part of a right line 4° 5', which then makes the perpendicular equal to half the exterior side. This expression for his angle diminué, as is evident by inspection, is always equal to the excess of 45° above \( \frac{120°}{n} \) divided by the number of the sides of the figure; whereas it is always found without any reference whatsoever to the angle of the polygon, by dividing \( 120° \) by the number of the sides of the figure, and subtracting the quotient from 45°. And since the angle of the centre, or the angle subtended by one of the sides of the figure, is equal to \( \frac{360°}{n} \), this angle diminué is had by taking from 45 degrees a third part of the angle of the centre.

His angle diminué gives the angle of the baflion, or flanked angle, in a square equal to 60 degrees, in a pentagon equal to 66 degrees, in a hexagon equal to 70 degrees, and in a construction on part of a right line equal to 90 degrees.

The flanked angle, or the angle formed by the lines of

Vol. IX.
tant from the counterfearp, which distance therefore forms its ditch. The principal object in erecting this counter-guard is to conceal from the enemy's view the low flanks opposite to it, whilst its narrowness or small breadth puts it out of his power to place his guns in after he has taken it.

The salient angle of his ravelin is determined by the intersection of two arcs, described from the shoulders of the two adjoining bastions, with a radius equal to the distance between them. Its face produced meets those of the bastions about 6 toises from the shoulders and are bounded on the lines or faces of the counter-guards produced, which also determine the gorge of the ravelin.

The ditch of the ravelin is from 10 to 12 toises broad, and that it may be the better defended, Mr. Blondel takes, in the face of the bastion, a space equal to this breadth, commencing six toises from the shoulder, in which he makes a low battery of 1 or 5 feet high, and another on the inside of the same height with the parapet of the place, and retired about 9 toises within the face.

The ditch before the counter-guards is 10 toises broad. The ravelin not only covers the shoulders and the outworks of each bastion, but likewise defends the ditch of the counter-guard, as he takes as much of its face as is sufficient for seeing or discovering all that to make two batteries in, viz. a low one and a high one in the same manner as he does in the faces of the bastions. He allows no more terre-plain in the ravelin, than is just enough for the recoiling of his guns, leaving all the rest of its inside empty for the purpose of being able easily to countermine the rampart, and to prevent the enemy from making a lodgment in it, after he may have forced it.

The better to cover the batteries in the face of each bastion, which defend the ditch of the ravelin, he adds in the angles of the counterfearp of the ravelin *lunette*, in the form of lozenges, allowing 20 toises for the semi-gorge in each. These have their faces parallel to the counterfearps of the 4 toises before the ravelin and counter-guard, and the ditch before them 8 toises broad.

The author likewise makes a *lunette* in his great ditch from 7 to 9 toises broad, which he carries quite round the work to prevent the low flanks, which would otherwise easily accessible, from being got at. A smaller or narrower *lunette* might also be made in the ditches of the outworks, particularly when there are batteries in the demi-lunes or ravelins.

The calculations for the angles and lines of a construction on the sides of a polygon, according to Mr. Blondel's method, are made in the following manner.

Since the figure referred to is a hexagon, the angle of the centre is equal to 60 degrees, the angle of the polygon to 120, and the angle *diminué*, B A F or A B E, to 25 degrees.

The flanking angle, A E B, is 70 degrees, and the flanked angle, N A G, or D B S, is equal to 70 degrees. Therefore half the flanked angle, L B O, or F A P, is equal to 35 degrees.

The tensile A G, and of course the face A C of the bastion, is found by the following analogy.

As the sine of the angle A G B
Is to the sine of the angle A B C,
So is the exterior side A B
To the tensile A G, of which the face A C is one-half.

From the sine of defence A F, which is seven-tenths of the exterior side A B, we get the complement G F or G E, and the curtain E F of course by this analogy.

As the sine of the angle E F G
Is to the sine of the angle E G F,
So is the complement E G
To the curtain E F.

And as the sum of the angles C E F, E C F, is equal to 180°—the angle *diminué* C F E (25°) = 155°, and C F, E F, are known, we have this analogy.

As the sum of the sides C F, E F
Is to their difference,
So is the tangent of 75°, half the sum of the angles,
To the tangent of half their difference.

Half the difference added to half the sum, gives C E F the angle of the flank, and taken from half the sum gives E C F the supplement of A C E the angle of the *épaleur* or shoulder.

And for the flank C E we have the following analogy.

As the sine of C E F, the angle of the flank,
Is to the sine of the angle *diminué* C F E,
So is C F
To the flank C E.

The demi-gorge E P is determined by first finding the lengthened curtain F P by this analogy.

As the sine of the angle A P F, which is known,
Is to the sine of the angle E A P which is also known,
So is the line of defence A F = 70° of A B
To the lengthened curtain F P.

Then from F P so found take the curtain E F, and there will remain the demi-gorge E P.

tant from the countercarp, which distance thence forms its ditch. The principal object in erecting this counter-
guard is to conceal from the enemies' view the low flanks
opposite to it, whilst its narrowness or small breadth puts it
out of his power to place his guns in after he has taken it.

The salient angle of his ravelin is determined by the in-
tersection of two areas described from the shoulders of
the two adjoining bastions, with a radius equal to the dis-
tance between them. Its faces produced meet those of the
bastions about 6 toises from the shoulders and are bounded
on the lines or faces of the counter-guards produced, which
also determine the gorge of the ravelin.

The ditch of the ravelin is from 10 to 12 toises broad,
and that it may be the better defended, Mr. Blondel takes,
in the face of the bastion, a space equal to this breadth, com-
muting six toises from the shoulders, in which he makes a
low battery of 4 or 5 feet high, and another on the inside
of the same height with the parapet of the place, and re-
tired about 5 toises within the face.

The ditch before the counter-guards is 10 toises broad.
The ravelin not only covers the shoulders and the millions
of each bastion, but likewise defends the ditch of the coun-
terguard, as he takes as much of its face as is sufficient for
seeing or discovering all that to make two batteries in, viz.
a low one and a high one in the same manner as he does in
the faces of the bastions. He allows no more terre-plain
in the ravelin, than what is just enough for the recoiling of
his guns, leaving all the rest of its inside empty for the
purpose of being able easily to countermine the rampart,
and to prevent the enemy from making a lodgment in it,
after he may have forced it.

The better to cover the batteries in the face of each bas-
tion, which defend the ditch of the ravelin, he adds in the
angles of the countercarp of the ravelin lunette, in the
form of lozenges, allowing 20 toises for the demi-gorge in
each. These have their faces parallel to the countercarps
of the ditches before the ravelin and counterguard, and the
ditch before them 8 toises broad.

The author likewise makes a lunette in his great ditch
from 7 to 8 toises broad, which work to prevent the low flanks, which would be otherwise eaily accessible, from being got at. A smaller or narrower lunette might also be made in the ditches of the outworks, particularly when there are batteries in the demi-lunes or
ravelins.

The calculations for the angles and lines of a construction

on the sides of a polygon, according to Mr. Blondel's me-
thod, are made in the following manner.

Since the figure referred to is a hexagon, the angle of the
centre is equal to 60 degrees, the angle of the polygon to
120, and the angle diminish, B A F or A B E, to 25 degrees.
The flanking angle, A G B, is 130 degrees, and the flanked
angle, N A G, or D B S, is equal to 70 degrees. Wherefore
half the flanked angle, E B O, or F A P, is equal to 35
degrees.

The tenaille A G, and of course the face A C of the
ballion, is found by the following analogy.

As the sine of the angle A G B
Is to the sine of the angle A B G,
So is the exterior side A B
To the tenaille A G, of which the face A C is one-half.
From the line of defence A F, which is seven-tenths of
the exterior side A B, we get the complement G F or G E,
and the curtain E F of course by this analogy.

As the sine of the angle E F G
Is to the sine of the angle E G F,
So is the complement E G
To the curtain E F.
And as the sum of the angles C E F, E F C, is equal to
180°—the angle diminish C F E (25°) = 155°, and C F,
E F, are known, we have this analogy.

As the sum of the sides C F, E F
Is to their difference,
So is the tangent of 7° 30', half the sum of the angles,
To the tangent of half their difference.
Half this difference added to half the sum, gives C E F
the angle of the flank, and taken from half the sum gives
E C F the supplement of A C E the angle of the epincl or
shoulder.
And for the flank C E we have the following analogy.

As the sine of C E F, the angle of the flank,
Is to the sine of the angle diminish C F E,
So is C F
To the flank C E.
The demi-gorge E F is determined by first finding the
lengthened curtain F P by this analogy.

As the sine of the angle A P F, which is known,
Is to the sine of the angle F A P which is also known,
So is the line of defence A F = tan of A B
To the lengthened curtain F P.
Then from F P is found take the curtain E F, and there
will remain the demi-gorge E F.

CONSTRUCTION.
CONSTRUCTION.

This ingenious author also gives a table of the lengths of the different lines in his construction on the two following suppositions:

1st. That the exterior side of each figure is equal to 200 toises.

And 2dly. That the exterior side of each figure is equal to 170 toises.

Mr. Blondel was undoubtedly a man of considerable talents and eminence, and had travelled over the greatest part of Europe, America, and the West Indies, making sensible and judicious observations on the various modes of fortifying, practised by different nations.

His acuteness however in discovering the mistakes committed by others, and his anxiety to avoid them, did not prevent him from falling into still greater ones himself. He did not attend sufficiently to the great expence that the execution of his method would unavoidably occasion, or to the numerous artillery that would be required for its defence.

Imagining, that places are generally lost for want of sufficient flanks, he makes three, one behind another. They are however so near to each other, that the rubbish of the higher ones must certainly render the lower ones useless: and were shells to fall into the lower ones they must unquestionably destroy the troops for want of room to avoid them. They are moreover too open and liable to be destroyed from the covert-way, as the counter-guards are not broad enough to cover and screen them from the enemies' fire. The low flanks are too narrow and too much confused. Before shells, however, were much used at sieges, they might have afforded a good defence.

He makes no use of traverses. But this is not to be imputed to him as a fault or omission, as rocket-firing was not used in his time.

His great ditch appears to be too wide, being not less than 25 toises before the faces of the baftions.

His angle diminué must be allowed to be preposterously great, as he makes it of as many degrees as it ought to be in a construction on a straight line, or on the sides of a polygon of an infinite or indefinite number of sides.

The following is the construction according to Mr. Dombelle's method.

Like Count Pagan he establishes three sorts of fortification. But instead of constructing inwards like him, he constructs outwards. His three sorts he denominates the little royal, the mean, and the great royal. The interior side of the little royal is equal to 60 rods of 12 Paris feet each, or 120 toises, that of the mean is equal to 70 such rods or 140 toises, and that of the great royal is equal to 80 such rods or 160 toises. His manner of fortifying in all the three is the same, and is the following.

Having determined on the side A B, (fig. 4.) (which we shall here suppose to be that of a hexagon,) for the mean, or little royal, allow a fifth part of it for the demi-gorges A C, B D; and a fourth part of it for the flanks C E, D F, each of which must make, with the curtain C D, an angle of 100 degrees. Then the points, G, H, of the baftions are ascertained by the rafant lines C H, D G, and the whole operation or construction is furnished.

As the construction in this figure is supposed to be made outwards on three of the sides of a regular hexagon, the angle A O B of the centre is equal to 60 degrees, and the angle G H K of the polygon is equal to 120 degrees. But the angle E C D of the flank is by construction equal to 100 degrees, the demi-gorge A C or B D is equal to a fifth part of the interior side A B, and the flank C E or D F is equal to a fourth part of A B. Conseqently the sum of the angles C D E, C E D, is given equal to 80 degrees, and the sides C E, C D, are given; wherefore we have this analogy.

At the sum of the curtain C D and flank C E
Is to their difference,
So is the tangent of 40° half the sum of the angles C D E, C E D
To the tangent of half their difference.

Hence the angle diminué C D E or C D G, the angle C E D the supplement of the angle C E G of the epaule or shoulder, and A G D half the flanked angle, or half the angle of the baftion, are given.

And as the lengthened curtain A D or B C is given by the construction equal to four fifths of the interior side A B, we have the following analogies for D G, the line of defence, and A G the capital of the baftion.

As the line of A G D, half the angle of the baftion,
Is to the line of the angle A G D,
So is the lengthened curtain A D To the line of defence D G.
And,
As the line of A G D, half the angle of the baftion,
Is to the line of the angle diminué A D G
So is the lengthened curtain A D To A G the capital of the baftion.

In like manner we obtain D E from the triangle C E D by means of the following analogy.

As the line of C D E, the angle diminué,
Is to the line of E C D, the angle of the flank,
So is the flank C E which is given
To the right line D E, which taken from D G, the line of
defence, gives E G the face of the baftion.

And as in this figure, which is supposed to be a hexagon, the exterior side G H, or line joining the flulant angles of two adjoining baftions, is equal to O G the perpendicular distance of the point I, the intersection of the lines of defence from G H is obtained by the following analogy.

As radius
Is to the tangent of I G Z, the angle diminué,
So is G Z, the half of G H or O G, in this figure,
To I Z, the perpendicular distance of I from G H.

And the perpendicular distance of the intersection of the rafant lines, or lines of defence, from the curtain, is found by this analogy.

As G H or O G in this figure
Is to the curtain C D,
So is I Z
To the perpendicular distance I Y of I from C D.

And in any other regular figure than a hexagon, G H is found by this analogy.

As O A, the radius of the circumscribing circle,
Is to the interior side A B, which is given,
So is O G = O A + A G
To G H, the side of the exterior polygon.

And as radius
Is to the tangent of I G Z, the angle diminué,
So is G Z equal to half G H,
To I Z, the perpendicular distance of I from G H.

And as G H, the side of the exterior polygon,
Is to C D the curtain, which is known,
So is I Z, the perpendicular distance of I from G H,
To I Y, the perpendicular distance of I from the

curtain.

Mr. Dombelle, in the construction of each of his three sorts of fortification, makes the angle E C D or F D C of the flank, always equal to 100 degrees, and the angle diminué G D C or H C D invariably equal to about 20° 56'.

For
CONSTRUCTION.

For CD being always equal to three-fifths of AB, and CE equal to a fourth part of AB, the ratio of \( CD + CE \) to CD - CE is a given or constant ratio, being that of 17 to 7, whatever be the length of AB. And the construction of his mean fortification gives the demi-garde AC or BD, equal to 28 toises, the curtain CD, equal to 8\( \frac{2}{3} \), the lengthened curtain ED or BC, equal to 11\( \frac{2}{3} \), the line of defence DF or CH, equal to 3\( \frac{1}{3} \), the capital AG or BH of the bastion, equal to about 0\( \frac{3}{5} \), the face CE or HF of the bastion, equal to about 6\( \frac{1}{10} \). And in all the three the ratio of DY half the curtain, to DY the perpendicular distance from it to I, the intersection of the lines of defence, or of GZ, half the side of the exterior polygon, to ZI, the perpendicular distance from it to the said point of intersection, is given or constant, being always that of radius to the tangent of 20° 50'. The construction of his mean fortification on the sides of a hexagon gives ZI, equal to about 38,884 toises, and YI to about 16,066 toises.

This author makes his main ditch, or the ditch of the body of the place, 12 rods of 12 Paris feet each, or 24 toises broad, beyond which and opposite to the curtain he places a ravelin, the salient angle of which is in the intersection of two arcs described with the lengthened curtain AB, or BC, as radius from the extremities A, B, of the interior side AB, and the faces of which produced across the main ditch would terminate on the shoulders ii, i, of the square ordnans, that cover his rounded flanks or caissons, which are described in the following manner.

From the extremities C, D, of the curtain, and perpendicularly thereto, he draws two other flanks, C, i, D, i, meeting the lines of defence in the points i, i, lengthening the faces GE, HF respectively by Ei, Fi in order to have room enough in each flank of every bastion for two covered ones, which are constructed in the following manner:

To take the two lines Gr, Hr, equal each to a third part of Gi or Hi, (Ci, Di being drawn from the extremities C, D, of the curtain C, D perpendicularly thereto), and the lines ik, ik, also equal each of them to a third part of Ci or Di. From the points r, r, r, r, drawn right lines, rkl, rkl, through the points k, k, terminated at the points l, l, by the right lines Ci, Di, drawn perpendicularly to the lines of defence GD, HC, which must be produced till they meet the radii of the polygon in some points as p, p, in order to take upon the same radii the distances pg, pg, for terminating the covered flanks, of which the common centre x is found by describing from the extremities Db, Cb, of the right lines Ci, Di, arcs with a radius equal to three-fourths of Cb or Di.

The distance between the two covered flanks on each flank of every bastion is equal to 12 rods of 12 Paris feet each, or twenty-four toises, and the parapets every where arc to inch rods or 4 toises thick.

The caissons which Mr. Bonbelle adds at the points of the bastions, and which, in cases of necessity, may serve as retrenchments, are described by taking on the capitals of the bastions the right lines Gs, Hs, equal respectively to half the lines Gr, Hr, and describing from the points s, s, as centres, arcs rr, rr, for the caissons, each of which has its parapet 4 toises broad. They are somewhat lower towards the points of the bastions than the other parts of the bastions, and the ways to them are through palfages as o, o, in the bastions.

This author covers his ravelin with a fort of counter-guard or tenaille beyond its ditch, which he makes 8 rods of 12 Paris feet each, or 16 toises broad, or a third part of the breadth of his great ditch, thus rendering his ravelin a tenailled, or horned half-moon.

Round covered flanks were first invented by the Italians; and Mr. Bonbelle uses them in order to render them the more capacious, and the fitter for resisting the shock and effects of the enemies' cannon. They seem, however, to have too much convexity, advancing too far towards the centre of each bastion, and leaving too small a distance between the two high flanks.

As his flanks are great, he makes use of no second flanks on the curtains. But contrary to sound sense and reason, and inconsistently with the genuine principles of construction, he makes them of the same lengths or sizes in all polygons. His angle dimidiate also is invariably of a given magnitude, viz. of 20° 50', which by his construction on the sides of a square leaves the flanked angle, or angle of each bastion, equal only to 45° 8' in a pentagon, to 66° 8', in a hexagon, to 75° 8', and so on. His angle dimidiate in a square, is therefore more than double what it ought to be, by upwards of two degrees. And in a pentagon it does not fail quite 7½ degrees short of being twice as great as it should be in reality. He makes it even greater in a square than it ought to be in an octagon.

Mr. Vauban in his method fortifies inwards; and like Count Pagan, from whom he has borrowed his perpendicular for the hexagon and all higher polygons, begins with the perpendicular to the exterior side, and the parallel lines of defence. He does not, however, make the faces of his bastions so long, or his flanks quite so short. And he omits second flanks as not of very great moment, as they can be added at any time, without changing either the flanks or curtains.

Differ, as in Count Pagan's construction, the exterior side AB in the point C (fig. 5.) At the point C erect a perpendicular, CD, equal to an eighth part of AB in the square, to a seventh part of AB in the pentagon, and to a fifth part of AB in the hexagon and all higher polygons. From the extremities A, B, through the point D, draw the lines of defence AD, BD. On these take AE, BF for the faces of the bastions, equal each to two seventh parts of AB, and take EH, FG, each equal to EF, the distance between the shoulders E and F. Then join the points G, H, for the curtain GH. And if a similar construction be made on each of the other sides of the figure or polygon, we get the matter-line of the curtains and bastions, or the principal or outline of the body of the place. To this must be added a rampart from 10 to 12 toises broad at the base, and elevated more or less above the level of the place, on the outer part of which, at top, there is raised a parapet three toises broad at the base, and elevated above the rampart from 6 feet to 7. The ditch of the body of the place, or the great ditch, is 20 toises wide opposite to the flanked angles or salient angles of the bastions, and it is formed by describing from the angles with a radius of 22 toises, circular arcs, and drawing right lines from the epaules, or shoulders, to touch these arcs. For the parts of these lines lying between their intersections and the points of contact, together with these arcs, form the outline of the ditch.

The foregoing figure is a regular hexagon, and the exterior side is here supposed to be equal to 180 toises.

To determine the flanking angle S (fig. 6.) of the half-moon or ravelin, let off 50 toises on the perpendicular DC, produced beyond the exterior side AB; from the point S draw right lines to the counterface of the great ditch, so that if produced across the same, they would, according to some authorities, terminate on the epaules or shoulders of the bastions, but according to others, about 3 toises from the shoulders on the faces of the bastions. These lines to drawn from...
CONSTRUCTION.

from the flanant angle S. of the ravelin to the counterflank,
form the faces S. L. S. M. of the half-moon or ravelin. It is
generally supposed that when the faces S. L. S. M. of the
ravelin terminate when produced across the great ditch on
the faces of the bastions a few toes from the epauls or
shoulders, they cover the flanks much better than they do
when they terminate on the shoulders themselves.

The ditch before each ravelin is 12 toises broad; its
counterflank is parallel to the faces, and is made of a cir-
cular form, before the flanant angle of each like the ditches
before the flanant angles of all works in general.

When the ravelin is made with flanks, as PN, QO, the
faces S. P. S. Q. when produced across the great ditch,
ought to terminate on the faces of the bastions 5 toises at
least from the epauls or shoulders.

When a ravelin has flanks, they are commonly made by
setting off 10 toises from L to P, and M to Q, from the
extremities of the faces, and by drawing them from the
points P. Q. parallel to the capital S. of the ravelin.

There is sometimes a redoubt made in a ravelin, which is
done by settling off from the extremities, L, M, of the
faces on the semi-gorges L. M. M. L, and then drawing right
lines for its faces parallel to those of the ravelin. The ditch
before such a redoubt should be 6 toises broad, and its
counterflank parallel to its faces.

Orillons and retired flanks are described in the following
manner.

The front, AEG, HFB, being described as above
taken, EA equal to a third part of the flank EFG. From
the opposite flanked angle B, draw the right line B a, on
which produced take &b, equal to 5 toises. Take also on
the line of defense, EFG, produced, Ge equal to 5 toises,
and join Ge. On b as a base describe the equilateral tri-
gle bGe, and from the angular point G as a centre, denote
the circular retired flank Ge with the radius fG or fc.

Again, if ED be bisected in the point c, and ed be drawn
perpendicular to Ed to meet a perpendicular to the face
AE, from the point E in the point d, and if from the
point d as a centre a circular are be described with dE as
radius, we shall get the circular orillon EA.

ab is called the revers, or back part of the orillon, and
to the enforcement or depth of the fatemate or concave
flank be.

In like manner are the retired or concave flank bI, and
the circular orillon FG described.

The orillons are useful in covering the retired or concave
flanks, which by means of them cannot be seen but directly
in front. And as Mr. Vauban makes his orillons round,
they cannot be so easily destroyed as they might be were
they of any other figure or form.

The calculation of the lines and angles of a construction
on a polygon, according to this method of Mr. Vauban, is
as follows:

If AB be supposed to be the side of a hexagon, the
angle of the centre will be equal to 60°, and the angle
of the polygon to 120°. And as the perpendicular CD is by
the construction equal to a sixth part of AB, the angle
diminished ABD or BGH is determined by the following
analogy:

As AC or BC, the half of ABD; or, As 2
To is CD the perpendicular, f or, Is to 1,
So is radius
to the tangent of the angle CAD or CBD, which is
nearly equal to 18° 26' 6". Wherefore the flanked angle
or angle of the flank is equal to 53° 6' 48" nearly. And
since the triangle EFG is isosceles by the construction, and
the angle EFG, which is equal to the angle ABD, is of

enfilme equal to 15° 26' 6", we have the angles FEG,
EGF, equal each to half the excess of 18° 26' 6",
or to 8° 40' 57" nearly. Wherefore the angle EGF
of the flank, which is equal to the angle FGE, together
with the angle GFE, or angle diminished, is equal to 99°
45' 30". And the angle AEG of the epaul, or shoulder,
being equal to the angle EGF or EGD, together with
the angle EGD, which is equal to the angles ABD, BGD,
taken together, or to twice the angle diminished, is equal
to 117° 45' 30".

Now since AC, half of the exterior side AB, is given, and
CD is found by the foregoing analogy, AD is known,
its square being (47 E. I.) equal to the squares of AC and
CD; and as AE is equal to two sevenths of AB, the exter-
ior side ED is known. But AD is to ED, as AB is to EF or FG,
which are of course known. Or, either of
these lines may be found by the following analogy.

As the line of the angle EFD, which is equal to the
angle diminished, or to 18° 26' 6"
Is to its opposite side DE,
So is the line of the angle EDF, which is equal to 18°
twice the angle diminished, or to 15° 26' 6"
To the opposite side EF, the distance between
the epauls.

And if from EF, or its equal EH, there be taken ED,
the complement DH, or its equal DG, will be known.
Wherefore the curtain GH is determined by either of the
two following analogies.

As AD
Is to the exterior side AB,
So is the complement DG or DH
To the curtain GH.

Or: As the line of the angle diminished DGH
Is to the line of the angle GDH, which is 117° 45' 30"
So is the complement DH
To the curtain GH.

The flank E is easily found by means of either the tri-
gle EFG, or the triangle EGD, as in the following
analogies.

As the line of the angle FGH, which is 8° 46' 57"
Is to the line of the angle EFG, which is 8°
twice the angle diminished, or 18° 26' 6"
So is EF the distance between the two opposite epauls
To the flank E.

Or: As the line of the angle EGD, which is 8° 46' 57"
Is to the line of the angle EDG, which is 8°
twice the angle diminished, or 15° 26' 6"
So is ED the distance from the epaul to the interfe-
cence of the lines of defence
To the flank E.

And as half the flanked angle is equal to 41° 33' 36",
and the angle AHG, which is equal to the angle diminished,
to 18° 26' 6" nearly, the angle formed by the capital of
the bastion, and the lengthened curtain, or the curtain HG
produced to meet the same, will be equal to 120° or 18°
more. Wherefore the lengthened curtain is found by this
analogy.

As the line of 120° or 18°
Is to the line of 41° 33' 36", half the flanked angle,
So is AH
To the lengthened curtain: from which, if the curtain
HG be taken, we get the demi-gorge.

And the capital of the bastion is found by this analogy:

As the line of 120° or 18°.
Construction.

Is to the sine of 15° 25' 0", the angle diminished.

To the capital of the bastion.

And the perpendicular distance, D1, of the curtain from the intersection of the lines of defence is found by the analogy, as A B is to C D, so is G H to D1.

Supposing the exterior side A B, as in his mean fortification, to be equal to 100 toises, the principal lines belonging to the construction may easily be found, as in the following manner.

The perpendicular C D being by construction = \( \frac{A B}{6} \)

is = 30 toises.

The tenaille A D or B D being equal to \( \sqrt{BC^2 + CD^2} \)
is equal to \( \sqrt{10000} \) = 94.8633298 nearly.

The face B F of the bastion is commonly equal to 50 toises, or two-leavens of A B nearly.

The distance D F of the epaule F from the intersection D of the lines of defence being equal to B F - D F, is equal to 10.\( \sqrt{30} \) = 44.8633298 nearly.

If from the epaule F there be drawn F I perpendicular to the exterior side A B, we shall have B I = \( \frac{BC \times DF}{BD} \)

5 = 90 toises = \( \frac{BD}{2} \) = 47 = 341149 toises nearly; and F I = 5 = 10 toises = \( \frac{CD \times BF}{BD} \) = 15.813883 toises nearly.

The distance E F, between the two opposite epaules, E, F, or its equal E H or F G, is equal to A B - 2 B I = A B - B D = 182 - 50 = 48.13167 toises nearly.

The complement D G or D H being equal to F G - D F = 230 - 10 = 360 toises = 40.26334 toises nearly.

The perpendicular distance D I of the intersection of the lines of defence from the curtain G H being = \( \frac{CD \times DG}{BD} \)
is equal to 12.732861846 toises nearly. Consequently the perpendicular distance C I between the exterior side A B and the curtain G H being equal to C D + D I, is equal to 46.3232861846 toises nearly.

The curtain G H being equal to six times D I, is equal to 138.\( \sqrt{10} \) - 360 toises, or 76.5943171 toises nearly.

If F M be drawn perpendicularly from the epaule F to A H, the line of defence, E m, being equal to \( \frac{EF \times BC}{BD} \)
is equal to 5 = 10 - 90 toises, or 82.76299365 toises nearly.

The perpendicular F M being to E M as C D is to B C, is equal to a third part of E M or \( \frac{18.\sqrt{10} - 50}{2} \) toises, or 26.021 toises nearly.

The distance m H of the point m from the extremity H of the line of defence being equal to E H - E M, is equal to 270 - 84.\( \sqrt{10} \) toises, or 43 = 68765442 toises nearly.

The distance D m of the point m from the intersection D of the lines of defence being equal to E m - D F or E m - D E, is equal to 24.\( \sqrt{10} \) - 40 toises, or 35.894653848 toises nearly. But since F E H is an isosceles triangle, the angle F E H or D B C is equal to twice the angle m F H, which is therefore equal to 9° 13' 30" nearly.

The flank F H being equal to \( \sqrt{FM^2 + mH^2} \) =

3 = 16.109 - 50.\( \sqrt{10} \) toises, is equal to 27.2732895 or 27.7767008 toises nearly. And if from the extremity H of the line of defence A H there be drawn H M to meet the face F D of the bastion in the point m, we shall have H M equal to

\[ \frac{DH \times FM}{mD} = \frac{230 - 60 \times 10}{18.\sqrt{10} - 30} \]

toises, or 30.1720 toises, exceeding the perpendicular C D to the exterior side by 0.1976 of a toise only.

And as F M is a fourth proportional to D M, m H, and D F, or is equal to

\[ \frac{mH \times DF}{Dm} = \frac{270 - 84.\sqrt{10} \times 50}{10 - 30} \]

toises, it is equal to 5.161 toises nearly. And D M is equal to 30.362 toises nearly.

Now in Count Pagan's construction, from whom Mr. Vauban has borrowed the length of his perpendicular, on which the other parts chiefly depend, the flank F H is equal to 18.\( \sqrt{10} \) - 33 toises, or 23.021 toises nearly, which falls short of the perpendicular F M, drawn from the epaule F, in Vauban's construction, to the line of defence A H, by 3 toises, and of the flank F H by 3.3322805 toises. In any polygon, having its exterior side equal to 100 toises, their perpendiculums are equal, as well as the fanatical angles of their bastions. And we are persuaded, that even the greatest admirers of Vauban can afford no good reason for his not having followed Count Pagan also, with regard to the position of his flank, and placed it at right angles to the line of defence, instead of making them meet in an angle of 80° 40' 57". There is great reason to suppose, that the Count would have made the face of his bastion considerably shorter than he did, had he not intended to have three flanks instead of one. He makes it 55 toises. But it is naturally to be presumed, that he had intended to construct with a single flank, he would have bisected the perpendicular distance between his orillon and inner flank, (which is 19 toises,) and drawn his flank at right angles to the line of defence through this point of bisection, thereby forming a more complete construction for the body of the place than Vauban has done. And it is somewhat remarkable, that this line nearly coincides with the perpendicular H m, to Vauban's line of defence, from its point H of intersection with the flank. Had he, therefore, instead of taking 5 toises from the face of Count Pagan's bastion, taken 10, and then placed his flank at right angles to the line of defence, he would, without lengthening this line, have given the face of his bastion its proper length, and, at the same time, made the flank itself about equal to the perpendicular, as it ought to be, since perpendiculums to the exterior sides of polygons were first introduced into construction for the sole purpose of obtaining flanking defences. The lengths, however, with both these authors, as well as the other writers on fortification, are merely arbitrary, and by no means derived from reasoning either on the properties of the figures, or their relative degrees of importance and capability of defence. For there appears no reason for giving the same perpendicular to a hexagon and every other polygon of a greater number of sides, as Vauban has done, or to all regular figures above the square, as Count Pagan has done.

This author retains part of the facade-bray, which used to go round the whole body of the place, at the distance of from 4 to 5 toises from the flanks, making use of it as tenaille opposite to his curtains, which are made differently.
A tenaille is commonly from two to three feet only higher than the level ground of the ravelin. The tenaille \(a b c d e f g, \text{ Plate VI. fg. 7.}\) is constructed by first setting off from the capes \(B, F, \) on the lines of defence \(E, F, g,\) equal each to three toes, for a paille Rouge between it and the flanks of the bastions; then taking \(a g, f g,\) for its faces, equal each of them to 16 toes, by describing from the shoulers \(b, f,\) as centres, arcs with a radius equal to \(b f,\) and then by intersecting these arcs from the same shoulers as centres, with a radius equal to 10 toes, for its flanks \(b, f e,\) some, however, make the faces \(a b, g f,\) equal to half the lines \(a D, f D, g D\) respectively, and place the flanks at right angles to the lines of defence, which is certainly the best position for them.

The tenailles \(a b c d, e f g b, (f g, f S.)\) are without flanks, and have their faces on the lines of defence. The paille Rouge between them, as well as the pailles between them and the flanks, are three toes wide. These are called "\(a\) simple tenailles, and the foregoing is called a "reinforced tenaille. There is also a third sort of tenailles, which have only faces \(a b, g f,\) and flanks \(b c, f e,\) without a curtain.

Simple tenailles, with their faces on the lines of defence, but without flanks, are not so well calculated for scouring and defending the ditch as either the "reinforced tenailles are, or those with faces, and flanks without curtain. However, as they are not liable to be enfiladed, Mr. Vauban has generally preferred them to the other two, in most of the places which he fortified.

The "reinforced tenailles defend the ditch much better, and add low flanks to those of the bastions, but are liable to have their own flanks enfiladed, an inconvenience that might be remedied by constructing them in such a manner as to be covered by the extremities of the parapets of the opposite ravelins, or by the adjoining lunettes. These are well calculated for scouring not only the ditch, but also the level ground of the ravelin, and the ditch before the corps de guard, reduit, or redoubt, commonly made within it, which cannot be so well feen or defended from any other parts.

Those with faces and flanks only, have the same advantages with thefe as to the defending or scouring of the ditch, but are also, like them, liable to have their flanks enfiladed, which should be guarded against in the same manner.

The better to scour and defend the ditch, and oppose its paille Rouge, this further places it in, opposite to the middle of the tenaille, or of the curtain, a caponiere, or double way, covered with a parapet raised three feet above the bottom of the ditch. It is about 15 feet broad, is perpendicular to the curtain, and is parfalled on both sides. This work is good and very useful, as it commands without being com- manded, and serves as a paille for the musketeers from the body of the place to the outworks. He thus has four flanks for the defence of his ditch, namely, that of the body of the place, that of the orillon, that of the tenaille, and the caponiere.

Tenailles are reckoned to necessary, that it is with good reason that there are few places fortified without them. For when the ditch is dry, the spaces behind them serve as places of arms, from which the troops may fallly to oppose the enemies' defcent of the ditch, to retard his operation, and destroy his works in it, and then retire to them as places of safety. They also render the communication between the body of the place and the ravelins more easy and secure, which is a great advantage, as the ravelins are thereby enabled to make a much better defense than they otherwise could do, being readily supplied at any time with troops and necessaries. And when the ditch is wet, the spaces behind them serve as harbours for boats, which armed men can make use of, both for opposing the paille of the ditch, and for facilitating the communication between the tenailles and the ravelins.

This fortifier, in order to increase the strength of a place, places frequently works called lunettes (which literally signify small obstructions) on both sides of his ravelin. He sometimes makes one face of his lunette perpendicular to the middle of the face of the ravelin, and sometimes perpendicular to the face of the ravelin, and to as produced to the same about one-third from the faliant angle. In the former case he makes that face of the lunette equal to 30 toes, and determines its other faces by taking for the demi-gorge 25 toes, on the counter-scarp of the great ditch from that of the ditch before the ravelin; in the latter he makes the demi-gorge equal to 20 toes only. The ditch before the lunettes is 12 toes broad, the thicknees of the parapet is equal to three toes, and that of the rampart to eight, as in the ravelin.

When he makes use of lunettes, he sometimes covers the faliant angle of the ravelin with a work called bonnet, of which the faces are parallel to those of the ravelin, and when produced bifect those of the lunettes. The ditch before it is ten toes wide.

Tenailon. The term tenailon is sometimes applied to a "reinforced tenaille; but it is generally confined to a work somewhat like a lunette, made on each side of a ravelin, but differing from a lunette in this circumstance, that one of the faces of a tenailon, though it is 30 toes long, like that of the lunette, is in the direction of the ravelin produced by one of its ditch, whereas that of the lunette is perpendicular to it. The other face of the tenailon is determined by taking 15 toes on the counter-scarp of the great ditch from that of the ravelin. There is sometimes a tenailon a battery 15 toes long, and 10 toes retired from the front and parallel thereto.

There are generally retrenchments in tenailles which have their parapets either parallel to their fronts or perpendicular to their other faces, which, when produced, terminate on the faces of the bastions. The ditch before such a retrenchment is about three toes wide, and as these works are commonly made of earth, without any revetment of masonry, there is a bankette, called bern, before the parapet, next to the ditch, about eight feet broad, to prevent it from falling into the fame.

As to the construction of counter-guards, horn-works, crown-works, covert-ways and places, detached redoubts, second ditches, and covert-ways, and profiles. See the fame under these articles respectively. Mr. Vauban, in his second method with tower-bastions, according to the plans of Landau and Besford, begins with his construction towards, and fortifies outwardly in the following manner.

Supposing \(A B (f g, f),\) to be the interior side of the hexagon of 120 or 130 toes, draw \(A C, B D\) from the centre thereof, through the extremities \(A, B;\) set off six toes from \(A\) to \(B,\) and from \(B\) to \(C,\) through the points \(b, c,\) draw right lines at right angles to \(A B,\) on which set off six toes from \(B, f,\) and \(c, b,\) and four toes from \(b, d,\) and \(c, e,\) to \(g,\) and from the points \(f, d,\) draw perpendiculars \(f r, d n,\) to the capital \(A C,\) as also from the points \(b, g,\) perpendiculars to the capital \(B D,\) Then, if \(r, e, c, f, p,\) the points \(E, F,\) will be the faliant angles of the tower-bastions, of which \(E f, d\) and \(f b, g q,\) are the halve.

If on the capitals \(A C, B D,\) there be taken \(E, F, D,\) equal each to 40 toes, the points \(C, D,\) will be the faliant angles of the counter-guards before the towers. From the points \(C, D,\) draw the lines of defence \(C r, D b,\) to the points \(c, b,\) where the flanks of the towers intersect the cur-
CONSTRUCTION.

On these set off 36 toises, from C to G, and D to H, for the face CG, DH, of the counter-guards. The flanks and tenailles are found or determined as in his first method.

The ditch before the faillant angles of the towers is 6 toises broad, and its counterfcarp is drawn to the extremities of the flanks of the counter guards. The right line, which joins the ends of these flanks, determines the infide of the tenailles.

The ditch before the counter-guards is 12 toises broad at the faillant angles; and its counterfcarp is drawn towards the opposite shoulders, in the same manner as in his first method.

The capital of the ravelin is 45 toises, and its faces, when produced, terminate on those of the counter-guards, about 10 toises from the shoulders. Ten toises, however, are cut off from the faces of the ravelin, for the flanks which are parallel to its capital.

The ditch before the ravelin is 10 toises broad, the covert-way five, the demi-gorges of the places of arms 12 each, the faces 17 each, and the glacie is 30 toises broad.

The construction of Mr. Vauban's third method, according to the plan of New Briisach, is applied to an octagon, of which the exterior side is equal to 180 toises, and is made inwards. The perpendicular to the exterior side is, as in his first method, equal to 50 toises. The faces of the counter-guards are each of them equal to 60 toises. The flanks are found by setting off 22 toises, in arcs described from the opposite shoulders, as centres, and with the distance between as radius. A right line drawn through the extremities of the flanks, parallel to the exterior side, to meet the capitals of the counter-guards, determines both the infide of the tenailles, and the faillant angles of the tower-batillon.

And if another right line be drawn parallel to this, at the distance of 9 toises from it, the points, where it meets or intersects the capitals of the counter-guards, will be centres of the towers; from which points, if seven toises be set off each way for their demi-gorges, the positions of their flanks, which are perpendicular to the said line, will be determined. For each of these flanks, five toises are set off outwards, and four from the said line. And the line joining the infide of the flanks at the end of four toises completes the towers.

The ditch is 6 toises broad before the faillant angles of the towers, and its counterfcarp meets the line joining these angles, within 15 toises of the extremities of the flanks of the counter-guards.

The great ditch before the counter-guards is 15 toises broad, and its counterfcarp is parallel to the faces. The capital of the ravelin is 35 toises in length, and that of the redoubt within it, is equal to 25 toises. The faces of the ravelin are drawn towards those of the counter-guards, within 15 toises from the shoulders, and these of the redoubt are parallel to these. Twelve toises are cut off from each face of the ravelin, and fix from each of the redoubts by the flanks, which are parallel to its capital. The ditch before the ravelin is twelve toises wide, and that before the redoubt is fix. The covert-way and glacie are the same as in his second method. The profiles also are nearly the same in both. This method, indeed, differs but little from his second, except in two small flanks, of about four toises each, which in this he makes in each curtain, that are not in the other. The parapets of his counter-guards, on both sides of the faillant angles for the distance of about twenty feet, are raised four feet higher than the red, to prevent these works from being annoyed by ricochet-batteries.

In Mr. Vauban's first method of military construction, it may not be amiss to give a table of the principal parts thereof, for drawing the matter-line by, as also an ichnographical one of the principal dimensions of the body of the place, tenailles, ravelin, covert-way, traverse, and places of arms, as published with his approbation (for he never published anything himself respecting it.)

</table>

The traverses on the sides where their banquettes are, or on their infides, are from 3 to 3 1/2 feet high, and from 3 to 4 on the outside, towards the covert-way, which they four at the re-entering angles.

He gives his captives a banquet on each side, and the parapet of the place two or three, to suit men of different heights or stature, that they may all of them fire on the same level.

He makes a cut opposite to each traverse in the parapet of the covert-way, 4 1/2 or 5 feet deep, for the soldiers to pass, which he flushes up with a small merlon, except at the failing angles, where such cuts could not be seen by those who defend the place.

When he gives flanks to his ravelin, he makes places of arms in its ditch, perpendicular to its faces, and near the angles of the epaules, to prevent the passage of the same. When the counterchange of the ditch is revetted, or faced with masonry, he makes steps at all its angles for the convenience of the troops, and the service of the covert-way. Each detached piece or work should, for a similar reason, have a pair of flairs to lead up to it.

He makes the countermines of a place under the terreplain of the rampart, on a level with the ditch, and about ten feet distant from the revetment, to which they are parallel, and have a communication with it through small arched heads, or passages. From the countermines of the place men go down into the caponiers, and then up into the countermines of the covert-way, from which heads or passages are carried on under the field to fourmets or small mines, made for blowing up the besieger's works, and retarding their approaches.

He was of opinion, that when an eminence falls gradually from its summit towards the glacis of a place, works ought to be made one before another, with their flanks or flank ed angles sufficiently raised; that the most distant ought to cover all the rest, and draw its defence from them; and that they ought all of them to be built in such a manner, as to prevent an enemy from making a retreatment in the first, without being exposed to the fire of the second; or in the second, without being exposed to that of the third, and so on.

The glacis should as often as possible be composed of pebbles, or of stones covered with turf, since the besiegers can work but slowly in it when it is made, and the parapets thrown up in it by the pioneers, are apt to occasion their being killed or wounded, as the cannon-shot of the place striking against, scatter the stones, and make them fly in different directions.

He observes, that the bridges of his curtains do not interfere with the fire from his flanks along the faces of the bastions in the ditch, and he prefers that ditch which, by means of flanes, can be hilled or emptied at pleasure.

The construction of the Chevalier de Ville's method of fortifying is the following.

He begins inwardly, and conducts outwards. He makes his flanks equal to the demi-gorges, and each of them equal to a sixth part of the side of the figure or polygon on which he constructs. In the square and pentagon, he determines the flanked angle or failing angle of the bastion by a radius line; but in all figures and polygons of a greater number of sides than five, he makes it equal to a right angle, by describing a semicircle, as EGN on a right line, (fig. 10.) Enjoining the epaules E and N, thereby making a second flank, as D, C, H, which increases with the number of sides in the figure or polygon. The length A G, of the capital of the bastions is, in this case, equal to the gorge line C P, or the distance between the points where the flanks of the bastion meet the adjoining curtains, a circumstance which furnishes an easy method of finding the points of the bastions.

In constructing his casemates, or retired flanks and oil lions, he sets of from C and D, on the flanks E, E D, F, lines equal each to a third part of C E or D F, or of the demi-gorge, as D a, for influence, on D F. He also takes F b in the face H F produced, equal to D a, and then draws b c parallel to F a, to meet a right line joining a, and G the point of the opposite bastion. Then b c is the front of the orillon, when it is made square. But when he makes it round, he describes two arcs from b and e, as centres, with a radius equal to b c, and from their intersection as a centre through the points b, e, he describes the arc of his orillon.

The calculation of the lines and angles, according to his construction, may be made in the following manner.

If we suppose A B to be the side of a hexagon, the angle A O B of the centre will be equal to 60 degrees, and the angle A B S, or A B T, of the figure, equal to 120°. And as the flank is by the construction perpendicular to the curtain, the angle E C D of the flank is, of course, equal to 90 degrees. But as the flanked angle E G N is also equal to 90 degrees, the half of it, A G I, is equal to 45 degrees, and consequently the angle diminué A I G, being equal to half the excess of the angle of the polygon above the flanked angle, is equal to 15°. And the angle of the epaule is of course equal to 105°.

Wherefore, if A B be affined of a given length, whether equal to 120 toises, or otherwise, the capital A G of the bastion, and the gorge-line C P, which is equal to it, is easily found by the following analogy, and the isosceles triangle C A F.

As the line of the angle A C P, or A P C, half the excess of 180° above the angle of the polygon, or half the angle of the centre.

Is to the line of the angle of the polygon or centre

So is the flank of the bastion or

To the gorge-line C P, or capital of the bastion A G.

And the radiant line G I, in the oblique-angled triangle A G I, is found by this analogy.

As the line of the angle diminué A I G

3 U 2
CONSTRUCTION.

Is is to the fine of the angle GAI, or its supplement
OAI, half the angle of the polygon,
So is the capital AG of the baflion.
To the rafant line GI.
And the line AI is obtained from the fame triangle, by this
analogy.

As the fine of AIG the angle diminué
Is to the fine of A GI, half the flanked angle,
So is the capital AG of the baflion.
To the line AI.

From which, if there be taken the flank or demi-gorge,
there will remain the complement CI; which, taken from the
curtain CD, leaves the fecond flank DI. The comple-
ment CI is also easily found from the right-angled tri-
gle, ECI, by the following.

As radius
Is to the tangent of the angle C E I = 90° — the angle
diminué,
So is the flank EC, a sixth part of AB,
To the complement CI.
The fide GH of the exterior polygon is determined by
taking a fourth proportional to OA, AB and OA + AG.

The foregoing methods of construction have been called
the French manner, particularly those of Count Pagan and
Mr. Vauban, who borrowed from him the length of his per-
cpendicular, which is the principal part of construction, and
that on which all the other parts chiefly depend. Vauban's
method, however, has been chiefly followed on account of
its plainness and simplicity, with a single flank. It is pro-
per, nevertheless, to give the constructions of some of those
methods of fortifying that have been made use of in other
nations.

The Italians, who have not been anxious about making
the flanked angle, or angle of the baflion, either right or
obtuse, but prefer having it acute for the purpose of get-
ting a second flank on the curtain, have several methods of
fortifying delivered by their authors, amongst which that of
Sardi has been esteemed one of the best.

He begins inwards and contracts outwards, supposing AB
equal to 800 geometrical paces or feet (fig. 11.). Of these
he allows 150 for the demi-gorge AC or BD, and the fame
for the flank CE or DF, which he places perpendicularly
to the curtain CD, on which he takes an eighth part DI for
the second flank, making I the point in the curtain, from
which the rafant line drawn through E the extremity
of the flank or angle of the épaule, gives the faliant point
G of the baflion on the lengthened radius OA. And this
operation, continued round the figure or polygon, completes
the construction.

He makes a cafemate in each flank, capable of holding
three pieces of cannon, by letting off from the extremity
of the curtain on the demi-gorge, a line equal to a third part
of the flank, and the fame on the flank itself. And he
makes his orillons either square or round.

He places square cavaliers on the middle of his curtains,
of which the faces are parallel to the parapet of the ramp-
art, and 30 feet distant from the fame. In each of these
he puts 7 pieces of cannon, three of which look into the
field, and the other four towards the two adjoining baflions
to flank each breach as the besiegers may make in the
faces of them, and prevent them from giving the assfult.

The calculation of the principal lines and angles in Sardi's
construction, may be made in the following manner.

Since the interior line AB is by supposition equal to
800 geometrical paces or feet, and the demi-gorge AC,
and flank CE, each equal to 150 of thefe, the curtain CD
is equal to 500, and the fecond flank DI, which is the
eighth part thereof, is equal to 625. Consequently the
complement CI is equal to 417° 45 feet or paces.

But if we suppose AB to be the side of a hexagon, the
angle AOB of the centre will be equal to 60°, and the
angle AAB or ABT of the polygon will be equal to 120°.
And the angle ECD of the flank is by the construction
equal to 90 degrees.

The angle diminué CIE is therefore found from the
right-angled triangle ECI by this analogy.

As the complement CI
Is to the flank CE,
So is the radius
To the tangent of the angle diminué CIE, which is about
18° 55½. If this be added to the angle of the flank,
which is equal to 90°, we get 108° 55 for the angle CEG
of the épaule. And if the fide angle diminué of 18° 55 be
taken from the angle OAI, or half the angle of the
polygon, which is here equal to 60°, we get 41° 5 for the
angle AGI half the flanked angle. Consequently the
flanked angle is about 85° 10.

If to the complement CI we add the demi-gorge AC,
we get AI equal to 587½ such feet or paces, and the rafant
line GI is therefore found from the oblique-angled tri-
gle AIG by the following analogy.

As the fine of half the flanked angle A GI
Is to the fine of the angle GAI, or of half the angle of
the polygon,
So is the line AI
To the rafant line GI.

The capital AG of the baflion is also obtained from the
fame triangle by this analogy.

As the fine of half the flanked angle AGI
Is to the fine of the angle diminué AIG,
So is the line AI
To the capital AG of the baflion.

If to the curtain CD we add the demi-gorge AC, we
get the lengthened curtain AD, equal to 650 such feet or
paces, and from thence by means of the oblique-angled tri-
gle GAD the rafant line GD in the following manner.

As the sum of the lengthened curtain and capital AD, AG,
Is to their difference,
So is the tangent of half the fum of the angles AGD, ADG,
or of one quarter of the angle of the polygon,
To the tangent of half their difference, which is found
to be about 12° 31½. This taken from 36° one quarter of the
angle of the polygon, or 12°, leaves 17° 29½ for the
angle ADG, and added to the fame gives 42° 51 for the
angle AGD. Therefore,

As the fine of the angle ADG
Is to the fine of the angle GAD, or of half the angle of
the polygon,
So is the capital AG of the baflion,
To the rafant line GD.

The Italian writers on fortification feem fond of having
the flanked angles, or angles of the baflions acute, in order
that the faces of the baflions, on the fame side of the place,
may defend one another, and serve as flanks when the cafe-
mates and flanks are battered down or ruined. But the fecond
flank on the curtain is by this construction too small to
make the flanked angle always acute. To make it answer
this purpose, it would be an improvement of it to make the
fecond flank increase in length, as the number of the baflions
or of the fides of the figure increases.

It is perhaps worthy of remark, that the angle ADG
by
CONSTRUCTION.

by this constitution on a hexagon, exceeds that subtended by the true perpendicular of a hexagon by about 17° only.

The angles of the square and pentagon are too small for a second flank. And the Chevalier de Ville, whose construction much reprehends Sardi's in several respects, appears to have borrowed from him the idea of making his flanks equal to his demi-gorges. He takes care, however, to avoid second flanks in the square and pentagon, and in other figures to make them increase with the number of the sides of the figure.

The following is the construction of the Dutch method of fortifying according to Marolais.

Before he begins his construction he ascertains the magnitude of the flanked angle, or angle of the baflion, by adding 15° to half the angle of the polygon, which makes it in the square equal to 65°, in the pentagon equal to 69°, in the heptagon equal to 75°, in the heptagon equal to about 70° 17', in the decagon equal to 87°, in the dodecagon equal to 90°, which he also allows for in all figures or polygons of a greater number of sides.

He makes the curtain IK (fig. 12) equal to 36 rods of 12 Paris feet each, or 72 toises, the face of the baflion AF equal to 24 inches rods or 48 toises, making the ratio of the curtain to it a fegalateral one, or that of 3 to 2. He makes the flanked angle F MI equal to 40°, when he wishes to have only a single flank, in order that the demi-gorge MI may be to the flank in the ratio, nearly of 6 to 5, and equal to 35° only, when he intends to have a covered flank, making then the ratio of the demi-gorge to the flank about that of 7 to 5.

Let AB be an exterior side. Make the angle BAO equal to half the angle of the polygon. Bifect the same by the right line AP. Take the angle APE equal to 75° 30'. On the right line AE set off from A 48 toises for the face AF. From the epaule E draw the perpendicular FG, and produce GF indefinitely towards I, making at the point F an angle IMF of 50°. Draw through the point P, where the line FM meets the radius AO of an indefinite right line, MN, parallel to the exterior side AB, which will be a side of the inward polygon. Take the curtain IK, equal to 72 toises, and the line GH equal to it. Join KH, and on it take KL equal to the flank IF. Make the demi-gorge KN equal to the demi-gorge IM, and HB equal to GA. Draw the face BL, and the capital BN, which, being produced, will meet the capital AM also produced in the centre O.

The calculation of the principal lines and angles of the construction on the sides of a polygon fortified, according to Marolais's method, may be made in the following manner.

If we suppose AB to be the side of a hexagon, we have the angle of the centre equal to 60°, the angle of the polygon equal to 120°, and consequently OAB half the angle of the polygon equal to 60°. Wherefore OAE, half the flanked angle, is equal to 37° 30', which taken from OAB, half the angle of the polygon or 60°, leaves 23° 30' for the angle diminuèd EAB. But the angle of the flank is a right angle by the construction. If to this then there be added the angle diminuèd, we shall have 112° 30' for the angle AFI of the epaule or shoulder, from which if the angle IMF, which is equal to 50°, be taken, there will remain 62° 30' for the angle AFI. The angle AMF is 85°.

The capital AM of the баflion is found from the oblique-angled triangle AMF by this analogy. As the sine of the angle AMF is to the sine of the angle AFI, So is the face A FI of the баflion To the capital AM.

And the line IMF is found by this analogy. As the sine of the angle AMF is to the sine of the angle F AM, So is the face A FI of the баflion To the line IMF.

The flank IF is found from the right-angled triangle MIF by this analogy.

As radius
Is to the sine of the flank-forming angle IMF = 40°.
So is the line IF.
To the flank IF, which is equal to about 19 toises.
And the demi-gorge MI is found from the same triangle by this analogy.

As radius
Is to the sine of the angle IMF = 50°.
So is the line IMF.
To the demi-gorge MI, which is equal to about 22 toises, the double of which or 45 toises added to the curtain IK, which is equal to 72 toises, gives the interior MN equal to about 117 toises.

The exterior side AB is determined by means of the line AG, which is found from the right-angled triangle AGF, by this analogy.

As radius
Is to the sine of the angle AGF = 67° 30'.
So is the face AGF of the baflion, which is equal to 48 toises.
To the line AG, which is equal to about 44 toises, the double of which added to GH, that is, equal to 72 toises, gives 162 toises for the exterior side AB.

The second flank KE is determined by means of the complement EI, which is found from the triangle ETF, by either of the following analogies.

As the sine of the angle diminuèd I EF = 22° 30'.
Is to the sine of the angle E FI = 67° 30',
So is the slant IF.
To the complement EI.

Or, As radius
Is to the tangent of the angle E FI = 67° 30',
So is the slant IF.
To the complement EI, which is equal to about 45° 10', and which taken from the curtain, which is equal to 72 toises, leaves 26 toises for the second flank KE or IC.

The perpendicular distance of the intersection of the lines of defence, from the middle of the exterior side AB, is found by this analogy.

As radius
Is to the tangent of the angle diminuèd, which is = 22° 30',
So is half the exterior side AB.
To the perpendicular from it to the intersection of the lines of defence, which is therefore equal to about 32¼ toises.

This construction furnishes an easy method of working on the ground, when through interruptions from buildings, hedges, thickets, &c. and from the unevennesses and irregularity of the ground itself, a regular polygon cannot easily be described by finding the centre of the circumference of the circle. For such a polygon may be traced on the ground by means of the miter lines of the curtains and baflions, setting off first successively the angle of the polygon without any reference to the centre. This author, however, instead of making his flank equal to his perpendicular, as it ought to be, makes it fall short of the same by not less than 1 3½ toises.

There are other methods of construction delivered by Dutch writers, which, however, are hardly deserving of notice. And
as in all their methods, they make a second flank on the curtain, and for the most part draw at the same time the counter-scarp of the great ditch parallel to the faces of the balistons, they render the defence very defective. For the branches of the counter-scarp being thus parallel to the fuchiant lines, will, when produced, frequently meet the curtains, and will of course cover the greatest part of the ditch itself, from the view of the flanks of the balistons. And as the principal part of the ditch is thus fien by the second flanks only, which are easily mined, the entrance into it is rendered easy to the besiegers.

The following is the construction of the Spanish method of fortifying.

Take the interior side A B (fig. 1.) equal to 120 toifes. From A to C, and B to D, let fall 20 toifes or a fith part of A B, for each of the demi-gorges A C, B D. On perpendiculurs to A B at the points C, D, take C E, D F, equal repectivefly to AC, BD, or to 20 toifes each, or a fith part of A B. Let O be the centre of the circle, which circumference the polygon, of which A B is a side. From D through F, and C through F, draw right lines to meet the radii OA, OB, of the said circle, produced in the points G, H. Then E G, F H will be the oppofite faces of the balistons C E F Q, D F H R, and A G, B H their capitals. And the fame construction continued on the other fides A M, M T, T V, V N, N B, completes the operation.

The calculation of the principal lines and angles of this construction is made in the following manner.

Since A B is equal to 120 toifes, and A C, B D, each equal to 20, the curtain C D is equal to 80 toifes. And since C E, D F, are each equal to 20 toifes, or the fith part of A B, and also perpendicular to A B by the construction, C D is to C E as four to one, and as radius to the tangent of the angle C D E, which is therefore equal to about 14° 2'. Wherefore the angle C E D is equal to about 75° 58', and the angle C E G of the epaule or shoulder is equal of course to about 104° 2'. These angles, therefore, are the fame in all polygons.

But the flanked of confluence, with the angles of the polygons.

Now, if we fuppose A B to be the side of a hexagon, we have the angle A O B of the centre equal to 60°, and the angle M A B or A B N of the polygon equal to 120°. Confequently half the flanked angle O G D or A G D, which is equal to the excess of O G H or O A B, half the angle of the polygon, above the angle diminute A D G or C D E, is equal to 45° 58'; and the whole flanked angle, or angle P G E of the balifon, is equal to 91° 56'.

The capital A G of the balifon, is found from the oblique-angled triangle A G D, by this analogy.

As the fline of half the flanked angle A G D, which is 45° 58',

is to the fline of the angle diminute A D G = 14° 2',

So is the lengthened curtain A D, which is 100 toifes,

To the capital A G of the balifon, which is equal to about 33.73 toifes.

And the reftant line or line of defence D G, is found from the fame triangle by this analogy.

As the fline of half the flanked angle A G D = 45° 58',

is to the fline of the angle D A G = 120°,

So is the lengthened curtain A D, which is 100 toifes,

To the reftant line or line of defence D G, which is equal to about 120.46 toifes, or 120.5 toifes nearly.

But D E is equal to \[ CE + CD = \sqrt{20^2 + 80^2} = 4\sqrt{425} \] toifes = to 83.86 toifes nearly. Wherefore the face G E of the balifon is equal to 37.6 toifes nearly.

The gorge-line C Q is found from the ifofeles triangle C A Q, by the following analogy.

As the fline of the angle A C Q = half the angle of the centre

is to the angle of the polygon C A Q,

So is the demi-gorge A C, which is 20 toifes.

To the gorge-line C Q, which in a hexagon, as this figure is fupposed to be, is equal to about 34.64 toifes.

The line O G being equal to about 173.73 toifes, the exterior side G H, when A B is the side of a hexagon, will also be equal to about 173.73 toifes. But G H is always determined by taking a fourth proportional to O A, A B, and O G.

The perpendiculur distance K L of the interfeftion of the lines of defence, from the exterior side G H, is found by this analogy.

As radius L is to the tangent of the angle diminute L G K = 14° 2',

So is G L, or the half of G H, the exterior side.

To the perpendiculur K L, which in the hexagon, as this figure is fupposed to be, is equal to about 19.2 toifes, falling short of the flank C E by about 0.5 of a toife, or eighteenths of a toife.

The Spaniards, who are rather partial than otherwife to obtufe flanked angles, have no second flank on the curtain, but always contract their fortifications with a reftant, and never with a ficitant line of defence, not minding whether the flanked angle or angle of the balifon be acute, right, or obtufe. Their mode of construction, except as to the second flanks, and the making of the flanked angle right, is the fame with that of the Chevalier de Ville, above defcribed, which being compounded of the Italian and Spanish methods, has on that account been called the compofed draught, or the compofed method of construction.

Let A B (Plate VII. fig. 1.5.) be the side of a regular hexagon inscribed in a circle, and equal to 160 toifes. Set off from its extremities A and C on it A C, B D as demi-gorges, and each equal to an eighth part of A B, or to 20 toifes. From the points C and D on right lines perpendicular to A B take C E, D F, as flanks each equal to 20 toifes, or an eighth part of A B also. Take the curtains C I, D K, from the points C, D, and A, B, each equal to 40 toifes, or a fourth part of the interior side A B; and from the points I, K, on right lines, drawn perpendicularly to A B inwards, take I L, K M, for the retired flanks, each equal to 20 toifes, or the eighth part of the interior side. Join the points L, M, by drawing L M for the retired curtain. From the extremities L, M, thereof through the points K, I, draw the right lines I, K, M, which being produced, will pass through the outward extremities E, F, of the flanks C E, D F, and will meet the lengthened radius O A, O B, in the points G, H, which will determine the faltant points of two of the balifons. And a similar operation continued quite round on the other fides of the balifon, will complete the construction.

As the foregoing figure is fupposed to be a regular hexagon, the angle of the centre is equal to 60°, and that of the polygon to 120°. And as M L is to L I, as 40 to 20 or 2 to 1, the natural tangent of the angle diminute L M I, or M G H to unity, as radius is equal to \(\frac{1}{4}\) or to 0.500,000, which is nearly equal to the natural tangent of 20° 34'. If this angle be taken from 60°, half the angle of the polygon, there will remain 33° 26' for half the flanked angle, or half the angle of the balifon. The flanked angle therefore, or the angle of the balifon, is in a hexagon equal to 60° 34'.
To the line GI, which is equal to 94.31 toises nearly.

And the capital AG of the balloon is found from the same triangle by this analogy.

As the line of AG, half the flanked angle = 33° 26'

Is to the line of the angle diminute AG 43° 34'

So is the line AI, which is equal to 60 toises,

To the capital AG of the balloon, which is equal to about 48.704 toises.

But the line IM is equal to \( \sqrt{1L^2+LM} = \sqrt{23^2+42^2} = 49.59 \) toises nearly.

But EI is equal to 1 M. Wherefore GE, the face of the balloon, being equal to GI - EI, is equal to about 49.59 toises, or 49.06 toises nearly.

The short or little line of defence GM or HL, being equal to GI + IM, is equal to 94.31 + 49.72 toises, or 144 toises nearly.

The lengthened radius OG, and consequently the exterior side GH, when AB is the side of a hexagon, is equal to 165 + 44.72 toises, or 209.72 toises.

The perpendicular distance of the intersection I, of the lines of defence, from the exterior of G H, is found by either of the two following analogies.

As radius

Is to the tangent of the angle diminute i GH = 26° 34',

So is the exterior side GH, or 102.36 toises,

To the perpendicular distance of i from the same.

Or, As radius

Is to the line of the angle diminute i GH = 26° 34',

So is the little line of defence GM = 132 toises,

To the perpendicular distance of the point i from GH,

which is equal to about 62.160 toises.

This method was adopted for the purpose of constructing on a large front, and thereby increasing the number of bastions. And to keep the lines of defence G M H L, within mischief, a curtain LM retired inward, is made equal to a fourth part of the interior side A B, and opposite to the middle thereof. This manner of fortifying has been called the order reinforce or re-inforced order, concerning which several Italian and Spanish authors have written large treatises. Like most other writers on fortification, who have delivered different methods of construction, they very ably make their angle diminute invariably the same in all polygons, without assigning any good reason for doing so. Drawn from the natures or properties of the polygons themselves, the facility or difficulty of embracing them respectively, or from their relative degrees of capability of defence. In this method, the perpendicular distance of the intersection i of the lines of defence, from the exterior side GH, is more than thrice the length of the flank CE or DF.

Of Coehorn or Koeaam's methods.

The famous Minno, baron of Koeaam, who took many of the places, which the celebrated marshal Vauban had fortified, published three methods of construction, the first for a hexagon, the second for a heptagon, and the third for an octagon. The publication of his treatise on fortification however took place before he had acquired that great experience, which justly procured him the reputation of being one of the first engineers, that has ever appeared in Europe; and the methods delivered in it are not reducible to practice. That he afterwards thought so highly is evident from the towns which he fortified. For if, after acquiring experience in the attack of places he had really been of opinion that the methods he had published, were capable of making such a prodigious resistance or defence as he endeavoured in his book on fortification to show, that they were, it is a circumstance difficult to be accounted for, that he never once thought of using them, when he had frequent opportunities of doing so. It ought also to be remembered, that his system of fortification was published before the method of firing en ricochet was either practised or invented.

In his first method the works occupy twice as much ground as they do in Mr. Vauban's, and being entirely of earth, low, and liable to be easily surprized, would require as many men, at least, for their defence. His second and third methods are, in fact, impracticable, as the fortification in each of them takes up five times as much ground as the town or place it surrounds.

This being the case, we will just give a general description of them. In all the three he begins inwards and constructs outwards. The first he applies to a hexagon and supperposes the surface of the water to be only about four feet lower than the level ground. In this he constructs from an interior side of 150 toises, from the extremities of which he fets off on the fame 29 toises for each of the demi-gorges and 80 toises on the lengthened radii of the hexagon for the capital of each of the balloons. He thus leaves 72 toises for the length of his curtain. From the extremities of the interior side he takes, on the lengthened radii respectively, 40 toises for the points of intersection of the higher faces of the balloons, which are also equal each to 40 toises, and parallel to the lower faces that are in the lines of defence. The space between the lower and higher faces of the balloons is a dry ditch, the bottom of which is only about six inches above the level of the water in a wet ditch. Behind the lower parapet there is a balonnette of three feet and a rampart of five, and under this ramrart is a stone gallery, that runs from one end of it to the other, and is divided into several apartments, which are shut with doors. There is also a gallery, which goes from the falant angle formed by the lower faces to that formed by the higher with loop holes at small distances from one another, looking into the dry ditch. There are likewise rows of palisades placed parallel to the higher face at the distance of four toises from them.

The great ditch is 24 toises broad, and its counterescarp is parallel to the lower faces of the balloons. The demi-gorges of the ravelin are each equal to 29 toises, and the faces each to 45 toises. The dry ditch between the lower and upper faces of it is 16 toises broad. The rampart is 28 feet broad, the balonnette three, and the parapet 25. The lower faces are parallel to the higher ones.

The angle diminute, or the angle formed by the exterior side, and either line of defence, is in this method equal to 24° 30° 48'.

His second method he applies to a heptagon, and supperposes the level of the ground to be only about three feet above that of the surface of the water. In it he constructs outwards from an interior side of 126 toises in length, from the extremities of which he takes on the fame 30 toises for each of the demi-gorges. On the lengthened radius of the heptagon he fets off 72 toises for the capital of each of the balloons, at the extremities of which he draws eight lines forming with the said capitols angles each of 40°, and on these lines he fets off 60 toises for the faces of the balloons respectively. From the fallant angles of the balloons as centres with radii equal to the distance from the same to the extremities of the demi-gorges 30 toises distant from those of the interior sides he describes arcs, in which he fets off respectively chords equal each to 30 toises, and on these chords describes the mean flanks which are arcs of 60°.

The outline of his higher flank is 33 toises distant from...
that of the mean, and this flank is an arc described from the
fame centre, that the mean flank is described from, having
its chord equal to 40 toises.

The dry ditch round the body of the place is 20 toises
broad before the faces of the bastions, to which its coun-
tercarp is parallel. There is a wet ditch before his tenaille's
10 toises broad with two bridges at each end near the
millions, the one of which leads directly across it and the
other along the face of the bastion.

The faifant angle of the ravelin is 125 toises distant
from the curtain of the body of the place and is of 70
degrees of magnitude. The faces are each 50 toises long, and
the faces of the redoubt in it are 16 toises distant from the
faces of the ravelin, and each 14 toises long. The wet ditch
before the lower faces of the ravelin is 24 toises broad, and
the work beyond that ditch, which he calls the second
countercarp, is 20, and parallel to the ditch.

The faifant angle or angle of the bastion in this method
is equal to 85°, and the angle diminué or the angle formed
by the exterior side and either line of defence is equal to
twenty-four degrees and two sevenths. In his first method
the angle of the bastion or flanked angle is equal to 70°
4° 24'.

He applies his third method to an octagon, of which
the side is equal to 110 toises, and from which he constructs
outwards; from its extremities he sets off 21 toises for each
of the demi-gorges. On the lengthened radii, or radii of
the octagon produced, he sets off from the said extremities
of the interior side 64 toises for the capitals of each of the
bastions, the faces of which he supposes to be each equal
to 54 toises, and the faifant or flanked angle equal to 85°.
He thus makes his curtain equal to 68 toises.

In his first and second methods he has three flanks includ-
ing that of the tenaille. But in this he has only two, the
lower of which is determined or found by describing an arc
through the extremity of the tenaille from the faifant angle
of the opposite bastion as centre and letting off from the
said extremity in the said arc a chord equal to 20 toises, on
which an arc of 60 degrees is described for the flank.
The upper flank is described from the same centre,
that the lower one is described from through one ex-
tremity of the curtain, and its chord is equal to 30 toises.
The wet ditch before the body of the place is 20 toises
broad, and its countercarp is parallel to the faces of the
bastions.

The capital of the detached bastion is equal to 100
toises, its faces are directed towards the faifant angles of
the inner bastions. The dry ditch between the lower and
higher faces of the detached bastions is 20 toises broad;
and the higher faces are parallel to the lower, and each of
them 31 toises long. The ditch before the detached ba-
tions 24 toises broad. It is evident, that in this third method
of Coehorn the angle diminué or the angle formed by the
exterior side and either line of defence is equal to 25 de-
grees. For since the angle of the centre in an octagon is
equal to 45°, that of the octagon is equal to 135°, from
which, if the flanked angle, that by the construction is
equal to 85°, be taken, we get 50° for the double of the
angle diminué, which is of course equal to 25°.

Of Mr. Belidor's methods.

This author delivers three methods of construction, the
first he applies to an octagon, of which the side is equal to
200 toises. In the three he begins outwards and contracts
inwards. In the first he makes the perpendicular to the
exterior side equal to 50 toises, the faces of his bastion
equal each to 70 toises, and he finds his flanks in the same
way with Mr. Vauban in his first method. He makes
his bastion with flanks each to about 26 toises. On the
line joining the extremities of these flanks he constructs in-
ward, erecting a perpendicular to the middle thereof equal
to 13 toises, through the inner extremity of defence and
takes on them the faces equal each to 22 toises. The
parts of the lines of defence from their intersection to the
points where they terminate the flanks, are each equal to
14 toises. The dry ditch before this front is 10 toises
broad at the inner extremities of the bastions, and its coun-
tercarp produced terminates at the opposite shoulders.
He connects the flanks of the bastions with the curtains
or lines joining the faces of the inner front by means of
works in the form of arcs called ram's-horns, which are
described from the middle points of the said faces as centres
with a radius of 25 toises. The faifant angle of the re-
doubt in his bastion is in the intersection of the two ad-
joining curtains produced, and the faces of it terminate on
those of the inner front within three toises of the epaules
or shoulders. The ditch before it is 3 toises broad. It has
a stone wall in the faces from three to four feet thick with
loopholes. Mr. Belidor adds no outworks to this method of
construction, which has certainly the advantage of all those
with detached bastions. The retracements within are capa-
cible of a good defence, but occupy too much ground, par-
ticularly the ditches, that might be better disposed of. The
flanks of such large bastions as his are too small. The
great ditches are too large, being 20 toises broad at the faifant
angles of the bastions with its countercarp directed to-
wards their shoulders.

In this method his angle diminué or the angle formed by
the exterior side and either line of defence is equal to 26°
35° 45° and of course the angle of his bastion or the flanked
angle, as the construction is applied to an octagon, is equal
to 81° 52° 12°.

His second method of construction he also applies to an
octagon, of which the exterior side is equal to 200 toises,
the perpendicular to which, from the middle point thereof,
he makes equal to 55 toises. The faces of his bastions,
which are detached, are each equal to 70 toises, as in his
first method. And the flanks as well as in the first are
found in the same way as Mr. Vauban's.

The right line, that passes through the inner extremities
of his bastion, serves as an exterior side for constructing
the inward polygon on, the perpendicular to which, at the
middle point thereof, is equal to 5 toises, through the inner
extremity of which the lines of defence are drawn. On
these the faces are set off, each equal to 24 toises; and the
flanks are chords of arcs described from the opposite shoul-
ders of the detached bastions as centres.

The inward polygon is in fact nothing else than a strong
wall, behind the curtain of which, and at the distance of
about 18 feet from it, there is an epennement or a parapet
of earth 3 toises thick. And within the bastions there are
cavaliers, of which the fronts are circular arcs, described
with a radius of from 21 to 24 toises. Their flanks are
each equal to 7 toises, and their gorges to 32 toises each.
The countercarp of the ditch before this inner polygon
is distant from it at the faifant angles, and is parallel to the
curtain.

His tenailles, called ram's-horns, touch the outer lines of
defence within three toises of the epaules or shoulders of
the detached bastions, and are so described as to meet the
said lines of defence inwards, beyond their intersection in the
points, where the countercarp of the inner ditch meets the
fame.
The outline of the curtain between the ram's-horns is 9 toises beyond or without the inner ditch.

The exterior line, from the retreatment within his detached bastion is constructed, runs across the same, and meets the faces thereof about 20 toises from the caponiers, or shoulders, the perpendicular to which line at the middle point thereof is equal to 17 toises. Through the inner extremity of this perpendicular the lines of defence for the retreatment are drawn. On these lines, from the faces of the bastion, those of the retreatment are set off equal each to 20 toises. The chord, on which the orillon is described, is equal to 5 toises, as is also that on which the retired flank is described. Both are made according to Mr. Vauban's method. The circular curtain of this retreatment, and the rounded part of the ditch adjoining it, are described from the falant angle of the inner construction next to it, with a radius of 25 toises. The great ditch before the falant angles of the detached bastions is 20 toises broad, and as it is supposed to be dry, Mr. Belidor made a caponiere from the curtain between the ram's-horns to the ravelin of about 18 or 20 feet wide, the parapets of which he made terminate on both sides in a slope or glacis.

The capital of the ravelin he makes equal to 66 toises, and that of the redoubt within it equal to 30 toises. The faces of the ravelins are directed towards those of the retreatments within the detached bastions, and those of the redoubt within it to the shoulders of the said bastions. The batteries in the ravelin are retired 8 toises back from the faces of it. The ditch in front of the ravelin is 12 toises, and the breadth of that before the redoubt is equal to 7 toises.

The demi-gorges of the lunettes are each equal to 25 toises, and their faces are perpendicularly directed towards those of the ravelin and detached bastions. The ditch before them is 8 toises wide, and the batteries in them are retired 8 toises back from their faces, and are each of them 15 toises long. The covert-way is 6 toises broad.

In this method the angle diminué, or the angle formed by the exterior side and either line of defence, is equal to 25° 48' 39'; and as the construction is applied to an octagon, the angle of the bastion, or the flanked angle, is of course equal to 27° 23' 42'.

It is manifest that in this construction the perpendicular to the exterior side, or of the great polygon, is much longer than it ought to be, since it exceeds the true perpendicular belonging to a polygon of 30 sides. For the angle diminué, which it gives, is greater than the true angle diminué belonging to a polygon of 30 sides, by upwards of one degree. And the angle of the bastion, or flanked angle, falls short of the real flanked angle in a polygon of 30 sides, by not less than 3°. The bastions are thereby made by far too large and extensive. The great ditch appears also to be too wide, as the excavation of it will furnish more earth than what is wanted for raising the ramparts. The works indeed, taken altogether, are too expensive to be erected. For it would require almost a whole army to defend them, besides such a prodigious quantity of stores and ammunition, as cannot be allotted for the service or defence of any one place.

Mr. Belidor applies his third method of construction, as he does his first and second, to an octagon, of which the exterior side is equal to 200 toises. But he makes the perpendicular to it at the middle point thereof equal only to 40 toises, which is very nearly indeed equal to the true perpendicular of an enneagon of the same exterior, and therefore comes nearer to the true perpendicular of an octagon than that which has been described for it by any other writer on fortification. On this account we will give the construction of part of the body of the place on an octagon according to this method.

Let AB (Plate VIII. fig. 15.) be equal to 200 toises inside of an octagon. Bisect AB in the point C, and draw CD perpendicular thereto. From C to D let fall to D, equal to 40 toises, and from the extremities A, and B, of the exterior side AB, through the point D, draw the lines of defence. On them take AE and BF for the faces of the bastions, equal each to 55 toises. The parts DA, DB, between the intersection, D, of the lines of defence, and the broken parts of the curtain, take each equal to 35 toises, and the length of each of the broken parts remains equal to 25 toises. The orillon is equal to 9 toises, and is part of a flank found according to Mr. Vauban's method. The flanks are retired 8 toises, and are arcs of 65° each. The outlines of the ram's-horns are 13 toises distant from one another. The palisades at their extremities are each 3 toises wide. The outermost or lowest is described with a radius of 30 toises, and the other is described from the same centre. By making the same construction on two other sides of the octagon, the positions of the other faces, AG, BH, of the bastions is determined as well as the magnitude of the flanking angle of each. He places cavaliers in the gorges of the bastions.

The capital of his ravelin is 44 toises. The demi-gorges of it are each equal to 31 toises, and its flanks, which are directed towards the shoulders of the bastions, are each of them equal to 9 toises. The ditch before the ravelin is 10 toises wide, and the covert-way is 6 toises broad.

The glacis before the flanking angles of the bastions is 15 toises broad. The demi-gorges of the places of arms are each equal to 26 toises, and those of the redoubts or stone walls within them to 20. And the faces are parallel to the opposite demi-gorges. He makes arrows and detached redoubts after the manner of Mr. Vauban, but gives flanks to his arrows, which are parallel to the palisades of 10 toises wide, that lead to them.

In this his third method of construction, the angle diminuit, or the angle BAC, or ABD, formed by the exterior side and either line of defence, is equal to 21° 48' 5", which differs from the true angle diminuit of an enneagon by about 3 minutes only. And as it is applied to an octagon, the angle of the bastion, or the flanked angle, is of course equal to 0° 23' 59'.

It must be allowed that this construction for the body of the place is good. The ram's-horns are unquestionably well contrived, and are much preferable to tenailles, as they cannot be enfiladed from any one place, as they refit better. by their bending or curvature outwards, the enemist's batteries, and render the flanks much superior to any batteries that the besiegers can erect against them. Like a mere constructor on paper, however, he makes so many outworks, that they occupy a vast extent of ground, cannot be defended but by a very numerous garrison, and uncommonly large supply of ammunition, artillery, and provisions, and cannot be erected but at an immense expense.

The learned and ingenious Mr. Ozanam has given four methods of construction, in all of which he begins inwards, and fortifies outwards, from an interior side of 120 toises, and at the same time places or takes his flanks on right lines drawn from the centre of the polygon through the extremities of the demi-gorges set off on the interior side, or on the same.
CONSTRUCTION.

has sides. In the square the demi-gorge is therefore equal to 24 toises, in the pentagon to 25, in the hexagon to 26, in the heptagon to 27, and so on to the decagon, in which the demi-gorge being equal by this rule to 30 toises, he makes it continue of this length in all higher polygons. He makes each flank equal to four times as many toises as the number of the sides of the polygon, allowing 16 toises for it in the square, 20 in the pentagon, 24 in the hexagon, 28 in the heptagon, and 30 on to the decagon, where the flank being by this rule equal to 40 toises, continues of that length in all higher polygons.

The angle formed by right lines from the salient angle, and either shoulder or epaule of his bastion, he calls the flank-forming angle.

The following is a table of the lines and angles of a fortified polygon, from the square to the dodecagon, according to his first method of construction, the inward or interior side being equal to 120 toises.

</table>

The following is this construction on a hexagon, of which the exterior side is equal to 120 toises.

Let A, B, C, F, D (fig. 16.) be a regular hexagon, inscribed in a circle, of which the radius, A O, is equal to 120 toises. From the extremities A and B, set off A L, B M, for demigorges, equal each to 20 + 6 or 26 toises. In like manner set off A P, C Q, B a, D b; C T, E V, E e, F Y, F Z, D X; equal each to 26 toises. From the centre O, through the points, L, M, a, P, Q, T, V, e, Y, Z, X, draw the right lines O L, O M, O a, O e, O c, O Q, O P, O T, O V, O Y, O Z, O X, equal each to 6 x 4, or 24 toises. From the points L, M, through the points K, I, draw right lines to meet the radius O B, O A, lengthened or produced in the points H, G. From the points a, b, through the points c, d, draw right lines in like manner, and so on round the figure. This operation will determine the salient angles of the bastions, and all the parts of the construction.

The calculation of the different lines and angles in this construction may be made in the following manner.

Since A B is equal to 120 toises, if from it there be taken the demi-gorge A L, or B M, which is equal to 26 toises, there will remain 94 toises for the lengthened curtain, A M, or B L, from which, if 26 toises be taken, we get the curtain L M, equal 68 toises. But as this figure is a hexagon, the angle of the centre is equal to 60°, and the angle of the polygon to 120°. The little radius is also of course equal to 120 toises.

The angle, I L M, of the flank, or its equal, A L O, is found by the means of the following analogy.

As the sum of the sides O L + A L = 145 toises, Is to their difference O L - A L = 94 toises, So is the tangent of half the sum of the angles A L O, A O L = 60°, To the tangent of half their difference, which is equal to about 48° 7'. This angle added to 60° gives 108° 7' for the
CONSTRUCTION.

the angle L M of the flank, and taken from 60° leaves 
11° 57; for the flank-forming angle A O L, or A O I.

In like manner the angle diminui, L M I, or M G H, is 
found from the oblique-angled triangle L M I, by means of this 
analogy.

As the sum of the sides L M, L I, which is equal to 92 
toises,

13° to their difference, which is equal to 44 toises.

So is the tangent of half the sum of the angles L M, 
L M I = 35° 56½°,

To the tangent of half their difference, which is equal to 
about 10° 27½°. This angle, taken from 35° 56½°, leaves 
about 1.9° 49½ for the angle diminui L M I, or M G H,

This and added to 35° 56½ gives about 55° 4' for the angle 
L M I; consequently the angle G I L of the epaule is equal 
to 124° 56'. And if 33° 28½, which is equal to twice the 
angle diminui, be taken from 180° we get 146° 24', for the 
flanking angle G I H, or I I K. Double the angle diminui, 
or 33° 28½, taken from 120°, the angle of the polygon 
leaves 86° 22' for the flanking angle, or angle of the bafton.

The angle diminui, 16° 49½, taken from 108° 18', the angle 
of the flank leaves 91° 18½ for L K, or L I H, the inner 
or inward flanking angle.

The line of defence, G M, is found from the oblique- 
angled triangle, A G M, by means of the following analogy.

As the sum of A G M, half the flanked angle, or 43° 11½, 
I, to the sine of the angle of the garge, G A M = 120°,
So is the lengthened curtain A M = 94 toises.

To the line of defence G M, which is equal to about 119 
toises.

And the capital, A G, of the baftion, is found from the 
false triangle, by means of this analogy.

As the line of A G M, half the flanked angle, or 43° 11½, 
I, to the sine of the angle G M, A M = 109° 49½.

So is the lengthened curtain A M = 94 toises.

To the capital A G of the baftion, which is equal to 
about 30½ toises, to which, if we add the little radius O A, 
which is equal to 120 toises, we get 150½ toises, for the 
great radius O G, to which the exterior side, G H, is equal, 
as the figure is a hexagon. And in every polygon, the 
exterior side, G H, is a fourth proportional to the little 
radius O A, the great radius O G, and the interior side 
A B.

The face, G I, of the baftion, is determined by finding the 
line I M from the oblique-angled triangle, I M L, by this 
analogy.

As the line of the angle diminui I M L = 16° 49½, 
I, to the sine of the angle I M L of the flank = 108° 17½,
So is the flank I L, which is equal to 24 toises.

To the line I M, which is equal to about 79½ toises, and 
when taken from I M, the line of defence, leaves about 40½ 
toises for G I, the face of the baftion.

The angle A O B is called the angle of the centre.
The angle B A C is called the angle of the polygon.
The angle N G I is called the flanked angle, or angle of 
the baftion.
The angle I I K, or G I H, is called the outward flanking 
angle.
The angle G I L is called the angle of the epaule or 
shoulder.
The angle L M I is called the angle of the flank.
The angle A O L, or M G H, is called the angle diminui.
The angle A O L is called the flank-forming angle.

P N G I L is called a baftion.

A P, or A L, is called the demi-gorge of the baftion.
The line joining the points P, L, is called the gorge of 
the baftion.

The angle I K L, or I L H, formed by the flank I L, 
and the line of defence L H, is called the inner flanking 
angle.

A B is called the inward or interior side.
G H is called the outward or exterior side.
O A is called the little radius.
O G is called the great radius.
I L, or K M, is called a flank.
I M is called the curtain.
A M, or L B, is called the lengthened curtain.
G M, or I L H, is called a line of defence.
A G is called the capital line, or capital of the baftion.
A I, or H K, is called the face, or point of the baftion.
The flank I L is called right flank, when it makes a right 
angle with the curtain; oblique flank when it makes an 
oblique angle with the same; and acute flank when it 
makes an acute angle with the curtain; as it does by 
Errard's method in figures up to the octagon. When 
the orillon is rounded or formed by the arc of a circle, it is 
called a round orillon, and when it is rectilinear, or formed by 
the face of the baftion, produced a few toises beyond the 
epaule, and a right line drawn from the extremity of the said 
prolongation, either parallel to the flank, or nearly so, it is called a 
fluent orillon. It is made for the purpose of covering part 
of the flank, which for that reason, or in order to be the 
more effectually covered, is taken a few toises inwards from the 
flank itself towards the centre of the baftion, and is generally 
made in an arc of a circle, though it would be better in a 
right line, or on the chord of an arc. It is on this account called 
the retired, or covered flank, and sometimes the eunatum, and 
place-bofts. And its depth, or enforcement, on the line of 
defence, produced beyond its intersection with the 
curtain, as well as its distance from the outside of the orillon, 
is called the retrace or retracement of the flank, or the platform 
of the eunatum.

The line Q S is called flank, because it defends the face 
G N of the opposite baftion. For, in fortification, to flank 
has the same meaning or signification with the phrase to 
defend. When the line Q S is not compos'd of the face 
G N of the baftion, and a prolongation thereof to the angle 
Q of the flank, it is called flank-fibant, because a mufketer, 
at its extremity Q, can fire, or ftifer, as the French 
term it, at or against any part of the face G N. Hence the 
line Q S, drawn from the said extremity Q of the flank, is 
called the flant-line of defence, and sometimes only the 
flaunt-line. It is also called the great line of defence. But 
when in the face G N of the baftion produced, meets the cur-
tain Q P, in any point, R, between the points Q and P, or 
in any point R nearer to the said baftion, the line G R is 
called the reftant-line of defence, or simply the reftant-line, 
and also the flant-line of defence, being shorter than the line 
Q S, because, a mufketer cannot from the point R fire at or against 
any part of G N, the face of the baflion, but can only rafe 
or fire along it. The part Q R of the curtain intercepted 
between the lines G Q, G R, is called the second flank, as 
also the fire or the curtain, because from every point in it, 
except the extremity R, one may flout or fire against every 
part of the face G N. Second flanks are not always, nor 
indeed frequently, made. And when there are none, there 
are no flaunt lines, but only reftant-lines of defence, in which 
case the flanks are called reftant flanks, because from their 
extremities, that join the curtains, one can only rafe or fire 
along the faces of the opposite baftions, but from any inter-
mediate points between those extremities and the epaule, 
he can fire at or against the said faces. The flanks form 
the principal defences, since an enemy cannot, whilst they 
remain entire, approach the body of the place. And they 
are;
CONSTRUCTION.

In his third method of construction he makes his demi-gorges, as in the second, of the same length as in the first, and his flanks of the same length as in the second; but instead of limiting the flanked angle or angle of the bastion to a right one, by supposing a semicircle to be described on a right line, joining the two epaules, he supposes it to remain always acute, by making the capital AG equal to the gorge-line PL.

The calculation of the principal lines and angles in this construction is easily made.

In his fourth method he has no second flanks, but makes all the defences rafant. He considers this method as more general than the three foregoing ones, which it certainly is, since it does not limit the lengths either of the demi-gorges or of the flanks, which, in this as well as in the others, are always on right lines, drawn from the centre of the polygon, through the extremities of the demi-gorges. And although the demi-gorges become greater with the number of the sides of the polygon, they increase so slowly, that in one of 60 sides the demi-gorge is only equal to about 37° 42'. The following is his construction for this method.

From the centre O of the polygon or figure, draw a right line perpendicular to the inward or interior side AB. Divide this perpendicular into such a number of parts, as exceeds the number of the sides of the figure or polygon by unity. Set off two of these parts from each extremity of the inward or interior side, which is always supposed to be equal to 120 toises for each demi-gorge, and take three of them from the said extremities on the little radii produced for the capital of each bastion. Then, from the outer extremities G, H, of these capitals, which are the points of the bastions, draw right lines to the points M, L, where right lines, drawn from the centre through the extremities M, L, of the demi-gorges, intersect the interior side. And these rafant lines, so drawn, will determine both the faces G, I, H, K, and the flanks L, M, K.

By this construction, which is very simple and easy, the flanked angle or angle of the bastion begins to become obtuse in the enneagon, where it is equal to about 98° 6', and grows more and more so in the higher polygons. This angle, however, increases but slowly, or at the rate of about one degree in each successive polygon, amounting in the decagon to about 106° 26'.

The calculation of the principal lines and angles, in this construction, is easily made in the following manner.

The perpendicular, from the centre O of the polygon to the inward or interior side AB, is found by this analysis. As radius:

1. Is to the tangent of the angle OAB = 60°,
2. So is half the interior side AB, or 60 toises.
3. To the perpendicular from O to AB, which is equal to about 104 toises. Wherefore the gorge AL being, by this construction, equal to two-sevenths of this perpendicular, is equal to about 29 3/7 toises; and the capital AG, being equal to three-sevenths of it, is equal to about 44 4/7 toises. The lengthened curtain AM is consequently equal to about 90 toises. Wherefore the angle diminuid AMG, or 1ML, is easily found from the oblique-angled triangle AMG, by this analysis.

As the sum of the sides AM, AG, which is equal to 134 3/7 toises,

4. Is to their difference, which is equal to 45 5/7 toises,
CONSTRUCTION.

So is the tangent of half the angle OAM, or 50°.
To the tangent of half the difference of the angles AMG, AGM, which is equal to about 11° 6'. Consequentlie the angle AGM, or half the flanked angle, is equal to about 41° 6', and the angle diminuèd LMI to about 18° 54'. Wherefore the flanked angle, or flankant angle of the baflion, is equal to about 82° 12', to which adding the angle of the centre, or 60°, we get the flankant angle G & H, equal to about 142° 12'.
The angle ILM, in this construction, is obtained by means of the following analogy.

As the sum of the perpendicular from O to A B and half L M, or 134° toises,
Is to their difference, which is equal to 745 toises, or as
405 to 224,
So is the tangent of 45°, which is equal to radius,
To the tangent of 23° 42', which added to 45°, gives
73° 42' for the angle OLM, and consequently 106° 18' for the angle A LO, or its equal ILM, the angle of the flank; to which if the angle diminuèd L MI = 18° 54' be added; we get the angle G I L of the caponier, equal to 125° 18'. And if from the angle OLM there be taken the angle A O B, or half the angle of the hexagon, we get 15° 42' for the flank-forming angle A O L.
The flank IL is found from the triangle ILM by this analogy.

As the sine of the angle I LM, which is equal to about
54° 48',
Is to the sine of the angle diminuèd I ML, which is equal to about 18° 54',
So is the curtain L M, which is equal to about 60° toises,
To the flank I L, which is equal to about 24 toises.
And the perpendicular distance of the interference i of the lines of defence, from the exterior side G H, is found by this analogy.

As radius
So is the half of the exterior side G H, which is equal to about 85.25 toises.

To the perpendicular distance of i from G H, which is equal to about 28.165 or 28.16 toises nearly, exceeding the flank by 4.16 toises.

Mr. Mullen, in his "Elements of Fortification," has delivered what he is pleased to call a new construction. It differs, however, from Mr. Vauban's first method only in the following particulars.

1st. Instead of supposing, like Vauban, each flank to be the chord of an arc described from the shoulder or epaule of the opposite baflion as centre, he supposes it to be the chord of an arc described from the interference of the line of defence and countercarp produced.

2dly. He makes his retired flanks rectilinear, instead of making them in circular arcs.

3dly. Instead of using Vauban's tenailles before the flanks, he places ramparts before them.

4thly. He makes his orillon 5 toises long only, instead of 6, like Mr. Vauban.

Lately, instead of drawing the right line, which terminates the retired flank from the flankant angle of the opposite baflion, like Mr. Vauban, he draws it from a point on the face 5, or rather 10, toises within the said angle.

For, in his construction of this method, he begins, like Vauban, in his first method outwards, and constructs inwards. Like him he also supposes the exterior side of the polygon to be equal to 180 toises; and after observing that the perpendicular may be of any length, as the 6th, 5th, or 4th part of that side, he, like him, also fixes on 39 toises for its length. Like him also he marks the face of his baflion equal to 50 toises, or 12° of the exterior side.

He determines the flankant angle of his ravelin in this manner: he sets off on the face of his baflion from 12 to 15 toises from the shoulder or epaule, and from the opposite angle of the baflion as centre, with the distance therefrom on the line of defence to the extremity of the line, set off from the shoulder on the face of the baflion, he interferes the perpendicular to the exterior side, produced beyond it outwards.

He also gives the construction of a place with detached baflions from an inward or interior side of 1.6 toises, applied to an octagon, in which he substitutes small baflions instead of Vauban's tower-baflions. In this method, he makes the demi-gorges of his small baflions each equal to 12 toises, the capitals of his detached baflions each equal to 55 toises, and their faces each to 60 toises. He determines the flankant angle of his ravelin, by describing from the extremity of the flank, as centre, through a point in the face of the opposite baflion, about 20 toises from the shoulder, an arc to intersect the right line, in which is the capital of the ravelin.

He likewise gives the construction of a place with detached orillon-baflions, beginning outwards, and constructing inwards from an exterior side of 200 toises, and applying it also to an octagon.

He makes his perpendicular, in this construction, equal to 40, or a fifth part of the exterior; the faces of his baflions equal each to 55 toises; the radius of the arc, that serves to determine the position of his flank, equal to 22 toises; the width of the ditch of the flankant angles equal to 16 toises; his orillon equal to 5 toises; and he keeps his flank retired 5 toises.

The marquis de Montalembert has published a large treatise on fortification, in which he makes much use ofcalculate and arches so much condemned by the Chevalier de Ville. His construction is in fact the same with Mr. Blondel's, applied to a right line or polygon, of an indefinite number of sides. For in this extreme case, which is of all others the most defective, Mr. Blondel's construction leaves no curtain, but gives the perpendicular equal to half the exterior side, and the angle diminuèd equal to 45°.

In defending, however, from the right line or polygon of an indefinite number of sides, Mr. Blondel's construction affords a curtain, which gradually increases as the number of the sides of the polygon decreases, whilst the angle diminuèd at the same time gradually decreases, which in a hexagon, by his rule for determining it, viz. by taking from 45°, a third part of the angle of the centre of the polygon, is equal to 25°. But the marquis de Montalembert makes his angle diminuèd in every polygon, and on all occasions, invariably equal, to 45°. His construction is formed by the placing of triangles contiguous to one another, or by the juxtaposition of the angles at the bases of triangles in such a manner, as to make the other sides form re-entering angles equal each to a right angle, from which circumstance it is called la fortification perpendiculaire. It therefore affords no curtains or baflions, but when the elevation is of only an ordinary height, it necessarily creates dead parts from the re-entering angles quite to the flankant ones, or throughout its whole extent.

It may indeed be alleged, that these dead parts can be removed by calculating the retrovolved, countercarps, caponiers, &c. &c. and no doubt they may. But what good reason can be assigned for adopting a mode of construction, which creates every where those very defects, which in constructing the body of any place, it has hitherto been the first object and principal business of every fortifier to avoid, and then
then having recourse to a number of expensive, and otherwise unnecessary, contrivances, merely to get rid of the defects thus created.

As we understand that this system of fortification has been much disapproved of by some of the ablest engineers, on the Continent of Europe; and as the late duke of Richmond, when master-general of the ordnance, was so partial to it that it was with much difficulty and after a great deal of discussion, that the engineers in the Portsmouth division, could persuade him to adopt Vauban's first method in preference to it, for the new pentagonal fort, that has been erected on Portsea island, near Lancing town; a candid and impartial comparison between these two methods of construction may not be useless to professional men, or unacceptable to the public. But we cannot make a comparison between them, more ably, correctly, and scientifically, than it is drawn in an anonymous publication of 1794, re-published in 1825, in the following words.

"It is manifest then, that after a work is once adapted to the ground it is to occupy. &c. the first consideration is to construct it in such a manner, as to leave no dead parts; that is, to leave no such parts as cannot be seen, fired on, or flanked from other parts. That this is a fundamental maxim, and ought to be a primary object of attention in the construction of every work, is manifest from this circumstance: that, were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be raised along the exterior sides of figures themselves, or the curves circumfering them, as along the several parts of the two figures, into which the sides are usually broken for this purpose. The strength of a work, indeed, depends chiefly on its flanks; since an enemy cannot approach the body of the work, whilst the flanking defences remain entire. But if there be dead parts, the moment an enemy gets to them, he finds himself in a state of security, and out of the reach of the besieged's fire. An idea therefore of the necessity of avoiding them has always made such a forcible impression on the minds of able fortifiers, as to induce them to limit the heights of sections. For even when the side of a polygon is 180 toises long, and is broken into two demi-baillons, and a curtain with flanks, if the section of the work be very high, the guns in these flanks cannot fire or suffer the ditch but at too great a distance. When it is only of an ordinary height, it is well known that the guns in the flanks do not see the ditch effectually nearer than the intersecion of the lines of defence, which in Vauban's construction is 44.8683 toises, or 45 toises nearly from the shoulders of the bastions, and 40.2653, or 40 toises and a quarter nearly from the re-entering angles formed by the curtain and flanks. When the exterior side, therefore, is less than 180 toises, the section ought to be kept proportionally lower, provided only it be not so low as to expose the body of the place to surprise. But if it once be admitted as a maxim, that a fortification ought to be constructed without the least regard to any flanking defence, and that the avoiding of dead or uneven parts is an object not worthy of attention; it is evident that the rectilinear and curvilinear are greatly preferable to the zig-zag or triangular construction formed by constructing triangles on the sides of any right-lined figure or polygon. The fire from a straight line is the best of the direct kind that can be obtained, being equally and uniformly distributed. And the enemy cannot advance against it directly, without a good deal of demy, inconvenience, and trouble, but must carry on his approaches somewhat in the way commonly practised, till he gets to the dead parts in front of it: when, unless contrivances be made of that have no natural or inseparable connexion with the construction itself, it will cease to be formidable for want of flanking defences. This observation likewise holds good in a great measure with regard to regular curves, from which the fire is also regularly distributed. The interior area too in each of these defences, and within the same encirclement, length of encloiture, or extent of rampart, is much greater than in the triangular construction, which naturally, instead of producing any fire that is direct or at right angles to the exterior sides, produces no good flanking one for itself, but causes a continuity of dead parts, when the section is high and the lines of defence but short, to reign throughout its whole extent. An enemy can approach it without annoyance from the besieged in lines bifacing either the faifant or re-entering angles, or in short in lines directed to any intermediate points whatever between these angles.

It must therefore be allowed, that the triangular construction, whether the re-entering angles be right ones (as in the "Fortification perpendicular" of the marquis de Montalembert), or acute or obtuse ones, is naturally the most defencable and ill contrived of any that can possibly be thought of or conceived: for it creates dead-part throughout the whole extent almost of the work, and is equally defective of flanking fires for itself, and of a good or well distributed direct one against the enemy.

The marquis, fig. 4, planche 15, vol. i. of his performance, gives what he calls his regular construction in a dodecagon, of which the exterior side is 180 toises. The radius of the circumserbing circle is of course equal to 347.733297; or 347.7335 or 348 toises nearly, and the perpendicular distance from its centre to the exterior side 335.4883457; or 335.4845, or 326 toises nearly. Consequently the annular area occupied by his construction is equal to that of the incribed circle, in the circumstance of which his re-entering angles are of 90°, or which comes to the same thing, to half the area of the circle circumserbing the dodecagon. But if Vauban's construction be made on the sides of the same figure, the annular area occupied by it will be to that of the incribed circle, to which the curtains are tangents at the points, where the perpendiculars produced meet them, as 34950.228 to 85538.24, or as 17520 to 42909 nearly, or in small numbers as 20 to 40 nearly.

The exterior area between the construction and the sides of the dodecagon in Montalembert's method is to that in Vauban's as 8100 to 4270.2657, or in small numbers, as 19 to 1 nearly 1 and as both the faifant and re-entering angles in the former are less than in the latter, this difference of loft area will be considerably increased in practice. For in the marquis's construction, each of the faifant angles contains 60 degrees, and each of the faifant ones 90°; whereas in Vauban's the faifant angle of each baflion is 115° 7' 48", and each of the re-entering ones formed by the flanks and curtain is 95° 15' 3".

Montalembert's construction gives the enceinte or boundary of the body of the place equal to 3054.70128 toises, exceeding Vauban's, which is equal to 2771.1856, by 283.41708 toises.

When he infers or intercalates triangles having their faifant angles right ones and in straight lines, as in figures 3. 5. 7 and 8, planche 15, after the method pointed out in fig. 1, he loses still more area in proportion to the interior space. And the very circumstance of his having recourse to different centres of construction, even on figures that are regular, is sufficient to create a suspicion, that he did not understand even his own method in its full extent.

Although he must certainly be considered as a very thallow and superficial geomcter, the reason for his not fixing on any polygon under a dodecagon for illustrating his regular construction, is very obvious; for no regular figure of a smaller number

5
number of sides, will by it give falient angles of sixty degrees, which is the smallest angular magnitude that engineers have generally reckoned admissible in fortification. I can see no good reason, however, (lays our author) for his abandoning regular polygons, when he has occasion for more triangles than twelve, and by way of interpolation inferring the additional ones to this number between right lines, parallel to the sides of triangles, squares, or rectagles, since a construction on the sides of a regular polygon furnishes much more interior area, with a comparatively but trifling increase of length in the enceinte or enclosure of the body of the place.

The comparison, which he draws, p. 197, (illustrated by fig. 9, plane 15.) between Vauban's method on the sides of a square, of which each is equal to one hundred and eighty toises, and his own on the sides of a dodecagon inscribed in the circle circumfcribing this square, is a very improper and unfair one. In this figure, each of the lines, which he calls his lines of defence, is equal to 45.5874 toises, and must, with a section of an ordinary height, have dead parts in front of it throughout its whole extent. Each of the sides is equal to 65,884.6 toises very nearly, and not to 66 toises one foot, as from his scale he erroneously states it to be. The most candid and impartial mode of comparing these two methods of construction together is to suppose both to be made on the sides, of one and the same figure. The marquis's construction, however, on the sides of a square, neither leaves interior area nor falient angles. For its re-entering angles meet in the centre of the circumfcribing circle. But as in it the lines of defence when equal form angles of 45° with the exterior side, each of the falient angles, which it gives in any polygon, is equal to the excess of the angle of that polygon above 90°; or which comes to the same thing, to the excess of the re-entering angle formed by the lines of defence above the angle at the centre of the figure, since the excess of the angle of any regular polygon above 90° is equal to the excess of 90° above the angle at the centre of the circumfcribing circle subtended by one of its sides. Consequently, when the polygon has an indefinite number of sides, or becomes a straight line, the falient angle is equal to ninety degrees. Thus a square with this construction gives no falient angle at all; a pentagon one of 13°; a hexagon one of 30°; a heptagon one of 38° and four sevenths; an octagon one of 45°; an enneagon one of 50°; a decagon one of 54°; an endecagon one of 57° and three elevenths; a dodecagon one of 60°; a polygon of 18 sides one of 70°; a polygon of 36 sides one of 80°; and so on indefinitely. By this construction on a pentagon, of which the side is equal to 180 toises, the re-entering angles come within 34 toises of the centre of the circumfcribing circle; and within 19, if the exterior side be only equal to a hundred toises. How little interior area then would have been left, had this construction been made of for the new pentagonal work on Fortuna island, called Fort Cumberland, of which one of the exterior sides is equal to 120 fathoms, and each of the other four to a hundred! Even on a hexagon, of which the side is equal to 180 toises, it brings the re-entering angles within 66 toises of the centre of the circumfcribing circle, and gives the annular area occupied by it to the area of the inscribed circle as 2 1/2 to 4 - 2 1/2, or as 6.464 to 1, or in small numbers as thirteen to two nearly. If be even made on parts of one and the same straight line as exterior sides, of which each is equal to 90 toises only, the perpendicular distance between that line and the right line parallel to it through the re-entering angles exceeds that between the parallel right lines, limiting Vauban's construction on parts of one and the same straight line as exterior sides equal each to 180 toises, or two of the others, by 2.2756 toises, and only becomes equal to it, when the exterior side is reduced to 85.2498 toises.

The angle (108°) of a pentagon exceeds 95° by 18°, which is equal to the excess of 95° above (72°) the angle of the centre. But 18° are equal to $90° \times \frac{1}{5}$ or $360° \times \frac{1}{10}$, in like manner the excess of (120°) the angle of a hexagon above $90°$ is equal to $15° + 12° (= 30°)$ the excess of 90° above (60°) the angle of the centre, that is, $360° \times \left(\frac{1}{5} + \frac{1}{6}\right)$. Wherefore we get $360° \times \left(\frac{1}{4.5} + \frac{1}{5.6}\right) \times$, &c. indefinitely or $ad^f substantiatis$ $= 90°$, and of course $\frac{1}{4.5} + \frac{1}{5.6} + \frac{1}{6.7} + \frac{1}{7.8} + \&c. = ad^f infinitum$, and innumerable other forms, may easily be derived from common geometry and the angular relations of rectilinear figures. But the summation of infinite series is a subject which it is not my intention to enter into the consideration of at present.

There is a circumstance attending this construction, which, I dare say, never occurred to the marquis. It is this: though on the sides of a square it brings the re-entering angles to the centre of the circumfcribing circle, and leaves neither interior area nor falient angles; yet, if it be made on the sides of any given regular polygon, and the re-entering angles be joined by right angles forming a similar polygon, and on them a similar construction be made, and so on indefinitely or $ad^f infinitum$, it will never bring the re-entering angles to the centre of the circle circumfcribing the given polygon, but nearer to it than by any given right line or distance. And if spirals be supposed to pass from the angles of the polygon through the angular points of equal angles in endles or indefinite succession (each equal to 45 degrees, together with the same angle of the construction and the complement of its half) formed by the lines of defence taken singly from the first in the indefinitely successive constructions, will pass round the centre of the circle circumfcribing the given polygon, and a definite number of times without ever reaching it; and the area between any two of these spirals commencing from one of the exterior sides of the polygon will become nearer in point of equality than by any given space or area to such a part of the polygon, as is expressed by the number of its sides, without ever equalising it. The sum or aggregate of these lines of defence, in decreasing geometrical progression and endless succession, can always be expressed by a given definite straight line.

From what has been observed, the following inferences may certainly be very fairly and impartially drawn respecting Montalembert's construction. 1st. When the exterior sides are short, it naturally creates, with a section of an ordinary height, dead parts throughout its whole extent. It may perhaps be alleged, that this capital defect can be removed by caismed defences with artillery near the re-entering angles on a level almost with the ditch. To a certain degree it certainly may: but that method of construction, which by itself naturally removes every such defect without any obfolute or adventitious contrivance, is surely entitled to preference in the opinion of every able or intelligent fortifier.
CONSTRUCTION.

34thly. His slanting angles are too small, being less in a dodecagon than Vauban's are even in a square; for in a dodecagon his slanting angle is only equal to sixty degrees, whereas in a square Vauban's is equal to 60° 55' 39", and in the dodecagon 113° 7' 48". This is unquestionably an essential defect.

35thly. It furnishes no fire that is direct or perpendicular to the exterior sides. That this is a great defect cannot be denied.

44thly. Opposite to each re-entering angle, at the distance only of 90 toises from the exterior side, there is a quadrangular space (which no fire from the place cou'd command, or touches), commencing in an angle of 90 degrees, and terminating in one of 30 degrees, at the same distance from the exterior side with the centre of the dodecagon.

55thly. Opposite to every slanting angle, and at the distance from it only of about 254 toises and a half, there is a space that is not secured or commanded by the fire of the place, which commences in an angle of 90 degrees, widens till its breadth becomes equal to the radius of the circle circumferencing the dodecagon, and then runs on indefinitely at that width between parallel lines.

66thly. The greatest width of each of the first-mentioned spaces not traversed by the fire of the place is to the corresponding width of each of the spaces traversed by it as 104 to 137, nearly: and the greatest width of each of the last-mentioned spaces not traversed by the fire is to the corresponding width of each of the spaces traversed by it as the radius of the circle circumferencing the dodecagon to 137-76 toises, or as 204 to 100, nearly.

77thly. As the respective breadths of these spaces not covered by the fire of the place bear so great proportions to the corresponding breadths of those covered by it, and, as the distance between every two of them is only equal to one of his lines of defence, or 127,2794 toises, the besiegers may advance almost to the very creft of the glacis without any interruption from the fire of the besieger. But it is an important object in defence to keep the besiegers at a distance from the body of the place as long as possible. For when they once get within the distance of serious musketry from it, they will infalubly silence artillery, whether the embrasures be open or covered at top, or whether the guns be in canister or not.

88thly. The besiegers may easily destroy his principal covered musketry-defences before they are exposed to his principal caffeinated defences with artillery, which being low, to take off the dead parts unavoidably occasioned by the very nature and badness of his construction, are chiefly calculated for defending the passage of the ditch, and cannot annoy an enemy till he gets to the very creft of the glacis, after which every thing almost, except battering in breach, is determined without artillery.

Lastly. The great proportion which the annular area, occupied by his construction, bears to that of the incircled circle, will for ever render it unfit for the purpose of fortifying any considerable town or city.

The marquis de Montalembert's construction has no claim even to originality, if we except the great improbability (I had almost said folly) of making the lines of defence in it form the same angle in all figures, and on all occasions; for when applied to a straight line (as in fig. 1, planche 15, vol. 1) it is the same with Mr. Blondel's. In this case both give the perpendicular equal to half the exterior side, the angle diminished to 45°, the slanting angle or the bastion equal to 50°, the same line of defence, the same flanking or re-entering angle, and no curtain. The only difference between them consists in this, that Mr. Blondel, in defending from the right line or polygon of an indefinite number of sides to inferior polygons, makes his angle diminished gradually according to the rule he has delivered for ascertaining its magnitude, whereas the marquis keeps his in all figures invariably the same. [Mr. Blondel's rule for ascertaining the angle diminished is the following: add fifteen degrees to one-third part of the excess of the angle of the polygon above 90 degrees.] Mr. Blondel's construction on an indefinite right line gives the perpendicular nearly double what it ought to be; and the marquis, by keeping this preposterously large perpendicular in all figures on the same exterior side and his angle diminished invariably, finds the slanting angle of his dodecagon equal only to 60°, the smallift that is generally considered by engineers as admissible in fortification. This circumstance, therefore, by the marquis's own acknowledgment, renders his construction inapplicable to any polygon of a smaller number of sides than twelve, and is certainly sufficient of itself to demonstrate not only its impropriety, but, I believe I may venture to say, even absolute absurdity. It in fact furnishes nothing but star-figures with re-entering angles of 90°; and it is manifest that no regular figure of this sort under a dodecagon will give slanting angles of 60°.

Notwithstanding these observations, which I have certainly made with the strictest attention to truth, and, I flatter myself, also to candour, I am heartily disposed to allow every point of merit to the marquis's voluminous performance, that either his grace or any other person can point out as really belonging to it. I never can be hostile to any person who even endeavours to enlarge the poudria, either of abstract science or professional knowledge; for the very attempt is laudable. And I must confess I am inclined to believe, that some of his caffeinated contrivances might, in certain situations and circumstances, be advantageously united with Vauban's construction. I cannot help considering him however as rather a superficial geometer, and as a very loofe and incorrect writer. But to prevent the possibility of charging me with misrepresentation in regard of his incorrectness, I will briefly quote his own words.

In his "Décours Prélinaire," p. 38, he says, "Le premier système de M. de Coehorn est absoiment le même que celui du Comte de Pagan, auquel il a seulement ajouté une tour cintrée à chaque orillon, pour défendre les faces hautes des bastions." That he should have hazarded such an assertion is to me astonishing. For these two methods differ widely and essentially. In Coehorn's first method, which is applied to a hexagon, for instance, the ratio between the perpendicular and exterior side is very different from what it is in Comte Pagan's: since in the first the angle formed by the exterior side and line of defence is equal to 24° 38' 48", whereas in the last it is only equal to 18° 26' 46°. The difference is 5° 12' 42". The slanting angle of the bastion in a hexagon by Comte Pagan's method is equal to 83° 7' 46", whereas in Coehorn's first method it is only 70° 42' 24", falling short of the other by 13° 25' 24°. These are capital and essential differences. And every person who chooses to examine them will find them very different in many other respects. Vauban indeed appears to have borrowed more from Pagan than Coehorn has done. For, in any polygon having its exterior side equal to 180 toises, their perpendiculars are equal as well as the slanting angles of their bastions; and I am persuaded that even the greatest admirers of Vauban can assign no good reason for his not having followed Comte Pagan also with regard to the position of his flank, and placed them at right angles to the line of defence instead of making them meet in an angle of 80° 46' 57". There is great reason to suppose that the Count would have made the face of his bastion considerably
CONSTRUCTION.

fiderably shorter than he did, had he not intended to have three flanks instead of one. He makes it 55 toises. But it is naturally to be presumed, that had he intended to con-

struct with a single flank, he would have bisected the per-

pendicular distance between his orillon and inner flank (which is 20 toises) and drawn his flank at right angles to the line of defence through this point of bisection, thereby forming a more complete construction for the body of the place with single flanks than Vauban has done. And it is somewhat remarkable, that this line nearly coincides with a perpendicular to Vauban's line of defence from its point of interference with the flank. Had he therefore, instead of taking five toises from the face of Count Pagan's bastion, taken ten, and then placed his flank at right angles to the line of defence, he would, without lengthening this line, have given the face of his bastion its proper length, and at the same time made the flank itself about equal to the per-

pendicular, as it ought to be, since perpendiculars to the ex-

terior sides of polygons were first introduced into con-

struction for the sole purpose of obtaining flanking defences.

Were I at present treating formally of fortification, I would deliver a very simple method of construction for rendering the flanks always equal to the perpendiculars to the sides of the polygon.

The lengths however assigned to the perpendiculars are merely arbitrary, and by no means derived from reasoning either on the properties of the figures or their relative degrees of importance and capability of defence. For there appears no reason for giving the same perpendicular to a hexagon and every other polygon of a greater number of sides, as Vauban has done, or to all regular figures above the square, as Count Pagan has done. In like manner Cochon's perpendiculars are too long, and merely arbitrary: for in his first method, which is applied to a hexagon, the angle formed by the exterior side and line of defence is, as I have already observed, equal to 24° 39' 48"; in the second, which is applied to a heptagon, 24 degrees and two sevenths; and in the third, which is applied to an octagon, 25 degrees. This angle in Delabor's first and second methods applied to an octagon is also too great, being in the former equal to 26° 33' 54", and in the latter to 29° 48' 59". In his third method however, which is also applied to an octagon, it is equal to 27° 48' 5" and is not so much distant from what it really ought to be, as it differs only about three minutes from the angle subtended by the true perpendicular of an enneagon.

The perpendiculars are also a great deal too long in Blon-
del's method, which, when it is applied to a straight line or polygon of an indefinite number of sides, gives one equal to half the exterior side.

Le marquis, vol. i. p. 191, says, "Mais d'es que lignes de défense peuvent avoir jusqu'à cent cinquante toises, et les hypotenus environ deux cent dix-huit toises, il fuit que le rayon de ce polygone régulier inscrit dans le cercle peut être de quatre cent vingt-six toises et demi, le rapport du côté du dodecagone à son rayon étant comme quinze à un, est en effet environ, et ce rayon est de peu pres celui d'un polygone à baillons de quinze côtés, par conféquent de quinze baillons.

A right-angled triangle however, having each of the sides containing the right angle equal to 150 toises, does not give the hypotenuse equal to 216 toises, but to 212.132 toises, which, as the side of a dodecagon, gives the radius of the circumcirculating circle equal to 409.876 toises very nearly, and not to 421 as he flites it to be.

In page 203 he falls into the same mistake.—Take how-

ever his own words:—

"Mais l'on a vu, comme il est aisé de le sentir, qu'il est un terme où le rayon d'un cercle ne pourroit plus déter-

miner le côté de notre manière de forteriser : et ce terme est

celui où la corde de l'angle au centre de trois degrés que le rayon donnerait, pafferaient deux cent vingt toises, puisqu'alors cette corde prise pour diagonale aurait deux côtés de plus de cent cinquante toises chacun, qui est une distance plus grande que celle admirable pour la portée des armes à feu de

but en blanc."

Here he mentions 150 toises as the greatest admissible length for each of the lines of defence, and 225 for the cor-

responding hypotenuse, or exterior side, which he calls the

diagonal. But the fact is, that a hypotenuse of 210 toises, gives either side of an icosoids right-angled triangle consti-

tuted on it greater than 155 toises and a half. There are many mistakes of a similar nature in this gentleman's per-

formance, who appears to have used scales much more than calculation. The exposure of error, however, is an unpleasant task, even when the elucidation of truth is the object."

From the whole of what is above delivered, it appears evi-

tent, that the magnitude of the angle diminués, and of the perpendicular to the exterior side, on which the other parts of the construction chiefly depend, is with all the writers on forti-

ication a mere arbitrary assumption, for which they do not even attempt to assign any reason, and much less any good one, drawn from the nature of the polygons themselves, the various degrees of difficulty in embracing them, or their respective degrees of capacity of defence. The truth is this, that every polygon has a perpendicular belonging to it, of a precise and determinable length, or bearing a given ratio to the exterior side. And the ascertaining of the true per-

pendiculars belonging to all different polygons is the great

dideratum now wanted for perfecting military construction.

We understand, that Mr. Glenie, formerly of his majesty's corps of engineers, has had in his possession a complete in-

vestigation of this important problem for upwards of twenty-five years. But as he has not yet chosen to make it known to any person, we could not expect him to communicate it to us. He has, however, been pleased to furnish us with the following rules, which have been made known to several individuals, both for regular and irregular construction, on the latter of which nothing of extensive application or much delivering of notice has as yet been delivered by the writers on forti-

ication.

A short paper on fortification, delivering a method of con-

struction for always making the flanks either equal to the perpendiculars to the exterior sides, or in any given ra-

tio to them, and also a rule alike applicable to regular and irregular construction; and, in its application to the latter of thieves, infinitely more extensive than all that has been hitherto published on the subject. By James Glenie, esq.

A.M., and fellow of the Royal Societies of London and Edinburgh.

"After the invention of gun-powder, the ancient method of securit and fortifying places was gradually departed

from. Various important alterations were introduced into fortification, as the construction and man-

agement of artillery became more and more improved. Many treatises have been written on the subject in different nations and languages. And could we for a moment sup-

pose improvements in the art military to have kept pace with these publications, we must naturally conclude, that military construction has by this time reached almost all the perfection it is capable of. But although war has been a profession in Europe, and the attack and defence of places has been studied as a science for almost the two centuries past, it is a certain and undeniable fact, that no writer on forti-

fication has as yet either discovered or demonstrated the true lengths of those lines, on which the other parts of the con-

struction of a work chiefly depend; viz. the perpendi-

culars.
culars to the sides of a polygon, from which the body of the place is to be contructed. No writers on this subject have allligned any sufficient, good, or even plausible reasons for the lengths they give to these lines. With them all, without an single exception, the perpenculars to the exterior sides of a work are mere arbitrary assumptions, and not the result either of any scientific or professional investiga-
tion. Even Mr. Muller, in the three new confructions which he gives in his "Elements of Fortification," in imitation of others, affumes those lines in a manner altogether arbitrary, without allligning any reason whatsoever for such assumptions. In page 76 of his said elements, in his problem for determining the several parts of a front of a fortification," he makes use of the following words: "But as to the length of the perpencular CD, it is no ways determined; for some engineers make it twice as long as others; they seem indeed to derive from one another merely out of contradiction; since none of them, that I know of, has given any reason for this practice." This observation sufficiently shews, in what an imperfect state military confruction remains even at present. For the true lengths of the perpenculars form the great deliberatum in it, fixed on them the flanking defences chiefly depend, for the sole purpose of obtaining and preventing dead parts, the sides of a polygon are broken, either of them into a curtain with two demi-battlions to form the respective fronts of the work. And it must be allowed, that when a work is once adapted to the ground, it is intended to occy, and its position is fixed on, the first consideration after determining the true lengths of the perpenculars to the exterior sides, is to contruct the whole of it in such a manner, as to have no dead parts; that is, to leave no such parts, as cannot be seen, fired on, or flanked from other parts. That this is a leading or fundamental maxim, and ought to be a primary object of attention in the construction of every work, is manifest from this circumstances, that were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be erected on the exterior sides themselves of a fortification as on the figures, into which they are usually broken for that purpose. The strength of a work, indeed, it must be confessed, depends chiefly on its flanks, since an enemy cannot approach the body of the place, whilst the flanking defences remain cut off. But if there be any dead parts through a deficiency of such defences, the moment an enemy gets to them, he finds himself in a state of security, and out of the reach of the beleaguered's fire. The absolute necessity of avoiding them, has always made such a forcible impression on the minds of able fortifiers, as to make them limit the height of fections. For even when the side of a polygon is not more than 180 toises, or 360 yards long, and is broken into a curtain with two demi-battlions, if the section of the work is very high, the guns in the flanks cannot see or fire the ditch but at too great a distance; and it is well known, that when it is only of an ordinary height, they cannot see or command it effectually, nearer than the interfection of the lines of defence. But were it even to be alleged, which would however be an allegation altogether inadmissible, that a fortification ought to be contructed without the least regard to any flanking defences, and that the avoiding of dead or unfeen parts is an object unworthy of attention, it is evident that the rechilinster is preferable to the zig-zag or angular confruction formed by the placing of triangles contiguous to one another, or by the juxta-position of angles at the bases of triangles. For the fire from a slant line is the best of the direct kind that can be obtained, being equally and uniformly distributed. And the enemy cannot advance against it directly, without a good deal of delay, inconvenience, and trouble, but must carry on his approaches from behind the way commonly practised, till he gets to the dead parts in line of it, when it will cease to be formidable for want of flanking defences. The angular or zig-zag line, on the other hand, has no good direct fire, and indeed no flanking fire whatever, where it is most wanted, or can be of any utility; but a continuity of dead parts, when the section is of a sufficient height, reigns throughout its whole extent. An enemy can approach it without being exposed to any direct fire from the beleaguered, that can annoy him, in the lines bisecting either the flankant or re-entering angles, or, in short, in lines directed to any other intermediate points whatsoever, between these angles.

And it is no les evident, that the direct fire from the circumference of a circle, or from any other curve, that returns into itself, is much more equal and uniform, and better distributed than that from an angular or zig-zag line.

That able general and forther, the celebrated marshal Vauban, whole systen has been followed in Europe, in contructing from the sides of a square, made the perpencular an eighth part of one of them, in a pentagon a seventh part, and in a hexagon, and all polygons of a greater number of sides, a sixth part. For this practice, however, he has not assigned any reasons. It is impossible indeed to assign any good reason for giving to a polygon of twenty or thirty sides, or to a contruction on part of a right line, which may be regarded as a polygon of an indefinite or infinite number of sides, and to a hexagon, or a figure of only six sides, the same length of perpencular. Any per-
son, without even a knowledge of geometry, to enable him to draw deductions from the properties of figures themselves, who reflects but a little on the subject, mult natura-
clude, that there can be no found or good reason for doing fo. The truth, in fact, is this, that every polygon has a precise and determinate perpencular of its own, proportional to and connected with its capability of being defended, and of being embraced by a beleaguered enemy, as, says Mr. Glicne, I shall clearly demonstrate in a subfequent paper, that may ere long be presented to the society, as we have shewn, how an inordinate number of infinite series may not only be derived from, but also summed geometrically by means of polygons: and I make no doubt, that had Vauban posseffed a sufficient knowl-
edge of mathematics for the purpose of applying them to the improvement of the theoretical part of his professon, he would have discovered the precise or genuine lengths of perpenculars, which different polygons ought to have, and would have regulated his practice accordingly, in the numerous works he contructed. Unwilling to give into prolixity, I will not, at present, enumerate the different lengths of perpenculars to the sides of one and the same figure or polygon, which the various writers on fortification have affirmed, although the enumeration would prove beyond controversy, that in affurcing them they were guided by their own whims and fancies, and not by any just or determinate rule. It mult however be regarded as a singular fact, that though perpenculars to the sides of polygons were first introduced into construction, for the sole purpose of obtaining flanking defences, not one of these writers, in even treating formally of regular fortification, has either offered, or attempted to deliver, a method of contruction for rendering the flanks always equal to the perpenculars as they ought to be. To supply this defect I will now proceed to give such a contruction, which, like many other things in science, most pregnant with utility, and most extensive in their confructions, has probably been hitherto overlooked chiefly on account of its simplicity.
**Construction.**

Let \(AB\) (fig. 17.) be a side of any given polygon, either regular or irregular. Let it be bisected in the point \(C\), and let \(CV\) be an indefinite perpendicular to \(AB\) at the point \(C\). Through the point \(O\) let indefinite right lines \(AS, BT\), be drawn from the points \(A, B\), and let \(CD, CE\), be each equal to one-half of \(AO\) or \(BO\). Draw the right lines \(DF, EG\), parallel to \(CV\) till they meet \(AS, BT\), in the points \(F, G\); and from the said points \(F, G\), draw \(FK, GL\), perpendicular respectively to \(BT, AS\). Then I say that \(FK, GL\), are each equal to \(CO\).

**Demonstration.**

Since by construction \(AD\) is equal to \(BE\), and \(AC\) to \(BC\), and \(CO\) is perpendicular to \(AB\), the angle \(CAO\), or \(DAF\), is equal to the angle \(CBG\) or \(EBG\), and \(DF\) is equal to \(EG\), being parallel thereto. Wherefore \(FG\) is parallel to \(AB\), and equal to \(DE\), which is equal to \(AO\) or \(BO\). Consequently, since \(FK\) is perpendicular to \(BT\), and \(GL\) to \(AS\), by construction, the triangles \(ACO\), \(FKB\), \(FLG\), are equiangular and equal, and \(CO\), \(FK\), \(GL\) are equal. Q. E. D.

Thus then the flanks \(GL\), \(FK\), drawn at right angles to the lines of defence \(AL, BK\), or \(AS, BT\), are by this very simple construction always equal each of them to the perpendicular \(CO\), whether \(AB\) be the side of a regular or an irregular polygon.

The perpendicular distances \(FL, GK\), of the flanks \(GL, FK\), from the shoulders \(F, G\), of the demi-baftions \(AFK, BGL\), are each of them equal to half the exterior side \(AB\). And each of these perpendicular distances \(FL, GK\), is to the curtain \(KL\), as the sine of the angle formed by either flank, and said curtain, to the sine of the angle at the shoulder of either demi-baftion, that is, as the cofine of the angle formed by the exterior side, and either line of defence, to the cofine of twice this angle.

From the similarity of the triangles \(ACO, ADF, BCO\), \(BEG\), we have each of the faces \(AF, BG\), of the demi-baftions equal to \(\frac{AO \times AD}{AC}\) or \(\frac{AO \times AC - 2}{AC}\), or to \(\frac{AO \times 2AC - AO}{2AC}\). Now if \(AB\), or \(AC\), be denoted by \(2P\) and \(AO - AC\) by \(2Q\), each of these faces will be exprest by \(\frac{P + 2Q}{2} \times \frac{P - 2Q}{2}Q\), or \(\frac{P - 2Q^2}{2P}\), which, when the perpendicular \(CO\) is but small, is nearly equal to the half of \(AC\), or to a fourth part of the exterior side \(AB\).

Each of the angles \(AFK, BGL\), of the shoulders of the demi-baftions is equal to a right angle, together with the angles \(BAO, ABO\), formed by the exterior side \(AB\), and the lines of defence.

**Scholium.**

In like manner may a construction be delivered, which will make each of the flanks \(FK, GL\), have any given ratio \(m : n\) whatever to the perpendicular \(CO\). For if \(CD\) or \(CE\) be taken to \(\frac{m}{2}\) as \(n : m\), we shall have \(DE\) equal to \(\frac{AO \times m}{n}\), or \(n : m :: AO : DE\) \((FG) :: CO : GL\) or \(FH\). And if \(AC\) be denoted as above by \(P\) and \(AO\) by \(P + 2Q\), each of the faces \(AF, BG\), of the demi-baftions, will, in this case, be equal to \(\frac{2n - m}{n} \times P + \frac{n - m}{n} \times 2Q - \frac{m \times 2Q^2}{n} - \frac{n}{P^2}\).

Mr. Muller, in the preface to his "Elements of Fortification," expresses himself in the following words:

"Notwithstanding the art. - others."

"For the true art confineth in - weakness."

Mr. Muller certainly treats of irregular fortification in a more direct and particular manner than any other author that wrote on the subject before him. But his constructions on the sides of an irregular polygon are similar to that which he makes use of on the sides of a regular one. His perpendiculars in both are mere arbitrary assumptions, and the flanks, as well as the faces, of his demi-baftions in each front of both are equal. The rules therefore delivered by him, as well as by the other writers on fortification, may justly be regarded as only applicable to regular construction. For although they treat of irregular fortification, they suppose the perpendiculars to bisect the external sides, the lines of defence, drawn from the extremities of any one of these sides, to equal or in right lines with it, and the correspondent parts, such as the faces and flanks let fall from the face, to be equal, alike, and similar. They do not so much as even contemplate or once speak of any case, wherein the lines of defence make different angles with the exterior side, or wherein either the flanks or faces of the same front are of different lengths, or unequal to each other. It frequently happens, however, that an engineer cannot prefer this equality between either the faces or the flanks let off from the same exterior side, without losing the principal advantages arising from the nature and situation of the ground, and deviating from what ought to be the leading maxim in the construction of every work, namely, the proportioning of the fire of each part, as nearly as possible, to that which the enemy can bring against it; or, in other words, the defence in every place to the attack. To remove this difficulty and inconvenience, and to enable engineers to practise with facility and expedition the whole possible variety of irregular construction, I will proceed to deliver a rule, which I have had in my possession for nearly twenty-two years, but have not till now thought proper to communicate to the public. Its simplicity has, I suppose, been the principal cause of its being so long unnoticed or unattended to. It is easily and expeditiously carried into practice. It is applicable to regular and irregular construction, and in its application to the latter is infinitely more extensive than all, that has hitherto been published on the subject.

This rule is derived from the following very simple geometrical proposition.

If from the extremities of any given right line, two right lines be drawn in any angles, either equal or unequal, and from any two points in these lines, two other right lines be drawn reciprocally meeting them, produced beyond their intersection in any given angle, the angles formed thereby at these points, will be equal between themselves, and each of them equal to the two first mentioned angles, together with the given angle.

**Demonstration.**

Let \(AB\) (fig. 18.) be the given right line, from the extremities \(A\) and \(B\), of which right lines \(AF, BE\) are drawn, making any angles \(FAB, EBA\), therewith whatever, either equal or unequal; and from any two points, \(C\) and \(D\), in these lines, let other right lines \(CE, CD\) reciprocally meeting them, produced beyond their intersection \(I\) in angles \(CIE, DFI\), each equal to the given angle. I say that the angles \(\triangle YAE\)
CONSTRUCTION.

ACE, BDF, formed thereby, are equal, and that each of them is equal to the angle CEI or DFI, together with the angles FAB and EBA.

For (by 32 E. 1.) the angle ACE is equal to the angle CEI, together with the angle CIE: and by the same proposition, the angle CIE is equal to the angle FAB, together with the angle IBA. Therefore ACE is equal to CEI or DFI, together with FAB and EBA.

In like manner, BDF is equal to DFI or CEI, together with FAB and EBA, and consequently is equal to ACE, Q. E. D.

From the foregoing very simple proposition is derived the following rule.

Whether the angles, which the lines of defence drawn from the extremities of any exterior side make therewith, be equal or unequal, and the angle made by another flank with its line of defence be equal, or greater, or less than a right angle; in every case, the angle of either shoulder is equal to these three angles taken together; that is, to the angle formed by either flank with its line of defence, together with the two angles formed by the lines of defence with the exterior side.

By means of this rule, an engineer may trace out any work, however irregular, in an tenth part of the time requisite for tracing out even a regular work of the same size and dimensions, by the methods of construction hitherto prescribed and made use of. He is under no necessity of finding the centre, or of erecting perpendiculars to the exterior sides, which, in irregular construction, cannot be fixed and ascertained without calculation, trouble, and inconvenience; but after determining in his own mind on the angles, which the lines of defence are to make with the exterior sides, and laying them down, fixes the positions of the flanks, and lets them off from the shoulders, almost as expeditiously as he can walk over the ground. He may use it in woody places, with nearly as much ease and facility as in those that are clear and open; and in every situation, in short, where he can see to the distance of a few yards on each side of him. By it he can trace out in the field, and even in the face of an enemy, with almost mathematical exactness and accuracy, and much more expeditiously than by the tentative and inaccurate random-methods commonly made use of, and without the aid of a theodolite, plain table, or other bulky or cumbersome mathematical instrument: for a pocket Hadley's sextant, which will be useful on most occasions, is all that is necessary in any situation.

It may not perhaps be improper to mention the circumstance that first led me to think of this rule, and gave rise to the putting of it in practice. In summer, 1783, Colonel Moncrieff, Lieutenant Fiddles of the Engineer corps, and myself, went one afternoon to trace out a large pentagonal work, near Stoke's Bay House and Gomer Pond in the Gosport division, on one of the fronts of which it was thought advisable, from the nature of the ground, to have the flanks of different lengths, and thereby to vary the directions of their fire, and those of the faces of the embalmments, from those which the ordinary method of construction would have given. Colonel Moncrieff, who, though he was commonly and justly reckoned a good judge of ground and positions, was, from the inapplicability of the customary rules to such a case, totally at a loss for the construction. He had Muller's "Elements of Fortification" in his hands, but could derive no aid or assistance from them. His embarrassment, and the novelty of our situation, which none of us had thought of beforehand, let me a

thinking seriously how we might surmount the difficulty. After a few minutes reflection, I discovered the following rule, which I immediately applied on the spot, and very expeditiously. I might, however, as well as others, have overlooked it even to this moment, had it not been for the incident now mentioned. For the simplest and most useful things are generally least attended to. I gave copies of it in writing to these two gentlemen at their request, and another to his grace of Richmond.

There are various maxims delivered by the writers on fortification, which relate to the construction and defences of the works, independent of the general considerations for or against the erection of the fortifications themselves, in different circumstances and situations. A number of these maxims, however, are very questionable, and, on due examination, would be found to be inadmissible, having been laid down by men who did not understand the true principles of construction.

The following may, perhaps, be justly regarded as the most unexceptionable of the maxims that are commonly delivered.

1. There ought to be no part in the whole circuit, or extent, of a fortres or fortification that cannot be seen, flanked, or defended from some other part. That this is not only an admissible but a fundamental maxim, and ought to be a primary object of attention in the construction of every work, is manifest from this circumstance: that, were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be erected on the right lines themselves, which form the exterior sides of polygons, as on the figures, into which they are usually broken for this purpose. The strength of a work indeed depends chiefly on its flanks, since an enemy cannot approach the body of the place while the flanking defences remain entire. But if there be dead or unseen parts, the moment an enemy gets to them he finds himself in a state of security, and out of the reach of the besieged's fire.

An idea, therefore, of the absolute necessity of avoiding them, has always made such a forcible impression on the minds of able fortifiers, as to induce them to limit the height of sections. For even when the side of a polygon is equal to 180 toises, or to 360 yards, and is broken into two demi-bastions and a curtain with flanks, if the section of the work be very high, the guns in those flanks cannot fire or scour the ditch, but at too great a distance. When it is only an ordinary height, it is well known, that the guns in the flanks do not fire the ditch effectually nearer than the intersection of the lines of defence, the distance of which, in Vauban's construction, from the epaulies or shoulders, is equal to 45 toises nearly. Mr. Blondel's construction, therefore, in polygons of a great number of sides, and that of the marquis de Montalembert, which is nothing but Mr. Blondel's on a straight line or a polygon of an infinite or indefinite number of sides, are in this respect radically defective, creating dead or unseen parts throughout their whole extent, which cannot be removed but by calculating and contrivances, that have no natural connexion whatsoever with the constructions themselves.

2. The defence of every part ought to be always within the certain reach of musket-shot, in order to be defended both by great and small fire-arms: for if any parts be at too great a distance from those that flank them, to be within the reach of a serious and efficient fire of musketry, or can be defended by cannon only, the enemy may dismount these cannon by the superiority of his, and thereby destroy the defences of such parts at once. But if they be defended by
CON

by both cannon and musketry, should one of these two species of defence be destroyed, the other will still remain.

It has been frequently alleged, that a musket-shot will not kill at a greater distance than 150 toises, or 300 yards, or 900 feet. If this be true, the great line of defence, or the distance from the flanked angle or salian angle of the bastion to the opposite flank, ought not to exceed 150 toises, or even to be equal to fo many toises. If, on the other hand, the line of defence were to be about two-thirds of that length only, or equal to about 100 toises, the bastions would be too near to one another, and too small, which would both increase their number in the same circuit or enceinte, and lessen their strength or capability of defence.

The length of the great line of defence, in order to render the fire more certain and efficient, is therefore commonly supposed to be equal to from 130 to 140 toises only.

3. All the defences should be as nearly direct as possible: for soldiers naturally fire directly before them. The lines of defence, therefore, should be either like Count Pagan’s, perpendicular to the flanks, or nearly so.

4. A fortification ought to be equally strong on all sides: for if he not, an enemy may attack it on the weak side, and avail himself of its inequality of strength.

To these maxims we will take the liberty to add a few others, that are not to be found in the writers on fortification, but which we, nevertheless, conceive to be entitled to the most serious consideration. They are the following, and we are favoured with them by Mr. Glenie.

1. In regular construction, the two flanks in each front ought to be equal each of them to the perpendicular to the exterior side of the polygon, or nearly so, since perpendiculars to the exterior sides of polygons were introduced into construction for the express purpose of obtaining flanking defences. And in regular construction, when it is necessary (as it generally is, in order to make field-works suit the ground they occupy) to make the two flanks in the same front unequal, their sum or lengths taken together should be equal to twice the perpendicular distance from the intersection of the lines of defence to the exterior side, or nearly so.

Mr. Glenie, in the foregoing paper, has given a very easy method of making the flanks in regular construction, either equal to the perpendiculars, or in given ratios to them.

2. The face of the bastion, in regular construction, ought never to exceed one-fourth part, or two-eighths of the exterior side. The construction, which gives each of the flanks in the same front equal to the perpendicular, makes the face of the bastion equal to a fourth part of the exterior side very nearly.

3. The flanked angle, or salian angle of the bastion, ought never to be less than an angle of about 71°, and should never exceed 120°. In Count Pagan’s method, however, and that of Mr. Vauban, who has followed him, this angle in a polygon of only 18 sides is equal to about 13° 47° 45°; in one of 30 sides, to 131° 7° 45°; and in a construction on a right line, or part of a polygon of an infinite or indefinite number of sides, to 143° 7° 45°.

4. The angle of the escarp or shoulder should not be less than an angle of about 108°, and ought never to exceed an angle of 150°.

5. The flanks of the flank ought not to be less than an angle of about 110°, nor greater than one of about 120°.

6. The outward flanking angle, or the angle formed by the lines of defence at their intersection, ought not to be less than 120°, nor ever greater than 160°.

Lastly. Different polygons have different perpendiculars, which have respectively given ratios to the sides of the polygons. And the perpendicular that truly belongs to any polygon of a given number of sides, is different from that which belongs to any other polygon of a different number of sides; the exterior side in each of the polygons being supposed invariable or the same. A construction on the sides of any polygon of a given number of sides, ought to be made with the perpendicular that peculiarly belongs to it. An investigation, however, of the various perpendiculars that respectively belong to various polygons, from the square up to the right line, which may be regarded as part of a polygon of an indefinite or infinite number of sides, has never as yet been delivered by any writer on fortification; and it now forms the great deliverum in military construction.

CONSTRUCTIVE TREASON, in Law, was defined by 25 Edw. III. cap. 2. See TREASON.

CONSAULES LUDI, among the Romans, the same with Circenses ludii. See also CIRCUS.

CONSULTA, in Antiquity, feasts which were held among the ancients, in honour of the god Confus, i.e. Neptune; different from those other feasts of the same deity called Neptunalia.

They were introduced with a magnificent cavalcade, or procession on horseback; because Neptune was reputed to have first taught men the use of horses: whence his surname of THORUS, Equesiris.

Evander is said to have first instituted this feast: it was re-established by Romulus, under the name of Confus; because it was some god under the denomination of Confus, that suggested to him the rape of the Sabines. It is said, that it was with a view to this rape, that he formed this institution. This, however, is certain that it was to this feast all his neighbours were invited; when, taking advantage of the solemnities and sacrifices, he seized the women. To draw the greater concourse of people, he gave out that he had found an altar hid under ground, which he intended to consecrate, with sacrifices to the god to whom it had been originally erected.

Thofe who take upon them to explain the mysteries of the heathen theology, say, that the altar hid under ground, is a symbol of the secret design of Romulus to seize his neighbours’ wives.

The consualia were of the number of feasts called sacred; as being consecrated to a divinity. Originally they were not distinguished from those of the Circus: whence it is, that Valerius Maximus says, that the rape of the Sabines was effected at the games of the Circus.

Plutarch observes, that during the days of this solemnity, horses and asses were left at rest, and were driven up with crowns, &c. on account of its being the feast of Neptunus Equesiris. Fellus says, the cavalcade was performed with mules; it being an opinion, that this was the first animal used to draw the car.

Servius gives us to understand, that the consualia fell on the thirteenth of August; Plutarch, in the life of Rumulus, places them on the eighteenth, and the old Roman calendar on the twenty-fifth of that month.

CONSUBSTANTIAL, in Theology, a term of like import with coexistential; denoting something of the same substance in kind with another. That this is the meaning of the term ipsores has been shown by Petrarius, Curellys, Gudwyth, Le Clerc, Clarke, &c. &c.

The orthodox believe the Son of God to be consubstantial with the Father.

The term ipsores, consubstantial, was first adopted by the fathers.
fathers of the council of Nice, convened A. D. 325, and consisting of 318 bishops, to express the orthodox doctrine more precisely, and to serve as a barrier and precaution against the errors and subtleties of the Arians; who owned every thing excepting the confubstantiability.

At the Nicene council, Eunæbius proposed a creed, in which he avoided the word ἰδιός, and anathematized every impious hereby, without specifying any; but his advice was not followed; ἰδιός was inferred, and the Arian doctrines were anathematized. Disputes ensued among the bishops concerning the meaning and the conceptions of the word ἰδιός. Eunæbius assented to it, declaring at the same time in what sense he understood it. His sense of confubstantial was, that the Son of God was not like created beings, but received his existence and his perfections from the Father in a different and an ineffable manner. Others gave other senses to it; and the debate, says Sozomen, the ecclesiastical historian, (i. 23. et Soz. ii. 18.) was like a battle fought in the dark. Sozomen however was a confusantialist, so far as even to believe that miracles were wrought by the Monks in favour of that doctrine; though he intimates, that the bishops of each party disputed about words of which they had no ideas, and charged one another with conceptions and inferences, which neither side would own. By the word ἰδιός the Nicene fathers meant, not the fame numerical individual substance, but the same general substance or subsistence. As amongst men, a son is ἰδιός with his father, that is, of the same human nature; so, in their opinion, the Son of God is ἰδιός with the Father, that is, of the same divine nature. By this word, therefore, they intended to express the same kind of nature, and so far a natural equality. But according to them, the natural equality did not exclude a relative inequality; a majority and minority, founded upon the everlasting difference between giving and receiving, causing and being caused. They had no notion of distinguishing between person and being; between an intelligent agent, and an intelligent active subsistence, subsistence, or entity. When they said, that the Father was God, they meant that he was God of himself, originally, and uncreated, Θεός ἵναι ἰδιός, and ὁ Θεός. When they said that the Son was God, they meant that he was God by generation or derivation, ὁ Θεός ἴδιός. The unity of God they maintained; and they defended it, first, by considering the Father as the first cause, the only undivided and self-existing; secondly, by supposing an intimate, inexpressible, and incomprehensible union, connection, indwelling, and co-existence, by which the Father was in the Son and the Son in the Father; and thirdly, by saying, that in the Father and the Son there was an unity of will, design, and content, and one divine power and dominion, originally in the Father, and derivatively in the Son. In process of time Christians adopted a notion, that the Son was τοῖς ἰδιόσι to ἰδιόσι, of the same individual substance with the Father and the Holy Spirit; and they seem to have done this with a view of securing the doctrine of the unity.

The Arians declared, that the word was God, as having been made God; but they denied that he was the same God, and of the same substance, with the Father; accordingly, they exerted themselves to the utmost to abolish the use of the word. The emperor Constanine used all his authority with the bishops to have it expunged out of the symbols; but it still maintained itself, and is at this day, as it was then, the distinguishing criterion between an Arian and an Arian.

Sandius will have it, that the word confubstantial was unknown till the time of the council of Nice; but it is certain it had been before proposed to the council of Antioch, held A. D. 275, in which Malchion directed and governed, and in which Paul of Samosata had been condemned; though the had there the fortune to be rejected. Curcellus, on the other hand, maintains, that was an innovation in doctrine in the council of Nice, to admit an expression, the use whereof had been abolished by the council of Antioch.

According to St. Athanasius, the word confubstantial was only condemned in the council of Antioch, insomuch as it implied the idea of a pre-existent matter, prior to the things formed of it; now, in this sense, it is certain, the Father and the Son are not confubstantial, there having been no pre-existent matter.

In another council, held at Antioch, A. D. 341, consisting of about 100 bishops, the Arians made a creed and left out the term ἰδιός; but wanting it to be approved by both parties, they called the Son the unchangeable image of the essence, counsel, and power of the Father, the first born of every creature. The disputes, however, between the confubstantialists and the Arians, and also the Semi-Arians or viz. the homoeans, continued to be carried on with great violence, particularly in the Eastern part, for several years. One remarkable difference has been observed between the creeds which were proposed by the contending parties. The confubstantialists drew up their creed with a view to exclude and diftrust the Arians; whereas the Arians had no design to distrust the confubstantialists, but usulually proposed creeds to which Athanasius himself might have assented; so that if the compilers were Arians, their creeds were not Arian. The Semi-Arians agreed with the Arians in rejecting the word ἰδιός, but differed from them in excluding the perfections and dignity of the Son higher than the Arians did, and in affirming that he was ἰδιός of like substance and like to his father in all things. Dr. Clarke's doctrine, in his "Scripture Doctrine, &c." as stated by Le Clerc, (Bibl. Choix. xxvi. 419) seems to be the same with that of the Nicene council, excepting that he uses not the word "confubstantial.

Before the end of the fourth century the confubstantialists differed and disputed among themselves, whether in the Trinity there were three hypostases, or one hypostasis. See HYPOSTASIS AND TRINITY.

CONSUBSTANTIATION, a tenet of the Lutheran church, with regard to the doctrine of the real presence of Christ, or the manner of the change made in the bread and wine, in the eucharist; though the term confusantiation was substituted in the room of transubstantiation, at the close of the thirteenth century, by John, named Pungens Afinus, a doctor of the university of Paris.

The divines of that profession maintain, that, after consecration, the body and blood of our Saviour are substantially present, together with the substance of the bread and wine; which is called confusantiation, or proposition.

This notion, as the bishop of Meaux justly observes, has all the disadvantages, which the Romanists, and Sacramentarians, charge on another, without having a single advantage that can be claimed by either. It has all the absurdity which the latter charge upon the former, insomuch as it represents the same body existing in different places, at the same time; and insomuch as it represents a substance existing without its accidents, or under the accidents of another substance; but has not the advantage of simplicity which the Roman doctrine has. In interpreting literally the words, "this is my body." On the Lutheran hypothesis the expression ought to have been, not "this is my body," but "in, with, and under this is my body." For the Lutherans
CON

therans maintain that the bread remains unchanged, and is that which is seen, touched, and tasted; but that the body of Christ, the same which he had upon the earth and now in heaven, accompanies the bread. Hence it appears, that the words are to be understood neither according to the letter, nor according to any figure of speech ever heard of before. It is neither literally Christ's body, nor figuratively the sign or symbol of his body; but it is something with which his body is accompanied. The Lutherans, by maintaining this doctrine of consubstantiation, were obliged to adopt another hypothesis not less absurd, viz. the ubiquity, or the omnipresence, and consequently the immensity of the body and human nature of Christ; hence they were called Ubiquitarians. See also Impanation, Transubstantiation, and Lutheranism.

CONSEUGRA, in Geography, a town of Spain in New Cadile, containing two parishes and three convents. It belongs to the knights of Malta; 25 miles S. S. E. from Toledo.

CONSETUDINIBUS ET SERVIITUS, in Law, a writ of right, which lies for the lord against the tenant to foreclose his lord of the rent, or service due to him, by cultus, or tenure, for his land. This compels a specific payment or performance of the rent or service, and there are also others, whereby the lord shall recover the land itself in lieu of the duty withheld.

CONSUL, the appellation that was given to the first, or chief, magistrate in the Roman government, vulgarly and commonly called the Roman Commonwealth; though it was composed of royalty, aristocracy, and democracy, as much as the government of Great Britain is, and was, perhaps, in several respects, the most energetic and efficient mixture of these three simple forms that has ever existed in the world, particularly for the purposes of conflict and security against subjugation.

After the destruction of royalty at Rome, and the expulsion of Tarquinius Superbus, and his family from thence, in the 244th year of the city, a confular form of government was established in the 245th year in its stead; the people choosing to have some share in the management of public affairs themselves; they accordingly chose two officers, or magistrates, annually, who were invested with sovereign authority, and were originally called pretors, a praebenda, according to some writers, but a prætexta according to others. These were afterwards called consules, a consulado, because it was their duty to consult with the senate, with the people, and with each other. From their acting as judges, they were called iudices; or from their presiding supreme command they were denominated by the Greeks' ΘΗΑΤΟΝ. The first consuls were Brutus and Colatinus. The office of the consuls lasted a year; and if either of them died in the course of the year their consulate, a new one was to be elected. In the beginning of the republic the consuls entered on their office at different times; at first, on the 23rd or 24th of February, (vi. or vi. Kal. Mart.) the day on which Tarqin was said to have been expelled, which was held as a festival, and called "regimini fœbus," afterwards on the 1st of August, (Kal. Sext.) which was at that time the beginning of the year, i. e. of the consular, not of the civil year, which always began with January;—in the time of the Decemviri, on the 1st of May, (Id. Maii);—about 50 years after, on the 1st of December, (Id. Decemb.);—then on the 1st of July, (Kal. Quint.), which continued till near the beginning of the second Punic war, A. U. 550, when the day came to be the 15th of March, (Id. Mart.):—at last, A. U. 598, or 600, it was transferred to the 1st of January (in Kal. Jan.), which continued to be the day ever after. After this, the consuls were usually elected about the end of July, or the beginning of August. From their election to the 1st of January, when they entered on their office, they were called "consules delignati," and whatever they did in public affairs, they were said to do it by their "authority," not by their "power." This interval was made so long, that they might have time to acquaint themselves with the duties of their office, and that inquiry might be made whether they had gained their election by bribery. If, upon trial, they were convicted of that crime, they were deprived of the consulship, and their competitors, who accused them, were nominated in their place. They were also fined, and declared incapable of bearing any office, or of coming into the Senate, by the Calpurnian and other laws. (Cic. pro Sylla, 17 and 32. Cic. pro Cornel. Muren. 23, &c. Sall. Cal. 18.)

On the 1st of January, the senate and people waited on the new consuls at their houses; whence, being conducted to the capitol, they offered up their vows, and sacrificed, each of them, an ox to Jupiter; and then began the exercise of their office, by holding the Senate, confuting it about the appointment of the Latin holidays, and about other things relating to religion. Within five days they were obliged to swear to observe the laws, as they had done when elected.

The consuls were at first chosen only from among the Patricians, but afterwards also from the Plebeians. L. Sextius was the first plebeian consul, and the second year after him Lucius Stolo; from whom the law, ordaining one of the consuls to be a plebeian, was called "lex Licinia." Sometimes, but rarely, both consuls were plebeians; the patricians generally engrossed this honour. The first foreigner who obtained the consulship, was Cornelius Balbus, a native of Cadiz; who became so rich, that, at his death, he left to each of the citizens, refiding at Rome, 25 drachms, or denarii, i. e. 165. 12d.

The legal age for enjoying the consulship (vestas con- fusaria) was 43; and whoever was made consul at that age, was said to be made in his own year; but we meet with some few exceptions from this rule. (See Ages.) Before any person was made consul, it was necessary for him to have gone through the inferior offices of quaestor, exilium, and pretor. No one could be created consul a second time till after an interval of ten years. But these regulations were not strictly observed.

The insignia of the consuls were the same with those of the kings, except the crown; namely, the toga praetexta, fella curia, the scephe, or ivory staff, and 12 lictors, with the fasces and securis. He who had the greater number of suffrages was called "Consul prior," and his name was marked first in the calendar; he also had the fasces first, and usually presided at the election of magistrates for the next year. All persons went out of the way, uncovered their heads, dismounted from their horses, and rode up to the consuls as they passed by them. When a pretor happened to meet a consul, his lictors always lowered their fasces. Verrius, called Poppicola, took away the securis from the fasces; i. e. he took from the consuls the power of life and death, and only left them the right of scourging, at least within the city; for without the city, when invested with military command, they still retained the securis, i. e. the right of punishing capitally. Poppicola likewise made a law, granting every one a liberty of appealing, from the consuls to the people; and that no magistrate should be permitted to punish a citizen, who thus appealed: a privilege which was also enjoyed under the kings. The consuls originally possessed kingly powers, both in civil and military
military matters. But afterwards, when the consuls came
to be much employed from home, or abroad in war, and
could not be present either to hear or determine civil causes,
there was an officer constituted, under the designation of \textit{praetor urbanus}, and frequently called by Ciceron \textit{praetor Romanus},
with power to judge matters of law between citizen and
citizen. And for the convenience and accommodation, in
this respect, of the great number of strangers that were
always at Rome, another officer was appointed to judge
cases between them, with the appellation of \textit{praetor person-}
grinus. And, as provinces came to be added to the Roman
state, and the number of causes was of course greatly in-
creased, there were eight praetors appointed, which number
continued till the time of Julius Caesar, who raised it to ten.
The consuls, whilst they remained in Rome, and before
they led out Roman armies into the field, were masters of all
public affairs. For all the other magistrates, the tribunes of
the people alone excepted, were subject to them, and bound
to obey their commands. They introduced embassadors
into the senate and gave them audience; and they received
all letters from the governors of provinces, and from foreign
kings, and states. They also proposed to the senate the
subjects of their debates, and directed all the forms that
were observed in making their decrees. It was equally a
duty likewise, belonging to their office, to attend to those
affairs that were transacted by the people; to summon, or
call together their general assemblies; to report to them,
when assembled, the resolutions of the senate; and to ratify
whatever was determined by the greater number. The laws
which they proposed, and got passed, were commonly called
by their name. The year was named after them, as it used
to be at Athens, from one of the archons. The consuls
had the command over the provinces, and could, when
authorized by the senate, call perions from thence to Rome,
and punish them. (See Province.) Their authority was
so great, that kings, and foreign nations, in alliance with the
republic, were considered to be under their protection. In
dangerous conjunctures, the consuls were armed with abso-
lute power by the senate. In all the preparations that were
made for war, as well as in the whole administration, and
management of things in the field, they possejed an authority
almost absolute. For to them it belonged to impose on the
allies whatever services they judged necessary or expedient;
to appoint the military tribunes; to enrol the legions, and
make the necessary levies; and to inflict punishments in the
field on all that were subject to their command. In addi-
tion to all this, they had the power to expend whatever
sums they might think convenient, or requisite, from the
public treasuries, and were attended for that express purpose
by a quaestor, who was always ready to receive and execute
their orders.

When a Roman army encamped, the consular tent was first
pitched, and the ground on each side of it marked out for
it, and on the breaking up of a camp, it was the first tent
that was permitted to be struck; and one entire company of
soldiers were always flattened round it.

When an action had taken place, in which any of the
soldiers had shown signal proofs of courage, the consul
assembled the troops together, and commanded those to
approach who had distinguished themselves by any eminent
exploit. And after bowing on each of them separately,
or apart, the commendation that was due to that particular
instance of their valor, and after recounting likewise all
their former actions that had ever merited applause, he
then distributed among them the following rewards:—To him
who had wounded an enemy a javelin;—To him who
had killed an enemy, and flung him of his armour, a
goblet, if he were in the infantry; and if in the cavalry, a
javelin in ancient times, but afterwards furniture for his
horse. These rewards, however, were not bestowed on
soldiers, who, in a general engagement, or in the attack of a
city, had wounded or spoiled an enemy; but on those only,
who in separate skirmishes, and when any occasion offered,
in which, though they were not necessarily required to
engage in single combats, threw themselves voluntarily into
danger, and with danger, provoked the combat. In taking
a city by storm, those who first mounted the walls were
honoured by the consul with a golden crown. And those
who saved the lives of any of the citizens, or of the allies, by
covering them from the enemy in the time of battle, received
premises from the consul, and were also crowned by the
persons whom they had thus preferred.

Although the consuls were the dispensers of military re-
wards and punishments; although they were entrusted with
the absolute direction of the preparations that were made for
war, and exercised an uncontrolled authority in the field;
although their powers and authorities, when they were pre-
fent in Rome, made strangers sometimes suppose the govern-
ment to be a kind of simple royalty; they were in truth, so
dependent in different respects, both on the senate and the
people, that without their aid, they were unable to accom-
plish any design. Armies require a continual supply of
necessaries. But neither corn, nor habits, nor even the
military apparatus, could at any time be transmitted to the
legions, without an express order of the senate. It was also
the senate that either compelled the consuls to leave their
designs imperfect, or enabled them to complete the projects
that they had formed, by sending a successor into each of their
several provinces on the expiration of the annual term,
or by continuing them in their respective commands. The
senate also had the power of either aggrandizing and ampli-
fying the victories that were gained, or of depreciating and
debasing them. It was also necessary for the consuls, how-
ever far they were removed from Rome, to preserve the
good affections of the people. For though the consuls might
make treaties, the power of ammulling, or ratifying, rested
entirely with the people. And what was of still greater
moment, the consuls, on quitting their office, were bound
to submit the whole of their past administration to the judg-
ment of the people. On this occasion they made a speech,
and swore that they had done nothing against the laws.

Consuls were even continued under the emperors after the
republic was destroyed, but consuls were not more than little
more than an honourable title; which, however, the people
were fond of keeping up; as stemming it some remains of their
ancient liberty. As long as the emperors condescended to disfigure
the servitude which they imposed, the consuls were still
elected by the real or apparent suffrage of the senate. From
the reign of Diocletian, even these vestiges of liberty were
abolished, and the successful candidates, who were invested
with the annual honours of the consulship, attempted to
abolish the humiliating condition of their predecessors.
In the epistles which the emperor addresed to the two consuls
elect, it was declared, that they were created by his sole
authority. The title of consul, however, though the real dignity and
substantial power that accompanied it were lost, was still
the most splendid object of ambition, the noblest reward of
virtue and loyalty. The emperors themselves, even after
Constantinople became the seat of empire, who disdained the
feint shadow of the republic, were conscious that they
acquired an additional splendour and majesty as often as they
assumed the annual honours of the consular dignity. It
wilted for a long time, and at last the distinction of
consuls finally ceased, in the 13th year of Julian, A.D. 361,
whose despotical temper might be gratified by the extin-
guishment of a title, which alarmed the Romans of their
ancient freedom; after him, no emperor either created any
consul, or confirmed the dignity of consuls. Baal is the last in
the consular list, for the year 541. By this time, the dignity
was depreciated to that degree, that it was conferred on the
nearest per sons: indeed, Justinian endeavored to retrieve it 25 years after,
and created himself consul, but without effect. Indeed, the annual consuls
long lived in the minds of the people; they applauded the graci-ouss condescension of successive princes, by whom it
had been suppressed by custom, could be abolished by a law
of Leo the philosopher. Afterwards the title was visited,
as we learn from the emperor himself.

From the establishment of the republic, and the consulate
under L. Jun. Brutus, and L. Turius Collatinus, to the con-
sulate of Baal, i. e. from the year of Rome 244, or 245, 599
years before Jesus Christ, to the year of Rome 1394, the
space of 299 years, the years were accounted by the con-
suls; but from the time of Baal, in the year of Chrisl. 541,
we find no mention made of consuls, or confuls; but the

time was then computed by the years of the emperors'
reigns, the judicature, and those of the Christian era.

Indeed, for some time after the consulate of Baal, the
years are marked thus; p. c. 541, consulatum Baalii, 1, 2, 3, &c.
(See the Fasti Consularia o' M. D'Ambrois.) That
author reckons 100 pairs of consuls, besides the substitute
consuls, jujfeeli, elected to supply vacancies by death, and
yet there were but 1049 years, and consequently only so
many consuls.

The perpetual consulates of the Eastern emperors, which
comprise the Fasti Byzantini, commenced in the year of Christ
507, and ended in 668, in the last year of Constan-

Ivantine Pagonatus would have the consulates insepara-
ble from the empire; which it continued to be till the time
of Constantine Porphyrogenetus.

In this form of government, the empire and consulate
were closely united, that the emperor Irene would needs assume
the consulatc when the whole was only regent of the empire.

But the French kings, those of Italy, and the Saracen
princes who commanded in Spain, taking on them the title of
consul, as well as emperors of Constantinople; these last
defiled it, and laid it aside; so that the name was only
continued to the magistrates of some cities, and certain other
officers, as is shown by F. Pagi.

Under the emperors there were ordinary consuls, honorary
consuls, and jujfeelii; which last also subsisted in the time of
the republic.

In the middle age, we find the word consul used for comes,
count, and proconsul, for viccount; as is observed by Spel-
man, and De Marco.

And thus consul, in our law books, signifies an earl. Draf-
lib. i. cap. 8, tells us, that as comes is derived from comita, so
consul is derived from consulendo; and in the laws of
Edward the Confessor, mention is made of viccomes, and
vicconsules.

Consul, at present, is used for an officer established by
virtue of a commission from the king, and other princes, in
the ports and factories of the Levant, on the coasts of Africa,
Barbary, Spain, and other foreign countries of any con-
siderable trade; to facilitate and dispatch business, and pro-
\nc\n\nc\ntect the merchants of the nation.

Vol. IX.

These commissions were never granted to persons, as con-
suls of the French nation, under the age of thirty years.
When the consulate is vacant, the most ancient of the de-
puties of the nation were to discharge the function thereof,
till the vacancy should be filled up by the king.

The consuls are to keep up a correspondence with the
ministers of England residing in the courts wherein their
consulates depend. Their business is to support the com-
merce and interest of the nation; to dispose of the sums
given, and the presents made, to the lords and principals of
places, to obtain their protection, and prevent the insults
of the natives on the merchants of the nation. There are
also consuls of other nations established in the Levant, es-
pecially French and Dutch.

Consuls also denote judges elected among the merchants
and dealers, in ports and trading towns, chiefly in France;
to terminate, gratia, and on the spot, without any process,
such differences and demands as may arise relating to their
merchandizes, bills of exchange, and other articles of com-
merce.

The first jurisdiction of consuls established in France, is
that of Tholouse; the edict of whose establishment bears
date 345, under the reign of king Henry II.; that of Paris
followed fourteen years afterwards. By degrees, they were
established in most of the considerable trading towns in the
kingdom.

Consul, Chief, or Premier Consul, the chief or chief of
the magistrates, who each of them bore the name of consul
in the late constitution of France, which has been succeeded
by its present military dictatorship. Napoleon Buonaparte,
the present emperor of France, was appointed chief consul,
in consequence of the revolution that took place in 1799.

Consular, of or belonging to a consul: as for exam-
ple, a consular camp, a consular army, the consular digni-
ty, the consular authority, and so on.

Consular comitia, and medall. See the substantives.

CONSULATE, or Consulship, the office of consul,
which was instituted by the Romans, in the year of Rome
245, after they expelled Tarquin the Proud.

CONSULTATION, in Law, a writ whereby a cause,
formerly removed by prohibition from the ecclesiastical court
to the king's court, is returned thither again.

If the judges of the king's court, upon comparing the
lith with the fuggition of the party, find the fuggition
false, or not proved; and therefore that cause to be wrong-
fully called from the court-christian; then, upon such deli-
eration, or consultation, they decree it to be returned
again, and the writ obtained herein is called a consultation.

And, even in ordinary cases, the writ of prohibition is
not absolutely final and conclusive. For, though the ground
be a proper one, in point of law, for granting the prohibi-
tion, yet, if the fault that gave rise to it be afterwards es-
hlished, the cause shall be remanded to the prior jurisdiction.
If, e. g. a culprit be placed in the spiritual court, a pro-
hibition ought to go; but if he be accused in a civil court
that court has no authority to try it; but, if the fact of such a custom be brought to a com-
petent trial, and be there found false, a writ of consul-
tation will be granted. For this purpose the party pro-
hibited may appear to the prohibition, and take a declaration,
(which must always proceed, the fuggition, and so plead to
issue upon it; dazing the contempt, and traversing the ca-
se upon which the prohibition was granted; and if the
issue be found for the defendant, he shall then have a writ of
consultation. The writ of consultation may also be, and is
frequently granted, by the court without any action brought,
which, after a prohibition filed, upon more sufficient es-

CONSUMPTION.

fication, the court are of opinion that the matter suggested
is not a good and sufficient ground to stop the proceedings
below. Thus careful has the law been, in compelling the
interior courts to do ample and speedy justice; in preventing
them from transgressing their due bounds; and in allowing
them the undisturbed cognizance of such causes as by right,
found on the usage of the kingdom or act of parliament,
do properly belong to their jurisdiction. Blackf. Com.
vol. iii.

CONSUMMATE ESTATE. See Tenant by curtesy.

CONSUMMATION, the end, period, or completion,
of any work.—Thus, we say, the consummation of all
things: meaning the end of the world. By the incarnation,
all the prophecies are to be consummated.

Consummation of marriage denotes the last act of mar-
rriage, which makes its accomplishment.

CONSUMPTION, in Medicine, popularly named a de-
cline, is a generic term, occasionally applied to different
diseases, the most obvious symptoms of which are a gradual
decline of the strength and functions of the body, and a
diminution of its bulk, in consequence of the decrease or con-
sumption, as it were, of the fat and muscular parts. From
whatever cause, therefore, the nutrition of the body is im-
peded, consummation will be the consequence. The nutri-
tion of the body may be impeded either by force great in-
ternal disease, which disturbs the functions, especially that
of digestion; or by deficiency of nutrition; or by great
evacuations or discharges of blood, or fluids secreted from
the blood. These considerations have led no theologians
to treat of consumption under three divisions or genera, with
the titles of Phtisis, Tubes, and Ateophia: the first being
produced by internal organic diseases; the last by the
deficiency, or the abstraction, or corruption, of nutritious
matter.

1. Phthisis, from signifying consumption in general, is
confined to that species which originates from disease of the
lungs: this form of consumption being the most frequent
and fatal. It is defined "emaciation, with hectic fever,
cough, and commonly with purulent expectoration." The
emaciation is occasioned by the disturbance in the function
of digestion, which the daily fever produces; by the im-
pediment to the function of respiration, which the diseased
lungs are unable to carry on; and by the great discharges
by expectoration, sweating, or diarrhoea, which latter fre-
cquently alternate with each other.

2. Tubes, which, in the Latin language, is synonymous
with phthisis in the Greek, has been arbitrarily restricted
by no theologians to that form of consumption, which is not ac-
compained by cough. It is defined, "emaciation, with hectic
fever." Any local disease of long continuance, such as afeceles,
ulcers, &c. which excites a hectic fever, may become the origin of a
	
Tubes. But the most frequent occurrence of tubes is observed in scrofulous habit, the for-
cula being always flow in its progress: and one of the
mmost common varieties of tubes arise, where scrofula at-
tacks the glands of the mesenteric. In this case, emaciation is
produced, not only by the disturbance of functions, and
the events of the hectic fever, but by the physical imped-
iment to the nutrition of the body, occasioned by the morbid
condition of the mesenteric glands, through which the chyle
cannot pass, in order to enter the thoracic duct, and thence
to be poured into the blood-vessels.

3. Ateophia, derived from the primitive particle α, and
νηθρία, meaning a defect of nourishment, has been adopted
to denote the simple emaciation and loss of strength, which
is not accompanied with hectic fever, nor originates from
any organic disease; but depends altogether on the priva-
tion, corruption, or abstraction, of that which would other-
wise support the strength of the body. It is defined, "em-
aciation, without fever." Hence atropia occurs in those
who have suffered great evacuations, as from salivation, ha-
orrhage, sweat, laceration, &c.: in those from whom nutriment is abstracted in undue proportion to their strength and
digestive powers, as in nurses suckling stout children, or
continuing them at the breast too long; and in those whose
nutriment is corrupted, as the falt provisions, which excite
scars.

For a view of the nature and requisite treatment of the
different kinds of consumption, see the following articles:

Tubes Mesenterica (or Mesenteric Consumption),
Cullen's Synopsis Nofol. Clafs i. ord. 4. and Clafs iii.
ord. 1.

CONSUMPTION, Pulmonary, the phthisis pulmonalis
of medical writers, from δίσας, or δίσος, constringe, con-
sume, a delighting and very fatal disease, distinguished by the oc-
urrence of a frequent cough, with expectoration of puriform
matter, hectic fever, emaciation, and debility; to which,
in the latter stages, colliquative sweats, often alternating
with diarrhoea, supervene.

In this disease the number, degree, and progress of the
symptoms are extremely various, in different cases. It
usually commences in an inoffensive manner, with a light
and short cough, which is often hectic remarked by those afflicted
with it, but soon becomes habitual; or with an occasional
cough, which is more severe. At the same time, the
breathing becomes easily hurried by any bodily motion, the
patient grows thinner, and becomes languid and indolent.
In this state be sometimes continues for a year, or even for
two years, without making any complaint, excepting that
he is affected by cold more readily than usual, which fre-
cquently increases his cough, and produces catarrh. This
however, is sometimes relieved, is supplanted to have arisen
from cold alone, and therefore gives no alarm either to the
patient or to his friends, nor leads them to take any precau-
tion. But upon some occasion of catching cold, as we com-
monly speak, the cough becomes more considerable; is par-
ticularly troublesome, when the patient lies down at night,
and in this state continues longer than is usual in the case of
a simple catarrh. This may more particularly attract at-
tention, if the increase and continuance of cough occur during
the summer season.

The cough, in many instances, continues for a long time
dry, or without any expectoration: frequently, however, it
is accompanied, from the first, with an expectoration of a
blackish or blueish mucus, or of tough phlegm; the expec-
toration being generally most considerable in the morning,
in confluence of the accumulation of the matter during
sleep. This matter becomes by degrees more copious, more
vivid, and more opake; at length a yellow or greenish
colour, and of a purulent appearance, sometimes broken
with blood. As these changes take place, and the cough
increases, the breathing at the same time becomes more dif-
cult, and the emaciation and weakness go on also increas-
ing.

In the female, as the disease advances, and sometimes
early in its progress, the menstres cease to flow; and this cir-
cumstance, although doubtless an effect, the sex themselves
are generally disposed to believe to be the sole or principal
cause of the disease. During this progress some pain is
commonly felt in the thorax, at first under the sternum,
especially, or almost solely, on the occasion of coughing:
but very often there is a pain in one side, sometimes dull
and oppressive, sometimes sharp and shooting, and such as
to prevent the person from lying easy upon that side. Even
when
CONSUMPTION.

when no pain is felt, it generally happens that phthisical persons cannot lie easily on one of their sides, the difficulty of breathing being increased, and the cough excited by the attempt.

These symptoms have seldom continued long, before the pulse becomes frequent, sometimes to a considerable degree, without much of the other symptoms of fever. As it proceeds, the skin becomes dry and hot, especially the palms of the hands and soles of the feet; a circumferibled flush appears on the cheeks; transient chills are often felt by the patient, or he is exceedingly liable to cold; and commonly a regular morning and evening febrile paroxysm takes place, the evening exacerbation being always the most considerable, and terminating in sweats during the night.

The mind is generally little or not at all impaired during the progress of pulmonary consumption; sometimes it is even more acute than in the previous state of health; and the patient is generally confident of recovery, and his spirits buoyed up by hope to the last extremity. But the gradual loss of flesh and strength, the sharpness of the features, the pearly whitenss of the eyes, the incursion of the nails, and sometimes the loss of the hair, but too evidently mark the decay of the bodily functions. At length a colliquative diarrhœa, sometimes occurring together, but most commonly alternating, with the night sweats, contributes still farther to reduce the patient's strength; and death is frequently preceded by oedema of the feet and legs, and apæthesia in the mouth and throat, and occasionally by delirium.

Great numbers of people are repeatedly exposed with impunity to the circumstances which excite consumption of the lungs: it is only on a constitution of a peculiar nature, predisposed to the disease, that these exciting causes operate. This predisposition is frequently hereditary, descending from parents whom the disease had attacked, or who had, at some period of their lives, been afflicted with some form of scrofula. It is marked by a peculiar inattentivity and weakness of the vascular system, more especially of the lungs: insomuch as the person is subject to frequent catarrh, and spitting of blood. It is also distinguished by external peculiarities of form and appearance. Persons poising what has been denominated the fagunee temperament, namely, having fine skin, with large veins, soft hair, light eyes, a florid complexion, tall and thin person, long slender neck, narrow chest, and projecting shoulders, may be considered as having the phthisical predisposition: and those of the fagunee-melancholic temperament, combining with the fine skin and complexion, and slender form of the former, the dark hair and eyes, and dilated pupils of the melancholic temperament. This combination connotes in general a temperament of peculiar beauty; but in the eyes of the medical phlogistonists, a tinge of its delicacy is not the least imprompt which it excites. Phthisis sometimes occurs also in persons who may be said to possess a fagunee-phlegmatic temperament, i.e. who have the slender form and delicate constitution, with an habitually pale complexion, and without the disposition to acute inflammation, which belongs to the fagunee: it occurs occasionally too in temperaments almost entirely melancholic. See Temperament.

In those who have a constitutional predisposition to the phthisical state of the lungs, the disease is excited by various causes of irritation in those organs. Thus it is frequently induced by common inflammation of the lungs, or their membranes, by pleurisy, peripneumony, catarrh, whooping-cough, asthma, and the cough connected with measles; by frequent over-exertion of the lungs in speaking, singing, or blowing musical instruments; by inspiring certain kinds of dust or vapour; by haemoptysis, or spitting of blood; by sudden variations of the atmospheric temperature; by compressing the chest by tight bandages, &c. Of some of these causes we shall speak more particularly.

A great majority of the cases of pulmonary consumption is referred, by the sufferers, to a common cold or catarrh, as their origin; the expectoration of mucus, which belongs to catarrh, being gradually changed to an expectoration of pus, and hectic fever superimposing. But Dr. Cullen thinks that this supposition is not easily to be admitted; insomuch as catarrh is properly an affection of the mucous glands of the trachea and bronchies, analogous to conyza, and less violent kinds of fore-throat, which very seldom terminate in suppuration. He is of opinion, that the apparent catarrh, in such instances, was in fact the beginning of phthisis, for which it may have been mistaken, as the resemblance between the two is so great as commonly to preclude the means of discrimination. This difficulty, however, he admits, presses upon us the necessity of paying minute attention to every catarrhal cough, especially in those who bear marks of the temperament which is predisposed to consumption. This observation has been inculcated, indeed, from ancient times. "Quod si mai linea eft," says Celsus, "et vera phthisis eft, inter initia protinus occurrere necassarum eft; neque enim facie hic morbus, cum inveteraverit, evincitur," lib. in cap. 22. The attention of friends and parents cannot, indeed, be too strongly urged upon this point: to neglect the slightest catarrhal affection, which continues longer than the usual short period of a few days, is to neglect the only period of suppressing a disease, which almost invariably tends to fataly.

Hæmoptysis, or spitting of blood, is enumerated among the causes of consumption, and certainly very frequently proceeds it. But this occurrence may, perhaps, be confidered far more than catarrhal symptoms, as a sign of the commencement, and not a cause, of the disease; more especially when it occurs independently of external violence. Numerous infallences of hæmoptysis have occurred, from blows and wounds, in which ulceration did not ensue, or at least was of short duration, and did not materially injure the constitution. But when it comes on without any obvious external cause, and especially in persons of one or other of the temperament already described, ulceration, expectoration of pus, and all the differing symptoms of phthisis are generally to be apprehended. In such cases, there is either a peculiar tenderness of the vascular system in the lungs; or, what is perhaps more generally the fact, an incipient obstruction, as tubercles, which render the small vials liable to give way, when the circulation through them is increased by any exertion, or receives an irregular impetus from the action of coughing occasioned by cold. In this way, catarrh may lay the foundation of phthisis. Spitting of blood, however, if not among the first symptoms, very frequently occurs in the course of the disease, especially in the stage of purulent expectoration.

When inflammation of the lungs terminates in extensive suppuration, producing one or more collections of purulent matter, termed vomices, the great irritation often produces hectic fever, which, together with the expectoration of pus, continues after the vomices burst, and the patient is cut off with the ordinary train of symptoms belonging to phthisis. Persons who are occupied in various employments, by which the air they breathe is contaminated with various infallences, in the form of a fine powder, are peculiarly liable to be seized with phthisis. Thus hair-dresters, bakers, masons, bricklayers'-labourers, laboratory-men, coal-heavers, and chimney-sweepers, are frequently subject to the most obdurate pulmonie diseases; as are also, in an equal degree, the
CONSUMPTION.

dressers of flax and feathers, and the workmen in the ware-
houses of leather-fellers. Many persons, thus engaged, 
struggle a long time with a constant, hard, troublesome cough, 
which at length terminates in consumption. See 
Willan on Diseases in London, p. 301.
The exanthematic disease, such as small-pox and 
measles, the latter of which, more particularly, often lays 
the foundation of consumption, seem to operate by occa-
sioning some morbid change in the constitution, which 
may be considered rather as a predisposition than an actual state 
of disease. Dr. Cullen attributes this change to an anomaly 
left in the fluids by these exanthemata, which he believes to 
be the same with the anomaly which prevails in scrofula. 
But if we would avoid hypothetical language, all that can 
be said is, simply, that a predisposition to phthisis and to 
scrofula is occasioned by these diseases. The measles, in-
deed, may not only induce the predisposition, but, by the 
irritating cough which it leaves behind, may actually occa-
soon a consumption of the lungs.
The venereal disease, or the irritation of the mucous 
membranes necessary for its cure, or both combined, appear 
also to excite a predisposition, and lay the foundation of 
consumption.

Dr. Cullen has enumerated, among the exciting causes of 
phthisis pulmonalis, and as the most frequent of them all, 
tubercles in the lungs. In the majority of cases these un-
doubtedly exist; but we must consider them as constituting 
the essential part of the disease itself, and, if not originally 
induced by some of the causes above enumerated, excited into 
a state of activity by some one of them, perhaps most fre-
cently by the common catarrh. Of the pulmonary tu-
bercles, the best morbid anatomy of the times gives the 
following account.

There is no morbid appearance, he says, so common in 
the lungs as that of tubercles. These consist of rounded, 
firm, white bodies, interspersed through their substance.

They are, he believes, formed in the cellular structure, which 
connects the air-cells of the lungs together, and are not a 
morbid affection of glands, as has been frequently imagined.

There is no glandular structure in the cellular connecting 
membrane of the lungs; and on the inside of the branches 
of the trachea, where there are follicles, tubercles have never 
been seen. They are at first very small, being not larger 
than the heads of very small pins; and in this case are fre-
cently accumulated in very small clusters. The smaller 
tubercles of a cluster probably grow together, and form one 
larger tubercle. The most ordinary size of tubercles is about 
that of a garden pea; but they are subject in this respect to 
much variety. They adhere pretty closely to the substance 
of the lungs, and have no peculiar covering or capulse, and 
have little or no vascularity. When cut into, they are found 
to consist of a white smooth substance, having great firmness, 
and often contain in part a thick curdy pus. But when the 
put is in considerable quantity, it is thinner, and resembles 
very much the pus from a common sore. In cutting into 
the substance of the lungs, a number of absceses is some-
times found, from pretty large tubercles having advanced to 
the extent of suppuration. In the interstices between these tu-
bercles, the lungs are frequently of a harder, firmer texture, 
with the cells in a great measure obliterated. The texture 
of the lungs on many occasions, however, round the bound-
aries of an abscence, is perfectly natural.

I have sometimes, Dr. Wallis continues, seen a number of 
small abscesses interpersed through the lungs, each of which 
was not larger than a pea. The pus in these is rather thicker 
than what arises from common inflammation, and resembles 
serous pus. It is probable that these abscesses have been 
produced by a number of small scattered tubercles taking on 
the process of suppuration. The lungs immediately sur-
rrounding these abscesses are often of a perfectly healthy 
structure, none of the cells being closed up by adhesions. 
See Bailey's Morbid Anatomy, p. 66, et seq.

This accurate delineation of the condition of the lungs in 
the last stage of consumption, sufficiently evinces the imposs-
ibility of a cure by medicine, and may contribute farther 
to enforce an attention to its earlier symptoms.

It must not be omitted, however, that although the slighted 
symptoms of catarrh often prove the commence-
ment of a fatal phthisis; on the other hand, catarrh does 
ocasionally put on the appearance of phthisis, yet remain- 

Dr. Willan observes, in his "Reports on the Diseases 
in London," "many persons who had catarrhal coughs in 
March, were farther affected with spitting of blood, thick, 
viscid expectoration, pains within the chest, hectic fever, 
and diarrhoea, interchanging with night sweats, but reco-
vred notwithstanding in the month of April." He con-
cludes "that ulcerations in the lungs had not been produced, 
and that the expectorated fluid, so alarming in its appear-
ance, was perhaps only composed of a puriform secretion, 
and an increased discharge of mucus, circumstances usual 
under other membraneous inflammation." Reports, p. 4 
and 147.

But it must be added, that effusion has shewn, that 
even this condition of lungs has proved fatal, with the usual 
symptoms of phthisis.

To aid in distinguishing whether the matter expectorated 
be pus, or mucus only, several tests have been propounded; 
which, taken together, may afford us the means of an accu-
rate conclusion. 1. The colour; mucus being naturally 
transparent, and pus always opaque. When mucus becomes 
opaque, as it sometimes does, it becomes white, yellow, or 
greenish; but the latter mentioned colour is hardly ever to 
be met with in pus. 2. The consistence; mucus is more 
viscid and coherent, so as not readily to be diffused in 
water; pus is more readily friable, being broken into 
ragged fragments by a little agitation in water. 3. The 
smell; no odour is in general perceived in mucus, but fre-
cently in pus. 4. The specific gravity; it being usual for 
the mucus of the lungs to swim on the surface of water, and 
for pus to sink in it; but in this we may be deceived, as pus 
which has engendered a great deal of air may swim, and 
mucus that is free from air may sink. 5. The mixture 
which is discernible in the matter brought up; for if a yel-
low or greenish matter appears surrounded with a quantity 
of transparent or less opaque and less coloured matter, the 
more strongly coloured may generally be considered as pus. 
6. Chemical tests. Mr. Charles Darwin's experiments shewed 
that the vitriolic acid dissolves both mucus and pus, but most 
readily the former; that if water be added to such a solution 
of mucus, this is separated, and either swells on the surface, 
or, divided into globules, is suspended in the liquor; whereas, 
when water is added to a like solution of pus, this falls to 
the bottom, or by agitation is diffused so as to exhibit an 
uniformly turbid liquor. Again he shewed, that a solution 
of sulphuric acid, after some time, diffuses mucus, and 
generally pus, and if water be added to such solutions, the 
water is precipitated, but the mucus not.

With respect to the pragmas of consumption, its tenden-
cy in general must be considered as extremely bad. In con-
stitutions, where all the delicacy of the temperaments be- 
fore described is observed, and more especially if an hered-
tary predisposition can be traced, the moat trivial symptoms 
are alarming. The particular degree of danger must be esti-

cated from these circumstances, from the mode in which the 
disease commenced, from its duration, and the flowens
CONSUMPTION.

or rapidity of its progres, the number and degree of the symptoms present, and the effects which medicine has already produced. The following aphorisms, the result of Dr. Cullen's observation, are worthy of attention.

"A phthisis pulmonalis, from haemoptysis, is more frequently recovered from, than one from tubercles.

"A phthisis from a suppuration, in consequence of pneumonic inflammation, is that which most rarely occurs in this climate; and a phthisis does not always follow such suppuration, when the abscess formed soon breaks, and discharges a laudable pus: but, if the abscess continue long shut up, and, till after a considerable degree of hectic has been formed, a phthisis is then produced, equally dangerous as that from other causes.

"A phthisis from tubercles has, I think, been recovered: but it is, of all others, the most dangerous; and, when arising from a hereditary taint, is almost certainly fatal.

"The danger of a phthisis, from whatever cause it may have arisen, is most certainly to be judged of by the degree to which the hectic and its consequences have arrived. From a certain degree of emaciation, debility, profuse sweating, and diarrhœa, no paroxysm recovers.

"A mania coming on, has been found to remove all the symptoms, and sometimes has entirely cured the disease; but, in other cases, upon the going off of the mania, the phthisis has returned, and proved fatal.

"The pregnancy of women has often retarded the progress of a phthisis, but commonly it is only till after delivery, when the symptoms of phthisis return with violence, and soon prove fatal."--Furt Lives, parag. 983.

Treatment. It will readily appear, from what has been said above, that the cure of pulmonary consumption must be exceedingly difficult; in the latter stages, perhaps impossible. Many instances, however, have occurred, where the attention of the patient to the incident symptoms, and his early adoption and steady pursuit of proper measures, have averted the fatality of the disease. When it is deeply rooted, alleviation of the sufferings is all that can be hoped for.

The treatment of a beginning consumption will depend much upon the peculiar constitution of the patient, as well as on the nature of its origin, and of the symptoms which it exhibits; but most particularly upon the prevalence of an inflammatory disposition, or of a general debility of the habit; these opposite states being both accompanied by great irritability; and the principal indications will be to diminish the inflammatory action and irritability; and in the latter stages, just mentioned, to avoid debilitating measures, and to support the strength as much as is consistent with the inflammatory irritation that may exist.

Where there is considerable strength, and a complexion flirid, if there is much pain in the chest, or if the pulse be quick and sharp, perhaps small bleedings from the arm may be resort to, and occasionally repeated; or blood may be drawn from the chest, near the seat of the pain, by means of leeches or cupping. But this discharge should be always effected after a cautious examination of the circumstances; for the debility which is apt but too speedily to ensue, may be thus accelerated, and, with it, the worst symptoms of the disease. It is now well understood, that the appearance of the bloody coat on the blood drawn, is by no means alone an evidence of the necessity of drawing more; for it will appear in phthisis, nearly as long as the arteries have power to propel it. The old doctrines respecting the bloody coat, have doubtless led to much practical error; but no one now considers pregnancy a disease which requires constant bloodletting; or ues the lancet in the hot phase of an intermittent fever, although under both these circumstances, the bloody coat is constantly found. In consumption occurring, as it most commonly does, in delicate habits, the practice of repeated venesection decidedly accelerates the fatal course of the disease. Blilters, on different parts of the chest, will better answer the purpose of relieving a local inflammatory disposition. Blities and fociata have a similar effect, but the constant discharge tends to debilitate, and the irritation to counteract, in some measure, the good effects of the evacuation.

During the use of blisters, or other local discharge, the internal use of medicines, which have been denominated refrigerant, may be also resort to, with some advantage; such are acids, especially the vegetable, and certain neutral facts, as crystals of tartar, nitre, &c. The last named fact has been strongly recommended by Dr. Dickson, (see Med. Obs. and Inquiries, vol. iv. p. 208,) especially where there is haemoptysis, administered in small doses frequently; "when given early in an hemorrhagie," he says, "I can almost equal-ly depend upon it, as upon the cortex peruviana in a genuine intermittent." But general experience does not warrant this encomium to its extent. We believe the digitalis to be the most efficacious medicine, in repressing that inflammatory action of the arterial systen at large, and of the pulmonary arteries in particular, which commonly goes on at the commencement of phthisis, whether accompanied by pitting of blood or not. The latter it commonly suppresses, and we have frequently seen a febrile irritation, bordering on hectic, attended with a sharp and quick pulse, a dry ringing cough, and commencing emaciation, speedily subsides under its administration. The digitalis may be given in combination with the acids, or with nitre, in a mucilaginous liquid. The cerufa acetata, or acetate of lead, was formerly employed in considerable doses, especially by the continental physicians, with the view of counteracting inflammatory action, and of suppressing haemoptysis. The medicine, it would appear, is poifoned of some efficacy; but the danger of inducing paralysis, and pulmonary and other effects, which result from the poison of lead, is sufficient to deter us from its use. Where the inflammatory action is high, we should be cautious in employing opiates, with a view to allay the cough; as, in such cases, opium in any form proves too stimulatine; but where there is languor and debility, and lefs of the fanguine temperament, and the cough extremely haraffing, opiates may be employed with benefit; they will fave the strength of the patient, by appeasing the incessant irritation of coughing, which tends to wear him down, and deprive him of sleep.

Medicine, however, will not alone secure the patient from the deleterious progress of the disease. He will be required to pay strict attention to his diet, and to every external circumstance that can influence the functions of the body. His meat and drink, his clothing, his exercise, his sleep, and even his amusements, must be regulated with a rigid correctness, so that the whole may combine, with medicine, to accomplish the fame object, that of ridding the constitution of a diæase of fatal tendency, and restoring it to its healthy condition. Diet, regimen, and medicine, must be combined in it to remove the bulcs of the patient. He must regulate his life chiefly upon this principle; that every thing which can heat or irritate the bod, or excite any increased or irregular action of the arterial systen, must be shunned; and every measure which can support the constitution, without infringing on the laft-mentioned precept, zealously adopted.

The diet of the consumptive, in the early stage, of which we now speak, should be light and nourishing, and such as is found to be adapted to his digestive powers. Animal food should
should be avoided; and vegetable matters, in the various forms of preparation, with the ripe faccharine and tub-acid fruits, and milk, be made the exclusive nourishment of the patient. Milk is particularly serviceable, as being very nutritious, and easily digestible, without stimulating the system, and should be considered as the basis of the patient's diet. In some habits, however, where the digestive powers are feeble, or where there is a peculiar idiosyncrasy, cow's milk is not readily digested; a load at the stomach, or acidity, or head-ach, ensue after it is taken. In such cases, the whey which is produced by separating the curd part, or the butter-milk which is left after the separation of the oily part, or butter, may be substituted with advantage. Or the patient may have recourse to the lighter milk of the goat or the ass, which contains a smaller proportion of those heavy parts. The acidity which milk occasions in the stomach of some people, may be occasionally corrected by the admixture of lime-water. Some of the alkaline preparations from vegetables, may be used in conformity with this plan, such as the arrow-root, tapioca, &c.; and it is scarcely necessary to add, that with these, as with all other food, wine, spirits, and fermented liquors, must be most judiciously avoided. A mucilaginous vegetable has lately been introduced, which, in feeble habits, seems calculated to assist this plan; namely, the lichen idiosyncas, which may be taken boiled in milk, and which, with its nutritive qualities, combines a very mild tonic power, which somewhat aids the digestive.

While every thing is done, by means of medicine and diet, to repress inflammatory action, while we moderately support the strength of another measure, that more efficacious, should be adopted, by those who have the power; they should remove to meet the winter in a warm and more equable climate. Cold, but especially sudden vicissitudes of cold and heat, appear to be the most irritating circumstances to a beginning consumption; and there are many living testimonies of the benefits which have been derived from an early visit to a more genial atmosphere. Portugal, the south of France, and Italy, have been attended to, as well as the more regular and moderate climates of Madeira and St. Helena. Where these climates cannot be visited, some parts of our own island may be tried, as being milder than the rest; as Devonshire, and the neighbourhood of Brixton; which latter place possesses the additional advantage of a wholesome tepid water. Influences of the indigency of all these places, are, indeed, but too numerous; but much of this is to be attributed to the patients themselves. They perish in waiting the refult of time, or of the lefs efficacious means of relief, until relief is altogether beyond their reach. "It seems too often to be the fate of consumptive patients," says Dr. Fothergill, "to do that which they ought to have done first; and, by this preposterous conduct, shorten their own lives, and afflict all who have any regard for them." (Med. Obs. and Inq. vol. v. p. 369.) The same intelligent physician affirms, that the Brixton water is, in his opinion, an efficacious medicine; and that he has "often found it of signal benefit to consumptive patients;" but "it is before the approaches to a confirmed phthisis that patients ought to repair to Brixton; otherwise, a journey thither will be, not only without benefit, but will be probably detrimental." Ibid. Those who have visited the pump-room at the hot-wells, must have seen, with pity, the hopeless condition of the poor creatures who are dragged thither, to their personal detriment, and the discredit of an useful medicine.

Exercife, by various modes of生成, has been frequently employed as a remedy for consumption. Sydenham, indeed, asserted, that riding on horseback is as efficacious in the cure of phthisis pulmonary, as the bark in ague, or mercury in the venereal disease, provided the journeys be long enough. An example is related in Dr. Darwin's "Zoology," vol. ii. (the case of the late ingenious Dr. Curnock of Liverpool,) in which an hereditary phthisis was removed, by persevering in a daily journey; at first in an easy carriage, and subsequently, as the strength increased, alternately in the carriage and on horseback. Some physicians, however, are of opinion, that exercise on horseback is more efficacious than otherwise, in phthisis. (See Dr. Dickson's paper, before quoted.) Simulating seems to be considered at present as the most efficacious mode of generation, especially if a long voyage is taken, which is a double recommendation of the removal to a warmer climate. As a sort of substitute for this kind of genial motion, swimming has been recommended as a remedy for phthisis, and Dr. Carneshead Smith has written a treatise in its favour. In the use of any, or all these modes of gentle exercife, however, the same precept must be pursued; they must be retorted to early in the disease.

If the plan, now detailed, has not been adopted in such time and mode, as to have checked the disease; if it has, therefore, advanced to the confirmed state, with prevalent expectoration, hectic fever, and profuse night sweats; the principal object of medicine becomes merely palliative, and confined to the alleviation of urgent symptoms. If the cough is exceedingly urgent, opiates may be administered more liberally than in the early stage. At this period, some of the more stimulating expectorants are employed by some practitioners, with a view to facilitate the discharge of the matter which loads the lungs; such as the oxymel, or other preparation of fopall, the various balsams, and fopall of the guaiacum. But the experience of the most observing physicians has decided against the utility of these drugs. (See Dr. Fothergill, loc. cit. Dr. Cullen, loc. cit.) There may be occasional circumstances in particular contiguities, where the objections may not exist, as in a cold phlegmatic habit, or where there is considerable debility of circulation, with little inflammatory tendency; but these are not common. The colliquative fivets and diarrhoea frequently alternate with each other, and medicines which relieve the one, are liable to increase the other. The diluted sulphuric acid has a considerable influence over the night sweats, and opium is an efficacious medicine against the colliquative diarrhoea. But the opium seems to favour the occurrence of the perspirations, and the acid tends to excite the action of the bowels. These medicines, therefore, must be combined, or used singly and alternately, according to the circumstances of the case. Opium may be also given by way of enema, when the diarrhoea is obstruente.

Some practitioners, presuming that the hectic fever, and the whole series of phthisical symptoms, were dependent on debility alone, have recommended the use of tonic medicines, and a generose diet, in the state of confirmed phthisis; and several cafes are on record, in which this plan appears to have been attended with success. (See Dr. May's Papers, Lond. Med. Journ. vol. ix. and xi.) But we have already observed, supported by the authority of Dr. Willan, that carthahl affections occasionally put on the symptoms of phthisis, and recover under the ordinary means. There are also cafes of this fort, in which there is, we believe, no ulceration, but only a purulent secretion from the membranes, which nevertheless terminate fatally, with the want symptoms of phthisis; and perhaps it is in such cafes, that a tonic treatment is actually successful. But we have
no means of distinguishing these cases from the more general instances, in which abundant experience has taught us, that all stimulating or corrodent medicines and food tend to augment the cough and expectoration, to increase the hectic fever, and therefore to accelerate the destruction of the constitution, even in the last stages.

Emetics, repeated daily, have also been recommended, as a remedy for phthisis. They afford, we believe, a temporary relief to the respiration and cough, but nothing more. On the contrary, the continued repetition of such an irritant, and such a derangement of the natural action of the stomach, necessarily tends to debilitate and impair the functions of this viscus, and to weaken the constitution at large.

Before we conclude, we cannot omit mentioning an illusion, which was fostered in the minds of some enthusiastic physicians, after the discovery of the composition of atmospheric air by the chemists. It was found that oxygen was the great stimulant of life, and the source of the salutary change of the blood, which is marked by its florid colour. From the general fluid colour of the blood of the phthisical, it was supposed that consumption was occasioned by a general hyper-oxygenation of the system; and hence, by an easy inference, the breathing of air, in which the proportion of oxygen was diminished, by the addition of some azotic air, such as carbonic acid gas, or carbonated hydrogen, was suggested as a probable remedy for consumption. Cakes were even published, illustrative of the extraordinary efficacy of this new medicine. But the light of experience has opened the eyes of the visionary, and the phantom has disappeared. It has even been shown by the experiments of the French chemists, that the admission of oxygen, or, at least, its disappearance in the lungs, is influenced principally by the rate of the body, and not by the proportion existing in the air which is inspired.

Consumption, mesenteric. See Tables mesenterica.

Consumption, in Farriery, is also a diftinct incident to horses, consisting in waste of mucus in the lungs, attended with a bloody fever. In this disorder bleeding in small quantities is recommended: mercurial purges, and a powder of native cinchona, gum guaiacum and nitre, of each one pound, in the quantity of an ounce twice a day; spring grubs, and salt marshes, are also of great service, when there is any prospect of a recovery. See Condition.

CONSUMUS. See Consulalia.

CONTA, in Geography, a river of Italy in Genoa, which runs into the sea near Albenga.

CONTACT, (from the Latin contactus,) means the meeting, or mutual touching of two things. The word is universally used in the common affairs of life, as well as in scientific subjects.

In geometry a line is said to touch another line, or a surface, or a body; and a plane figure, or surface, is said to touch another surface or a solid, when the former meets the latter; but, being produced, does not cut it. Thus amongst the definitions of the third book of Euclid's "Elements of Geometry," a right line is said to touch a circle, when meeting with the same, and being produced, it does not cut it. Also two circles are said to be in mutual contact when they meet, but do not cut each other. Thus the mathematical meaning of the word contact is clear and definite, nor can any doubt arise in the speculative mind concerning the nature of it; the abstract ideas of a line, of a surface, or of a solid, being perfect and independent of any physical qualities of a doubtful or uncertain nature.

The contact of two spherical bodies is only in one point; and the same holds of a tangent and the circumference of a circle. See TANGENT. Hence, because very few surfaces are capable of touching in all points, and the cohesion of bodies is in proportion to their contacts; these bodies will stick fast together, which are capable of the greatest contact. The contact of curve lines or surfaces, with either straight or curved ones, is only in points; and yet these points have different proportions to one another, as Mr. Robartes has shown in the Philos. Trans. vol. xxvii. p. 470; or Abr. vol. iv. p. 1.

In mechanics and in philosophy the contact between two bodies is said to take place, when one body, being brought near another body, cannot be approached nearer to it without, in some measure, affecting its state, be it of motion or of rest. Thus a stone, being gradually moved towards another stone, is said to come in contact with it, when its progress is either absolutely, or partially, obstructed by that other stone. Or, if they be both at rest, and contiguous to each other, they are said to be in contact, when one stone cannot be moved towards the other, without either urging the other forward, or being stopped by it, or lying without making an impression upon its surface. The same thing must be understood of the contact between any other bodies. But the great question in philosophy is, to determine whether the bodies which thus hinder, or affect, each other's state of rest or motion, do actually come in contact with each other's surface in the strict mathematical sense, or they exact that hindrance, opposition, reflexion, &c. in virtue of a repulsive power, which acts at a certain indefinite small distance from their surfaces. This question seems, at first sight, to be easily determined; but, when duly considered, it will be found to involve certain properties of matter in general, and certain effects, which, in the present state of knowledge, are far from being thoroughly understood, or sufficiently examined.—The reasons which suggested the above-mentioned doubts, concerning the contact of bodies, and the answers which may be offered in elucidation of the subject, being fully deserving of notice, we shall now endeavour to relate them in a regular and copious manner.

Sir I. Newton, having placed a glass lens of a figure slightly convex, upon the flat surface of another glass, and having pressed the one against the other, observed certain coloured rings formed between the two glasses, and concentric with the point of contact in the middle of the glasses, which point was marked by a colourless dark spot. He further observed, that those rings of prismatic colours, and the dark central spot, became larger when the glasses were pressed harder against each other, and became diminished in size when the pressure was diminished.—From the known figure of the glasses employed in this experiment, it is evident that a certain space or a film of air must remain between their contiguous surfaces; that this space, or film of air, became thinner when the glasses were pressed hard against each other, and vice versa; lastly, that at the centre, where the glasses may be presumed to have been in real contact, the want of space, or of air, rendered that spot colourless. In this experiment it is supposed, that the colours are owing to the space or film of air between the glasses; hence the central spot exhibits no tinction; and therefore, that when any prismatic colours appear between the contiguous surfaces of two glasses, their contact cannot be perfect. Nearly the same thing is observed when two flat pieces of glass are pressed against each other; prismatic colours being likewise seen between them, though not in rings, but in rows, which assume various directions, according as the pressure may happen to alter the surfaces of the glasses. And these colours cannot be made to disappear without the application of...
of an enormous degree of pressure; hence it is inferred, that, though of two bodies one may support the other, or push it forward, yet their contact may not be perfect. Professor Robison reckons the force with which two pieces of glass must be pressed against each other, in order to produce a perfect contact, as equivalent to the pressure of 10,000 pounds for every square inch of surface; so that if two pieces of glass strike against each other, without exerting a pressure equal to 10,000 pounds per square inch of surface, they may affect each other's motion, and yet not come actually in contact. In consequence of the above facts and observations it is supposed, that a repulsive power exists on the surfaces of bodies, and that this power is extended to a very small and inappreciable distance beyond the surface.

Another argument to prove the existence of the above-mentioned repelling power on the surfaces of bodies, is derived from the phenomena exhibited in an electrical experiment. When an electric jar is discharged through a metallic chain in a darkened room, sparks of electric light are visible between the contiguous surfaces of the links. Dr. Priestley, considering this effect as arising from the want of perfect contact between the links, endeavoured to render it perfect by stretching the chain, until on making the discharge no such sparks should be seen. This he accomplished by making one end of the chain fast on a firm body, and appending weights to the other end. Thus proceeding, he found that a very considerable weight was necessary to be applied, before the sparks could be made to disappear between the links, when the jar was discharged through the chain. This induced Dr. Priestley to conclude, that the links of the chain could not be brought into actual contact without the application of a great force; since the electric sparks are visible only when the electric fluid in passing through a body or a series of contiguous bodies, meets with some obstruction, or interruption of continuity.

Besides the existence of the above-mentioned repelling or repulsive power on the surfaces of such gross bodies as come under the cognizance of our senses; it is farther supposed, that each component particle of such bodies is indued with the same repulsive power; in consequence of which they are not actually in contact with each other, though they form the same firm and impenetrable compound. And the existence of this power has been inferred from the phenomena of contraction and expansion. "Whatever opinion," says Dr. Young, "we may entertain, with respect to the ultimate impenetrability of matter in this sense, it is probable that the particles of matter are absolutely impenetrable to each other. This impenetrability is not however commonly called into effect, in cases of apparent contact. If the particles of matter confining water, and steam, or any other gas, are of the same nature, those of the gas cannot be in perfect contact; and when water is contracted by the effect of cold, or when two fluids have their joint bulk diminished by mixture, as in the case of alcohol, or sulphuric acid, and water, the particles cannot have been in absolute contact before, although they would have reflected with great force any attempt to compact them. Metals too, of all kinds, which have been melted, become permanently more dense when they are hammered and laminated."

Whatever wish to form a proper estimate of the merits of the above-mentioned arguments, and of the validity of the proposition which they are intended to establish, must necessarily take into the account all the other properties of matter, which have been discovered and confirmed by repeated and universal experience; for, should it appear impracticable to reconcile the former with the latter, then such other explanation of the phenomena ought to be substituted as may be attended with less contradiction and greater simplicity.—That there is a mutual and universal attraction amongst all the particles of matter, is now no longer to be doubted; that this attraction is extended to all distances under certain determinate laws, has been sufficiently established by strict mathematical reasoning upon the grand phenomena of the world; that the surfaces of several bodies, like those of polished glass or metallic bodies, when placed contiguous to each other, manifest a considerable degree of attraction, is well known; and, lastly, that the component parts of bodies cannot be separated without a considerable force, is shown by daily and common experience. Yet, notwithstanding all these evidence of attraction between the bodies of the universe at all distances, we are told that a considerable repulsive power exists on the surfaces of bodies, and even that every individual particle of matter is endowed with a similar power; so that in the hardened bodies, such as a diamond, a flint, a piece of metal, &c. which cannot be divided without an immense force, the component particles are not actually in contact with each other. But let us endeavour to explain the phenomena, upon which the above theory is established, in a simpler and more satisfactory manner.

In the experiments with the glass, it is said that their actual contact is prevented by a power of repulsion on their surfaces, which cannot be overcome without a very extraordinary pressure. Would it not be more natural to suppose, that the contact cannot be easily effected on account of the inequalities of the surfaces, and of the hardness of glass? The surface of the glass may be said to be slightly convex or perfectly flat, and such as may appear to be for common purposes. But if a person examines how the surfaces are formed and polished; if he considers the alterations of figure which are unavoidable occasioned by the partial dilations or contractions arising from heat; and the difference of the former and latter, in the interposition of the flat particle of glass, on the surfaces of the air itself: he will be easily persuaded, that these facts are by no means really flat or uniformly convex in the strict meaning of these words. It is true that the action of those causes, as the inequalities that are produced by them, are exceedingly small; but it is of small effects that we are speaking. Upon the whole, therefore, it seems, that when the flat and convex glasses in the Newtonian experiment, or the two flat glasses, are placed one upon the other, they do not actually touch each other, but in a few points only, and with their more prominent parts, and that the other more depressed parts of their surfaces cannot come into actual contact, until the former are depressed to the level of the latter, by the application of an external force; so that the application of this force is not required by the existence of a repulsive power, but by the necessity of depriving the more elevated parts, in order that the lower or hollow parts may come sufficiently near to each other. This idea seems to derive additional confirmation from the degree of pressure which must be applied, &c. being, at least apparently, proportional to the hardness of the bodies employed. Thus, in glass, which has a great degree of hardness and rigidity, a considerable pressure must be applied for the purpose. Bring two pieces of cold wax close to each other, and the one will pull the other forward without adhering to it, because in that cold state the contact can take place in a very few points only; but if those pieces of wax be prolonged by heat, it will be found, that one of them cannot be caused to pull the other without adhering to it, because in that state their surfaces are easily adapted to each other, and instantly increase the number of points of contact.

The appearance of sparks between the links of a metallic chain, when an electric jar is discharged through it, may be explained...
explained in a similar manner, without having recourse to a
power of repulsion, &c. for, in consequence of their figure,
and of the inequalities of surface, the links cannot touch
each other in more than a very few points, through which
the electric fluid must pass; and though in those points the
contact be perfect, yet the electric fluid either melts them or
renders them red-hot, and of course affords the appearance
of luminous sparks, in the same manner, and for the same
reason, which renders a very fine metallic wire red-hot, or
fuses it, when an electric jar is discharged through it; namely,
because it is not large enough to afford a free passage
between the electric fluid. So that if in the slender wire, where
there is no interruption of continuity, the passage of the elec-
tric power is rendered manifest to our eyes, it may be evi-
dently premised that the sparks may appear between the
links of the chain, though those links may be in actual con-
tact. That the light disappears when, by stretching the
chain, the points of contact are multiplied, needs no farther
explanation. But the circumstance which contributes to the
production of the sparks, is the adhesion of dirt or dust, or
the partial oxidation of the surface of the links; considering
that chains for electrical purposes are generally made of brass
or iron, which are very liable to a superficial oxidation.

With respect to the last argument, derived from the con-
traction and dilatation of bodies, we may observe, with
professor Prevost, that the diminution of bulk does by no means
prove that the component particles of bodies are not in im-
mediate contact; for a person may easily conceive an infinite
variety of arrangements or dispositions of the elementary
particles, which will admit of contraction and dilatation, with-
out the least interruption of contact. Those particles, for
instance, may be disposed in the form of rings which, by
becoming more extended ovals, or more circular, will occa-
sion an enlargement, or a contraction of the aggregate. The
particles may be supposed to be arranged in rows, and these
rows may be disposed at certain angles with each other; so
that the bulk of the aggregate may become expanded or con-
tracted according as those angles are enlarged or diminished;
and so forth. That some such arrangement is not only pro-
bable, but does actually take place in most bodies (whence
it may be inferred to take place in all bodies) is clearly indi-
cated by the crystallization of several bodies; viz. a regular
arrangement of their particles; as in zinc, bismuth, frozen
water, salts, &c.

Contact, angle of, is the angle HLM (Plate III.
Geometry, fig. 51.) formed by the arc of a circle M L, with
the tangent H L, at the point of the contact.

Euclid demonstrates, that the right line H L, standing
perpendicular on the radius C L, touches the circle only
in one point: nor can there be any other right line drawn
between the tangent and the circle.

Hence, the angle of contact is less than any rectilinear
one; and the angle of the semicircle between the radius
CL, and the arc ML, is greater than any rectilinear acute
angle.

This seeming paradox of Euclid has exercised the wits of
mathematicians: it was the subject of a long controversy be-
 tween Peletarius and Clavius; the first of whom maintained
the angle of contact heterogeneous to a rectilinear one; as
a line is heterogeneous to a surface: the latter maintained
the contrary.

Dr. Wallis has a formal treatise on the angle of contact,
and of the semicircle; where with other great mathe-
ematicians, he approves of the opinion of Peletarius. See
Angle of Contact.

CONTAGION, frequently used as synonymous with
Vol. IX.
The contagion, by which these fevers are propagated, is generated in three ways:—by the confinement of the healthy animal exhalations or effluvia in a crowded, and ill ventilated place;—still more readily by the confinement of morbid effluvia, although the disease be not originally contagious; and glibly, by the exhalations from putrifying dead animal matter.

1. Many facts have been recorded, which shew that the natural effluvia of the living body, become the source of contagious fevers, when accumulated and concentrated in close apartments. Mr. Howel and others, who escaped, from the black hole of Calcutta, were feized with typhus fever. Dr. Lind informs us, that in a frigate, which failed from North America, with a healthy crew, a malignant fever broke out before her arrival in England, during very bad weather, which affected a considerable number of the men, and of which the Surgeon's mate, boatwain, and some others died. "Thus," he remarks, "a seafomed found crew became infected, as it would appear, from the clovenfe or damp below, occasioned by the hatchway being kept flutt." (On Fevers and Infections, chap. i. § 2.) Sir John Pringle has observed that the hospitals of an army, not only when crowded with sick, but at any time when they are crowded, and especially in hot weather, produce a fever of a particular kind, and often mortal. "I have observed the same fort to arise," he adds, "in full and crowded barracks, and in transport-ships when filled beyond a due number, and detained long by contrary winds; or when the men have been long kept at sea under close hatches in stormy weather. Hospital-ships, for distant expeditions, have for this reason been generally destructive both to the sick and their attendants. (Obf. on the Dif. of the Army, part iii. chap. 7.) But contagious fevers are much more readily produced, under circumstances of confinement, where uncleancines has also conspired: hence such fevers originate most frequently among the poor, and even the most fevere pestilence, when not imported, is generally to be traced to some quarter chiefly inhabited by the poor.

2. Where people, labouring under any diseases, are crowded together, more especially if the apartments are imperfectly ventilated, contagion is readily generated. Sir John Pringle remarks, that contagious fever "is incidental to every place, ill aired and kept dirty, that is filled with animal exhalations from foul and diseased bodies; and on this account, jails and military hospitals are most exposed to this kind of pestilential infection: as the first are in a constant state of impurity, and the latter are so much filled with the poisonous effluvia of sores, mortifications, dyseretic and other putrid excretions: nay, there is reason to apprehend that when a single person is taken ill of any putrid disease, such as the small-pox, dyseretic, or the like, and lies in a small close apartment, he may fall into this malignant fever." Loc. Citat. It is very common, indeed, to observe mild febrile attacks among the poor, which, though originating from cold or other causes, become contagious in their course, in consequence of the confined and dirty situations in which the patients live.

3. Contagion occasionally originates from the putrifying effluvia of animal and vegetable matters. Thus it often happens that typhus fever spreads itself over the adjacent country, when the dead are left unburied on the field of battle. Forelos mentions a contagious fever, which raged at Egmont, in North Holland, occasioned by the putrefaction of a whale, which had been left on the shore. And Senec gives an account of a malignant fever, excited by the offal of a city being accumulated without the walls. It was received.
CONTAEGION.

received into a ditch filled with water, and, while it was covered with the water, was not attended with any bad consequence; but when the quantity increased, so that it rose above the surface, a dreadful fever spread through the city, and its neighbourhood; so that, where four hundred used to die yearly, the deaths were incaresed to two thousand. Willon on Febrile Diseases, loc. cit.

The most important part of our inquiry respecting contagion, relates to the mode and circumstances of its communication from individual to individual, and of its general spreading, with a view to discover the means of suppupling it, or preventing its extension. This inquiry is, of course, limited to the contagions which are tangible or diffusible in atmospheric air; since it is obvious that the indiffusible contagious may be avoided, by shunning the contact of the diseased. And it must be premised, that all the visible contaminations, whether of a specific origin, as that of small-pox, measles, scarlet fever, or malignant sore throat, or arising from the usual change of the animal cibation, jaundice, and hospital fever, and perhaps the plague, have been found, by experiments, to be propagated according to the same laws, and to be suppressed by similar means.

Whenever a contagious epidemic disease prevails, a great general alarm is excited, in consequence of a notion, that the seeds of an evil so generally destructive must be diffused through the atmosphere at large; and that, if we flir abroad, we breathe contagion at every step. This opinion has been promulgated by physicians of high rank and authority; but recent observations have shewn that it is erroneous: thus at once removing all grounds for this unnecessary alarm, and directing our attention to those means of precaution and prevention, which can alone effectually contribute to our security.

Dr. Lind long ago affirmed, after an extensive experience in the great naval hospital at Halfor, that the infection of malignant fever, in common with that of the plague, "extends to no great distance from its source."—"In the open field," he adds, "this infection does not appear to diffuse itself above fifty or sixty feet from its source." Chap. iv. sect. 2.

With respect to the plague, it has been well ascertained by physicians, that its contagion does not contaminate the atmosphere in general, nor indeed to any great distance from the source of the poison. Dr. Patrick Ruffeli, who was in extensive practice at Aleppo for many years, particularly during the plague of 1760, 1761, and 1762, used to administer medicines to great numbers ill of the plague, every day, out of a direct window, about 15 feet above the ground, even in June and July; and, being short-sighted, he examined the forems within four feet; yet neither his family, nor any inhabitant of the square where he lived, were infected by the contagion of such a number of pestilential patients: and he affirms that it never spread in a large house, if communication were prevented. A numerous body of Franks live in Constantinople, and are uniformly deprived from the plague, by observing a few rules of cleanliness and separation, while the Turks die of it in multitudes around them. Dr. Martens, author of a history of the plague at Moscow, anno 1771, has shewn that the contagion was disseminated to a very short distance through the air: a fact, which was demonstrated by the successful conduct of the committee of physicians, appointed by the empehrs to attend the sick on that occasion. The just inference from these observations is, that the plague is principally propagated by actual contact or clore communication with the diseased, or their clothes, furniture, &c. "Solo agrorum et rerum infec-

In addition to such facts, which are flaeted by physicians of high respectability, we have the support of direct experiments, made respecting a contagion not less virulent and fatal than the plague itself, viz. that of the small-pox; by which the short distance, to which the poison is communicated through the air, is demonstrably proved.

Dr. O'Ryan, professor of physic in the college at Lyons, instituted the following experiments, which we shall relate in the words of Dr. Haygarth's translation: "I placed a large doll of cotton, foaked in various matter, on the needle of an oval table, whose leaf diameter was three feet. I fenced six children around it, three on each side of the table, in such a manner that all were situated within half a yard of the infectious cotton. This experiment was sometimes made in the open air, sometimes in the house. I took care to renew, every second day, both the various matter, and the inhabitation which contained it. I alternately used the poison taken from the inoculated and from the casual small-pox; and I copiously impregnated with it balls of cotton, wool, and silk. This operation, repeated during a whole week, morning, noon, and night, for an hour at each sitting, produced no effect.

I then sent away the children, delivering the parents to acquaint me, in case any indisposition appeared, and to bring them to me a fortnight afterwards, although no alteration should have taken place in their health. I declare that not only for that term, but for many succeeding months, during which I took care frequently to visit them, they all enjoyed perfect health. It was not till nine months after this time, that four of these children had a mild kind of small-pox.

Having concluded from these experiments, that the children could not have escaped infection, but because the various matter might have lost that fpring and that degree of energy, which perhaps it may possess on arising immediately from the human body, I placed a person, in the eruptive fever of the small-pox by inoculation, at the distance of about half a yard from four children properly prepared: each exposure continued one hour, and was repeated daily for a fortnight, reckoning from the commencement of the fever till the pustules were become perfectly dry. Not one of the four received the infection. Two months afterwards, I inoculated three of these children: they had the distemper in a very mild manner, and recovered without difficulty." Diff. feur les Fievres Infetdeues et Contagieuses. See Dr. Haygarth's Sketch of a Plan to exterminate Small Pox, vol. i. p. 79.

Again, proofs that the sphere of activity of fbrile contagion is extremely limited in the air, have been greatly multiplied since the institution of feverwards and houses of recovery, which were fuggestled by Dr. Haygarth, from the contemplation of such facts as we have just detailed. The feverwards, in the Chelsea Infirmary, are situated within thirteen yards of some other wards of the building; yet, during a space of above twelve years, the contagion of fever was never known to extend itself from thence. And Dr. Currie relates, in a letter to Dr. Clark of Newcastle, that contagious fever had not, during ten years, extended itself, in any one instance, from the fever-wards, either in the Liverpool Infirmary or in the workhouse, although the latter of these buildings has sometimes contained 3,400 persons.
CONTAGION.

In like manner, the house of recovery, in Gray's Inn Lane, London, which stands in a row, in contact with dwelling-houses on both sides, and which has had a constant succession of contagious fevers in its wards, has now (Dec. 1807) been open nearly six years, and no fever has occurred in its neighbourhood during the whole period. Nay, it has been farther ascertained, in these wards and houses, as well as in the habitations of the rich, that, in a clean well- aired room of a moderate size, the contagious poison is so completely disarmed of its virulence, by dilution with fresh air, as rarely to excite the distemper, even in nurses, exposed to all the putrid malaises of the breath, perpiration, and other discharges. See Dr. Haygarth's Letter to Dr. Percival, on the Prevention of Infectious Fevers, 1801. Dr. Clark's Collection of Papers respecting Fever-wards, Newcastle, 1802. Reports of the Institutions for the Suppression of Contagious Fever, in Dublin, London, Manchester, &c.

A sufficient number of facts, we truly, has been cited, to show that the popular opinion and apprehension are groundless, and that the most malignant contagious are never conveyed to any great distance through the atmosphere; but that they are, in fact, rendered inert and harmless, by dilution in the open air, and even in the air of a well-ventilated apartment. The necessary inference is, that all pellagra is propagated by near approach, or actual contact of, the infected, or by the conveyance of the contagious poison in articles impregnated with it.

Dr. Lind remarks, in the effay before quoted, "by a fixed attention to this subject for some years past, I am convinced, that the body of the diseased, kept exactly neat and clean, is not so liable to impress the taint, as his late wearing apparel, dirty linen, and uncleanliness of any sort about him, long retained in that impure state:—I say, these will contain a more certain, a more concentrated, and contagious poison, than the newly emitted effluvia or excretions from the sick." There is no doubt that such fomites spread and perpetuate many contagious diseases among us. It is ascertained that cotton, hair, and wool, are the substances most readily imbued with contagion, which becomes more virulent, when the air is prevented from having free access to them. If infected clothing, made of these materials, remain for some weeks in a full close room, or locked up in chests, and be then folded out during an unhealthy season, not only the wearers of it, but all who have intercourse with them, are presently affected, and contribute to spread the diseased. Thus the Europeans, says Dr. Lind, have carried the small-pox to almost all parts of the world, where their ships have opened a trade; though the feamen in those ships might not have been infected with it in their voyage. This poison has been conveyed, in an old blanket, to nations of Indians, some of whom it has almost extirpated. In the year 1746, while the French squadron, under the command of the due de D'Anville, passed the summer at Cheltenham, now Haltiax, an infectious fever prevailed among them, and cut off a great number of their men. On the return of the squadron to Europe, several blankets and old clothes, which had been used in their tents and hospital, were unfortunately left behind. These fatal receptacles of disease were soon after eagerly picked up by a party of Mimack Indians, who accidentally came to visit the place, who clothed themselves with some of them, others they carried home, and distributed among their tribe. The unhappy consequence of which was the almost total extirpation of the Mimack nation; few of whom survived. The English, upon traversing the country next summer from Annapolis Royal, were surprised with finding the dead bodies and skeletons of whole families lying unabraded in their huts, until the neutrals, who also inhabited that country, and the neighbouring In* dians informed them, that the Mimack had been cut off by the French blankets. In several of their huts, these blankets were found, where not one of the family remained. (Lind. chap. iv. sect. 2.)

Dr. Willan remarks, on the subject of fomites, that the houses of the poor in London are often so little taken care of, that in the apartments where contagious fevers have existed, enough of the contagion remains, to infect all the inmates who successively occupy the same premises; and he mentions some particular houses, in which the fomites of fever were thus preferred for a series of years. (Reports on Diff. of London, p. 256.) The same accurate observer states, that the scarlet fever, which, when epidemic, has often commenced in the easterly extremity of London, and spread westward, though it may have been sometimes imported with infected goods brought from abroad, will be more frequently found to have originated from the large repositories of old clothes, near the Tower, Earl Smithfield, and Ratcliffe Highway. "During the last year of my attendance at the Public Dispensary," Dr. Willan adds, "I had reason to think that a family in Wild-lane, Lincolns-inns-fields, was infected with Carllatina maligna by clothes bought in Monmouth-lane. More than fifty persons in the adjoining houses were soon affected with the disease, which afterwards travelled Drury-lane, and spread by Long Acre, and the streets connected with it, through several parishes in Welflimer." (On Cutan. Difeases, p. 301.) Thus also, and not by the impregnation of the atmosphere, the small-pox, measles, typhus, whooping-cough, itch, tinea capitis, &c. are perpetuated among us; and the febrile contagions are from time to time widely diffused.

A great number of facts are on record, which serve to show the extreme virulence of contagious poisons, which have been pent up and accumulated in close places, and have contaminated articles of clothing under such circumstances. In those periods of our history, when a few enlightened humanity was careless of the health of criminals, and prisoners in general, the occurrence of what were called black affizes was frequent in different parts of the country. The criminals, brought out of filthy and infected cells, with their clothes fully imbued with fomites, often spread a mortal contagion through the court, assemblage for the purposes of justice. "The most pernicious infection next to the plague," says Lord Bacon, "is the smell of the jail, where the prisoners have been long, and close, and naughtly kept, whereof we had in our time experience, twice or thrice, when both the judges, who sat upon the guilt, and numbers of those who attended the business, sickened upon it and died." One of the infallacies, to which Lord Bacon alludes, was doublets at the fatal affizes, held at Oxford, in the year 1577, at which Stow gives the following account in his Chronicle. "On the 4th, 5th, and 6th days of July, were the affizes held at OXon, where was arraigned and condemned Rowland Jenkins for a lecherous tongue; at which time, there broke amongst the people such a damm," (an expression in the language of those days, signifying bad air) "that almost all were smothered, very few escape that were not taken, here died in Oxon 300 persons, and sickened there, but died in other places, 200 and odd." Similar infections took place at the black affizes at Taunton, and also at those of Exeter, in 1569; at which last some Portuguese sailors spread the contagion, having been confided, without change of clothes, "in a deep pit and dark dungeon." The last black affizes at the Old Bailey were held so late as the year 1750. On the 14th of May the prisoners, who were brought into court, some of them labouring under small pox, had been kept more...
CONCAGN.

nearly a whole day in small, close, and crowded apartments. All the individuals, who were seated in the course of a draught of air, passing from the prisoners to an open window, were seized with the distemper: the rest escaped. The lord mayor and those of the bench who sat on his left hand were infected; while the lord chief justice, and the recorder, who sat on his right, escaped. Many of the Middlesex jury, on the left side of the court, died of it, while the London jury, who sat opposite to them, received no injury. On the 13th of May died alderman Lambert; on the 14th R. Cox, under-sheriff; on the 15th baron Clark; on the 19th T. Abney, justice of Common Pleas; T. Otway, barrister; W. Bare, ditto; W. Sharples, and four others; on the 20th, the mayor and eight of the Middlesex jury. See Gentleman's Magazine.

These facts, while they evince the active virulence of contagion, accumulated in fumites in unventilated and crowded rooms, afford, at the same time, evidence, that, except where it is carried at once by a direct draught of air, its tendency to diffuse itself, and its power when diffused, through the atmosphere in general, is very limited. It is only under such circumstances of concentration, that the virulence of contagion is ever so great, as to be infectious at more than a few feet distance. It has already been seen, that when arising from the body of the sick, either in the open air, or in well ventilated rooms, its influence is confined to a very small distance.

Before we point out the means of prevention from contagious diseases, which these facts and observations suggest, it will be necessary to attend more particularly to the circumstances of individual infection.

All individuals are not equally liable to be infected by contagion; and some, though the number is extremely small, escape altogether. Thus, there are persons who have gone through a long life without taking the small-pox. The constitution, however, appears occasionally to undergo such a change, in the course of life, that those who, in earlier years, had resisted the action of this contagion, have received it on some future occasion to its influence. There is a considerable difference, too, in the infectious degree of different contagions: thus, that of the whooping-cough affects a much smaller proportion of mankind, than that of the measles, or small-pox; and that of the scarlet fever excites the disease in children much more frequently than in adult persons. Again, the contagion, in some instances of pestilence, and, we believe, in the plague in general, is more fatal to the vigorous and middle-aged, than to the old on the one hand, or to children on the other. We were informed by a gentleman, who resided at Malaga, during the late pestilence at that place, that the appearance of the town, after the effusion of the fever, was remarkable, in consequence of the small number of strong, active, and well-looking people, who were to be seen; old people and children constituting almost the whole of the remaining population. In the typhus, or contagious malignant fever of this country, Dr. Haygarth infers, from accurate deduction, that about one in 150 escapes infection, though fully exposed to the contagion; which is less than one in twenty-four. (See Letter to Dr. Percival, p. 31.) It has been calculated that nearly the same number, or one in 25, is naturally exempted from the contagion of the small-pox. Upon this datum it was also calculated, that if two persons together have escaped the disease, the probability, that they were never both exposed to an infectious quantity of the poison, is above 400 to one; if three in a family have escaped, above 8000 to one. (Haygarth's Inquiry how to prevent the Small-pox, p. 24.) This mode of reasoning is equally applicable to typhus infection.

Now, as great numbers of people, visitors, nurses, &c., breathe the air of the chambers of patients, ill of contagions fever, and yet escapes infection, it is obvious that in almost all these cases, (at least in 22 out of 25) a sufficient dose of the poison had not been received. This leads us to an important inquiry, into the dose of typhous contagion requisite to produce infection. The quantity will vary, no doubt, according to different circumstances, but the observations of Dr. Haygarth, and of the physicians of fever-wards, and houses of recovery, have enabled us to judge with some accuracy of the limits of this variation. There appears to be a direct analogy between contagious miasmas and other poisons. The larger the dose of a poison or drug, the greater in general is the effect which it produces. Many of the most powerful and salutary medicines, when taken in too large a quantity, are poisons, as opium, antimony, mercury, fennel, thallium, &c. And, on the other hand, even arlene itself, the most virulent and unmanageable of the contagions, has, by the skill and attendance of physicians, been reclaimed from the class of miasmic substances, and by a diminution of the dose is judiciously held to be a safe and useful remedy. Further, in different constitutions, and in different maladies, there is a certain degree of variability in the operation of any drug. Thus four or six times the dose, e.g. of antimony or mercury, may be required for one patient more than for another, or for the same person in different diseases. In the same way the miasmic quantity of infectious miasmas admits of some variation.

It is clear, from the collected observations of Dr. Haygarth, and of those active and experienced physicians whose correspondence he has published, not to mention the experiences which fever-wards have lately afforded, that in a large, airy, and clean apartment, few or none even of the most intimate attendants catch the disease, where the patient labours under infectious fever. The nursey themselves, exposed to the effluvia of the excreta, and perpetually near, and often in contact with the sick, nevertheless hardly ever receive infection. The atmosphere of a room of these con-
CONTAGION.

upon this point to an indefinite extent, but the general safety of medical men under such circumstances is sufficient to prove, that air strongly impregnated with infectious miasms may be breathed for a short time, and air weekly impregnated for a long time, without any injury. We might, hence be almost led to believe, that the poisonous miasms do not generate a fever, till they have been respired without interruption, for several days together; and it is not improbable that, in some persons, such an accumulated quantity of the poison may be required.

There are, however, other facts which prove that this is by no means always the case. Infection is occasioned suddenly, in some instances, and from a very short exposure to a petilential air. Whether this is owing to peculiar susceptibility of the individual, or to the particular mode of receiving the contagious effluvia, is doubtful. The writer of this article, about six years ago, visited a poor family, of four persons, lying in the same bed, in an exceedingly close and dirty apartment, ill of contagious fever. He always had the precaution to throw open the window on entering the room, to flatten himself between the window and the bed, whilst he examined the sick, and to remain but a short time with them. He had relaxed his daily visits during a week, and with impunity, when for a short period of time he was attended by another physician, who designed to admit the patients into the House of Recovery, just then opened in Gray's-inn-lane. The latter took no precaution, but examined the skin of the sick minutely and closely, standing on that side of the bed towards which the air from the window impelled the contagious effluvia, and so near as to receive these effluvia and the breath in the most concentrated state. He took the infection, and his fever proved fatal. Here the infection of this excellent physician was attributable only to the full dose of the poison, which his incautious zeal induced him to inhale. In most cases, as in this, where a sudden infection takes place, a disagreeable fenation is excited at the moment of exposure, which different persons have described differently. Some have felt a sharp taste in the mouth, as if blue vitriol were dissolving in it, but which no washing or gargling could remove. Others have compared the first impression to that of an earthy exhalation from a newly-opened grave; the fenation extending down to the stomata, sometimes exciting innumerable tickness and stinging. Dr. Haygarth mentions that two of his patients, for whose recovery physicians, were infected suddenly by a short exposure. One of them thought that he caught the fever by creeping behind, in order to assist his patient; the other by inspecting morbid feaces. In both these cases, the exposure was such as might probably afford a full dose of the contagion. Dr. Lind is of opinion, that, in these diseases, the fumes, especially if very fæcid, are most communicative of contagion; next to these the breath; and lastly the effluvia from the body.

The activity of contagion is not always proportionate to the appearances of malignity in the diseased. Sometimes only one man in a ship may be fezzed with the pecatellar or with the yellow fever, says Dr. Lind, while all the rest continue unaffected. And the most malignant case of fever, that we ever witnessed, did not infect any of the family, though in a close and small house. And on the contrary, we have seen fevers, of the mildest description, which spread extensively: so that we fully coincide with Dr. Lind in his observation, that "fevers have often no peculiar characteristical symptom, by which they are known to be infectious," and again, when he says, "in some this fever will be more severe, in others more mild, and often most of the sick will be able to fit up through great part of the day, which cannot be urged as an argument against the infection, but only as a proof of its mildness." (Loc. cit. § v.) It is obvious, therefore, that great caution should be used in pronouncing fevers not infectious.

The period at which different fevers begin and cease to generate contagious effluvia is not absolutely ascertained. It seems most probable that in eruptive fevers there is no contagion till the eruption appears; and that contagion remains so long as any scab remains on the skin. This is clearly the case in small-pox.

The latent period of contagion, as Dr. Haygarth terms it, or the period which elapses between the exposure to contagion and the first appearance of the disease which ensues, is ascertained with tolerable accuracy in respect to the small-pox; but in typhous cases it appears to be extremely irregular. The small-pox from inoculation usually commences on the eighth or ninth day after the operation. Thus, of 810 inoculated cases, in 519 fever commenced before the ninth, and 291 on or after the ninth day. But from the testimony of Dr. Woodville, Clark, and Currie, the eruptive fever sometimes commences so early as the fifth day after inoculation; and three cases are related by Dr. Clark where it commenced so late as the 16th, 17th, and 25th day. The period in the usual small-pox is somewhat longer than in the inoculated; most commonly from 10 to 16 days. (See Haygarth, Sketch, &c. before quoted.) The latent period of the contagion of measles is from 10 to 14 days. (Willan on Cutaneous Dis.) But the latent period of typhous infection is much more irregular, and often much longer. Of a large number of cases listed by Dr. Haygarth, more than half commenced between the 17th and 33d day after exposure, a great proportion after the 27th, and almost all between the 20th and 60th. (See Letter to Dr. Percival, p. 20, et seq.) The fever occurred in only five instances before the 10th day. So that on the whole, it appears, that the latent period of typhous infection varies from a few days to two months. (Ibid. p. 68.)

This latent infection is probably often allowed to lie long dormant, or is excited into action at an earlier period, according to the occurrence or non-occurrence of circumstances which may render the constitution less capable of resisting its action. Thus persons who had some time previously been exposed to the influence of contagion, have been immediately seized, if put upon being wet with rain, or on exposure to cold and damp air, or after a debauch, or other such debilitating causes. During the prevalence of a pestilence, it has been observed that exposure to the damps of evening, especially in warm countries, is extremely dangerous. And Dr. Chisholm remarks, that those who were addicted to the abuse of intoxicating liquors, were most subject to the fever of Grenada. From the great length of time, indeed, which the contagion of fever often lies dormant, we may infer, with Dr. Lind, that it is probable, that, without the influence of those casual exciting causes, the contagion might never, in such instances, have affected the constitution.

Prevention of infection. The circumstances under which contagion is generated, and the modes in which it is conveyed and propagated, being understood, the means of preventing its production, and of avoiding its pernicious influence, when it exists, will readily suggest themselves. Instead of omitting all attempts at avoiding the contagion of a pestilence, as altogether fruitless, where the very pabulum of life, the common air, is charged with poisons; or of adopting the dangerous expedient of closing up every avenue of ventilation in our houses (Wilson on Fevers, p. 45, vol. 1), or of employing ufleks and absurd measures of precaution, we shall
shall proceed upon rational grounds to the use of effectual preventives. All those who contend that the spreading of contagion depends on some peculiar state of the atmosphere, admit that it is some occult quality in the air; that it is neither the heat nor the cold, the moisture nor the dryness, nor any other sensible condition of it, with which pejvulence is connected. The great Sydenham, after having noted attentively the state of the atmosphere and the weather, in different years, during which epidemics of different kinds prevailed, was obliged to confess that he could perceive no difference in seascans in which different contagions disfigured occurred. He, therefore, had recourse to a supposition equally gratuitous, that some unknown exhalations from the earth were the source of pernicious diseases.

But when it is considered, that contagion originates in accumulated and confined animal cilia, and is communicated either to those who approach, or come in contact with the sick, or by means of substances impregnated with contagious matter, and that, by these ways only, the means of prevention are obvious.

With respect to the casual origin of contagion, it is scarcely necessary to say, that cleanliness and ventilation, as they preclude the confinement and accumulation of the animal cilia, and secretions, will infallibly prevent the generation of the poison.

Where contagion exists, its farther communication may be prevented by avoiding contact or approach to the sick, and by confining the patient to a separate room, in which, if it be kept clean, and well ventilated, it has already been shewn, that the contagion will be inert, at a short distance from the sick; and therefore that the necessary attendants, and medical visitors, will receive no injury from respiring the air within it. In this way contagion has been prevented from spreading in large schools, and other places, where a number of people live together, as in workhouses and hospitals, of which some examples have been already given. Dr. Haygarth's rules for the prevention of infection, seem to comprise all the requisite means to be adopted, in houses where contagious fever exists; they are the following.

Rules to prevent infection.

1. As safety from danger entirely depends upon cleanliness and free air, the chamber-door of a patient, ill of an infectious fever, especially in the habitations of the poor, should never be shut; a window in it ought to be generally open during the day, and frequently in the night. Such regulations would be highly useful both to the patient and nurses; but are particularly important previous to the arrival of any visitor.

2. The bed curtains should never be drawn close round the patient; but only on the side next the light, so as to shade the face.

3. Dirty clothes, utensils, &c. should be frequently changed, immediately immersed in cold water, and washed clean when taken out of it.

4. All discharges from the patient should be instantly removed. The floor near the patient's bed ought to be rubbed clean every day with a wet mop or cloth.

5. The air in a sick room, has, at the same time, a more infectious quality in some parts of it, than in others. Visitors and attendants should avoid the current of the patient's breath,—the air which ascends from his body, especially if the curtains be close,—and the vapour arising from all evacuations. When medical or other duties require a visitor or nurse to be placed in these situations of danger, infection may be frequently prevented by a temporary suspension of respiration.

6. Visitors should not go into an infected chamber with an empty stomach; and, in doubtful circumstances, on coming out, they should blow from the nose, and spit from the mouth, any infectious poison which may have been drawn in by the breath, and may adhere to those passages.” (See Letter to Dr. Percival, p. 73, et seq.)

By observing these rules, not only numerous visitors, but the medical attendants, and the nurses themselves, who frequently move and otherwise affilt the sick, in fever-wards, and the wards of houses of recovery, entirely escape infection. This is proved, with scarcely any exception, in all the institutions of this fort throughout England and Ireland. During the last four years (the writer speaks from personal observation) only one instance of infection feizing a nurse in the London House of Recovery, occurred, and, in that case, the imprudently slept in a bed, just quitted by a convalescent, who had left the house, without changing the linen.

By the same rules, Dr. Haygarth secured the progress of a fatal case, when Winchester and other great schools were diffusing their scholars on account of this most contagious discompliment, which had spread alarmingly among them. Not one was infected after the plan of separation in an unvisited room was adopted, although all the boys remained in the same house. (Let. to Dr. Percival, p. 81.)

Contagion may, however, be extensively circulated by fumes, i.e. attached to clothing, furniture, and other articles, which mode of communication is, perhaps, the most to be apprehended, during the prevalence of an epidemic malady. Hence the severe laws of quarantine have been enacted, in order to prevent this country from the contagion of foreign pestilence, which might be imported with the articles of commerce. And it is not less necessary, during times of internal pestilence, to be watchful in regard to this point. It is not, however, by a flight and brief exposure to contagious misfits, that substances are sufficiently imbued with them, to communicate infection. Thus it is, on the whole, well ascertained that the clothes of visitors do not acquire a pestilential quality, so as to infect others. Upon this point, the experience of several observing practitioners coincides. Dr. Clark of Newcastle affirms, that in eighteen years practice, he never communicated the contagion of small-pox, nor of the scarlet fever, with ulcerated fore throat, to any one, even to children in his own family, although he had frequently, on the same day, visited many patients in those diseased, and in the most malignant stages of the latter, and afterwards had intercourse with other children liable to receive them. Mr. Henry adds his own experience, during nearly forty years, in Manchester, in testimony of the same fact, in regard to the contagion of small-pox. And the testimony of several other practitioners is equally strong, as to the non-conveyance of this contagion by their clothes.

Now, whatever is true of the contagion of small-pox, and of scarlet fever, is still more decisive as to typhous infection, which is less powerful than either. (See Haygarth, Sketch of a Plan, &c. pp. 369, 386, 404, &c.) Substances do not become sufficiently impregnated with the poison, in clean and ventilated places, except by being in a considerable time in contact with, or very near the sick, as the bed in which the patient lies, or the linen he wears; these fumes are chiefly produced in close and dirty places, where the contagion is concentrated by accumulation and confinement, as in the cells of jails, or in the apartments of the poor, in which cases, the utmost virulence of the poison is brought forth.

Where contagion of this degree of activity is produced, and is combined with articles of clothing and furniture, &c. the mere act of ventilation, which effectually prevents
its deleterious action, when arising from the body of the sick, is altogether inadequate to destroy its power in these 
infected. Hence various means have been devised, in all ages, 
for annihilating contagion. Among these, fire has been 
most generally employed, more especially with a view of 
annihilating, or applying the smoke or vapours from different 
substances, to the fource of the poisonous miasms. Hippo-
ocrates and Acron of Agrigentum, believing the air to be 
the medium of infection, are said to have ordered large piles 
of wood to be burnt in the streets and infected parts of 
Athens, by which means they checked the plague in that city. 
(Aeum. Tetrab. Phalarer. de Ind. et Ofir.) But however 
useful the fumigation of fomites may be, it does not appear to 
be of any utility when employed in the atmosphere in ge-

eral. In the year 1721, the plague raged at Toulon with 
with violence, that in the space of ten months it destroyed 
about two-thirds of its inhabitants. Many having inhaled 
upon fires being made in different parts of the city, the 
public records were consulted, and it was then found that, 
on a similar occasion, the same means had been tried without 
succes. The experiment, however, was repeated. Wood 
was laid before every house, and at the found of a bell, all 
the fires were lighted, by which the city was involved in a 

black smoke for nearly a whole day. The plague, however, 
fuddled no abatement. The same measure was repeated 

both at Marsilles and London, when the plague raged in 
these cities, with no better success. Nay, after the fires had 
been kept burning for three days in London, on the night 
which succeeded, no less than 4,000 died, although not more 
than 12,000 had been destroyed during the preceding three 
or four weeks. (Wilson on Febr. Dif. vol. 1. p. 464.) 

There is no doubt, however, that contagion, adhering to 
clothes and furniture, may be effectually destroyed by the 
vapours from various combustible and volatile substances. 
Dr. Lind recommends the fumes of tobacco to be diffused 
through the cells and infected apartments, in prisons and 
sheds, as well as for the purification of infected articles; he 
also advises the exposure of fomites, to the fumes of ful-
phur, from a charcoal fire, as an efficacious mode of puri-

fication. But he is perfectly convinced, he says, from long 
experience, that even the simple heat of a close confined fire, 
or the heat of an oven, is a destroying power which "no 
infection whatever can withstand." The efficacy of gun-power 
was ascertained by an accident, and Dr. Lind afterwards 
used it in wards where fivers were received, every morning. 
In a ship of war, a contagious fever prevailed, which had 
destroyed sixty men; when, in an engagement with the 
French, twenty-five barrels of gun-power were fired 
on board of her during the action; and, to the surprise of 
her officers, none of her men were afterwards attacked with 

fevers. 

Some strong smelling substances, as camphor, the va-
pours of juniper, and of Calcarilla bark, &c. have been 
occasionally resorted to as preventatives from contagion; 

but the power of these substances is very questionable, and 
they may be, perhaps, negatively prejudicial, as their aro-

matic odour may conceal the smell of bad air in the room 
of the sick, and thus prevent effective measures of salutary 
from being employed. 

These are not the means of which we profess of 
destroying contagion in fomites, seem to be the fumes of 
the mineral acids. The vapours of vinegar, and those of 
the sulphuric acid, have been long used with some degree 
of success; but those of the muriatic, and still more, per-
haps, those of the nitrous acid, appear to be complete an-
tidotes to accumulated contagion. The evidence of the 

efficacy of the nitrous acid fume, in purifying infected places

and substances, which was a few years ago laid before the 
House of Commons by Dr. Carmichael Smyth, was such as 
to induce that house to vote a national donation of five 
thousand pounds to him for the discovery. This vapour is 

easily obtained, by mixing with powdered nitre a little of 
the strong acid of vitriol or sulphuric acid; the latter com-
bines with the poisons, the base of the nitre, expelling at 
the same time the nitrous acid in fumes. (See Dr. C. 
Smyth's treatise on the subject.) 

The muriatic acid may be obtained in a similar manner, by 
using common sea or rock-lime, instead of nitre. 

Where contagion has been long pent up in close cells or 
rooms, it is apt even to adhere to the walls. In such cases, 
whilst-walking with hot or newly fired lime, is an efficacious 

aid of the acid fumigations. 

It is a curious fact, and perhaps wholly unaccountable 
upon any theory of the propagation of contagion, that peri-

tential diseases, after running an indefinite course, notwith-

standing all the measures adopted to restrain their progress, 
very frequently cease spontaneously, at a time when the walls 
of the houses, furniture, &c. must still be supposed to be high-
ly impregnated with the contagion. The fact is authenti-

cated by Dr. Ruffell, Dr. Lind, and several other phy-
cians of equal respectability. The cessation is not con-

nected with any sensible changes in the atmosphere. Warm 
weather is perhaps, on the whole, but not without many 
exceptions, more favourable to the production of contagious 
diseases than cold weather. But the worst fevers 

have often raged in the coldest seasons; as did the plague 
in London; and there have been instances of the plague 

furling a check as the weather grew warmer. (Wilson 
on Febr. Dif. p. 448.) 

During the prevalence of a contagious epidemic, tem-

perance and regularity, and care in avoiding all causes of 
dibility, (such as cold damp air, &c.) the use of the cold 

bath, and the preservation of an equal state of mind, are 
great personal preservatives. The general alarm which 
prevails during these periods of public calamity, is not among 
the faults of the cauca which contribute to extend the evil. 
It would be, therefore, injudicious to condemn the use 
of camphor, rosemary, and other aromatic substances, or car-

rying a quill filled with quicksilver, or other amulet, about 
the person, since whatever tends to inspire confidence in 
the mind, contributes to the security of the body. 

CONTARI, in Antiquity, a kind of horsemens, whose 

chief armour was the canteus, a kind of long spear. 

CONTARINI, GASPARD, in Biography, a cardinal of 

the church of Rome, was not more celebrated as a divine 
than as a politician. He flourished in the Venetian terri-

tories, and was nominated from that republic as ambassadoor 
to the emperor Charles V., after which he was raised to a con-

siderable station in the government of his country. He was 
ambassador also to Rome; and when pope Clement VII. 
surrendered to the imperial army, a commission was given 
to Contarini to negotiate for the liberty of the pontiff. In 
1535, he was created cardinal by pope Paul III.; and in 
1541, he was appointed legate to Germany, and with the 
other legates was appointed to preside at the general coun-
cil, which was afterwards held at Trent; he was, however, 

sent legate to Bologna, before that assembly met, where he 
died at the age of 65, in the year 1542. He was author of 
many works, and on various topics, in which he displays con-
iderable talent, and a mind superior to the times in which 
he lived. The principal pieces are "De Immortalitate 
Animae," "De Septem Ecclesiae Sacramentis," "De 
Potestate Papa," "De Predelectinatione," "De Libero Ar-

bitrio," and "Coniunctio Articulorum Lutheri." 

Con-
CONTRARI, Vincent, a considerable scholar in classical literature and antiquities, was born at Venice, in 1577, and attained the profeship of the Greek and Latin languages at Padua, which he held with great reputation till the year 1614, when he retired to Rome. From thence, taking a journey into Itria, he fell ill, and died at Venice in the prime of life, in 1617. The works by which he is chiefly known are "De Frumentia Romanorum Largitione," and "De Militari Romanorum Stipendio," Morari.

CONTRARINO, Cav. Giovanni, an historical and portrait painter, who was born at Venice in the year 1549, and who steadfastly pursued the solid and pure style of Titian, not withstanding the pernicious example of almost all his rival compatriots, who, losing the remembrance of those glowing and rich tints which had so long been the boast of the Venetian school, had adopted a manner in which the lights were so extravagantly contoured by the most obtuse and cutting shadows, as to give to their pictures the appearance and gloom of midnight representations. The principal works of Contrarino are at Venice, and evidence, independent of the beauties of colouring, a very competent knowledge of foreshortening and the "fato in fo," with an excellent talle of composition. One of his best and greatest performances is the ceiling of the church of St. Francisco di Paola, where, in the column, he painted the Resurrection of Christ, and on each side the Assumption and Nativity, together with the Evangelists and the four Doctors of the Church. He executed several memorable works for the court of the emperor Rudolph II., who conferred on him the honour of knighthood. His portraits bore so strong a resemblance to nature, that one of them, representing Marco Dolce, is said to have deceived his dogs and other domestic animals, who leaped up to the picture, supposing it their master himself. Thus artif died in the 56th year of his age, 1605. Lanzi, Storia Pictorica.

CONTAY, in Geography. See Conty.

CONTCHOUSONG, a town of Afia, in the country of Thibet; 320 miles N.E. of Laffa. N. lat. 30° 20'. E. long. 95° 26'.

CONE, del, Jacopino, in Biography, was born at Florence in 1510, and is said in his youth to have received from instructions in painting, in the school of Andrea del Sarto. Having completed his studies, he soon gave proofs of superior talents, both in historical and portrait painting, but whether he was invited under pope Paul III., was the theatre of his labours, and he was employed to paint the portraits of that pontiff and of his succesor Clement VIII., as well as those of the cardinals, the ambassadors, and other nobles of the court. In historical painting, he had no less success; and the frescoes, which he executed in the church of St. Giovanni Decollato, rank him among the best artists at the decorat or extravagant of the imitators of Micheangelo. An utter-piece in the famous church, representing the taking down from the cross, a composition of many figures, is considered his "chef d'oeuvre." He died at Rome in 1598. Baglione.

CONE, del, or Fassi, Guido, an artist who was born at Carpi, in the state of Modena, in the year 1584, and was the first inventor of the "fagiola," a species of composition, or paste, with which the finest marbles are with facility imitated, and which acquires sufficient hardiness to bear a polish. Some of the works of Guido, particularly two altars, are still existing at Carpi, where he died in the year 1649.

This art has since been brought to such a degree of perfection in several parts of Italy, that not only the finest marbles have been counterfeited, so as occasionally to deceive the best judges; but likewise bas-reliefs, vases, medals, and even pictures of great beauty, have been produced: see Info.

Vol. IX.

much that it is become an article of commerce. (See STAG, LIOLA.) Lanzi, Storia Pitterica.

CONTEMPLATION, an act of the mind, whereby it applies itself to consider, reflect on, and admire, the wonderful works of God, nature, &c.

Contemplation is the height of perfection of the mystic divines. See MYSTIC.

CONTEMPORARY, or Contemorary, a person, or thing, of the same time, or that existed in the same age, with another. Socrates, Plato, and Aristophanes, were contemporaries: the best histories are those of contemporary authors.

CONTEMPT, in the Doctrine of the Paffions, is a species of hatred, expressing in its general sense disapprobation or aversion, which arises from the mere consideration of a worthless object, especially if it be proposed to us under a pretence of its polishing excellence; or from misconception in things not of themselves vicious; as, where a person either acts below his station and character, or affects to do that for which he is not qualified. It is opposed to esteem or to emulation. This is one of those passions which in oratory belongs to demonstrative discourses. Thus Cicero (De Orat. lib. ii. c. 12.) endeavours to expose Caecilius, and bring him into contempt of the court, for pretending to rival him in the acclamations of Verres, for which he was altogether unfit.

Contempt, in Law, is disobedience to the rules, orders, or processes of a court, which hath power to punish such offence; and a man may be imprisoned for a contempt done in court, but not for a contempt out of court, or for private abuse. But for contempt out of court, an attachment may be granted. Cro. Eliz. 680.

Attachment also lies for contempt to the court, to bring in the offender to answer on interrogatories, &c. and if he cannot acquit himself, he shall be fined. 1 Litt. 305. If a sheriff, being required to return a writ directed to him, doth not return the writ, it is a contempt: and this word is used for a kind of misdemeanor, by doing something which is forbidden, or not doing what is commanded. 2 Rep. 36. As the degrees of this crime vary, the punishment is either or greater; sometimes a mere fine, and sometimes imprisonment.

If a defendant in chancery, on service of a subpoena, does not appear within the time limited, by the rules of the court, and plead, demur, or answer to the bill against him, he is then said to be in contempt; and the respective proceedings of contempt are in successive order awarded against him: these are attachment; attachment with proclamation; a committal of rebellion; and, finally, a sequestration. It is a contempt to institute a suit fictitiously, though the demand is real, either to hurt any person, or to get the opinion of the court.

The most remarkable instances of contempts may be reduced to the following heads: 1. Contempts of the king's writs: contempt in the face of a court; contempt of words or writings concerning the court; contempt of the rules or orders of the court; abuse of the proceeds of the court; and forgeries of writs and other decrees tending to impose on the court. 2. Hawk. P. C. c. 22. § 3. For an account of the contempts that are punished by attachment, see ATTACHMENT.

Contempts or misprisions (see Mispription) are offences against the king and government: such as the misadministration of high officers, in public trust and employment, usually punishable by the method of parliamentary impeachment, and subject to the penalties of banishment, imprisonment, fines, or perpetual disability: such is also the offence of embezeling the public money; and such are those cont.
tempts of the executive magistrate, which demonstate themselves by some arrogant and undutiful behaviour towards the king and government. Contests against the king's prorogative are a refusal to affit him by advice in his councils, and by peronal service in his wars, against a rebellion or invasion. To this classes may be referred the neglect of joining the "poite comitatus," or power of the county, when required by the sheriff or justices, according to the statute 2 Hen. V. c. 8; which is a duty incumbent upon all that are 15 years of age, under the degree of nobility, and able to trace. Contests against the prorogative are also a preference of the interests of a foreign potentate to those of our own, and doing or receiving any thing that may create an undue influence in favour of such extrinsic power; as by taking a pension from any foreign prince, without the king's consent; also, a disobedience to the king's lawful commands, refusing by writs out of his courts of justice, or by summons to attend his privy council, or by letters from the king commanding a subject to return from beyond the seas: and likewise disobedience to any act of parliament; all which contests are punishable by fine and imprisonment, at the discretion of the king's courts of justice. Contests and misprisions against the king's person and government may be by speaking or writing against him, cursing or wishing him ill, giving out scandalous stories concerning him, or doing any thing that may tend to degrade him in the esteem of his subjects, weaken his government, or excite jealousies between him and his people. Contests against the king's title, not amounting to treason or pramunire, are the denial of his right to the crown, in common and unadvised discourse; punishable by our law with fine and imprisonment. If any person affirm or maintain, that the common laws of this realm, not altered by parliament, ought not to direct the right of the crown of England; this is a misdemeanour, by stat. 15 Eliz. c. 1, and punishable with forfeiture of goods and chattels. A contest may also arise from refusing or neglecting to take the oaths, appointed by statute for the better securing of the government; and yet acting in a public office, place of trust, or other capacity, requiring the said oaths to be taken, viz. those of allegiance, supremacy, and abjection; which should be taken within six calendar months after attaining the age of 21. The penalties inflicted by statute 1 Geo. I. stat. 2. c. 15, are little short of those of a pramunire; being an incapacity to hold the said offices, or any other; to prosecute any suit; to be guardian or executor; to take any legacy or deed of gift; and to vote at any election for member of parliament: and after conviction the offender shall also forfeit 50l. to those who will sue for it. Contests against the king's palaces or courts of justice have always been regarded as high misprisions; and by the ancient law, before the conquest, fighting in the king's palace, or before the king's judges, was punished with death. And at present with us, by stat. 33 Hen. VIII. c. 12, malicious striking in the king's palace, where he resides, whereby blood is drawn, is punishable by perpetual imprisonment and fine at the king's pleasure; and also with all the losses of the offender's right hand. But striking in the king's superior courts of justice, as Westminster-hall, or at the assizes, is made full more penal. By the ancient common law, before the conquest, it was a capital felony; and our modern law subduces to the losses of life that of the offending limb; the crime, and even drawing a weapon, being punishable with the losses of the right hand, imprisonment for life, and forfeiture of goods and chattels, and of the profits of the offender's lands during life. (See Assault, &c.) A rescue of a prisoner from any of the said courts, without a blow, is punished with perpetual imprisonment, and forfeiture of goods, and of the profits of lands during life. Even in the inferior courts of the king, an affray, or contemptuous behaviour, is punishable with a fine by the judges there sitting; as by the steward in a court-leet, or the like. Those also who are guilty of any injurious treatment to such as are immediately under the protection of a court of justice, are punishable by fine and imprisonment. Lastly, to endeavour to dissuade witnesses from giving evidence; to diuise an examination before the privy-council; or to advise a prisoner to fland mute, are high misprisons and contests of the king's courts, and punishable by fine and imprisonment. If one of the grand jury diuises to any person indicted the evidence that appeared against him, he is guilty of a high misprison, and liable to be fined and imprisoned. Blackft. Comm. vol. iv.

CONTENEBRA, in Ancient Geography, a town of Italy, in Etruria, mentioned by Livy.

CONTENEMENT, a word in our Ancient Law-books, about whose signification authors are not rightly agreed. According to Home, it should signify the countenance, credit, or reputation, a person has, from and by reason of his freehold. In which sense it is used in the flat. 1 Edw. III. &c. where it stands as synonymous with countenance.

Others will have it signify what is necessary for the support and maintenance of men, according to their several qualities, conditions, or states of life. Thus, Seldman, Contenentum est affirmation, & conditionis forma, quae quis in republica subjicit. And in this sense it occurs in Magna Charta, cap. 14.

CON TfENSON, Vincnt, in Biography, a French Dominican monk, was born at Condom, in 1640, and celebrated in his time for considerable pulpit talents. He left behind him a work of reputation, entitled, "Theologia mentis et cordis," which has passed through several editions in folio and in octavo.

CONTENENT, in Mathematics, a term frequently used for the capacity of a vessel, or the area of space; or the quantity of any matter, or space, included in certain bounds. The content of a tun of round timber is 43 solid feet. A load of hewn timber contains 92 cubic feet: in a foot of timber are contained 1728 cubic or square inches, and as goes 1728 inches are contained in a piece of timber, be it round, or square: so many feet of timber are contained in the piece.

In gauging, the gallon for beer and ale is allowed to contain 282 cubic inches, and the wine gallon 231; the gallon of dry measure 272.

Hence, as oft as 282 cubic inches are contained in any vessel, round or square; so many gallons of ale or beer it holds; and the like may be observed of the other measures.

Multiply, therefore, one side of a square, or oblong, into the other; and divide by one of those numbers, according to the quality of the liquor; the quotient gives the area in gallons, upon an inch deep.

Though the work may be considerably shortened by only multiplying the sides of squares, or the diameters of rounds, into themselves; the product is the number of gallons, and parts, the vessel contains, upon an inch in depth: and when that receives an augmentation, by being two, three, or four inches deep, it then commences a field body, and contains as many gallons, and parts, as it has inches and parts deep.

A cubic foot contains six gallons and almost a pint of ale and beer; and seven gallons two quarts of wine. A cubic foot of dry measure contains six gallons and a half, and...
something more. A bushel of salt contains 56 pounds avoirdupois. See GAUDE.

CONTENTIOUS JURISDICTION, in Law, denotes a court, or assembly, which has a power to judge and determine differences between contending parties.

The lords chief justices, judges, &c. have a contentious jurisdiction; but the lords of the treasury, the commissioners of customs, &c. have none; being merely judges of accounts and transactions.

CONTENTMENT, in Pathology and Ethics, expresses the acquiescence of the mind in the possession of the good that is affiliated to us. It implies a perception that our lot might have been better, or that it is inferior to what others enjoy, or that it does not fully answer the expectations we had formed. An effort of reason, or of prudence, or of religious principles, is necessary to produce it. We compare our present with our former situation, or with the inferior lot of others; and thus learn to acquiesce in the degree of advantage which we have obtained. A regard to the dispositions of Providence, wise, righteous, and benevolent, will very much contribute to the acquisition and exercise of the virtue of contentment.

CONTESSA, in Geography, a small town of European Turkey, in the province of Macedonia, situated in the bay of the same name, with a good harbour, on the coast of the Archipelago ; 51 miles N.E. of Salonic. Long. 4:1°. 55'. At the entrance of the Gulf of Conetta is situated the island of Tagra. The French navigators also call this bay " Golfe de Rhodinie," from the corrupted name of the ancient town of Rhodié; but the Greeks designate it under the name of Orfano. It is the Sinus Strimonicos of the ancients.

CONTESI, in Ancient Geography, a people of Hispania Citerior, to the south of the Edetani. Their territory extended southwards as far as Betica, or at least to the extremity of the Tarragonenis, where are found some places dependent on the Bautiltani, who inhabited part of the eastern Betica.

CONTESI, a country of Spain, in the Tarragonenis, mentioned both by Pliny and Ptolomey. The former says, that this country was first called "Matavania," afterwards "Deltania," and then Contesia. Here the authors place the river Tader, the colony of Illici, Lacentum, Diniun, the river Sacro, &c.

CONTETTATIO LITIS, among Civilians, denotes a general affirmtion that the plaintiff hath no ground of action, which affirmation is afterwards extended and maintained in his plea.

CONTEX, among Divines and Critics, that part of Scripture, or other writing, which lies about the text, before or after it, or both. To take the full and genuine sense of the text, the context should be regarded.

CONTEXURE, a word frequently used in speaking both of the works of nature and art; and denoting the disposition and union of the constituent parts with respect to one another.

CONTHIL, in Geography, a town of France, in the department of the Marne, and district of Chateau-Salins; 2 leagues N.N.W. of Dieuze.

CONTHILA, in Ancient Geography, a borough of Greece, in Attica; placed by some in the Ptolemaic tribe, and by others in the Pandionide.

CONI, Giusto DE, in Biography, an Italian poet and lawyer. His verses are chiefly amatory; and they appeared under the title of "Della Morte," on account of the beautiful hand of his mistress, which is the subject of frequent adulation. He died in 1409, and his poems have been published at Venice, Paris, Verona, and Florence. He has been compared to Petrarch; but the best judges have regarded him as much inferior to that writer. Moretti.

CONTI, CESARE and VINCENZIO, two brothers, the former, a native of Ancona, was celebrated as an expectation painter of grotesques; the latter, born at Rome, was a painter of history.

Baglione enumerates many considerable works, in which these artists were employed at Rome, under the pontificate of Sixtus V. and Gregory XIII. Vincenzo ultimately settled in Turin, where he was taken into the service of the duke of Savoy. They both died during the pontificate of Paul V., Baglione.

CONTI, DOMENICO, of Florence, was the beloved disciple of Andrea del Sarto, and heir to his designs and studies. In gratitude and veneration to the memory of his great master, Conti, at his own expense, erected the monument still remaining in the cloister of the Nunziata, where the bust of Andrea is finely sculptured by the hand of Raffaello di Monte Lupo. Of Domenico's works in painting little is now known. Orlandi.

CONTI, CARLO, an engraver, native of Lorraine, in 1742. He established himself at Vienna, where he was reputed a good artist. He was living in 1799. Heinecken.

CONTI, FRANCESCO, an historical painter, born at Florence, in the year 1681. He travelled to Rome, where he became the disciple of Carlo Maratti. On his return, he acquired sufficient reputation to merit a place in the celebrated collection of portraits in the Florentine gallery. He died in the year 1760. Lanz, Storia Pitt.

CONTI, GIACOMO. See GIZIELLO.

CONTIGLIANO, in Geography, a town of Italy, in the duchy of Spoleto, near a lake to which it gives name; 3 leagues W. from Rieti.

CONTIGNE, a town of France, in the department of the Maine and Loire, and district of Segré; 3 miles N. of Chateauneuf.

CONTIGUITY, the relation of bodies touching one another. See CONTINUITY.

CONTIGUOUS, a relative term, under foot of things disposed to near each other, that they join their surfaces, or touch.

The houses in ancient Rome were not contiguous as ours are, but all insulated.

CONTIGUOUS ANGLES, in Geometry, are such as have one leg common to each angle; otherwise called adjoining angles, in contradistinction to those produced by continuing their legs through the point of contact, which are called opposite or vertical angles.

CONTINENCE, in Ethics, a moral virtue, by which we refit concupiscence. It should seem that there is this distinction between chastity and continence, that it requires no effort to be chaste, which results from constitution; whereas continence appears to be the consequent of victory gained over ourselves. The verb continere, in Latin, signifies to restrain.

CONTINENT, in Geography, a terra firma, main land, or a large extent of country, not interrupted by seas; so called, in opposition to island, peninsula, &c. See EARTH, OCEAN, &c.

Sicily is said to have been anciently torn from the cont-
CONTINENT.

The entire separation of Great Britain from the Continent must have happened long after the deluge, and that of Ireland from Great Britain at a still later period; for wolves and bears were anciently found in both, and these must have passed from the Continent into Britain, and hence into Ireland, as it cannot reasonably be supposed that they were imported thither. The divinitive force, says Kirwan (ubi supra), that separated Britain from Germany, seems to have been directed from North to South, but gradually weakened in its progress. Hence that island is sharpened northwards; but the impression must have been considerably weakened by the opposition of the granitic mountains that form the Shetland and Orkney isles. The rupture of the isthmus that joined Calais and Dover was probably effected by an earthquake at a later period, and gradually widened by tides and currents. Ireland was protected by Scotland from the violence of the northern shook; and therefore its separation from Scotland appears to have been late and gradual. That from England was probably diluvial, and effected by a southern shook. All these changes happened 3600 years ago; and there is no reason for thinking that the general level of the ocean has been since altered; but that of the continents seems to have varied considerably, being in some places higher and in some lower than it was in ancient times.

The world is ordinarily divided into two grand continents; the Old and the New; the Old comprehends Europe, Asia, and Africa; the New the two American, North and South.

The separation of the two continents Kirwan (ubi supra) supposes to have probably been the effect of excavation by volcanoes; at least, he says, this cause is adequate to such an effect; and it still exists in the most northern parts; the superior fertility of the western coast of America may arise from the lavas ejected on that coast. But however this separation was effected, we have no traditional account of it, and the period in which it happened is no less difficult to be ascertained than the cause which produced it.

M. Buffon affirms, that they were not separated when the elephants lived equally in the north of Europe, Asia, and America, the bones of which have been found in Russia, Siberia, and Canada. Hence he concludes, that the separation of the two Continents must have happened after the abode of these animals in the northern regions. But it has been doubted whether the remains of elephants and of the rhinoceroses that have been lately found in Siberia, even allowing that the temperature of this country was ever so fituated to the constitution of these animals as to admit of their living in it, belonged to animals which ever lived in it. As to the mode of their formation, we have different conjectures and theories, of which an account will be given under the articles DELUGE and EARTH.
CONTINENT.

Mexicoo Jamaica and Cuba; from thence along the peninsula of Florida, through Apalache, Chicachas, and from thence to St. Louis, Fort le Sieur; and terminates in the country bordering on Lake Affinibah to the extent of which is unknown. This line is interrupted only by the gulf of Mexico, is about 2500 leagues in length, and divides the New Continent nearly into two equal parts; that on the left containing 1,069,264 square leagues, and that on the right 1,070,926⁴; the difference of which is 1694, or scarcely 1⁴ degree square. This line is the middle of a belt of land, called the New Continent, and is inclined to the equator somewhat, less than 30°, but in an opposite direction to the former; for that of the Old Continent extends from the N. E. to the S. W.; but that of the New Continent from N. W. to S. E. The superficial contents of the Old and New Continents are about 7,080,992 square leagues, i.e. not near a third part of the surface of the globe, which contains 25,000,000 square leagues. Of these lines which divide the Continents into equal parts, it may be remarked, that they both terminate at the same degrees of N. and S. latitude; and that the two Continents make mutual advances, or projections, exactly opposite to each other; viz. those on the African coast, from the Country of Tartary, to Guinea; and those of America, from Guiana to the mouth of the Rio-Janeiro. It appears, therefore, that the most ancient lands on the globe are those which extend from 200 to 250 leagues on each side of the two lines above described.

Agreedly to this idea, it is found that, in the Old Continent, the most ancient countries of Africa are those which extend from the Cape of Good Hope to the Red Sea and Upper Egypt, and are about 500 leagues broad; and, consequently, that the whole western coast of Africa, from Guinea to the Straits of Gibraltar, are new lands. In the same manner, if we trace this line through Asia, and include an equal breadth, we shall find, that the most ancient lands of the world are the two Arabian, Perista, Georgia, Turcomania, a part of independent Tartary, Circisia, part of Mulucy, &c.; and, of course, that Europe, and perhaps also China, and the eastern part of Tartary, are comparatively new countries.

In the New Continent, we shall likewise find, that Terra Magellanica, the eastern part of Brazil, the country of the Amazon, and the Guianas, are old lands, when compared with Tucuman, Peru, Terra Firme, the islands in the gulf of Mexico, Florida, the Mississippi, and Mexico. Moreover it may be observed, that the Old and New Continents are nearly opposite to one another. The Old Continent extends farther north of the equator than south; but the New, farther south than north. The centre of the Old Continent lies in the 16th or 18th degree of N. latitude; and the centre of the New Continent lies in the 16th or 18th degree of S. latitude; as if they were intended to counterbalance each other. Besides, both continents resemble one another in this respect that they might be divided into two portions, which would be surrounded on all sides by the sea, except the two small islands of Suez and Panama. It is observable that the prodigious chains of mountains in these two continents run from W. to E. in the Old Continent, and from N. to S. in the New. In the Old Continent there are about 450 rivers which directly fall either into the Ocean, or into the Mediterranean and Black seas. But in the New Continent we know only of 135 rivers which fall immediately into the sea. Both the Old and New Continents appear to have been encroached upon by the Ocean in the same latitude; both are furnished with a great Mediterranean and a vast number of islands, which likewise lie nearly in the same latitude. The only difference is, that the Old Continent, being much larger than the New, has a Mediterranean on its west coast, to which the New Continent has nothing analogous. But both seem to have undergone similar revolutions. These revolutions are greatest near their middle parts, or between the tropics, where the motion of the sea is most violent. For other particulars relating to these Continents, we refer to the description of their respective countries.

It has been remarked, that a considerable portion of the elevated and solid matters or strata which form our Continents, are opposite to a large or deep ocean at the anti-podes or opposite side of the earth: and this circumstance affords matter for important reflections, when we take into our account that these parts, now so considerably elevated above the level of the Ocean, once formed part of its bottom, as appears from the nature and disposition of the strata themselves, but more especially from the shells and other aquatic remains found lodged in them, in a perfect and unbroken state, lying in the same manner and positions, as the shells, &c. of living animals are found to be distributed, on the bottom of the sea, in places where divers have had opportunities of examining them. The following observations were naturally presented themselves; has the quantity of water on the earth been so much diminished, as to by the continuance thus bare; or, has the centre of gravity of the earth been so deranged, as to occasion the waters to accumulate in particular places and leave others uncovered? For a long time there seemed little difficulty in solving the mystery, by answering the first question in the affirmative, on the principles of those who maintained, that the earth was only a hollow crufh or shell of matter, and that great part of the waters of the universal ocean had retreated into the internal cavities of the globe. But since the labours of British philosophers have concurred in proving, that the specific gravity of the earth is much diminishecl, or little more) and all the earth and stones (whose specific gravities do not exceed 2 or 2' on the average) are included; we are forced to conclude, not only that the central parts of the globe are solid, but composed also of much heavier materials, than those which constitute the superficial strata. And another circumstance also must be considered the improbability of any large cavities being filled with water in the interior parts of the earth, viz. the strata, which in universal are found, breaking and dividing even the hardest rocks and strata, into comparatively small and irregular fragments, so as to render them incapable of arching or supporting themselves over water without an actual contact or bearing upon each other: and accordingly cavers or grottos of any considerate size are rarely met with in mining, and these principally, if not entirely, in very hard limestone strata, near the surface, and carrying but a comparatively small load of superincumbent strata.

This ruptured and broken state of the solid matters of the globe, has probably fitted them for obeying the action of the centrifugal force generated by its diurnal revolution, and in affuming nearly the form of an ellipsoid, (as the late measurements of degrees upon the earth's surface in various parts of the world have shown,) otherwise, most probably, the equatorial parts of the earth must have been occupied by a zone of water instead of possessing islands and parts of Continents in common with other parts of the world, as they now do. Let the reader but consider the immense weight of solid matter which exists above the level of the sea, or general ellipsoidal lines of equilibrium, in one of our Continents, and suppose a cylindrical perturbation to be made under such Continent, quite through the earth to the opposite ocean, so
as to separate, for the sake of argument, this cylindrical column of the earth and water from the rest of the earth, (as the broken state of the frusta and the actual hardncss of their fragments entitles us to suppose possible) and it will appear, as a necessary consequence of equilibrium, that the continent and frusta under it to the centre of the earth must be equal in weight to the same space of Ocean at the antipodes, and the frusta under its bottom extending to the same centre; for if there were different, and we suppose the Continent to preponderate, it is plain from the waters of the Ocean covering the other end of the cylinder being at liberty to recede, that they would do so, and the Continent would sink and the bottom of the opposite Ocean would rise, until the equilibrium was restored; and in like manner if the frusta under the ocean be supposed the heaviest, a further protration and consequent elevation of the Continent, compared with its surrounding seas, would ensue. This view of the subjedt leads, in the opinion of the writer of this part of our article, to the conclusion, that a very large mass, or perhaps several masses of matter of a high specific gravity, now occupy the bottom of the Ocean opposite to the Continents and large islands, which were not there at the time that those Continents occupied a lower place in respect to the centre of the earth, and were covered by the universal Ocean; and he thinks, that he has discovered the source whence these very heavy and diluting masses of matter were derived, in the disappearance of some immense satellar body which apparently for a long period revolved round this earth, very near to its surface, and occasioned tides so rapid and enormous, as to heave up the land and break the frusta into innumerable fragments, permanently demodating some parts, when elevated above the point of equilibrium between the earth and satellite's attraction, and pouring down upon other parts of the surface, such torrents of the ruins of abraded frusta, as entirely to hide the frusta of these districts under alluvial coverings; forming, in numerous islands, hills of great height and extent, containing large and irregular fragments of rocks, and different known frusta, thrown together throughout their whole thickness and extent, in the greatest apparent confusion. For other observations and conjectures, relating to this subjedt see Earth.

The discovery of a southern Continent has been an object of curious and diligent investigation; but hitherto without success. Captain Cook's second voyage commenced in the year 1772, was undertaken with a particular view to the discovery of the question, concerning the existence of a southern Continent. In the prosecution of this voyage, and while he was proceeding southward in quest of a Continent, he fell in with ice islands, in S. lat. 56° 45' and 7° of longitude from the Cape of Good Hope; in his farther progress, he was stopped by other fields of ice, which led him to imagine, from a notion that these are formed in bays and rivers, that he could not be at a great distance from land. But having failed in S. lat. 55° 40' for more than 30 leagues along the edge of the ice without finding any opening, he found that this ice did not join the land; and therefore he thus discovered the fallacy of the general opinion, that ice is always a form of the vicinity of land. The observations of captain Cook confirmed those of other navigators, that the end of the southern seas is much more intense than that of equal latitudes in the northern hemisphere; and he also ascertained that this cold was not owing to the vicinity of a Continent, as had formerly been imagined. On the contrary, it was now determined beyond dispute, that if any such Continent existed in the easterm part of the southern Ocean, it must be confined within the latitude of 60°. Having advanced as far as S. lat. 62° 10' and W. long. 172°, he found the farther he proceeded that the number of ice islands very much increased; and in lat. 67° 31' and W. long. 142° 54', he got into such a clutter of these islands that it was both difficult and dangerous to escape them. Finding it impossible to get any farther to the southward, he determined to explore a considerable tract of sea to the north of his present situation, and then again to stand to the north. But in this he was unsuccessful; no land being discovered either in falling northward, eastward, westward, or southward, though he proceeded in the last direction as far as 71° 10' S. lat. and 105° 54'. W. long. It was now impossible to advance; and it was the opinion of the captain himself, as well as of most of the gentlemen on board, that the ice by which they were now stopped extended as far as the pole. The most southerly land discovered by this persevering navigator was that on which he bestowed the name of "Southern Thule," and which is situated in S. lat. 55° 13' 30'. W. long. 27° 45'. Here not a single herb of any kind was seen, but very high and barren mountains, the tops of some of which reached above the clouds; and we may observe, that this seems to be the only part of the world hitherto discovered, altogether unfit for the support of animal life. This country was discovered on the 31st of January 1775. Upon the whole, it may be concluded, that the greatest part of the southern Continent, if it has any existence, must be within the polar circle, where the ice is so encumbered with ice, that the land must be inaccessible. So great is the danger in navigating these southern seas, that captain Cook isfers on the most probable grounds, that such lands as lie to the southward of his discoveries could not be explored; and that even no man could venture farther than he had done. Thick fogs, snow-storms, intense cold, and every attendant circumstance that can render navigation difficult and dangerous, must be encountered; and all these difficulties and dangers are heightened to a very great degree by the inexpedibly horrid aspect of the country itself. It is a part of the world deemed by nature never to feel the warmth of the sun's rays, but to be buried in everlasting snow and ice. Whatever parts there may be in the coal, they are almost entirely covered with frozen snow of a vast thickness. If however any of them should be so far open as to invite a ship into it, she would run the risk of being fixed there for ever, or of coming out on an ice island. Besides, the islands and floats on the coast, the great falls from the ice-cliffs in the port, or a sudden snow-storm, might be attended with equally fatal effects. For these reasons captain Cook determined to abandon the pursuit of a land, whole existence was equivocal, but whose mutiny, if it could be discovered, was certain.

After captain Cook's persevering and fruitful travels through every corner of the southern hemisphere, who, for the future, says the editor of Cook's third voyage (vol. 1. Int. p. 56), will pay any attention to the ingenious reveries of Campbell, de Brofies, and de Buffon? or hope to effluft an intercource with such a continent as Maupertuis's fruitful imagination had pictured? A Continent equal, at least, in extent, to all the civilized countries in the known northern hemisphere, where new men, new animals, new productions of every kind, might be brought forward to view, and discoveries be made, which would open inexhaustible treasures of commerce. (See Maupertuis's Letter to the King of Prussia.) The author of the Preliminary Discourse to Bougainville's "Voyage aux Illes Malvines" computes, that the southern Continent (for the existence of which, he owns, we must depend more on the conjectures of philosophers, than on the testimony of voyagers) contains 8 or
8 or 10 millions of square leagues! We can now boldly take it upon us to disconform all expeditions formed on such reasonings of speculative philosophers, into a quarter of the globe, where our persevering English navigator, instead of this promised fairy land, found nothing but barren rocks, hardly affording shelter to penguins and seals; and dreary seas and mountains of ice, occupying the immense space allotted to imaginary paradies, and the only treasures there to be discovered, to reward the toil, and to compensate the dangers of the unavailing search.

CONTINGENCY, in Metaphysics, denotes the mere possible existence, or non-existence, of an object in any future time; and is opposed to necessity; which is. See also CHANCE and PROBABILITY.

CONTINGENCY of blood, in the writers of the laws of Scotland, is used for proximity of blood. Bayne, Crim. Law, p. 48.

CONTINGENT, literally signifies what may or may not happen, what is casual or uncertain, and depending upon chance. See CHANCE. But in military acceptance, it denotes the quota or proportion of troops, money, and ammunitions, which each of a body of legions or confederated sovereigns, or princes, furnishes upon emergencies, when required or called on, in virtue of and in support of the confederation. In the wars of the German empire, each prince and state, and all the members of the Germanic body, were obliged to furnish their contingent. In like manner the princes forming the confederation of the Rhine, are, at present, obliged to furnish their respective contingents.

CONTINGENT bill, of a regiment, is an account of the extra charges, which a regiment, in the due course of service, is from circumstances unavoidably and accidentally under the necessity of incurring.

CONTINGENT line, or tangent-line, in Dialling, denotes the intersection of the planes of the dial and equinoctial, and it intersects the subfible or subfilar line at right angles.

CONTINGENT legacy, is a legacy depending on the age of the legatee; if it be left to any person, when or if he attains the age of twenty-one, and if he dies before that time, it is a lapsed legacy; but if it is left to be paid when he attains that age, it is a vested legacy; and if the legatee dies, his representatives shall receive it out of the tellator's estate at the time, when it would have become payable, if the legatee had lived.

CONTINGENT, or Executive remainder, in Law, is where an estate is limited to take effect, either to a dubious and uncertain person, or upon a dubious and uncertain event: so that a particular estate, which does support a remainder, may or may not determine before the remainder may come. This kind of remainder is opposed to vested or executed remainders. 3 Rep. 25. See REMAINDER.

CONTINGENT use, in Law, is an estate limited in a conveyance of land, which may, or may not, happen, to vest, according to the contingency expressed in the limitation of such use. An use in contingency is such which by possibility may happen in possession, reversion, or remainder. 1 Rep. 121. See USE.

CONTINGENTS are sometimes also used by mathematicians in the same sense as ligments.

CONTINI, GIAMBATTISTA, in Biography, an architect who enjoyed considerable reputation at Rome in the latter part of the 17th and the beginning of the 18th century. He was born in the year 1641, and after having acquired at the schools a competent knowledge of languages, the Belles Lettres, and geometry, was placed by his father, who was likewise an architect, under the tuition of the celebrated Bernini. The instructions of his master were not thrown away, and Giambattista became employed by several of the first families of Rome. He constructed many of those magnificent altars and chapels with which the churches of Rome abound, and built the duomo of Vetralla as well as that of Vignarola. His works are enumerated by his biographer Lionel Pafcoii, who informs us that he lived highly respected, and died in 1723. Pafcoii.

CONTINUAL CLAIM. See CLAIM CONTINUOUS.

CONTINUOUS PROPORTIONS. When in a series of quantities the first is to the second as the second to the third, and the third to the fourth, the fourth to the fifth, &c., they are called CONTINUOUS PROPORTIONS; such are 1, 2, 4, 8, 16, 32, 64, &c., where the terms increase in a two-fold ratio; and 1, 3, 9, 27, &c., where they decrease in a triple ratio. Such a series is otherwise called a progression.

CONTINUANCE, in Law, is much the same as progression among the civilians. It denotes the continuance of a cause in court, by an entry upon the records there for that purpose. After issue or demurrer joined, as well as in some of the previous stages of proceeding, a day is continually given and entered upon the record, on which the parties are to appear, from time to time, as the exigency of the case may require. The giving of this day is called the "continuance," because thereby the proceedings are continued without interruption from one adjournment to another. If these continuances are omitted, the cause is thereby discontinued, and the defendant is discharged out die, without a day, for this term; for by his appearance in court, he has obeyed the command of the king's writ; and, unless he be adjourned over to a day certain, he is no longer bound to attend upon that summons; but he must be warned afresh; and the whole must begin de novo. It may sometimes happen, that after the defendant has pleaded, nay, even after issue or demurrer joined, there may have arisen some new matter, which it is proper for the defendant to plead; as, that the plaintiff, being a femofole, is since married, or that the heir has given the defendant a release, and the like: here, if the defendant takes advantage of this new matter, as early as he possibly can, viz., at the day for his next appearance, he is permitted to plead it in what is called a plea continence, or since the last adjournment. For it would be unjust to exclude him from the benefit of this new defence, which it was not in his power to make when he pleaded the former. But it is dangerous to rely on such a plea, without due consideration; for it confounds the matter which was before in dispute between the parties (Cro. Eliz. 49). And it is not allowed to be put in, if any continuance has intervened between the arling of this fresh matter and the pleading of it; for then the defendant is guilty of neglect or laches, and is supposed to rely on the merits of his former plea. Also it is not allowed after a demurrer is determined, or verdict given; because then relief may be had in another way, namely, by writ of audita querela. And these pleas continence, when brought to a demurrer in law or issue of fact, shall be determined in the same manner with other pleas. Black. Comm. vol. iii.

CONTINUANCES and effusions are amendable upon the roll, at any time before judgment—that is, they are the acts of the court, and at common law they may amend their own acts before judgment, though in another term; but their judgments are only amendable in the same term in which they are given. (3 Lev. 431.). Upon an Original, one term, or two, or three terms may be made between the issue and the return; and this shall be a good continuance for the defendant is not prejudiced by it, and the plaintiff may give a day to the defendant beyond the common day, if he will. But a continuance by capias ought to be made from term to term, and
there cannot be any mens rea term, because the defendant ought not to stay so long in prison. (2 Dauv. Abr. 150.) If a man recover upon demurrer, or by default, &c. and a writ of inquiry of damages is awarded, there ought to be continuance between the first and second judgment, otherwise it will be a discontinuance; for the first is but an award, and not complete, till the second judgment, upon the return of the writ of inquiry of damages. (Ibid. 153.) If the plaintiff be non-suited, by which the defendant is to recover costs; if the plaintiff will not enter his continuances, on purpose to save the costs, the defendant shall be suffered to enter them. (Cro. Jac. 316, 317.) The course of the court of King's Bench is to enter no continuance upon the roll, till after issue or demurrer, and then to enter the continuance of all upon the back, before judgment; and if it is not entered, it is error. (Trin. 16 Jac. B. R.) See Discontinuance.

Continuance of a writ, or action, is its holding in force from one term to another, in a cause where the defendant has not returned, or executed, a former writ issue out in the same action.

Continuance of assize. If a record in the treasury be alleged by one party, and denied by the other, certiorari shall be sued to the treasury and chamberlain of the exchequer; who, if they certify not that the said record is there, or likely to be in the Tower; the king shall then send to the justices, repeating the certificate, and will then to continue the assize.

Continuanda. See Assisa.

Continuando, in Law, a term used in a declaration of trespasses, where a plaintiff would recover damages for several trespasses in the same action. To avoid multiplicity of suits, a man may in one action of trespasses recover damages for many trespasses; laying the first to be done with a continuance to the whole time in which the rest of the trespasses were done; which is done in this form: continuando transfereat in pridem, &c. et predicta die, &c. et alio. See Terms of Law. 2 Roll. Abr. 545. Lord Raym. 24. 7 Mod. 152.) This declaration of trespasses may be alleged, where the inquiry is continually renewed, as by spoiling or consuming the herbage with the defendant's cattle; in which case the continuando is good. (1 Lall. Abr. 307.) Thus also trespass for breaking a house with continuando is good; and until a re-entry is made, the continuation of the possession is a continuing of the trespasses (Lutw. 1312.) But where the trespass is by one or several acts, each of which terminates in itself, and being once done cannot be again done, it cannot be laid with a continuando; yet if there be repeated acts of trespasses committed, (as cutting down a certain number of trees,) they may be laid to be done, not continually, but at divers times and days within a given period. Salk. 635, 639. Lord Raym. 823.

Continuando Processum. See Processum and Continuance.

Continuans Punctum. See Punctum.

Continuation of Motion. See Motion and Projectile.

Continuative Conjunctives, in Grammar, are those conjunctions, uniting both sentences and their meaning, which join those sentences only, which have a natural connection; in contradistinction to copulative, which join all sentences, however incongruous in significations. The latter merely couple sentences, and are applicable to all subjects, whose natures are not incongruous. The former, on the contrary, by more intimate connection, consolidate sentences into one continuous whole, and are therefore applicable only to subjects which have no essential coincidence. The principal copulative in English, is, and; the continuatives are, if, because, therefore, that, &c. E. G. "Lyrip. pus was a flattery, and Plician was a grammarian."—"The sun shineth, because the sky is clear." Continuatives, according to the distribution of Mr. Harris (Hermes, p. 244.) are either suppositive, as, if; or positive, as, because, therefore, &c. E. G. "You will live happily, if you live honestly."—"You will live happily, because you live honestly." The difference between these continuatives is this; the suppositives denote connection, without affording actual existence; and the positives imply both the one and the other. Moreover, positives are either causal, as, because, since, as, &c.; or collective, as therefore, then, &c.; and they differ in this respect, that the causals subjoin causes to effects, thus; "the sun is eclipsed, because the moon intervenes;" but the collectives subjoin effects to causes, thus; "the moon intervenes, therefore the sun is eclipsed." All these continuatives may be resolved into copulative. Instead of "because it is day, it is light," we may say, "it is day, and it is light."

CONTINUATO, in the Italian Musica, is used to direct a finger, or player, to continue or hold on a sound, in equal strength or manner; or to continue a movement in an equal degree of time all the way.

Continued Fever. A fever without remissions or intermissions. See Fever.

Continued Quantity. See Continuum, Continuity, Continued Body. &c. and Quantity.

Continued, or thorough buses, in Musica, is that which continues to play constantly, both during the recitatives, and to sustain the choir, or chorus.

Continued proportion, in Arithmetick, is that in which the consequent of the first ratio is the same with the antecedent of the second: as, 3:6::6:12. See Proportion.

On the contrary, if the consequent of the first ratio be different from the antecedent of the second, the proportion is said to be discrete: as, 3:6::4:8. See Discrete.

Continued scale, or fitches, in Architecture. See Scale.

Continued Artie, Community, Pedalg. See theabantives.

Continui Solution. See Solution.

Continuity is usually defined among Schoolmen, the immediate cohesion of parts in the same quantity. Others define it, a side of body, whereby its extremes become one: and others, a state of body resulting from the mutual implication of its parts.

Continuation relates to duration, and continuity to extension. We say, the continuation of a work, or an action; and the continuity of space or time; continuation of the same conduct; and continuity of the same building.

There are two kinds of continuity, mathematical and phisical. The first is merely imaginary and fictitious; hence it supposes real or physical parts where there are none. Physical continuity is, firstly, that state of two or more parts, or particles, wherein they appear to adhere, or constitute one uninterrupted quantity, or continuum; or between which we perceive no intermediate space.

The Schoolmen distinguish two other sorts of continuity; viz. homogenous, and heterogeneous. The first, where our senses do not perceive the bounds, or extremes, of the parts; and this agrees even to air, water, &c. The second, where our senses indeed perceive the extremes of certain parts, yet at the same time observe the same parts closely linked to each other; either in virtue of their situation or figure, &c.
and this is chiefly attributed to the bodies of animals and plants.

The continuity of bodies is a state merely relative to our sight and touch: e.g., if the distance of two separate objects be such, as that the visual angle they subtend is insensible to the eye, which it will be if less than sixteen seconds, the two separate bodies will then appear contiguous. Now, the result of several contiguous objects, is a continuity: so that any number of visible objects, being placed so as that the distances subtended angles of less than sixteen seconds, they will appear to form one continuum.

And hence, as we can determine the distance at which any given magnitude becomes invisible; it is easy to find at what distance any two bodies, however remote from each other, will appear as contiguous; and several, as forming one continuum. For the physical cause of continuity, see Continuum.

Leibnitz, an eminent mathematician, has supposed what he calls a law of continuity to obtain in the universe, by which all events that are executed or done in nature, is done by infinitely small degrees. He urges, that good enemies dictate this truth, nature non operatur per saeculum; or that nothing can pass from one extreme to another, without passing through all the intermediate degrees. Bernoulli Opera, tom. iii. p. 292.

This law seems subject to difficulties: rigorously taken, it supposes actual, and yet infinitely small changes, which some philosophers cannot admit; and if we suppose changes only perceptible to our senses, finite, the law of continuity is no less violated, than if the universe were to be suddenly destroyed, as M. Maupertuis justly observes. Mem. de l'Acad. de Berlin, tom. ii. p. 284.

This law of continuity led Mr. Bernoulli to reject all hard bodies as chimeras, and naturally impossible. CONTINUUM, in the Italian Music, is sometimes applied to baffo, to signify the thorough-bass. That basso continuo, is the continual, or thorough-bass. It is sometimes marked in music books by the letters B. C.

Continuo is also needed for a species of harmony mentioned by Julius Pollux, and which, says Zarlino, answers to the perpetual burden of our bag-pipes, which now and then must be harmonious.

CONTINUOUS FEVERS. See Continued fever.

CONTINUUM, or Continued quantity, in Physics, denotes a quantity, or co-extension, whose parts are not divided, but joined and connected together, so as to leave no room to determine where one begins, and another ends.

It is controverted, among philosophers, whether a continuum be infinitely divisible, i.e., divisible into infinitely proportionable parts?

The ancients attributed the rife of water, in pumps, to the love of continuity, and the abhorrence of a vacuum; because the weight and presse of the air were not then known.

Mathematicians divide quantity into continued and discrete.

The former being that which is expressed by lines, and makes the subject of geometry; and the latter comprehending those that are expressed by numbers, which make the subject of arithmetic.

In medicine and chirurgery, wounds, ulcers, fractures, &c. are expressed by the pharse soluto continuo, or solution of continuity.

In a critical sense, we say, there ought to be a continuity, i.e., a connexion between the parts of a discourse.

In the epic poem, particularly, the action should have a continuity in the narration, though the events, or incidents, be not continued. As soon as ever the poet has opened his subject, and brought his persons on the stage, the action is to be continued to the end; every character must be at work, and no such thing as an idle person to be seen.

F. Bolis observes, that, by retrenching dull languishing incidents, and intervals void of action, which break the continuity, the poem acquires a continued force, which makes it run equally throughout.

CONTOBABDITES, a sect in the fifth century. Their first leader was Severus of Antioch, who was succeeded by John the grammarian, and named Philoponus; and one Theodorus; whose followers were also called Theodians.

Some of them who were willing to receive a book composed by Theodorus on the Trinity, made a separate body, and were called Contobabdites, from a place not known, which Nicetomus does not mention, but which must apparently have been the place where they held their assemblies.

The Contobabdites allowed of no bishops; which is the only circumstance transmitted to us concerning them.

CONTOOOCOOK, in Geography, a river of the United States of America, in New Hampshire, which runs into the Merrimack, four miles N. of Concord.

CONTOPJECTAE, of nuxxes, pole, and comparis, in Antiquity, a fort of artificers who supported a pole on their foreheads so firmly, that boys could play, dance, and wrestle together on it.

CONTR, or kuntore, in Ornithology. See Concord.

CONTRITION, in Surgery, a twining or deformity of some part of the body; arising generally from a diseased structure of the bones, or an irregular action of the muscles. Thus a contortion of the back may be occasioned by a caries, or a rickety disposition in the vertebrae; and a contortion, or twining of the head, so that the chin shall be turned towards one shoulder, may arise from a paralysis, or a spasmodic state of the Feno-maiafoid muscle. But the nature of this disease is more particularly deferred under the article Distorsion, to which the reader is referred.

CONTRITE, or Contorti, in Botany, the twenty-ninth natural order in the Philosophy Botanica of Linnaeus, and the thirtieth of the Prelections. In the Philosophy Botanica, it consists of the following genera: ranuulosa, tetivita, cerbera, plumiera, tabernemontana, cameraria, periplaca, nerium, vinca, apocynum, cynanchum, ceropogia, alcopias, flapelia. In the synoptic table, annexed to the Prelections, they stand thus 1. Pericarp a follicle; tabernemontana; cameraria; plumiera; echites; nerium; ceropogia; vinca; apocynum; alcopias; cynanchum; periplaca; peregrina; flapelia: *emboithria, Forb. *ephahola, Aubl; *eleotonia; allamanda. II. Pericarp a capulce; macrocemum; manettia; cinchona, removed from cymode; portlandia; rudeleia; hillia; genipa. 111. Pericarp a berry; gardenia; mufitandra; randha; *fagara, Thomb.; carissa; pedesia; arundia; lyccum and cellarium, both removed from videpecule; *gnopogon, Forb. *willughbeja, Schreb.; melodinus, Linum. jun. IV. Pericarp a drupe; ranuulosa; cerbera. Those printed in italics were added by Linneas himself; those marked with an asterisk, by Gicke from other authors. The order was named by Linneas, from the form of the corolla, which is twisted in a direction contrary to the fun: its border, when open, resembles a wheel, each segment having generally unequall sides, with the shorter side placed under the longer side of the preceding one. Only three of the genera are natives of Europe, alcopias, vinca, and cynanchum: most of them are lacteet and poifoonous;
some highly deleterious. Root perennial. Leaves undivided, generally opposite, sometimes three or four together, rarely alternate. Inflorescence of ten singular, the peduncle arising from the side of the stem between the pairs of leaves, not from their axils. Calyx one-seated, five-cleft. Corolla regular, monopetalous, five-cleft: structure of the stamens in most genera very singular. Stamens five. Filaments two, or one with a double stigma. Germ generally superior.

CONTOUR, in Painting or Drawing, a French word, synonymous with contour, in the Italian, and outline in the English language. Perfection of outline constitutes, perhaps, the greatest difficulty in painting; although it is, properly speaking, only one of the requisites of design; yet the knowledge of it seems necessarily to precede a thorough acquaintance with all the remainder; and hence the adage of Annibale Caracci, not very delicately expressed in the Italian, “Give me but a correct outline, and fill it up as you please!” See Dessin.

Contour, also denotes compass, limits, or enceinte of a country, place, camp, plan, design, &c. It is the ground work of each of these things.

CONTOURNE, a French term applied to any animal that is flanding or pafting with its face towards the fimler side of the escutcheon. In English heraldry it is termed counter foallant.

CONTOURNATED, or CONTORNATED, a term applied among Antiquaries to a species of medals, so caled from the Italian contornato, encircled, on account of the hollow circle which commonly runs round them. They are distinguished from medallions, as they are sometimes denominated, not by their size, but by their thinness; faint relief; reverses sometimes in integlo, hollowed, not raised; and, in general, by their peculiar and inferior workmanship. Medallion writers have formed various opinions concerning these singular pieces of coinage. Some suppose that they were struck by Gallienus, to the memory of illustrious men, and celebrated athletes, at the time when he caused all the confectioners of his predecessors to be restored. This sentiment seems nearly to have been adopted by M. Mahudel, who says, (Hist. de l’Acad. des Belles Lettres, tom. v. p. 204.) that the contornati were struck originally at Rome, about the close of the third century. F. Hardouin conjectures, that they were not earlier than the 13th century; other antiquaries refer them to the fifth century; and others find instances of them as ancient as the time of Nero; others again attribute the invention of them to Greece, in her days of glory, and suppose that they were appropriated to the purpose of honouring the histories of great men, and principally of those who had borne away the prize at the solemn games; such are those which bear the names or images of Homer, Solon, Enclid, Pythagoras, Socrates, Apollonius Tyanaeus, and several Athletes, whose victories are expressed upon them by palms, and chariots, either biga or quadriga. Havercamp, in an express work on these pieces, thinks they were struck from the times of Constantine I. to those of Valentinian III. on account of the public games. Mr. Pinkerton (Hist. of Medals, vol. i. p. 232.) fuggles, that they were tickets for different places in the public games. The dye, appearance, device, inscription of the reverse—everything—confirmed this opinion; which he has found perfectly cononant to that of two or three of the first medallists in this country. This opinion is so far conformable to that of Havercamp, and others, that it supposes that these pieces were struck upon occasion of the games. But it differs in representing these medals, as mere tickets for places at the games; and still more in supposing them struck in all ages of the empire, from Augustus, downwards. Those who suppose them struck in the lower empire, are reduced to the deplorable dilemma of imagining, that Christian princes thought Nero’s head an honour to their games; and that they preferred the portrait of Apollonius Tyanaeus, the enemy of their faith, and those of other Pagan philosophers. Joubert indeed ascribes them to the upper empire, without determining whether they were struck under one prince, or all who gave games. Mr. Pinkerton is convinced, that they were struck under the various emperors whose names they bear; and that when Constantine I. introduced Christianity, they would almost vanish, instead of beginning, according to the opinion of Havercamp. The difference of workmanship, in these pieces, if accurately inspected, may give this of itself, independently of other reasons. Although these pieces are of different kinds, they are mostly of a size between two and three inches in diameter. Some have, upon the obverse part, the head of the emperor or empress, who gave the games; and almost a series of them might be formed from Augustus down to Gallienus. In confirmation of this opinion, it is further alleged, that those emperors, who were remarkably distinguished by their attachment to public diversions, occur very frequently on these pieces, which Mr. Pinkerton calls “ticket-medals,” whereas others appear more seldom, and those who never presented any games, not at all. Those with Nero on their obverses are so common as to be of very little value. Other obverses prefer the portraits of illustrious authors of antiquity, that are no where else to be found. Sallust, Horace, and other Roman writers, were delineated on these tickets, when the memory of their persons was yet fresh to the inhabitants of Rome, and we may therefore depend upon their portraits. This cannot be said of the Greek portraits of Homer, Solon, Pythagoras, Socrates, and others, all which our author supposes to have been struck at Rome, when Greek actors were to perform, or in the Greek cities, during the Roman empire. A few obverses present athletes, or actors in the games, and such are commonly represented holding a horse by the rein, or in some other attitude peculiar to their profession. On the reverses there is almost always a charioteer driving a chariot, or some similar device, peculiar to public games. Those struck for the theatre are the most scarce, and have sometimes on the reverse an actor at full length, with “Plaees,” “maggis tbe plaees,” or some such legend. One, in particular, has a bust of Sallust on the obverse, and on the other side three persons, one of whom bears an instrument, resembling the common flute; another an instrument like the scenic flute seen in the hands of Pan; while the third is declaring, “The legend is” “Petroni Places,” maggi thou plaes, Petronius. The person declaring is Petronius, who was, perhaps, that day, to make his first appearance upon the Roman stage; and the whole design, in this last instance, is so clear, that Mr. Pinkerton cannot forbear being surprised, that the intention of these tickets should so long have escaped the medallist authors. The supposition that they were tickets for different seats, or places, at the games, is further confirmed by the variety of marks to be found on the obverses of them. Some have a sprig of laurel; others a P, with an E below it, implying, perhaps, “pudium equiitare,” or the box of the equestrian order, which is very common; others bear a particular animal, or some such badge. All these marks, in tickets perfectly preserved, are cut in the brass, and then filled up with silver. The pieces of this class, with imperial portraits, are of little value; those bearing the images of illustrious men, are estimable, though not of great price. Apollonius Tyanaeus, who flourished in the reign of Domitian, and Apuleius, who lived in that of Antoninus the philosopher, are it believed, the latest
CONTRA, or Counter, in Composition. See Counter.

CONTRA, Lat. a preposition frequently used by the Italians in their Mixt: contrappunto, countertext; contra basso, double base; contralti, counter tenor; contrappunto doppia, double counterpoint; contrapporto semplice, simple counterpoint; contrappunto fiorito, fluid counterpoint, &c.

This Latin word, which the Italians have adopted, was originally applied to all the several parts defined to make harmony to a plain song or melody, as counterpoints or counterparts to the canto fermo. Thus, harmony in four and more parts was formed; as a basso, base; medius, mean or middle part; alto tenore, high tenor, from the situation of the clef on the staff; the disponent, sopran, treble, &c. When the alto tenor sung the part opposite or against the treble, it was called contralto or counter tenor; and when a lower part was employed than the base, it was called contra basso; the title now given to a double base.

CONTRA, in Surgery. See Counter-silence, Counter-extension, Counter-opening, Counter-stroke, &c.

Contra battuta, in Music, against, or out of time.

Contra fornem collationis, in Laws, a writ that lay where a man had given lands, in perpetual aims, to a religious house, hospital, school, or the like, and the governor, or managers, had alienated the lands, contrary to the intention of the donor, for the recovery of them. Reg. Orig. 258.

This was founded on the statute of Welfam. 2 cap. 1.

Contra fornum servitum, a writ that lay for the heir of a tenant, infodified of lands or tenements by the lord's charter, to make certain suit and service to his court; who was afterwards disfrained for more services than were contained in the charter. Reg. Orig. 176. Old Nat. B. ii. 162.

Contra fornum statuti, is the usual conclusion of every indictment, &c. laid on an offence created by statute.

If one statute be relative to another, as where the former makes the offence, and the latter adds a penalty, the indictment ought to conclude contra fornum statutorum. 2 Hale's Pl. C. 173. c. 24. Where there are several statutes, and it does not appear on which the information is founded, the conclusion, 'contra fornum statuti' is ill. Cro. Jac. 142. Pl. 19. Broughton v. Moor, &c.

CONTRABAND, in Commerce, a prohibited commodity; or a merchandise bought or sold, imported or exported, in prejudice, and contrary to the laws and ordinances of a state, or the public prohibitions of the sovereign.

The word comes from the Italian contrabando, of contra and bands, q. d. contrary to edict, or publication of prohibition.

Contraband goods are not only liable to confiscation themselves, but do also subject all other allowed merchandise found with them in the same box, parcel, or bale, together with the horfes, waggons, &c. which conduct them to the same.

In England there are two principal contrabands for exportation, wool and live sheep, which all strangers are prohibited from carrying out, on pain of having the right hand cut off; the other, that of sheep-skins and calf-skins, which all foreigners are in like manner prohibited from exporting, on pain also of having the right hand cut off; yet the subjects of England are allowed to transport the same from France to England. See Wool and Sheep.

Since the year 1652, when lists were formed of contraband goods, as to the import, and which included more than fifty different sorts, many regulations and statutes have been enacted; and these are so numerous and various, and so liable to change in the fluctuating state of commerce, that in a work of this kind it would be of little permanent utility to recite them.

In 1719 and 1720, an attempt was made in parliament to pass a bill for putting gold and silver, whether in coined species, or otherwise, among the number of contraband goods for exportation; but in vain, by reason of the strong opposition made by those who enrich themselves by the export of these metals; which, by the laws of the kingdom, are allowed to be sent away, upon entering them, paying the duty of the export, and making oath of their being foreign goods. Of this sort none being the coin or plate of the kingdom, melted down. See Customs.

CONTRACT, a mutual content of two or more parties, who promise and oblige themselves voluntarily, to do something, pay a certain sum, or the like.

As a contract is a mutual promise, the obligation of contracts, the f esse in which they are to be interpreted, and the cases where they are not binding, will be the same as of promises. See Promise. From the principle on which the obligation of promises is founded, viz. "that this obligation is to be measured by the expectation which the promisor any how voluntarily and knowingly excites," results a rule, which governs the construction of all contracts, and is capable, from its simplicity, of being applied with great ease and certainty: the rule is, that "whatever is expected by one side, and known to be so expected by the other, is to be deemed a part or condition of the contract." The several kinds of contracts may be comprehended under those of sale, hazard, loan of inconvertible property and money, and labour, including service, commissions, partnership, and the like. With regard to contracts of sale, the rule of justice, which ought principally to be inculcated in the making of bargains, is, that the seller is bound in confidence to disclose the faults of what he offers to sale. If it be deemed dishonour to magnify beyond the truth the good qualities of the commodity which we have to sell, is it less unjust to conceal its faults? The buyer in many cases has no security from impostion, but in the ingenuousness and integrity of the seller. This rule, however, admits of one exception, namely, where the silence of the seller implies some fault in the thing to be sold, and where the buyer has a compensation in the price for the risk which he runs: as where a horfe, in a London repository, is sold by public auction, without warranty; the want of warranty is notice of some unfoundness, and produces a proportional abatement in the price. (See Warranty.) To this head of concealing the faults of the article which we want to dispose of may be referred the practice of passing bad money. This practice has been sometimes defended by a vulgar excuse, that we have taken the money for good, and must therefore get rid of it: that is, in other words, we have been deceived, or imposed upon, but it may decay, or impose upon others. This excuse is much the same, as if one, who had been robbed upon the highway, should allege that he had a right to re-imburse himself out of the pocket of the first traveller he met: the justice of which reasoning the traveller possibly may not comprehend. (See Uttering of false money.) Where no monopoly or combination exists, the market price is always a fair price; because it will always be proportionable to the use and scarcity of the article. Innumerable questions relating to this kind of contract are determined solely by custom; not, indeed, that custom professes any proper authority to alter or avert the nature of right and wrong; but because the contracting parties are proufed
prefumed to include, in their stipulation, all the conditions which custom has annexed to contracts of the same sort; and when the usage is notorious, and no exception made to it, this presumption is generally agreeable to the fact. Thus, in justice as well as in law, what is called "the custom of merchants" regulates the construction of mercantile contracts.

By contracts of hazard are meant gaming and insurance. See those articles.

Contracts of loan comprehend those pertaining to inconsumable property, and to money. When the identical loan is to be returned, as a book, a horse, &c. it is called "inconsumable," in opposition to corn, wine, money, and those things which perish, or are parted with in the use, and can therefore only be restored in kind. The questions pertaining to this class of contracts are few and simple, and admit of an easy and obvious solution. If the thing lent be lost, or damaged by the use, or by accident in the use for which it was lent, the lender ought to bear the loss or damage. With regard to the loan of money, there exists no reason in the law of nature, why a man should not be paid for the use of his money lent, as well as of any other property into which the money might be converted. (See Interest and Usury.) For contracts of labour, see Servant, Commission, Agent, Factor, Steward, Attorney, and Advocate. See also Partnership. Under this head it may be observed, that in many offices, as schools, fellowships of colleges, professorships of the universities, and the like, there is a two-fold contract; one with the founder, and the other with the electors. The contract with the founder obliges the incumbent of the office to discharge every duty appointed by the charter, duties, deeds of gift, or will of the founder; because the endowment was given, and consequentially accepted, for that purpose, and upon those conditions. The contract with the electors extends this obligation to all duties that have been customarily connected with, and reckoned a part of, the office, though not preferred by the founder; for the electors expect from the person they choose all the duties which his predecessors have discharged; and as the person elected cannot be ignorant of their expectation, if he mean to refuse this condition, he ought to apprise them of his objection. Here it should be observed, that the electors can excuse the confidence of the person elected from this class of duties only; because this class results from a contract, to which the electors and the person elected are the only parties. The other class of duties results from a different contract; and with respect to the latter a question arises of delicate investigation, and of difficult solution, viz. how far the incumbent of an office may be allowed to deviate from the will of the founder, and to supplant him placed in circumstances similar to his own, and, in this new state of things, capable of forming a different judgment, and equally disposed to adapt his regulations and injunctions to the change of circumstances, which, in the course of ages, has occurred?—The best mode of curing the confidences of incumbents, in cases of this kind, is to introduce a reformation in many antiquated establishments, and in the laws, already obsolete, and, as it were, quenchless, by which they were designed by their unenlightened, but liberally disposed, founders to be regulated. Few of these contracts, to which we now refer, have, we conceive, been liberally and punctually fulfilled in modern times; and it would be unquestionably more conducive to the honour and welfare of ancient institutions, and of official incumbents, to establish regulations, which it is not thought proper to observe. It has been a question of some magnitude and difficulty, what offices may be constitutionally supplied by a deputy. A deputy, according to archdeacon Paley, may be allowed in all cases, to which the following objections do not apply: 1. Where a particular confidence is reposed in the judgment and contract of the person appointed to it; as the office of a rector, guardian, judge, commander in chief by land or sea. 2. Where the custom binds; as in the case of schoolmasters, tutors, and of commissioners in the army or navy. Where the duty cannot, from its nature, be so well performed by a deputy; as the deputy-governor of a province may not profess the legal authority, or the actual influence of his principal. 4. When some inconvenience would result to the service in general from the permission of deputies in such cases; e.g. it is probable that military merit would be much discouraged, if the duties belonging to commissions in the army were generally allowed to be executed by subordinates. In this connection, the non-residence of the parochial clergy, who supply the duty of their benefices by curates, presents itself to consideration; but as it will require a more distinct discussion, we refer to the article Non-residence. On the subject of this article, see Paley's Principles of Moral and Political Philosophy, vol. i. p. 142—163.

Contract is particularly used in Common Law, for an agreement or covenant between two or more persons, with a lawful consideration or cause. As, if I sell my horse for money; or covenant in consideration of 20l. to make you a lease of a farm; these are good contracts, because there is "quid pro quo," or one thing for another. Or, a contract which usually conveys an interest merely in action, may be thus defined: "An agreement upon sufficient consideration, to do or not to do a particular thing." In all contracts, therefore, our attention is directed to three points, viz. the agreement, the consideration, and the thing to be done or omitted, or the different species of contracts. In a contract, considered as an agreement, a mutual bargain, or convention, there must be at least two contracting parties, of sufficient abilities to make a contract, as where A. contracts with B. to pay him 10l., and thereby transfers a property in such sum to B. This property, however, is not in possession, but in action merely, and recoverable by suit at law; so that it could not be transferred to another person by the strict rules of the ancient common law, for no chose in action could be assigned or granted over. See Choice in Action.

This contract or agreement may be either express or implied. Express contracts are where the terms of the agreement are openly uttered and avowed at the time of the making, to deliver an ox, or ten load of timber, or to pay a stated price for certain goods. Implied are such as reason and justice dictate, and which, therefore, the law presumes that every man undertakes to perform. There is one species of implied contract, which runs through and is annexed to all other contracts, conditions, and covenants, viz. that if I fail in my part of the agreement, I shall pay the other party such damages as he has sustained by such neglect or refusal. In short, almost all the rights of personal property (when not in actual possession), do in great measure depend upon contracts of one kind or other, or at least might be reduced under some of them; and this is the method taken by the civil law, which has referred the greatest part of the duties and rights, of which it treats, to the head of obligations ex contractis, and quasi ex contractu. (Inst. 3. 14. 2.) See Assumpsit.

A contract may also be either executed, as if A. agree to change horses with B., and they do it immediately; in which case the possession and the right are transferred together;—or it may be executory, as if they agree to change next
next week; in which case the right only vellis, and their
reciprocal property in each other’s horse is not in possi
dition but in action:—for a contract executed (which differs nothing
from a grant) conveys a chose in possession; a contract execut-
tory conveys only a chose in action. For an account of the
consideration, upon which a contract is founded, see Consi-
deration.

A consideration of some sort or other is absolutely ne-
cessary to the forming of a contract, that a nudum pactum, or
agreement to do or pay any thing on one side, without any
compensation on the other, is totally void in law, and a man
cannot be compelled to perform it. However a man may
or may not be bound to perform such a contract, in honour
or confidence, which the municipal laws do not decide, it is
certain that these laws will not compel the execution of what
he has no visible inducement to engage for;—and, therefore,
our law has adopted the maxim of the civil law, that ex
nudis pactis non oritur actio. (Cod. 2. 3. 10. & 5. 1. 1. Br. &
St. d. 3. c. 24. Bro. Abr. tit. de te. 179. Salk. 129.) But any
degree of reciprocity will prevent the pact from being made:
nay, even if the thing be founded in a prior moral obliga-
tion, (as a promise to pay a just debt, though barred by
the statute of limitations,) it is no longer nudum pactum. And
as this rule was principally established to avoid the inconve-
nience that would arise from setting up mere verbal pro-
mises, for which no good reason could be assigned (Plowd.
308. 309,) it therefore does not hold in some cases, where
such promise is authentically proved by written documents.
For if a man enters into a voluntary bond, or gives a prom-
issory note, he shall not be allowed to aver the want of a con-
sideration in order to evade the payment; for every bond,
from the solemnity of the instrument (Hardr. 200. 1. Ch.
Rep. 157,) and every note from the subscripation of the
drawer (Lord Raym. 760,) carries with it an internal evi-
dence of a good consideration. Courts of justice will, there-
fore, support them both, as against the contractor himself;
but not to the prejudice of creditors, or Rangres to the
contract.

The most usual contracts, by which the rights of chattels
personal may be acquired, by the laws of England, are those
of sale or exchange, of bailment, of hiring and borrowing, and
of debt. See these articles respectively. See also Interest
and USURY, Bottomry and Respondentia, INSUR-
ANCE, and ANNUITY.

Every contract, whatever be its nature, implies in itself
an assumpst in law, for the performance of its; for a contract
would be to no purpose, if there were no means to enforce
its performance. See ASSUMPTION.

A dexterity occurs where a day of payment is limited in
a contract, and where it is not so limited. In the former
case, the contract is good prefixed, and an action lies upon
it, without payment; but in the latter, it is otherwise.
Thus, if a man buy any commodity, the contract is void, if
he do not pay the money prefixed; but if a day of pay-
ment be stipulated, there the one may have an action for the
money, and the other trover for the commodity. (Dyer, 52.
293.) Where a seller fays to a buyer, he will sell his horse
for a fixed sum, and the buyer fays he will give it: if he
prefently tell out the money, it is a contract; but if he do
not, it is no contract. (Noy’s Max. 67. Hab. 41.) The prop-
erty of any thing foid is immediately in the buyer by the
contract; though regularly it must be delivered to the buyer,
before the feller can bring his action for the money. (Noy.
88.) If a perfon contract to buy a horfe, or any thing elfe,
of another, and no money is paid, or earnest given, nor day
set for payment, nor thing delivered; in these cases, no
action will lie for the money, or the thing sold, but it may
be sold to another. (Plowd. 128. 509.) A11 contracts are
to be certain and complete. For an agreement to give fo
much for a thing as it should be reasonably worth, is void
on account of its uncertainty; fo is also a promise to pay
money in a short time, &c. or to give fo much, if a perfon
likes the thing when it begins to sell. (Dyer, 91. 1. Build. 92.)
But if a contract to give another 10l. for such a thing, if I like it
on seeing the thing, this bargain is said to be perfect at my
pleasure, though I may not take the thing before I have
paid the money:—if I do, the seller may have trepals againat
me: and if he sell it to another, I may bring an action on
the cafe against him. (Noy, 104.) If a contract be to have
for cattle sold, if the buyer do a certain thing, or else
to have 20l. it is a good, and sufficiently certain contract.
Halo, if I agree with a perfon to give him fo much for his
horse, as A. B. mall judge him to be worth, when he hath
judged it, the contract is complete, and an action will lie
on it; and the buyer shall have a reasonable time to demand
the judgment of A. B. But if he die before the judgment is
given, the contract is determined. (Perk. sect, 112. 114.
Slep. Ab. 294.) In contracts, the time is to be regarded,
and from which the contract is made; the words shall be
taken in the common and usual sense; and the law doth not
so much regard the form of words, as the substance, and the
mind of the contracting parties. (5 Rep. 83. 1. Build. 175.)
A contract for goods may as well be made by word of mouth,
as by deed in writing; and where it is merely written, but
not sealed and delivered, it is the same as if it were verbal.
But if the contract be by writing sealed and delivered,
and so converted into a deed, it is of another nature; and in this
case generally the action on the verbal contract is gone,
and some other action lies for the breach of it. (Plowd. 130. 309.
Dyer, 96.) Contracts, not to be performed in a year, are to
be in writing, signed by the party, &c., or no action may be
brought on them; but if no day is set or the time is uncer-
tain, they may be good without it. (Sta. 20 Car. II. c. 2.)
And by the same statute, no contract for the sale of goods
for 10l. or upwards, shall be good, unless the buyer receive
part of the goods sold, or give something in earnest to bind
the contract; or some note thereof be made in writing, signed
by the perfon charged with the contract. See SALE.

Consult. nude and quafi. See the adjectives, and

Consult. Simple. See SIMPLE and Debt.

Consult. Special. See SPECI ALTY and Debt.

Consult. Usurious, is a contract to pay more interest for
money than the laws allow.

It is a devavit in executors to pay a debt upon an ulu-
rious contract. See Usury.

Consult. of Marriage. The Romanists distinguish the

civil contract, which is the consent of the parties, from the

ingrement, which is the blessing of the priest.

These contracts are said to be null, which the law prohib-
its: such are all contracts between persons incapable of con-
tracting, as minors, religious, lunatics, wives without consent
of their husbands, &c.

In order to a good civil marriage, the parties must not
only be willing and able to contract, but actually must con-
tract themselves in due form of law. Any contract made,
per verba de praefenti, or in words of the present tense, and in
case of cohabitation per verba de futuro afo, between persons
able to contract, was before the act (26 Geo. II. c. 23,) deemed
a valid marriage to many purposes; and the parties might
be compelled in the spiritual courts to celebrate it in facie
ecclesiae. But these verbal contracts are now of no force, to
compel a future marriage. See Marriage.
Contract, Original, in English History, denotes that reciprocity of protection and subjection, which subsists between the king of Great Britain and his subjects. The duties resulting from these are what, according to judge Blackstone, (Comm. vol. 1) were meant by the convention in 1688, when they declared that king James had broken the "original contract" between king and people. But however, as the terms of that original contract were in some measure disputed, being alleged to exist principally in theory, and to be only deducible by reason and the rules of natural law; in which deduction different understandings might very considerably differ; it was, after the revolution, judged proper to declare these duties expressly, and to reduce that contract to a plain certainty. So that, whatever doubts might be formerly raised by weak and scrupulous minds about the existence of such an original contract, they must now entirely cease, especially with regard to every prince, who hath reigned since the year 1688. As to the terms of the original contract between king and people, the learned judge apprehends to be now couched in the coronation oath; which see also Constitution and King.

Contract is also used for the instrument in writing, which serves as a proof of the consent granted, and the obligation passed between the parties.

Among the ancient Romans, contracts, and all voluntary acts, were written, either by the parties themselves, or by one of the witnesses, or by a domestic secretary of one of the parties, whom they call a notary; but who was no public person, as among us.

The contract, when finished, was carried to a magistrate, who gave it a public authority by receiving it inter alia, into the number of the acts under his jurisdiction; giving each of the parties a copy thereof, and sealed with his seal. Which practice passed into France, where it obtained a long time. The conscientious performance of private contracts between man and man is frequently recommended in the Koran. For the prevention of disputes, all contracts are directed to be made before witnesses, and in case such contracts are not immediately executed, the same ought to be reduced into writing in the presence of at least two witnesses, (which seems to have been also required by the Jewish law, even in cases where it was not concerned) who ought to be Males and of the male sex; but if two men cannot be conveniently had, then one man and two women may suffice. The same method is also directed to be taken for the security of debts to be paid at a future day; and where a writer is not to be found, pledges are to be taken. Hence, if people trust one another without writing, witnesses, or pledge, the party on whom the demand is made is always acquitted if he denies the charge on oath, and swears that he owes the plaintiff nothing, unless the contrary be proved by very convincing circumstances. Sale's Koran, Intro. p. 139.

Contracts, in Rhetoric, furnish one head or clas of external arguments. (See Argument and Topics.) In this view of them, they are either public or private. Public contracts denote transactions between different states, as leagues, alliances, and the like; which depend on the laws of nations. Those are called private, which relate to less bodies, or societies of men, and single persons, and they may be either written or verbal. With respect to the force and obligation of contracts, the Roman law declares, that "nothing can be more agreeable to human faith, than that persons should stand to their agreements." Therefore in controversies relating to this kind of human testimony, the party, whose interest it is, that the contract should be maintained, will plead, that such covenants have the force of private laws, and ought religiously to be observed, since the common affairs of mankind are transacted in that manner; and therefore to violate them is to destroy all commerce and society among men. On the other side it may be said, that justice and equity are chiefly to be regarded, which are immutable; and besides, that the public laws are the common rule to determine such differences, which are designed to redress those, who are aggrieved. Indeed, where a compact has been obtained by force or fraud, it is in itself void, and has not effect either in law or reason. But on the other hand, the Roman lawyers seem to have very rightly determined, that all such obligations, as are founded in natural equity, though not binding by national laws, and are therefore called "nuda pacta," ought however in consequence and honour to be performed.

Contracted Vein, in Hydraulics, (Venæ contractæ of Newton,) is a name given to the contraction which has been observed in a stream of fluid leaving out of an aperture. When water, or other fluid analogous to water, issues out of an aperture in the thin side or bottom of a vessel containing that fluid, as at A, fig. 1 and 2. Plate I. Hydraulics, the size of the aperture being very small in proportion to the side or bottom of the vessel, the stream A B is not of the same shape throughout its whole length, nor is it of an uniform size. When the aperture is circular, the distance of the narrowest part of the stream, from the inside surface of the vessel, is about equal to the radius of the aperture. This narrowest part of the stream has been called the contracted vein; the whole stream itself having been usually designated the vein of fluid, by writers on the subject. From the place of the contracted vein forwards, the stream enlarges its dimensions, and sometimes divides itself into different smaller streams. The diameter of the contracted vein, or narrowest part of the stream, is subject to a little variation, arising from the size of the vessel in proportion to the aperture, and partly from the charge of the vessel, (viz. from the height of fluid in the vessel above the level of the aperture); hence the diameter of the contracted vein, as measured by different authors, has not turned out exactly of one invariable dimension; the difference, however, is not very material; as appears from the following table, which contains the different measurements of the contracted vein; calling the diameter of the circular aperture one.

</table>

From a mean of the above measurements, it may be concluded, that the diameter of the contracted vein is little more than eight-tenths of the diameter of the aperture. That short part of the stream which flows between the aperture and the greatest contraction, is not uniformly conical, but it approaches to the figure of an hyperbolic conoid.

This contraction of the stream is undoubtedly owing to the different directions, and different velocities, with which the various parts (or, as they are called, filamente) of the fluid are not exposed to the aperture, as is indicated by the fig. 1 and 2. Hence it has been observed, that when the aperture is very large in proportion to the size of the vessel, the contraction of the stream is less evident. And such, also, is in great measure the case, when the side of the vessel in which the aperture is made, is not very thin.
The various filaments of the fluid, which run from every part of the vessel in oblique directions towards the aperture, partly cross each other at the contracted vein; and this crossing, or tendency to cross, is one of the causes which enlarge the stream beyond that place. It is evident, that with apertures of different shapes, the form of the contracted vein, that is of the stream of that place, must vary considerably. But professur Venturi, dextrous in determining the effects of some of those variations from the circular shape, made the following experiments with orifices of peculiar shapes.

"In the orifice A B C D, (fig. 3.) the two sides A, B, are parallel to the horizon; the extremities are rounded; the width of this aperture is less than two lines, its length 18 lines, and the charge 35 inches. The section of the stream which issues from this orifice, first assumes the form E F, after which, the two extremities, E, F, approaching nearer and nearer to enlarge the middle part of the section of the stream, at 45 inches distance from the orifice, acquire the quadrangular form G H. The stream afterwards extends itself in the perpendicular direction, in the form of a large fan K L. I have repeated the experiment, by placing the longitudinal axis of the orifice C D vertically. In this case the same phenomena were produced, E F becoming vertical, and K L horizontal, both preferring their form."

The fluid filaments, which, issuing out of the orifice, pass near the two opposite borders A, B, are very near each other, and becoming convergent, they tend to unite at a very short distance from the orifice itself. The filaments C, D, are more remote, and, perhaps, less convergent; they cannot unite but at a greater distance than the two former. In this case, therefore, there are movements which tend to form two contractions, the one nearer, and the other more remote from the orifice; these two contractions counter balance each other in part. Their mutual opposition carries the effect, G H, to a distance five times greater than that of the contracted vein of a circular orifice, having a diameter of the same breadth as that of this orifice."

"In this experiment we see the cause of a phenomenon, which has been observed in some particular cases by Poleni and others, without giving the explanation. In very orifices of a right-lined figure through a thin plate, the angles of the contracted vein answer to the sides of the orifice and the contrary. When the quadrangular orifice has the situation M N O P, the greatest contraction of the stream is made at a greater distance than in a circular aperture; it assumes the form and situation Q R S T. The reason is, that the opposite angles M, P, are more remote from each other, than the sides I, V, whence the same thing happens as in the long orifice A C B D. In the same manner, the triangular orifice in the situation X, produces a contraction of the form, and in the situation Z, &c."

When the horizontal oblong aperture, C D, (fig. 3.) was used, the distance of the contracted vein from that orifice, was found to vary with the height of the fluid; as shown in the following table; from which it appears, that the contraction of the stream takes place at a greater distance, under strong charges, than in those which have but little elevation.

If a cylindrical tube be fitted to a circular aperture in the side of the reservoir, or vessel containing the fluid, and part of it be pulled into the interior part of that vessel, the contraction of the vein will be greater, and the quantity of fluid that runs out in a given time, will be less, than without such tube. If to the external part of the circular orifice, a short tube be adapted exactly of the shape of the contracted vein, or very nearly so, as in fig. 4, (it being a tube nearly conical, but with its sides a little convex inwardly,) the quantity of fluid that runs out in a given time, will be the same, or very nearly the same, as when the simple aperture is used, without such tube.

The velocity of the fluid is far from being the same in every part of the stream; for since the quantity of fluid multiplies pass through every transverse section of the stream in a given time, it follows, that the velocity must be inversely as the area of each transverse section. Therefore the velocity at the contracted vein is greater than at the circular aperture; and since the areas of the sections at those two places, are as the squares of their diameters, and the diameter of the contracted vein is to that of the circular aperture nearly as eight to ten, or as four to five; hence we may, as 16 is to 25, so is the velocity at the aperture, which we shall call one, to the velocity at the vein contracted; that is, as one to 1.56.

CONTRACTILE Force, that property, or power, inherent in certain bodies, whereby, when extended, they are enabled to draw themselves up again to their former dimensions. For the cause of this property, which is of the utmost consequence to a right understanding of the animal economy, see FIBRIS.

CONTRACTION, in Surgery, from con-tract, to draw together; a rigid or diffused state of any part in the body, but especially of the joints. This rigidity may arise from a morbid condition, either of the bones, ligaments, or muscles; and may proceed from a great variety of causes. Cullen has given four species of contractions; but Sauvages has multiplied them to the number of eleven! The surgeon who knows the cause and seat of this complaint, will not, however, pay much regard to those nosological distinctions, in the method of cure. If the morbid change arises from inflammation and thickening of the parts affected, he will use diuretic remedies, fevertaments, and emollient poultices; or, after the inflammatory state has subsided, he will employ electricity, friction, simulant embrocations, and moderate extension of the affected muscles, &c. If the rigidity be very obstinate, and the ligaments yield with great difficulty, the surgeon will use mechanical force more freely, and perhaps will enjoin the exercise of alternate bending and straightening the limb, by means of pulleys or flex springs, besides the occasional administration of the vapour-bath, or hot applications. The principles of the art being understood, and the nature of the office which comes before us, it will not be difficult, by steady perseverance, to overcome a great number of obstacles which present themselves, in the treatment of contractions.

When the disease is occasioned by an union of the bones which form a joint, the mobility of the limb is not to be expected. This species of contraction is named ankylosis, and is explained at large in a separate article of this work. (See ANKYLOSIS.) When one muscle is found in a state of permanent contraction, e.g. the sternomastoid of the neck, it is sometimes requisite to divide the muscle in order to effect the cure. (See DISTORTION OF THE NECK.) We understand that Mr. Carpe, surgeon of his majesty's forces, has invented many ingenious mechanical instruments, which will soon be made public, for the relief of this class of discares.
**Contraction**, in Grammar, the reduction of two vowels, or syllables, into one; as, 

- may, for may not; 
- should, for should not.

The Greeks abound with contractions, both in their verbs and their nouns.

In this language, two simple vowels concurring in the same word are generally combined into a diphthong; and in this case the concurrent vowels are said to be contracted.

Contraction is either simple or compounded; simple, when constituent vowels are retained unchanged; and compounded, when a new sound results. E.G. The contraction of τοὐχιμι into τοὐχι is simple; that of τωξιμιος into τωξιμιος is compounded. The first fort of contractions is called synecdsis, the second *crasis*.

When two succeeeding vowels have dots above them, they are separately sounded; but when contracted, they have over them the circumflex accent; hence τοὐξιμι has three syllables, but τοξιμι only two.

Every contraction, whether simple or compounded, is the coalition of two short vowels; and it takes place in nouns of every declension, in adjectives, in verbs, and in the combination of the article and prepositions with the succeeding words. Simple contractions are all reducible to the following rule.—Let the concurreing vowels, instead of being separated, be expressed by a single impulse of the voice; as ιο, αυ, αυ, ιν, &c. The difficulty lies in the compounded contractions; but all the varieties of these may be comprehended under the four succeeding cases.

1. If the two short vowels to be contracted be the same, they have already represented by one of them lengthened. Thus κα, κα, κα, are contracted into κα, κα, κα, respectively. Note, however, that, in the common tongue, the contraction of κα is not into κα, but into κα.

2. If the concurrent vowels be not the same, which is predominant in sound prevails over that which is subordinatet to it. The predominant vowel must in most inances be the prepositive; hence this preoccupies the organ, and thus demands a fuller enunciation. The subjunctive, therefore, is lost in the contraction; and its only effect is to length the prepositive, when a *doubtful* vowel, but to convert it, if faint by nature, into its correspondent long one. Hence κα, κα, κα, and κα are contracted into κα, κα, κα, respectively. The exceptions to the above principle are the following: verbs in μι of the first class, in order to be distinguished from the third person plural, have in the three singular, κα contracted into κα.

The diphthongs κα, κα, when succeeded by κα are contracted, the former into κα, and the latter into κα. If a vowel, or κα, precedes κα, they are contracted into κα.

By attention to the pronunciation of κα, κα, κα, it will be perceived that the first, having a fuller found, predominates over the second and third; and, therefore, κα are contracted, not into κα, but into κα. In the concurrent vowels κα, the latter prevails in found over the former, and consequently, the contraction is into κα, not into κα. Conformably to the second case κα would be contracted into κα; but its contraction, in the common tongue, like that of κα, is generally into κα.

The vowels μι, being predominant in found, and from their nature incapable of coalescing with those subjunctive to them, cause the subjunctive to be expelled: as ινα, αυ, αυ, a hawk, ευα, ευα, a serpent, υπερα, υπερα, fishes, &c. As the contraction is the union of two short vowels into one compound found, it follows, that a short vowel preceding a long one, as having no effect in lengthening a found which does not admit of different degrees of length, is dropped in the contracted form; as Απολλων, Απολλω, Apelles, Emperor, Emperor, Emperor, kings, winds, επιμηκον, I honour, &c.

When a vowel precedes a diphthong, it is either itself rejected, or it ceases to be rejected one of the constituents of that diphthong; thus, κα preceding κα, expels the subjunctive ια, but preceding κα, it is itself rejected. In like manner, ια is rejected, when preceding κα, or κα. When ια precedes κα, it requires in nouns and adjectives the rejection of the subjunctive: also in the infinitive mood of verbs in κα, ια preceding κα requires to be rejected; but in the second and third persons singular indicative, the prepositive is dropped. Before κα and κα, ια is itself rejected.

In the adjectives εκκακος simple, εκκακος double, or εκκακος: thus, εκκακος, εκκακος. See Jones’s Grammar of the Greek Tongue, on a new and improved Plan, part ii. chap. 1.

**Contraction**, in Logic, or Composition, a species of reduction, wherein the thing that reduces does also abridge, or bring the thing reduced into a lesser compass. The design of contraction is to bring things, which before were too lax and diffusive, nearer together; that so their mutual relation may appear the more clearly, and they may better strengthen and support each other.

To this head are referred the arguments, as they are called, of poems and orations; the titles and summaries of chapters, &c. See *Abridgment*.

**Contraction**, in a general sense, means diminution of the bulk, or extent, of any thing; the nearer approach of its parts to one another. This word is generally used in philosophy, in surgery, in grammar, in the arts, &c. In philosophy the contractions mostly noticed, are those which arise from a diminution of temperature. The shortening of the dimensions of a body is the general effect; but at certain periods of their contraction, bodies change their apparent state of existence; thus the vapour of water is contracted by a diminution of temperature from a higher degree, down to about 212° Fahrenheit’s scale; but below that degree, its contraction is very great, and it is thereby converted into fluid water, in which state it occupies not more than about the 1800th part of the space it took up a little before its conversion into water. Similar phenomena are to be observed with most other bodies, and the particulars which need be remarked concerning them, are the rate, the quantity, and the limits of contraction in different bodies. But those particulars being the reverse of the phenomena which are described under the denomination of expansion or dilatation, are with more perspicuity stated under those articles, to which the reader is referred. It is, however, necessary in this place briefly to state a few particulars which seem less regular, and some which arise, not from a simple cause, but from the compound effect of pressure, and of diminution of temperature.

When an elastic fluid is contracted by cold within certain limits, determined by a degree of pressure to which it is exposed, as well as by the nature of the fluid, its particles become subjected to the force of cohesion; they rush still nearer together, and form a liquid. Thus, when steam under the common atmospheric pressure, is cooled below the heat of boiling water, it is instantly condensed, and becomes water; but with a pressure of two atmospheres, it would be condensed at a temperature 36° higher, and with the pressure of half our atmosphere only, it might be cooled without condensation 35° lower than the common temperature of boiling water. And similar effects take place in vapours of other kind at higher or lower temperatures, a double pressure producing, in all cases, an equal disposition to condensation, with a depression of temperature of between 20 and 40 degrees, and most commonly...
of about 35° of Fahrenheit. Thus the vapour of spirit of wine is usually condensed at 172° of Fahrenheit; but with a double pressure it is condensed at a temperature 39° higher; and with the pressure of half an atmosphere, at a temperature 35° lower; and the vapour of ether, which is commonly condensed at 192°, requires a temperature 38° higher, with a double pressure, or as much lower with half the usual pressure. If the temperature be below the freezing point of the liquid, the vapour being sufficiently press'd the vapour may still retain its elasticity, but a further reduction of temperature or increase of pressure will convert it immediately into a solid."

Water, and all aqueous fluids, are gradually contracted by a diminution of temperature, until they arrive at a certain point which is about eight degrees above the freezing point; but below that point they begin to expand and continue to do so according as their temperature is lowered. Effects nearly similar have been observed with a few metallic substances.

Speaking of contraction, a remarkable phenomenon, of considerable importance in manufactures, obtrudes itself on our notice. It is the hardeness which certain bodies acquire in consequence of a sudden contraction, and this is particularly the case with glass and some of the metals. Thus glass vessels suddenly cooled after having been formed are so very brittle, that they hardly bear to be touched with any hard body. The cause of this effect is thus properly explained by Dr. Young. "When glass in fusion is very suddenly cooled, its external parts become cold steel, and determine the magnitude of the whole piece; while it still remains fluid within. The internal part, as it cools, is disposed to contract still further, but its contraction is prevented by the resistance of the external parts, which form an arch or vault round it, so that the whole is left in a state of constraint; and as soon as the equilibrium is disturbed in any one part, the whole aggregate is destroyed. Hence it becomes necessary to anneal all glass, by placing it in an oven, where it is left to cool slowly; for, without this precaution, a very slight caule would destroy it. The Bologna jars, sometimes called proofs, are small thick vessels, made for the purpose of exhibiting this effect; they are usually destroyed by the impulse of a small and sharp body, for instance, a single grain of sand, dropped into them, and a small body appears to be often more effectual than a larger one; perhaps because the larger one is more liable to strike the glass with an obtuse part of its surface." See Prince Rupert's Drop.

The hardening of steel is an effect of the same sort. The piece of steel is made red-hot, and, in that state, is suddenly cooled and contracted by immersion in water; in consequence of which it remains so brittle and hard, as not to suffer its being filed or hammered. If, instead of water, the piece of red-hot steel be plunged in oil, its contraction is not so sudden, and of course its hardeness will not be so great. If it be plunged in quicksilver, which cools it much, quicker than water, its hardeness becomes so great as to render it capable of cutting or scratching glass like a silicious body. But, on the other hand, if the piece of steel, after its having been rendered red-hot, be suffered to contract gradually in the air; then its texture will easily yield to the hammer or to the file.

The necessity and importance of attending to the minute variations in the bulk of bodies by heat and cold, was never before, perhaps, so strikingly exemplified, as in the government Trigonometrical Survey, begun under general Roy, in the year 1794, by the measurement of a base of 27424:9 feet in length on Hounslow Heath, near London. This base was first measured by long deal rods, which were found too liable on account of their great and variable contraction and expansion, and long glass rods or tubes were next tried wherein the sum of the expansions of the rods, during the operation, reduced to 0.2° of Fahrenheit's thermometer, amounted to 5 inches very nearly, and of the contractions to 1.8 inch nearly, making an addition of 4.2 inches to the length of the base, as measured by the glass rods, on account of their expansion and contraction during the operation; see Phil. Trans. 1785, p. 427. In 1791, this base was remeasured with a steel chain made for the purpose by Ramfden, with all imaginable attention to accuracy, and the correction necessary to be applied to the length of the base, on account of the excess of the expansions over the contractions of the chain during the operation, was found to be 34.2 inches, but from which 27.1 inches was afterwards deducted, for reducing the base to the length which would have resulted, from a measurement in the temperature of 68°, to which point of the thermometer's scale all lengths in this survey are supposed to be reduced. See Phil. Trans. 1795, p. 433.

Contraction of Strata, in Natural History. That clay and argillites have contracted during their hardening in the strata of the earth, Mr. Bergman infers from having observed, that the petrified shells found in these are commonly compressed and flattened, and that argil hardens by contraction, but those found in line-lime retain their primitive shape, because these harden chiefly by infiltration.

Contraction is frequently used, by anatomical writers, to express the shrinking up of a fibre, or an assemblage of fibres when extended.

Convulsions and fits are supposed to proceed from a preternatural contraction of the fibres of the muscles of the part concerned.

On the contrary, paralytic disorders generally proceed from a too great laxness of the fibres of the parts affected; or from the want of that degree of contraction necessary to perform the natural motion or action of the part.

In the first, therefore, the animal spirits are supposed to flow either in too great a quantity, or irregularly; and, in the last, the animal spirits are either denied a free passage into the part affected, or the tension of the fibre is supposed insufficient to promote the circulation.

Contraction evidently appears to be the true natural state of all muscles; for, if a muscle be at any time freed from the power of its antagonist, it is immediately found to contract; and is not, by any action of the will, or the spirits, to be reduced to a state of dilatation.

Contraction of the heart, arteries, lungs, &c. See Sympoles, Heart, Artery, Pulse, &c.

Contradictente. See Nenime contradictente.

Contradiction, a species of direct opposition, wherein one thing is found diametrically opposite to another.

The schoolmen usually define it, opposition inter ens et nonem mecho carenos: where, by ens, and nonens, are understood any two extremes, whereas one affirms, and the other denies; and it is said to be mecho carenos to distinguish it from the other species of composition; the extremes, here, neither agreeing in subject, as is the case in privation; nor in essence and kind, as in contrariety.
CONTRADICTION, freedom of. See Freedom.

CONTRADICTORY, imply a. See IMPLY.

CONTRADICTOR, in a legal sense, a person who has a right or title to contradict or gain say.

An inventory of the effects of a minor ought to be made in presence of his guardian, or trustee, who is the legal contradictor: a decree against a farmer has no effect on the landlord, the first not being the legitimate contradictor.

CONTRADICTORY Propositions, are opposites, one of which imports a mere, and asked, denial of the other.

Of these, therefore, one must be positive, and the other negative; as fiting, and not fiting: white, and not white. Contradictory propositions mutually destroy each other.

To have two propositions truly contradictory, they must be opposite, both in quantity and quality, i.e., one must be universal, and the other particular, which make the opposition of quantity; and the one affirmative, and the other negative, which make the opposition in quality. Thus, e.g., "All use of wine and silver is evil," false:—"Some use of wine and silver is not evil," true. To this it is necessary, that the one deny and the other affirm, the same thing, of the same subject, contradicted in the same circumstances: unless the question be about an essential attribute, in which case, no regard is had to circumstances; every thing having always its own essence. This the logicians express by affirmare et negare idem, de eodem, secundum idem.

There may likewise be contradictory propositions on a particular subject; e.g., an individual. These are called single contradictory propositions; as "Peter is innocent. Peter is not innocent, or is a criminal." Now to have these propositions contradictory, Peter must be considered at the same time, without which they may be both true; since there may be a time wherein Peter was innocent, and another wherein he was a criminal.

CONTRA-FISSURE. See Counter-fissure.

CONTRA-HARMONICAL Propotion, that relation of three terms, wherein the difference of the first and second is to the difference of the second and third, as the third is to the first.

Thus, e.g., 3, 5, and 6, are numbers contra-harmonically proportional; for 2:3::6:9.

To find a mean contra-harmonically proportional to two given quantities; the rule is, divide the sum of the two squared numbers by the sum of the roots; the quotient is a contra-harmonically mean proportional between the roots.

CONTRA-INDICATION, in Medicine, denotes such a symptom, or lot of symptoms, as indicate the necessity of remedies, which other symptoms, or the disease in general, forbid us to employ.

Thus, when inflammation of the lungs supervenes to a low or typhous fever, or vice versa, the nature of the fever requires cords and strengtheners for its cure, whilst the inflammation indicates, on the contrary, the use of blood-letting, and other debilitating expediens. Contraindications are always perplexing occurrences.

CONTRAIINT, Fr. refrained. This word is synonymous with strettto, in It. (which see.) It is an adj. which, in Mus. implies, whether in melody or harmony, the con strictain of a theme or ground.

CONTRALTO, It., the Counter-tenor. The compas of this kind of voice is usually very limited; it seldom goes lower than G, in the 4th space of the base, or higher than C, in the 3rd space of the treble. Senecino had no more than

fit or seven good notes in his voice; nor had Guadagni, in his younger days, when he was content with the force of his natural compass, which, like Senecino’s, were full, rich, and flexible. This species of voice is an octave above the base; and its clef, that of C on the 3rd line, the same as the alto viola, or tenor, among instruments.

CONTRAMANDATIO Placitis, in Law Books, signifies a repitting, or giving the defendant further time to answer; or, an impertinence, or counter-manning of what was formerly ordered. Leg. H. I. c. 59. See Countermand.

CONTRAMANDATUM, a lawful excuse, which the defendant, by his attorney, allege, to show the plaintiff has no cause to complain, fit dies placitis fit contramandatum. 11 Hen. I. See Countermand.

CONTRAMURE, in Civil Architecture. See Counter-mure.

Contramure, in Fortification, is a wall built before another to strengthen it, and to prevent its receiving any damage from the adjoining buildings. See Rampart.

CONTRA-POINTS, in Music. See Counter-point.

CONTRA-POSITIO, in Law, a plea or answer. Leg. H. I. c. 54.

CONTRA-POSITION, in Logic. See Conversion.

CONTRAPPUNTO. See Counter-point.

CONTRARIENTUM Rotulus. See Rotulus.

CONTRARIETY, that which denominates two things contrary to each other.

Contrariety consists in this, that one of the terms imports a negation of the other, either mediately or immediately; so that contrariety may be said to be the contral, or opposition of two things, one of which implies the absence of the other.

CONTRARIETY, freedom of. See Freedom.

CONTRARIES, are positive opposites; which being of the same kind, or same common nature, and subsisting by turns in the same subject, are as remote from each other as possible, and mutually expel each other. Such are whites and blacks, cold and heat, &c.

Hence, properly speaking, only qualities can be contraries; contrariety, in effect, only agrees to qualities per se; to other things it agrees per accident, or in ordine ad qualitatem.

CONTRARY, however, is often used in a more extensive signification, viz., for any inconstancy or difference between the nature and qualities of things. It is a popular maxim in philosophy, that contrariety juxta fide poista magis cunferunt; contraries set off one another. In this sense is the word contrariy used in the schools; and hence an argument à contrario.

This method of improving things, à contrario, is much used, and with good success, by F. Bourdaloue, in his Sermons.

CONTRARY, in Rhetoric. Contraries are things which, under the same genus, are at the utmost distance from each other; so that what we grant to the one, we utterly deny the other; e.g., "Virtue ought to be embraced, therefore vice should be avoided." F. de Colonia lays down three kinds of contraries in rhetoric; viz. adversatives, privinivs, and contradistinctors.

Adversatives are those that differ much in the same thing, as virtue and vice, war and peace: thus Tully, "Si multiformis fugimus, sapientiam lequamur; & bonitatem, & malitiam..."
Contrary motion of the parts, in composition, and of the hands in thorough-bass, has a pleasing effect, and precludes the succedence of 7ths and 8ths.

Contrary propositions, in Logic, universal propositions, one of which affirms, and the other denies, the same predicate of the same subject; as "every square is a parallelogram," and "no square is a parallelogram." These propositions differ in quality, but not in quantity, and therefore are distinguished from contradictory propositions, which differ in quantity and quality.

Contrary propositions cannot be both true, but may both be false: whereas, in contradictory propositions, one is necessarily true, and the other false.

Contrary point of figure. See Point.

CONTRA-SOGGETTO, in Music, a 2d subject in a fugue or canon, or a new subject, in contrary motion to the first.

CONTRA-TONES, in the German Musical Writings, are such as lie below the great obsidian of their tablature or literal notation, for the notes of the gamut. All notes on an organ, or other instrument which lie, more than two octaves below the tenor cliff note, or $\frac{2}{4}$, are said to be contra-tones. See Tablature.

CONTRAST, in Painting or Drawing. The proper introduction and management of contrasts of lines, forms, colours, lights, and shadows, form a very principal, and indeed indispensable, branch of the study of a painter; and there is perhaps nothing in the art which so necessarily requires a more than ordinary share of judgment and discretion. If contrats are only sparingly used, they seldom fail to produce a striking and happy effect; if they are too frequent, confusion in the composition, and a spotty disagreeable effect is the consequence; when they are entirely omitted, infipidity ensues. Contrasts in painting may, therefore, be compared to discord in music, which, when skilfully introduced, give double relish to the harmony, by preventing that nausia naturally attendant on an uninterrupted succession of sweets of any kind forever. The subject of contrats is necessarily connected with our inquiries respecting the great component parts of painting. We therefore beg to refer the reader to those articles. See Invention, Composition, Design, Expression, Clair-obscure, and Colouring.

Contrast, in Architecture, is to avoid the repetition of the same thing, in order to please by variety; as is done in the great gallery of the Louvre, where the pediments are, alternately, arched and angular.

Contrast, or Contrate, wheel, in Horology, denotes that wheel in watches which is next to the crown, whose teeth and hoop lie contrary to those of the other wheels; whence its name. See Watch-work and Wheel.

CONTRAVALLATION, or Counter-vallation, in Fortification. See Circumvallation.

CONTRAVENATION, a man's failure of performing or discharging his word, obligation, or duty, or the laws and customs of the place. The penalties imposed in cases of contravention, only pass for complimentary.

In a more limited sense, contravention implies the non-execution of an ordinance, or effect.

Contravention is supposed to be a degree below previration; and to be only the effect of negligence or ignorance.

In the French and other services, every commanding officer, of whatever rank, was responsible for the wrongs and trepilations committed by the troops under his command. He was obliged to pay the damages; and if himself set an example of such things, he was considered as doubly culpable, and was not only bound to pay the damages, but was otherwise punished.

CONTRAYERTA, in Botany. See Dorstenia.

CONTRAYERTA, in the Materia Medica, Dorstenia Contrayera, Linn. This is a perennial plant of South America, the root of which has long been used in medicine, and is still retained, though its medicinal powers are but moderate. It is said to have been first brought into Europe by Sir Francis Drake, about the year 1581, and from him called Draken.
It was then esteemed a very great alexiterial, and a
sovereign antidote against poisons.

Its juice is a violent poison, said to be used by the Perus.
vians to poison their arrows. Contrayerva signifies coun-
try-va, because the root of it is said to be an antidote against
the poison of its juice.

The root is knotty, reddish brown externally, and pale
within: its taste is sub-astringent, warm, and somewhat
bitter; but its acrimony is much flattened by the very large
quantity of mucilage which it contains. Contrayerva is a
gentle stimulant. Its use is almost entirely confined to the
pulvis contrayervae compositus, in which it is mixed with
crab's claws and chalk. The London Pharmacopeia directs
the preparation of it, by mixing 5 ounces, by weight, of
powdered contrayerva with 1/2 pound of compound pow-
der of crab's claws.

There is another kind of contrayerva brought from Vir-
ginia, more ordinarily called serpentinaria; this is very aro-
matic; it is but seldom preferred singly, though said to
have the same success against poisons and venoms with the
contrayerva of Peru. This is an excellent substitute for the
contrayerva. See Lewis's Mat. Med. and Newman's
Chn. Works.

CONTRE, Fr. in combination with words. See
Counter.

Contre-dance, Fr. Country-dance, taken from the lively
and familiar dance of our peasants and villagers in England.
Some, however, imagine that, during the Norman line, we
had this rural dance from the French contre-dance, in which
the partners are placed opposite or against each other. Of
this opinion was the late Mr. Donouy, dancing-master to
the royal family.

Contre-feux. The French make use of this expression,
in English, for an absurdity in composition or performance.

Contre-temps, Fr. is a breach of time, or false accentu-
ation. Rousleau. But M. Framery (Encycl. Meth.) is
not satisfied with this definition. According to him, an air
is a contre-temps, or out of measure, when the clores are
prepared on the accented part of a bar, and made on the unac-
cented part. The ear expects that the clofe or final part of
an air or movement should be on an accented part of a bar;
in common time of four crotchets, on the first and third;
and in triple time, on the first note of a bar. To this we
accede, except in Polifh airs, called Palomoge, or nity Palence,
where the clofe is made on the second note of a bar. See
Polonese.

Contrebia, in Ancient Geography, Sanctaer, a town
of Spain, in the country of the Carpathi, ealt of Complu-
tum. This town, in 571 or 572, was beleaguered by the Ro-
mans, under the conduct of Q. Flavius Placidus; and, in
consequence of the delay of succour, solicited from the Cel-
tibrians, was obliged to surrender. When the Celtiberians
afterwards arrived, they were surprized by the Romans, and
totally defeated.

Contrebi, in Geography, a town of Arabia, 180
miles S. of Mecuat.

Contres, a small town of France, in the department
of Loir and Cher, and chief place of a canton in the distriict
of Blois. Its population amounts to 1401, and that of the
canton to 10,105, persons, divided among 16 communes,
upon a territory of 265 kilometres in extent. It is situated
16 miles S. of Blois.

Conti, Antonio, in Biography, was the son of a
lawyer at Ferrara. In his youth he spent some time in the
study of art, which he practised many years in the two
capitals of Rome and Paris. Upon his return to Italy, he
settled at Cremone, where he studied the painting of land-
scape, under Francesco Baj. His pictures were frequently
embellished with flowers: a species of painting in which he
most excelled. But his claim to a place in this work rests
principally on a very extraordinary discovery which he made,
of the method of transferring pictures, painted in fresco on
the wall, to canvas, without in the smallest degree impairing
the original beauty of the painting. This he effected by
means of a strong cement, or rosin, which he spread over a
cloth, the same size as the picture he was desirous of remov-
ing. This was then firmly applied to the face of the fresco.
A panel of the same size was then fastened to the back of
the cloth, when the plaster or fresco was cut round to the
size of the cloth. After some days, the board with the
cloth was removed from the wall, drawing with it the paint-
ing. Another cloth, prepared with a cement still stronger
than the first, was then applied to the back of the picture;
after which the former cloth was removed, leaving the pic-
ture in its original state of perfection. He succeeded in
many experiments of this kind in Cremone, Ferrara, and
Mantua. This secret, however, has been seldom divulged;
and the late pope, Pius VI., for many years, gave a confi-
derable pension to the only person who was acquainted with
Rome, upon the condition of his removing no fresco
paintings from the Ecclesiastical State without his permis-
sion: wisely judging, that though the temples and palaces of
Italy might be deploited of oil pictures, the frescoes of the
great masters would at all times furnish sufficient example
for students, and ample gratification to the curious traveller.
Antonio Conti died in 1732, leaving a son named Fran-
cesco, who followed the footsteps of his father. Lanzi;
Storia Pittorica.

CONTRIBUTA, in Ancient Geography, Medina de los
Torres, a town of Spain, in the eastern part of Berta; is
called also "Julia Contributions.

CONTRIBUTION, the payment of each person's
quota, or the part he is to bear in some imposition, or com-
mon expense.

Contributions are either involuntary, as those of taxes and
imposts; or voluntary, as those of expenses for carrying on
some undertaking for the interest of the community.

When goods are cast into the sea, for the safe-guard of a
ship, or other goods, &c. abroad, in a tempell, there is a
contribution among merchants, towards the los of the
owners. (See Insurance.) And where a robbery is com-
mitted on the highway, and damages are recovered against
one or a few persons, in an action against the hundred, the
reel of the inhabitants shall make contribution to the fame.
27 Eliz. c. 13. See Robbery.

Contributions, Military, denote impositions, duties,
or taxes, which places and sometimes frontier country pays
to redeem themselves or purchase exemption from being pil-
laged, plundered, and infested by the enemy.

It would cost a prince often too much to make war en-
tirely at his own expence. If he adopt just measures ac-
cording to his finances not to run short of money, he takes
them also with his general for finding the means of aug-
manship or at least preserving his funds. These means are
contributions, which are of two kinds, viz. those which
are exacted in subsistence and commodities, and those
which are received in money.

Those that are paid in commodities, or subsistences, are
different sorts of grain, forage and provisions, carriage for
things wanted as well by water as by land, word of every
species, pioneers, and a particular treatment or entertain-
ment of troops in their winter-quarters and lodgings.

No levy ought to be made or taxes raised till a just
statement is procured of the situation of the country intended
to be laid under contribution, that the imposition may be rendered as equitable and little burdensome as possible. No demand, for example, is made of wood on those places that have only grain or meadows, or of land-carriages on those who make use of water-carriage.

The levy of different sorts of grain is made on those tracts or districts of country, that have quietly and peaceably reaped their harvest, and as it were by way of gratitude or acknowledgment for the tranquillity they have enjoyed, through the good behaviour and discipline of the army.

That of oats and other grain for horses should be made under the colour of pretext of regularity or good order, by which means a country is infinitely less burdened than it would be, were it abandoned to the avidity of horsemens, who would carry off the grain, wherever they might find it, either in a regular or irregular manner, or with orders or without orders.

That of forage should be made in the same manner, and a convenient time should be fixed on for the carriages that are to carry it to the places, where it is resolved it shall be consumed and made use of.

That of provisions is usually made, if it be possible, in those districts of country, where the troops cannot winter, to prevent the occasioning of a scarcity in that where they are to take up their winter-quarters.

Carriage, whether by land or by water, is necessary for filling the magazines made in the rear of the armies with ammunition and provisions; or for the taking of heavy artillery and ammunition to a place besieged; or for the removing of sick and wounded; or for the transport of materials defined for works.

Impositions of wood are made for palisades, for the construction of caissons and tables, &c. and for fuel to the troops in winter.

Pioneers are assembled or collected together to fortify posts designed for wintering the troops in; for throwing up with promptitude and expedition lines of circumvallation round a place besieged; for repairing roads and opening defiles; for the construction of lines made with a design to cover a country and thereby exempt it from contributions; and for levelling and filling the works made before a place after it is taken.

Utensils and necessary for the troops taken in an enemy's country are raised or obtained in two ways. The places, where they winter, should not furnish more of them than the conveniencies which the soldier finds in the house of his landlord, supposing there are no barrack in those places. But if there are barrack, the contribution in money is compensated by these commodities, and ought to be less than that which is raised in a level country or in towns, where there are no troops lodged.

The contribution in money is extended as far as possible. It is established in two ways; voluntarily over tracts of country within reach of posts and places defined for winter-quarters; or by force, whether by the army itself while it is advancing, or by large parties that are detached for penetrating into these parts which you wish to lay under contribution.

It is made also behind the places belonging to the enemy and rivers by means of terror, whether by incendiaries disguised, who spread and disseminate billets, or by different ways, in which small parties are made to pass the rivers, who endeavour to carry off some persons of consideration in the country, or to burn some large habitation, or dwelling place, or building.

A prince in fear ought to have an exact account kept of all contributions, and have those particularly looked after, who are employed in raising and collecting them, since it is but too common for them to make an improper use of what they raise or collect for their own personal advantage. And when the contributions are not judiciously assessed and demanded, the particular interest of those who impose them, or receive them, always prevails over the interest of the prince or soverign.

It is a great relief and easement in contributions, when they are imposed with justice, equality, and in an exact proportion to the abilities of those on whom they are raised; and when they are collected without insolvency, without severity or oppression, and without being converted to the profit or benefit of individuals; and when, in default of money, other goods and commodities are taken, as cloths, provisions, &c. but most of all when an army quits its own country to make war in that of the enemy or any other, whatever it may be.

Frederic I., or the Great, in speaking of the conduct of an officer sent out to levy contributions, expresses his sentiments in the following words: "Contributions are generally levied under one of the following circumstances; either being superior to the enemy you cover the whole country; or you make a part of it till the arrival of the enemy; or you are intercepted by their light troops."

"In the first case it is common for the commander in chief to fix the sum to be raised by the inhabitants, under pain of military execution. Upon this duty the officer must vigorously exert his utmost authority to make his sufferers observe the strictest discipline and decorum, lest the inhabitants should be ruined beyond recovery."

"The second case requires great circumspection in the officer, and a perfect knowledge of the country, that he may not be surprised by the unexpected arrival of the enemy; he must pre-determine his plan of retreat, and fix the place of general deposit; and for his farther security he must advance small detachments towards the enemy, that he may have early notice of their approach, and to interrupt all communication with the inhabitants."

"On his first arrival in the country, he will dispatc circulating billets of delivery, the duplicates of which are to be carried by the parties which are sent to levy the contributions. These parties are to have orders to return at a certain time, besides which they are to have sealed instructions indicating the places of second and third rendezvous, but these orders are not to be opened unless in cases of necessity."

"When contributions are to be raised in this manner, with the enemy at your heels, all lenity is out of the question. Where there is no coin to be had you must take any thing, that may be safely transported, or cattle, or hollages; but these only as your last resource. If you are close pressed by the enemy, it is best to divide your booty and lend it different roads, that you may save at least some part of it."

"In the third case, namely, when the enemy hinders the inhabitants from delivering their quotas, the peasants are in a great danger of total ruin. Nevertheless, as the exigencies of the army require it, you are to proceed with all possible rigour, and even to punish those who neglect to deliver their proportion at the time required, that the rest through fear may be more punctual in obeying the orders they have received."

CONTRIBUCIONE FACienda, in L. 1620, a writ which lies where several persons are jointly bound to the same thing, and one or more of them refuse to contribute their share.

If tenants in common, or joint, hold a mill, pro indiviso, and equally share the profits of the same; the mill failing to decay,
CON

The
decay, and one or more of them refusing to contribute to its reparation, the rest shall have the right de contributio
sanc
d to compel them. And if there be three copreccners of land that owe suit to the lord's court, and the eldest per
forms the whole; then may he have this right to compel the
refusers to a contribution. So when one suit is required for
land, and that land being sold to divers persons, suit is de
mended of them all, or some of them by dissent, as entirely
as if all the land were still in one. Reg. Orig. 175. F. N. B.
162.

CONTRITION, in Theology, expressés a real sorrow, re
fulting from the thought of having offended God; from
the sole consideration of his goodness; without any regard,
or, at least, independently of any respect, to the punishment
unrelated to the sin; accompanied with a detestation of sin,
and of ourselves on account of it. With this act of the
mind, it is said, that repentance, properly speaking, be
nings.

Some of the Roman doctors avow, notwithstanding the
practice of their church, that contrition is valid, and car
ries with it every thing necessary to obtain pardon, without
the ceremony, or as they call it, the sacrament of confec
tion and absolution.

And in this they make the difference between contrition
and Attrition (which see) to confit. This doctrine was
maintained by F. Seguenant upon St. Augulline; but it was
confurred by the faculty of Paris.

CONTROL. See COMPTROL.

CONTROLLER. See CONTROLLER.

CONTROLEES, Fr. the same as MUSTER-ROLLS, or
REGISTRY-BOOKS; which see.

CONTROLEUR General d'Artillerie, controller general
of artillery. This appointment was of an old standing in
France, and was next to that of grand master or master general
of artillery, except that of garde general d'Artillerie. It was
however suppressed, and in 1792 Louis XIV. created two of
fices in lieu of it, viz. that of directors general of artillery,
and that of commissary general of powder and salt-petre.
But by his declaration of the 21st July 1716, he superseded
these offices, and several others, and attached to that of con
troller general all the ancient functions, which that officer
afterwards exercised in their full extent, and which had been
established by the edicts and declarations of Francis I. and
his successors.

It is an office of great military importance, and much
reponsibility. He has a number of commissaries paid by
the state to act and manage under him, by his orders, and in
his name. They affit at the various proofs of powder and
pieces of ordnance, and can take and demand an account of
the purchases made in their absence by the principal officer
of artillery.

CONTROLEURS Provinciaux d'Artillerie, provincial con
trollers of artillery. These officers in France used to con
trol all the expenses and purchases in general, of whatever
kind they might be, that concerned the artillery, and could
refuse or reject the arms, ammunition, and in short every thing
that proved defective, on the deliveries of articles purchased
or contracted for. They have each of them a key of the
magazines where they reside. And upon entering on the
exercise of their office, they caused inventories to be given
to them by the gardes-magazines of every article in them,
of which they made a register, and on it added the receipts,
returns, and expenditures of stores, that they might be al
ways able to render an account to the controller general,
and the commandants of artillery. They often made their
visits, and chiefly at the same time that the commandants of
artillery made theirs. They gave certificates of the dead
and wounded, and made an inventory and sale of the effects
of the dead, with the concurrence of the commissaries, or the
major des equipages.

CONTROLEUR General de depots de l'Artillerie, controller
general of the expenses of the artillery. These officers kept
registres or accounts of the receipt and expenditure in money
which was made by the treasurer general of artillery, as well
as of the receipt and expenditure of pieces of ordnance, am
munition, and of purcahes.

CONTROLEURS des Guerres, war controllers. The func
tions of a controller des guerres are to keep a register and
control of the munitors and reviews of troops. See the ar
icle MUSTER-MASTERS.

CONTROLEURS d'Artillerie, controllers of artillery. See
the article CONTROLEURS Provinciaux d'Artillerie.

CONTROLEUR General des Ventes, controller general
of provisions. The undertakers used to choose for this em
ployment an old commissary who was perfectly acquainted
with the business, and was a person deserving of confidence.
He had a very extensive commission for inspecting and tak
ing cognizance of every thing that concerned provisions;
and the exercice of his duty was considered as conferring
of two parts; namely, that he should be in the first place
make himself properly acquainted with the state of the magazines
that were to supply the army, and in the second place
accompany the director general of provisions, to whom he
was subordinate when he should take the field.

The first thing which the controller-general of provisions
used to do, was to make a lift or statement of all the places
that depended on him, and of the commissaries who did duty
there. He inquired what were their functions, into their
character for zeal and spirit, the extent of their genius, their
capacity, what offices they had been employed in, what fa
milies they were of, or had, the places of their birth, their
age, and their manners.

He examined if the registers of the magazines were in
proper form, both as to receipts and expenditures, and ex
penses; as to the receipts, if the quantity in them is well
specified, the quality, the different names of the measurers,
the weights of the country reduced to avoid disproport weight,
in case it should be different; if the name of the feller, the
place of his abode, and the date of the purchase, are set
forth in the article.

As to the expense, he examined what supplies the com
missary had sent to the magazines, or procured, the nature
of the grain and flour, the quantities, and the copies of let
ters of carriage of the articles sent. After taking an extract
of the receipts and expenses, he saw what remained in the
magazine, how himself counted the sacks, and made a certified
state of the whole to be given to him.

The duties of this office, in short, were so many and
troublesome, that if this officer, who, we have already ob
erved, was subordinate to the director general of provisions,
literally fulfilled them, he could not have had so much as one
day of rest or repose during the whole continuance of a cam
paign. See COMMISSARY-GENERAL of Stores.

CONTROLEUR des Hospitaux Militaires, controller of mil
itary hospitals. Whenever a sick or wounded person enters
an hospital, this officer writes upon a register endorsed
and marked by a commissary of war, the military appellation
or designation of the person sick or wounded, the name of his
family, the place of his nativity, and the city nearest to that
place. He makes also two statements of his money and his
effects, one of which serves as etiquette au paquet, or ticket
to the parcel or packet, and the other is returned to the
sick or wounded man, in case of whole death an account is
rendered to the major of the regiment to which he belonged.
For
For the most part, however, the undertakers are the heirs or
inhabitants, for after a year and a day no part of either can be
demanded from them.
This officer signed the billets of soldiers when they entered
an hospital, and made them report themselves to him when
they went out. He obliged the overseers of inmates to render
an account of the dead immediately after their decease;
and that Remigii's death was the signal of his resignation.
In hospitals where there was no controller, every thing now
mentioned was executed by the director.
CONTROVERSY, in Law, a person who of his own head
devises or invents false or signed news. 2 Inst. 327.
CONTROVERSIAL DIVINITY. See Polemical
DIVINITY.
CONTROVERSY, or CAUSE, State of a, among An-
cient Rhetoricians, denotes the principal point in dispute be-
tween contending parties, upon the proof of which the whole
cause or controversy depends. Ancient writers have express-
ated it by several other names, as "the constitution of the
causa," "the general head," and "the chief question." (Quint.
Inst. Orat. l. iii. c. 6.) As this is the principal thing to every
controversial discourse, it also requires the proper consideration of the speaker, and should
be well fixed and digested in his mind, before he proceeds to
investigate arguments for its support. See Antony's ac-
count of his own method of pleading, in Cic. de Orat. l. ii.
c. 27; Quintilian (Inst. Orat. l. iii. c. 6) describes the subject
of this article to be "that kind of question which arises from
the first conflict of causes." In judicial cases, it immediately
succeeds the charge of the plaintiff, and plea of the defend-
ant. Our common law expresses it by one word, viz. the
issue: which fee. This interpreters explain by describing
it to be "that point of matter depending in suit, upon
which the parties join, and put their cause to the trial."
Thus, in the cause of Milo, the charge of the Clodian party
is, "Milo killed Claudius." Milo's plea or defence is, "I
killed him, but justly." Hence arises the grand question, or
"state of the cause;" "whether it was lawful for Milo
to kill Claudius?" That Claudius was lawfully killed by Milo is
what Cicero, in his admirable oration, in defence of Milo,
principally endeavours to prove. The whole of his discourse
is to be considered as centering at last in this point. Again,
in the case of Robespierre, the charge made against him is "that
he killed his father." But he denies the fact. The grand
question therefore to be argued is; "whether or not he
killed his father?" Cicero's defence in his defence of him is
to shew, that his accusers had not made good their charge.

Besides the principal question, there are subordinate
questions that occur in the course of a dispute, which should
be carefully distinguished from it: and more particularly
that, which arises from the reason or argument alleged in
proof of the principal question. Thus, in the cause of
Milo, his argument is, "I killed Claudius justly, because
he assassinated me." Unles the Clodian party be supposed
to deny this, they give up their cause. Hence therefore
subordinate questions arise; "whether Milo assassinated
Milo?" Cicero spends much time in the proof of this, as
the hinge, on which the first question, and consequently the
whole cause depended. But whatever may be the number
of subordinate questions, they are all dependent upon the first;
and though each of them has its particular state, yet neither
of these is what the rhetoricians call "the State of the Cause,"
which is to be understood only of the principal question.
Besides these subordinate questions, incidental ones are often
introduced, having some reference to the principal question
and contributing towards the proof of it, though they are not
necessarily connected with it, or dependent upon it. Each
of these has its "state," though different from that of the
"cause." Many questions of this sort occur in Cicero's
defence of Milo, occasioned by asperities that had been
thrown out by the Clodian party to the prejudice of Milo.
To each of these Cicero replies, before he proceeds to the
principal question. And therefore, though the question,
in which the "state of a Controversy" confisits, is said by
Quintilian to arise from the first proposition of the
speaker, yet, if we view the instance of Cicero, now adduced,
that it is not always the first question in order, upon which the
orator treats. It sometimes happens, that the same cause or
controversy comprehends more than one state. Thus in judi-
cial causes, every distinct charge occasions a new state.
All Cicero's orations against Verres relate to one cause,
found upon a law of the Romans against unjust executions,
made by the governors of provinces upon the inhabitants;
but as that prosecution is made up of as many charges, as
there are orations, every charge, or inditement, has its dif-
ferent state. It may be observed, that discourses of a
deliberative and demonstrative kind, as well as judicial,
are managed in a controverted way: and all controversies have
their "states." And therefore Quintilian very judiciously
observes (Inst. Orat. l. iii. c. 6) that "states belong both to
general and particular questions; and to all sorts of causes
demonstrative, deliberative, and judicial." As to the number
of these "states," Cicero and Quintilian reduce them to
three. "Three things," says the latter (Inst. Orat. l.
iii. c. 6) "may be inquired into in all disputes; whether
the nature of it, what it is, and how it is. And this is the
method which nature prescribes. For, in the first place, it is
necessary the thing should exist, about which the dispute is;
because no judgment can be made either of its nature or
quality, till its existence be manifest; which is therefore the
first question. But though it be manifest, that a thing is, it
does not frequently appear what it is; and when this is known
the quality yet remains; and after these three are settled, no
further inquiry is necessary." The first of these three states
is called the "original state;" the second is called the de-
definite state; and the third is called the state of quality. The
first occurs when it is inquired, "whether one person
killed another?" The second appears in an example
of Cicero; "whether to take a sacred thing out of a private
house be theft, or sacrilege?" The third is manifest, when
the contending parties are agreed both as to the fact, and
the nature of it; but the dispute is, "whether it be jut
or unjust, profitable or unprofitable, and the like?" as in the
cause of Milo. Aristotle (De Rhet. l. iii. c. 26.) and from
him Vossius (Inst. Orat. l. i. c. 6, § 7) add a fourth
state, namely that of quantity; e.g. "whether an injury
be so great as it is laid to be?" Quintilian, however, thinks
(ubi supra) that this may be referred to one or other of the
preceding states; since it depends upon the circumstances
of the fact, as the intention, time, place, or the like. The
importance and use of the preceding observations require
little illustration. Whenever a person engages in a contro-
versy, he ought in the first place to consider the main question
in dispute, to fix it well in his mind, and to keep it con-
stantly in his view: and it is equally necessary for his hearers
duly to regard this point, as they will thus be enabled to
distinguishing and separate from the principal question what is
only incidental, and to observe how far the principal question
is affected by it; to perceive what is offered by way of proof,
and of illustration; not to be misled by digressions, but to
discern when the speaker deviates from his subject and when
he resumes it; and to accompany him through the whole
discourse and through his whole chain of reasoning, as to
be able to judge, upon the whole, how far his conclusion is
fairly
CON

fairly drawn from his ascribed premises. A constant regard to the state of the cause, and principal point in dispute, is very necessary for this purpose. Although the putative treat of these states only as they relate to controversies, and become the full subject-matter of dispute between differing parties; yet every dispute has one or more principal heads which the parties usually propose to prove or illustrate. Ward's Ort, vol. i, let. vi.

CONTUBERNALES MAGISTRATUM, companions of the magistrates. These were young men defined for civil and military employments, whom the magistrates, in the time of ancient Rome, took into their department to be formed under their eyes and in their houses.

The same application of contubernales was also given to ten soldiers, who lived in one and the same room or under one and the same tent.

CONTUBERNIUM, in Antiquity, denotes a sort of connection or habitation that took place between male and female slaves in the middle ages. Although their masters or proprietors did not permit them to marry, they were allowed to form this kind of union. This practice so much prevailed, that during several centuries after the barbarous nations embraced Christianity, slaves, who lived as husband and wife, were not joined together by any religious ceremony, and did not receive the nuptial benediction from a priest; when this conjunction between slaves came to be considered as lawful marriage, they were not permitted to marry without the consent of their master, and such as ventured to do it without obtaining that, were punished with great severity, and sometimes were put to death.

CONTUCCI, Andrea, in Biography, likewise called Andrea Sanflovino, from a town in the Tuscan dominions, which gave him birth in the year 1460. Like Giotte he was the son of a simple shepherd, and, like him, his genius for design discoverer itself in childhood, by the drawings which he made in the sand, and the models which he amused himself with forming out of clay. These youthful productions were seen and admired by Simone Vepcucci, then chief magistrate of the town of Sanflovino: he perceived in them the propensities of the future fame of our young artist, and obtained the permission of his father to carry him to Florence, where, under the tuition of Antonio Puliabulo, he made a rapid progress, and ultimately became one of the most celebrated architects and sculptors of his age. The chapel of the sacrament, in the church of Santo Spirito at Florence, although small, is a beautiful specimen of the perfection in which he attained in the former art, and is so finely put together that it appears as if chiselled out of one stone. By this, and other works, he soon acquired an extended reputation; innumerable, that he was invited into Portugal, where he erected many edifices, and amongst others a palace with four towers for the king. After nine years residence in that country, he returned, loaded with presents, to Italy, and was employed by Leo X. in many considerable works; especially in the statues and baso-relieves which ornament the Santa Casa of Loreto. Several of his other productions in sculpture are at Rome, particularly two sepulchres within the choir of the Madonna del Popolo, and a fine group representing St. Anne, Christ, and the Madonna, in the church of St. Agostino. He died much regretted in the year 1529, at the place of his nativity. Milizia, Mem. degl. Architetti.

CONTUMACY, in Lexo, a refusal to appear in court when legally summoned; a disobedience to the rules and orders of a court having power to punish such offence.

The word is used in civil as well as in criminal matters; but more rarely in the first, wherein the words defaulter, and

CONTRARY, ordinarily supply its place: the refunding of the charges of contempt, judged at the hearing, is also the penalty of contumacy. In a criminal suit, the contumacious is condemed, not because the crime is proven, but because he is absent. By the Roman laws, there was no process in case of contumacy, during the first year of absconds: they only took an inventory of the goods of the fugitive, and if he died in the year, he died integra status; but, after the year was expired, he was deemed culpable.

In England, contumacy is to be prosecuted to outlawry. In France, all contumacies are amnesty'd, if the accused make his appearance in five years: if he die in that time, his relations are allowed to purge his memory.

CON, in Surgery, a bruise, from the Latin contusio. This term is applied to this kind of lesion which is occasioned by the application of a blunt substance to the surface of the body, with more or less violence, but without dividing the skin; it is also used, when any part has been pinched, compressed, or fractured. The first effects of a contusion are a laceration of fibres, or an entire loss of tone in the injured part; and its common symptoms are swelling and inflammation. A violent contusion occasions considerable blemishes, as well as amongst the many symptoms which, effusion of fluids into the neighbouring cellular texture, and even fractures of the bones, are the most frequent. (See ECHYMOSIS and Contused WOUND.) A violent contusion operates not only upon the part at which it immediately takes place, but also upon remote parts of the body; and the lesions thus produced are termed counter-injuries. See COUNTER ISSUERE.

The degree of the contusion does not always depend upon the force which has occasioned it, but also often upon the nature of the parts that have been bruised. The contusion is always violent, when there is a bone in the injured part, which is little covered with fleshy substance. In every such case of contusion, inflammation, with all its bad consequences, is to be apprehended. In healthy persons, violent contusions often produce as serious consequences; but in persons whose bodies are previously debilitated, flight contusions frequently produce gangrene and ulceration. Extravasated fluids, even though in large quantity, are diffused and absorbed, especially when they are situated in parts of a loose spongy texture, or amongst the many symptoms of which, effusion of fluids into the neighbouring cellular texture, and even fractures of the bones, are the most frequent. (See ECHYMOSIS and Contused WOUND.) A violent contusion operates not only upon the part at which it immediately takes place, but also upon remote parts of the body; and the lesions thus produced are termed counter-injuries. See COUNTER ISSUERE.

With regard to the cure, contusions frequently occasion more trouble to the surgeon than fractures; according as the operation and counter-operation of the force applied has been more or less violent, and also according as the patient does or does not give the injured part the requisite repose, which is equally necessary in cases of contusion as it is in fractures. The lighter degrees of contusion require nothing more than the use of external diffusive and astringent remedies; the habit of which are cold water, wine, brandy, vinegar, and solutions of sal ammoniac, or of alum, or decoction of Peruvian bark, &c. The weakened and stretched parts (if there be not much pain or inflammation) may also be supported by the pressure of a tight bandage; and when the contusion is of considerable extent, by bandaging the whole limb. When the patient is pellagrous, and the bruised part is of importance, a vein must be opened, or leeches applied to it.
In the more violent degrees of contusion, the patients require evacuations, especially cooling purgatives frequently repeated. External pressure and friction, when the extravasation is considerable, will greatly aid its absorption, and is therefore beneficial. The more important is the bruised part, and the more copious the extravasation, the more affi-
dately must all these remedies be employed; but in less exten-
sive contusions, the external applications may be suffi-
cient. However, the cold fomentations and spirituous affriments must not be applied without proper feclusion. A decoction of difunct herbs in wine, or in a mixture of equal parts of wine and water, especially when aponeurotic and tendinous parts have been much injured, produces often the greatest benefit; and to this may be added also sal ammoniac, when the pain and tension have abated. But if the skin be abraded, these affriming applications cannot well be employed.

Sometimes the pain increases, in spite of these applications, to such a degree, that emollient cataplasmes and oelcagious frictions become necessary: the following method is particularly recommended in such cases. Rub well the whole bruised part, above and below the contusion, especially below it, with good oil, and then cover the whole with a mixture of olive oil and strong wine-vinegar, formed into a kind of liniment by agitation. This mixture may be laid upon thick lint, wrapped round the whole part; thus, when the angle has followed the contusion, a part of the leg and foot must be covered with it. These dressings are to be renewed twice or thrice a day, till the swelling and pain dis-
appear. The whole part must then be frequently rubbed with camphorated spirit of wine. When this has been done for about three or four days, a cloth may be applied, spread with a thick ointment composed of white of egg mixed with crude alum. This may be repeated about three times, with intervals of 12 hours.

The yellow or blue spots that remain after the cure of contusions, may easily be made to disappear, by applying to them a mixture of bran, salt, and vinegar, boiled together till the bran has imbribed the fluids.

When the quantity of extravasated blood is very large, or when it is situated in a part which it cannot easily be ab-
forbed, or when it gives rise to symptoms which demand speedy relief, it must be immediately evacuated by an inci-
ion, and the fore treated like a wound combined with con-
tusion. The same practice must all's be observed, when the internal haemorrhage by which the extravasation is produced, proceeds from a large vessel, continues, and requires to be fliamed by some particular applications; or where, before the extravasation, other lesions of the parts are also present, as, for example, when the bone has been shattered. Should there still remain lumps of coagulated blood behind, after the use of the difunct remedies, these must also be removed by incisions, if they threaten to produce further mischief by their pressire.

Blows and contusions of the joints deserve particular at-
tention: for in these situations, especially in the knee joint, they are always dangerous. The confuses are violent pain and impeded motion; the pain is generally severe at first, but sometimes not. In the first case the ligaments, and in the second the glands, or interior parts, of the joint have been principally affected. In the latter case the conf-
sequences are dryly, or even luppuration of the joint, which frequently proves fatal. When the ligaments or other ex-
ternal parts of the joint have been injured, the part must be kept quiet, and treated, according to the peculiar circum-
stances of the case, with the remedies formerly mentioned, but especially we should have recourse to leeches: it may afterwards be washed with spirituous and saline applications.

When the pain has ceased, and there remains behind, as often happens, a stiffness in the part, the soap, liniment, and vapour bath may be employed with advantage. Should arthritic afflictions be superadded, speedy relief must be pro-
cured, and the dangerous confquences obviated by cupping, blisters, friction with flannel, and the internal use of cam-
phorated remedies. When the ligaments have been stretched and relaxed by a fall, the German surgeons apply, with good effect, small bags filled with the warm powder of plaster of Paris, mixed with a fourth part of sal ammoniac and common salt.

When the glands, or internal parts of the joint, have been injured, the surgeon ought not to intermit the application of appropriate remedies, till the pain has entirely ceased, especially repose, blood letting, and cold fomentations. The lesion of a joint, particularly of the knee, by a fall, blow, &c. easily gives rise to a white swelling of the part. In such cases the surgeon cannot employ too great care and attention, as the symptoms are so numerous and diversified, that it is in vain to expect a fortunate result from a careless and wanton practice.

Internal contusions are attended, more or less, with dis-
tressing and serious symptoms. If the head be violently con-
tused, there is danger left the brain should have suffered at the same time; or left the effused blood, lying long upon the cranium, should injure the bone by its pressire, if it be not speedily absorbed.

When the thorax has been violently contused, the heart, lungs, and large blood-velifs within the chest, are liable to partake of the injury; or a rib may be fractured, and may pierce the lungs, so s to occasion alarming confquences, if not death itself.

A general contusion of the abdomen, or a blow received upon it, may perhaps hurt the liver, stomach, uterus, bowels, &c. or may rupture an important blood-velff, and thus cause the death of the patient by the internal bleeding, inflammation, or luppuration.

The judicious surgeon will therefore, in such cases, con-
ider what internal parts are likely to have sustained an in-
jury, and will adapt his means to the peculiar circumstances which arise. See Concus5ion, Fracture, and Hemorrhage.

CONTWIG, in Geography, a small town of France, in the department of Mont-Tonne
e, and chief place of a canton in the district of Deux Ponts, with 780 inhabitants. The canton itself is composed of 16 communes, and reckons 4114 inhabitants.

CONY, a small town of France, on the river Seille, in the department of Sonme, 12 miles S.E. of Amiens, which formerly gave the title of pruce to the second line of the house of Bourbon Condé. It has only 759 inhabitants, but is the chief place of a canton, which, in 27 communes, and upon a territorial extent of 220 kilometres, reckons 6775 persons, and forms part of the district of Amiens; 3/4 leagues N.N.E. of it.

CONZ, a small town of France, in the department of Sarre, and chief place of a canton in the district of Treves. The number of its inhabitants does not exceed 351, and the whole canton has 31 communes, and a popula-
tion of 4972 individuals.

CONTZEN, Adam, in Biography, a Jesuit, and native of the duchy of St. Juliers, has been celebrated for his deep knowledge in the learned languages which he taught in the college of Munich, where he died in the year 1637, after having published "Commentarii in Evangelia in Epit.
Pauli ad Rom. et ad Corinth."
2 tom. fol. He wrote
4 E

Gen. Ch. Cal. none. Cor. monocarpous, bell, funnel, or wheel-shaped, smooth, more or less deeply fix-eleft; segments open or reflexed. Stigm. Filaments fix, awl-shaped, inserted into the corolla or the receptacle; anthers oblong, erect. Fil. Germ superior, globular; stig. trilobed, trigorous. Peric. Berry globular, spotted before it ripens, three-celled. Seeds one, two, or more in each cell, one or two of the cells frequently abortive.

* Corollas bell-flowered. Lilium convalium, Tourn.

** Corollas funnel-flowered. Polygonatum, Tourn.

4. C. verticillata, narrow-leaved Solomon's seal. Linn. Sp.Fl. 2. Mart. 4. Poir. 4. Wildl. 4. Eng. Bot. 138. (Polygonatum; Hall. n. 1344. P. angustifolium non ramosum; Bauh. Pin. 393. Tourn. Inf. 79. P. ramosum; Bauh. Pin. 304.) "Leaves in whorls." Root perennial, scoriaceous, erect. Stems two feet high, erect, commonly simple, angular, smooth, naked near the bottom. Leaves three or four in a whorl, five or seven at the top of the stem; lanceolate, acute, fleshy, glaucous underneath; stipules none. Flowers white, green at the tip; pedicels axillary, solitary, slender, branched, drooping, two or three-flowered; corolla a little narrowed at the mouth of the tube; divisions bearded within the tube, rather obtuse; stamens short, inserted into the mouth of the tube; style short. Berry globular, blue. There is a branched variety, described by Cufius and others as a distinct species. A native of many parts of Europe, of Scotland, but not of England. 5. C. polygonatum, angular Solomon's seal. Linn. Sp.Fl. 3. Mart. 5. Poir. 5. Wildl. 5. Flor. Dan. tab. 377. Eng. Bot. 280. Woodw. Med. Bot. tab. 44. (Polygonatum latifolium vulgare; Tourn. Inf. 78. Hall. Hab. n. 1342. P. latifolium bore majore odor; Bauh. Pin. 393. Barcel. 1.c. 711.) "Leaves alternate, half-embracing the stem; stem angular; pedicels axillary, generally one-flowered." Root perennial, creeping, scoriaceous, full of knots, which, when cut obliquely, are figured with veins, with f-some of what of the appearance of a feal, whence it is said to have obtained the name of Solomon's seal. Stems several, a foot and half high, erect, nodding at the top, simple, leafy half way down, angular, f-some of which two-edged, zigzag, smooth. Leaves nerved, smooth, unilateral. Flowers white, with a green line down the segments, nodding, sweet-scented; * unilateral on the side opposite the flowers; pedicels axillary, solitary or in pairs, almost always one-flowered; corolla oblong, a little narrowed in the middle; divisions spreading, bearded; stigmas inserted into the middle of the tube; anthers project beyond the base of the divisions; style half an inch long. Berry blue, with three seeds. A native of England and other parts of Europe. The root is mucilaginous, and forms of sincerity have been made into bread. It has long been employed in a dermatological poultice to various kinds of tumours, but more particularly to bruises, accompanied with extravasation of blood in the cellular membrane. It is also recommended as a cosmetic; and in the time of Galen was used by women to remove pimples and freckles of the skin. The berries, flowers, and leaves are extremely acrid, and said to be poisonous; but Point has often seen the young shoots in spring and found them as tender and wholesome as those of asparagus. 6. C. multi-flora.
**Corolla large, open, filiform, divided almost to the bottom; segments linear, obtuse, filaments half the length of the corolla; filaments capillary; anthers yellow, small, roundish; style the length of the filaments; stigma obtuse. Berries red. A native of North America. 11. C. trifolium. Linn. Sp. Pl. 7. Mart. 10. Poir. 11. Willd. 10. (C. floribunda racemosum, folis ovalis oblongis; Gmel. Sib. 1. tab. 6.) "Leaves embracing the stem, in three; raceme terminal, simple." Root perennial, much, jointed, knotty, with short slender filaments at each joint. Stem about three or four inches high, slender, crooked. Leaves generally three-foliate, rather acute, even-surfaced, imbricate, green on both sides. Flowers small, on long simple peduncles; corolla open, deeply divided; divisions ovate-acute; filaments very short, inserted into the receptacle; gynoecium. Berries red, round. Seeds three or yellowish, compressed, pointed. A native of the forests in Siberia. 12. C. bifolia. Linn. Sp. Pl. 8. Mart 11. Poir. 12. Willd. 11. (Polygonatum multiflorum; Gmel. Sp. Pl. 311.) "Leaves heart-shaped; flowers tetradynamous." Root perennial, small, fibrous, creeping. Root-leaves solitary, on long petioles, springing from filament parts of the root. Stem from a different part of the root, two or three inches high, slender, slightly angular. Stem leaves generally two-petioled, a little nerved, heart-shaped, acute, with two rounded lobes and some fine hairs at the base. Flowers white, small, shorter than the peduncles; peduncles very slender, quite simple, sometimes two together, from the axil of a small scale at the base; corolla deeply four-lobed; filaments long; anthers small, shorter than the corolla; style short, thick; stigma flabellate, bifid. Berries red, small, two or three-celled. A native of the mountainous parts of Europe, abundant in Sweden. Poiret observes that the petioled leaves are a rare singularity in the family of the Liliaceae.

**Propagation and Culture.—The lily of the valley requires a loose sandy soil and a shady situation. It is propagated by parting the roots in autumn, placing the fets a foot or more apart. This should be done every third or fourth year; their flowers will else be small and few. All the sorts of Solomon's seal are hardy. They prefer a light soil and a shady situation, and are proper to ornament plantations which are not crowded with shrubs. They are propagated in the same manner and require the same treatment as the lily of the valley. Miller.

**CONVENTES, in Ancient Geography, a people of Gaul, who derived their name from the Latin convenire. They were established by Pompey, after his return from the Spanish war, against Sertorius, at the foot of the Pyrenees. Their country is Comingens.

**CONVENT from the Latin convenire, meaning, of convenire, to come together; a multitude of religious, of either sex. See MONASTERY.

Convents are very numerous in Greece, as well as in many Popish countries; and they are generally, though not universally, sanctuaries confected to ignorance, superstition, and most frequently to sloth. In the Grecian states, the monks are denominated calypers, from καλυπτεῖν, καλύπτειν, good, and γενέας, geinæas, old man, a good old man. However, the Grecian convents are the habitations, not merely of old men, but of young boys, from 10 to 12 years of age, clothed in the habit, which consists of a plain long black gown, confined by a girdle.

**CONVENTA PACTA. See PACTA.

**CONVENTI, Giulio Cesare, in Biography, a Bolog.-
nef sculptor, who is spoken of in high terms by Malvafia, in his description of the magnificent funeral of Agostino Caracci, upon which occasion Conventi modelled a beautiful figure of virtue, which, with another, personifying honour, was represented, crowning with laurel, the bolt of the deceased artist. The celebrated sculptor, Algardi, received his first instruction in modelling from this master. Malvafia.

CONVENTICLE, a diminutive of conven, denoting, properly, a cabal, or secret assembly, of a part of the monks of a convent, to make a brige or party in the election of an abbot.

From the ill use of these assemblies, the word is come into disrepute; and now stands for any mischievous, seditions, or irregular assembly. F. Doutin observes, the accidental always extenuated the fifth general council an unlawful conventicle. The term conventicle is said, by some, to have been first applied in England to the schools of Wickliff, and has been since used to signify the religious assemblies of all in this country, who do not conform to the established doctrines and worship of the church of England.

Conventicle, however, in strict propriety, denotes an unlawful assembly; and cannot, therefore, be justly applied to the legal assemblies of protestant dissenters, in places of worship certified, or licensed, according to the regulations of law. See Toleration.

This term occurs in the statutes 2 Hen. IV. c. 15, and 1 Hen. VI. c. 3; and 16 Car. II. c. 4. (A.D. 1664), which statute was made to prevent and suppress conventicles. This statute, which was enacted for three years, having expired, was revived A.D. 1670, by 22 Car. II. c. 1., which enacted, that if any person of the age of fifteen years, subjects of this kingdom, shall be present at any conventicle, where there are five or more assembled, they shall be fined 5s. for the first offence, and 10s. for the second, and performing, or maintaining incur a penalty of 20l. for the first, and 40l. for the second offence. Also, suffering a meeting to be held in a house, &c. is liable to 20l. penalty. Julices of peace, on the oath of two witnesses, or any other sufficient proof, may record the offence under their hands and seals, and this record shall be taken in law for a full and perfect conviction, and shall be certified at the next quarter-sessions. They, and also confables, head boroughs, &c. have power to enter such houses, and seize persons assembled, &c. And if they neglect their duty, they shall forfeit 100l. And if any confable, &c. know of such meetings, and do not inform a justice of peace, or chief magistrate, &c. he shall forfeit 5l.

"One clauae in this act," says Mr. Hume (Hist. vol. vii. p. 457,) "is remarkable; that if any dispute should arise with regard to the interpretation of any part of the act, the judges should always explain the doubt in the sense least favourable to conventicles; it being the intention of parliament entirely to suppress them. Such was the zeal of the commons, that they violated the plainest and most established maxims of civil policy, which require, that in all criminal prosecutions, favour should always be given to the prisoner." The persecution under this act continued to be so severe, till the operation of the act was suspended by the exercice of a dissenting power, and the king's declaration of indulgence, A.D. 1671–2. However, alderman Love, member for the city of London, in the name of the dissenters, disavowed the dissenting power, though it had been exercised in their favour, because, as he declared in his speech, "he had rather go without his own defined liberty, than have it in a way so destructive of the liberties of his country, and the protestant interest: and this (he said) was the sence of the main body of dissenters." At length it was ordained by the lat. 1 W. & M. R. 1. c. 18, that protestant dissenters shall be exempted from penalties; though if they meet in a house with the doors locked, barred, or bolted, such dissenters shall have no benefit from that statute. By lat. 10 Anne, c. 2. officers of the government, &c. present at any conventicle, at which there shall be ten persons, if the royal family be not presently for express words, shall forfeit 40l. and be disabled. See Nonconformists and Toleration.

CONVENTION, in our Law-Books, is used when a parliament is called, which fits and is dissolved without any act passed, or judgment given. It is then said not to be a session of parliament, but a convention. See Convention infra.

Convention of Rouen, the fame with burse of Rouen. Convention, a treaty, contract, or agreement between two or more parties. See Contract.

Every convention between men, provided it be not contrary to honnely, and good manners, produces a natural obligation, and makes the performance a point of confidence.

Every convention has either a name, and a cause or consideration, or it has none: in the first case, it obliges civilly and naturally; in the latter only naturally.

Conventions entre fouverains pour restitution des defercurs, conventions among sovereigns for restitution of dissenters. By these sorts of conventions, the dissenters from all armies are taken up or arrested, if they get into the territories of a power, that is in agreement with that whole colours they have defected. Notice is given to the nearest commandant, who should fend people to find the dissenters at the expense of the corps, and should pay those who took them up, for their suffrance or support during the time of their detention.

Convention fercretes entre les officers d'un corps, secret conventions among the officers of a corps. See Concordat.

Secret conventions are also made in a treaty of peace, reciprocally agreed on, and concluded between the parties, who have received powers to treat. Then these conventions remain secret and concealed, till what was agreed on between the treating and contracting parties is put in execution.

Convention is much used both in ancient and modern pleadings, for an agreement or covenant.

In the book of rolls of the manor of Hatfield in Yorkshire, we have a record of a plesant convention, anno 11 Edw. III. between Robert de Roderham, and John de Ithen; the latter of whom sold the devil in a feering for three-pence halfpenny to the former, to be delivered on the fourth day after the convention; when, the purchaser making his demand, the seller refused to give him livery, to the great loss (as the record represents it), of forty shillings to the purchaser, &c. But it appearing to the court, that such a plea does not lie among Christians, the parties were adjourned to hell for judgment.

Convention is also the name given to an extraordinary assembly of parliament, or of the states of the realm, held without the king's writ. Of this kind was the parliament which restored Charles II. This parliament met above a month before his return, the lords by their own authority, and the commons, in pursuance of writs issued in the name of the keepers of the liberty of England, by authority of parliament; and sat full seven months after his restoration, and enacted several laws still in force.

The
The necessity of the case, in this instance, superseded all law; for if they had not so met, it was morally impossible that the kingdom should have been settled in peace. After the king's return, the first thing that was done, was to pass an act, declaring this to be a good parliament, notwithstanding the defect of the king's writs. (Stat. 12 Car. II. c. 1.) Nevertheless, though the king himself, who alone had a right to object, consented to waive the objection, it was at that time a great doubt among the lawyers (1 Sid. 1.) whether even this healing act made it a good parliament, and held by very many, says Judge Blackstone, in the negative: though, as he adds, it seems to have been too nice a scruple. And yet, out of abundant caution, it was thought necessary to continue its acts and sit in the next parliament, by statute 13 Car. II. c. 7. & c. 14.

The convention of estates, in 1688, after the retreat of king James II. upon mature deliberation, came to a conclusion, that king James, by his practices here, and his flight hence, had abdicated the kingdom; and that the throne was vacant; and therefore devoted to king William and queen Mary. Upon this their assembly expired as a convention, and was converted into a parliament.

In this case, the lords and commons, by their own authority, and upon the summons of the prince of Orange (afterwards king William) met in a convention, and therein disposed of the king and the kingdom. On this occasion, the peers and bishops, to the number of near 90, addressed the prince, desiring him to summon a convention by circular letters. In order to satyfy his mind by a more general and express declaration of the public consent, the following judicious expedient was adopted. All the members who had litten in the House of Commons during any parliament of Charles II., were invited to meet; and to them were added the mayors, aldermen, and fifty of the common council of London. This was regarded as the most proper representative of the people that could be summoned during the present emergency. They unanimously voted the same address with the lords. The prince, being thus supported by all the legal authority which could possibly be obtained in this critical conjuncture, wrote circular letters to the counties and corporations of England, and his orders were universally complied with. Accordingly, the English convention was assembled, June 22, 1689, and a vote was passed in a few days by a great majority of the commons, and sent up to the peers for their concurrence. The words which expressed it were these, "that king James II. having endeavoured to subvert the constitution of the kingdom, by breaking the original contract between king and people; and having, by the advice of Jesuits, and other wicked persons, violated the fundamental laws, and withdrawn himself out of the kingdom, has abdicated the government, and that the throne is thereby vacant." (See Abdication.) The vote was carried to the upper house, and there met with great opposition. After long debate, and free conference between the houses, and after having obtained the sentiments of the prince, with regard to the settlement of the government, the chief parties agreed, and the convention passed a bill; in which they settled the crown on the prince and princes of Orange; the sole administration to remain in the prince: the princes of Denmark to succeed after the death of the prince and princes of Orange; her posterity after those of the princes, but before those of the prince by any other wife. The convention annexed to this settlement of the crown, a declaration of rights, where all the points which had of late years been disputed between the king and people, were finally determined; and the powers of royal prerogative were more narrowly circumscribed, and more exactly defined, than in any former period of the English government. See Constitution.

This convention was assembled upon a similar principle of necessity with that of the restoration; that is, upon a full conviction, that king James had abdicated the government, and that the throne was thereby vacant; which supposition of the individual members was confirmed by their concurrent resolution, when they actually assembled. In such a case as the palpable vacancy of the throne, it follows "ex necessitate rei," that the form of the royal writs must be laid aside, otherwise no parliament can ever meet again. Let us suppose, for the sake of argument, that the whole royal line should at any time fail, and become extinct, which would indispensably vacate the throne; in this situation, it seems reasonable to presume, that the body of the nation, consisting of lords and commons, would have a right to meet and settle the government, otherwise there must be no government at all. Upon this, and no other principle, says Judge Blackstone, did the convention in 1689 assemble. The vacancy of the throne was precedent to their meeting, without any royal summons, not in consequence of it. They did not assemble without writ, and then make the throne vacant; but, the throne being previously vacant by the king's abdication, they assembled without writ, as they must do if they assembled at all. Had the throne been full, their meeting would not have been regular; but, as it was really empty, such meeting became absolutely necessary. Accordingly, it is declared by statute 1 W. & M. R. 1. c. 1. that this convention was really the two houses of parliament, notwithstanding the want of writs, or other defects of form.

In a similar convention, by circular letters from the prince, was summoned at Edinburgh, on the 22d of March 1689. As soon as the purpose of this convention was discovered, the earl of Balcarres, and vicount Dundee, leaders of the tories, withdrew from the city; and the convention having passed a bold and decisive vote, that king James, by his mal-administration and abuse of power, had forfeited all title to the crown, they made a tender of the royal dignity to the prince and princes of Orange.

The constitution of Great Britain having placed the representation of the nation, and the expression of the national will in the parliament, no other meeting or convention, even of every individual in the kingdom, would be a competent organ to express that will; and meetings of such a nature tending merely to sedition, and to delude the people into an imaginary assertion of rights, which they had before delegated to their representatives in parliament, could only tend to anarchy and confusion; and to overturn every settled principle of government.

Accordingly, an act of parliament was passed in Ireland, in the year 1793, to prevent any such meetings or conventions; and a few ignorant individuals, who in the same year had dared to assemble under that title in Scotland, were quickly dispersed, and their leaders convicted of sedition and practices; for which they were sentenced to transportation.

CONVENTIONAL Estates for Life, are those that are expressly created by the acts of the parties, in contradistinction to such as are merely legal, or enacted by construction and operation of law. See Estate.

Conventional Subrogation. See Subrogation.

CONVENTIONARY RENTS, in Rural Economy, is a term which is sometimes applied to the reserved rents of life leases. See Lease.
CONVENTIONE FACIENDA, in Law, is a writ which lies for the breach of any covenant in writing. Fitzherbert calls it a writ of conventual.

CONVENTUAL, something belonging to a convent See Conventile.

Conventual is particularly used, since the year 1559, for a religious who actually resides in a convent; in contradiction to those who are only guests, or are entertained there, or are in possession of benefices depending on the house.

Conventual likewise denotes a class of the order of Franciscans, who adopted the relaxation introduced into that order by pope Innocent IV, which allowed of property and possessions in their community. They were so called in opposition to the "Brethren of the Observance." This division took place in the year 1368.

Conventual Churcb, denotes a church that consists of regular clerks, professing some order of religion; or of dean and chapter, or other societies of spiritual men.

Conventual Prior, differs from a clausal prior, in that the former has the full right and authority of an abbett; the only difference between them being in the name; whereas the clausal prior is a dependent of the abbett, and derives all his authority from him.

The conventual prior is obliged to take priests' orders in a year, or at most in two years, from the day of his admission: in default whereof, the benefice becomes vacant. Some priories are actually conventual, i.e. they are flocked with religious: others are only conventual in habit, qu. gr. where there have been no religious during the space of forty years: the continuance of one single religious, keeps the priory conventual actus; for, in default of one, the priory becomes simple. See Prior.

By a declaration of the king of France, in 1668, it was decided, that a conventility never degenerates, or ceases, while there are regular places subsisting in it for twelve religious, with revenues for their support.

Conventual Auditor. See Auditor.

Convergency of Meridians, in Geographical Surveying, is the angle formed between the meridian of any place and the parallel to the meridian of any other place, drawn through the first mentioned place. Thus, if P (Plate II. Surveying, fig. 10.) be the pole of the earth, E Q a portion of the equator, P E a meridian drawn through a place or station G, and P Q a meridian drawn through another place R: then, if G R be a portion of a great circle passing through the places G and R, and a b be a portion of a small circle passing through G, parallel to the meridian of R (P Q), or perpendicular to the great circle a R, which is itself a perpendicular to the meridian P Q, in the point R, then is the angle a G P the angle of convergence of the two meridians P G and P R, at the place G. It is to be observed, that at the equator any two meridians, as E P and Q P, are parallel to each other; but on their departure from thence, they converge more and more as they approach towards the pole, where the angle of convergence (a G P) becomes equal to the angle of longitude E Q. It may also be remarked, that the angle of convergence, augmented by the excess of the three angles of a spherical triangle above 180°, is equal to the angle of longitude at the pole, on a sphere.

Phil. Trans. 1787, p. 218. The principles for applying this to an ellipsoïd figure of the earth, or to any other given spheroid, may be found in Mudge and Dalby's Trig. Survey, vol. i. art. 60, &c.

The late general Roy (Phil. Trans. 1787, p. 216.) has explained the mode of applying the convergency of two meridians, obtained by reciprocally observing the azimuth of a station on each, from the other, compared with the meridian there (determined by observations of the pole-star), to the finding of the difference of longitude, or angle at the pole between the meridians of those two stations, by a method somewhat different from that recommended by the Rev. Mr. Mitchell. Phil. Trans. lvi. In the progress of the Government Trigonometrical Survey, this method was first applied in the finding of the difference of longitude between Botley Hill station in Surrey (lat. 51° 10' 41" N. and long. 6° 8' 3" E. of Greenwich Royal Observatory) and Goudhurst steeple in Kent, about 23 miles distant; as also for setting the latitude of the latter place. Phil. Trans. 1790, p. 266. It was afterwards applied, in a not complete manner, to the determination of the difference of longitude between Beachy Head station in Sussex (lat. 50° 44' 23.7", long. 0° 15' 11.6" E.), and Dunnofe station in the Isle of Wight, wherein the bearing of each of these places, with the meridian of the other, was accurately fettled by observation, although the places are more than 64 miles apart; and whereas, the length of a degree of a great circle of the earth, perpendicular to the meridian in latitude 50° 41', was calculated to be 61182.3 English fathoms. The latitude of Dunnofe station, as determined by this operation, has since been verified by a series of accurate observations, made with a capital zenith fector, the last work of the celebrated Ramden, and has been found to err only 3% of a second in defect. See Dunnofe. This method of determining longitudes of stations, by the convergency of meridians, has since been applied to finding the longitudes and latitudes of Black-Down station in Dorsetshire, long. 2° 32' 22.4" W, lat. 51° 41' 14.7" N. of Butterston station in Devonshire, long. 3° 52' 47.5", lat. 50° 24'. 47' 3", and of St. Agnes Beacon in Cornwall, long. 3° 11' 55.7", and lat. 50° 18' 27.9'. Phil. Trans. 1805. But these deductions seem not to have all the pretensions to accuracy, of which the method is susceptible, for want of inaugural observations; the three last stations being so chosen as to be all visible from each other: and although the first of them is visible from Dunnofe, that station was not visited again, for the purpose of completing the observations; but one of the angles of this, and both the angles of the other two polar triangles, were made to depend on those of the intermediate chains of triangles. It is with the utmost regret that we observe any opportunities omitted of submitting this grand trigonometrical survey to all the possible tests of its accuracy, or of collecting and recording observations, likely to be of future use in drawing conclusions relative to the anomalies in the figure of the earth. The writer of this, from having affitied in the making of some hundreds of observations with the admirable theodolites, which are in the hands of major William Mudge, and his able affiliates employed on the trigonometrical survey, and from having been a witnes to the great skill and pains with which they are always used by their gentlemen, and from having twice applied his multiplied observations in accurately calculating the situation of many different objects, by series of 4 or 5, and in some cases 10 or 12, independent triangles, is enabled to assert, that an extreme degree of accuracy in the distances and horizontal angles may be obtained in this survey, perhaps unparalleled in any familiar undertaking. He lauds, therefore, that Ramden's fine zenith sector (described Phil. Trans. 1803) should, during any favourable season of the year, lie idle in the Tower, instead of being employed in determining the actual latitudes, and, with a theodolite, making pole-star observations, for obtaining the correct azimuths of all the many principal
principal stations, whose horizontal bearings and distances have been very accurately &tit in this suv.'y; which does equal honour to the government that patronizes it, and to the gentlemen by whom it is conducted.

CONVERGING CURVES. See Curve.

CONVERGING, OF CONVERGENT Lines, in Geometry, are those which continually approximate, or whose distance becomes continually less and less; in opposition to divergent lines, whose distance becomes continually greater. Lines that converge one way, diverge the other.

CONVERGING Rays, in Optics, are those rays which in their passage out of one medium into another, of a different density, are refracted towards one another; so that, if far enough continued, they will meet in a point, or focus.

All convex lenses make the rays converge, and concave ones diverge, i.e. the one inflects them towards a centre, and the other deflects them from it; and the more, as such lenses are portions of smaller spheres. On which properties, all the effects of lenses, microscopes, telescopes, &c. depend.

Ray coming converging out of a denser medium into a rarer, become more convergent, and concur sooner than if they were to continue their motion through the first. Rays coming converging out of a rarer into a denser medium, converge less, and concur later, than if they had continued their motion through the first medium.

Parallel rays, passing from a denser into a rarer medium, v.g. from glafs into air, the surface of the glafs being towards the air, will become convergent, and concur in a focus.

Diverging rays, or rays coming from a point, under the same circumstances, become converging, and meet in a focus; and as the radiant point comes nearer, the focus recedes farther off; if the radiant be near, the focus will be infinitely distant; i.e. the rays will be parallel: and if the point be brought nearer still, the rays will diverge.

CONVERGING SERIES, in Mathematics. See Series.

CONVERSANO, in Geography, a town of Italy, in the kingdom of Naples, and province of Bari; the seat of a bishop, suffragan of Bari; 15 miles E.S.E. of it.

CONVERSATION, DISCOURSE; these two words denote an interchange between two, or among more persons: with this distinction, that the conversation is used for any general intercourse of sentiments whatever; whereas a discourse means a conversation limited to some particular subject. Thus we say, a conversable man; meaning a man able to converse on a variety of subjects, or a man of general knowledge; but we do not say a discoursable man. The word discourse is generally used when we mention a superior talking to an inferior.

CONVERSATION Point, in Geography, a head-land on the south side of a bay on the coast of California. N. lat. 32° 30'. W. long. 119°.

CONVERSATIONS, denote evening assemblies held at Rome, where persons of both sexes met, not for instructive or even amusing conversation, but in order to fee and pay transient compliments to one another; and where a person may enjoy the happiness of being squeezed and pressed among the ballet company in the city. Several of these take place in the same evening, and they are formed by the passing visits of the same persons, who thus seek amusement by a mere change of place and company. These assemblies generally break up about 9 o'clock; a small party expected, who are invited to supper. They resemble our modern routs. Moore's View of Society, &c. in Italy, vol. i. p. 337. &c.

CONVERSE, in Geometry, &c. A proposition is said to be the converse of another, when, after drawing a conclusion from something first supposed, we proceed to suppose what had been before concluded, and to draw from it what had been supposed. Thus, it is demonstrated in geometry, that if the two sides of a triangle be equal, the two angles opposite to those sides are equal also; the converse of the proposition is, that if the two angles of a triangle be equal, the two sides opposite to those angles are equal also.

CONVERSE Direction, in Astrology, is used in opposition to direct direction, i.e. by the latter, the promoter is carried to the significator, according to the order of the signs: but by the former it is carried from exalt to woe, contrary to the order of the signs.

CONVERSERO, in Geography, an island of the Adriatic, near the coast of Illyria. N. lat. 45° 20'. E. long. 15° 44'.

CONVERSION, in a Moral Sense, a return from evil to good; resulting from a change, either of the natural de
eformity of the one, and amissableness of the other; or of the advantages and disadvantages that spring from the one and the other, respectively.

Or, it is the change of the heart, with regard to the morals, passions, desires, and pursuits; and of the mind, with regard to the sentiments, &c. See REGENERATION. For an account of the conversion of St. Paul, considered as an argument for the truth of Christianity, see PAUL.

CONVERSION, in Law, is where a person having the goods of another in his possession, converts them to his own use, without consent of the owner; for which the proprietor may maintain an action of trover and conversion against him.

This action of trover and conversion was, in its original, an action of trustpafs upon the want, and a recovery of dammages against the offender, from which it derived its name. Refusal to restore goods is, prima facie, sufficient evidence of a conversion, though it does not amount to a conversion. See TRoVER.

CONVERSION, Converfo, in Logic, a circumstance or affection of propositions, wherein the order of the terms, or extremes, is changed; so that the subject enters into the place of the predicate, and the predicate into that of the subject; without any alteration in the quality of either.

As, "No virtue is vice;" we may derive "No vice is virtue;" in which we see the subject of the former, made the predicate of the latter, and the predicate subject; yet both true.

Conversion is usually defined a due change of the order of the extremes, i.e. under such a habitude and coherence with respect to each other, that the one is rightly inferred from the other.

Hence, in every legitimate conversion, two things are required: 1. A communication, or reciprocation of terms; not in respect of words, but of order. 2. The inference of one proposition to the other.

Aristotle makes two kinds of conversion; the one simple, by others called universal; wherein nothing is changed beside the order of the extremes, i.e. the terms are transposed, without altering either the quality or quantity thereof: as, "No mind is body; No body is mind."

The second, per accidentu, called also particular; wherein, beside changing the places of the terms, there is a change of an universal sign into a particular one; as, "Every good man fludies the wefare of his country; some man that fludies the welfare of his country is good."

To these, some of A's followers add a third kind of conversion, called by contraposition; as, "Every man is an animal; every no-animal is no-man."
CONVERSION.

Conversion, in Rhetoric, &c. is understood of arguments which are returned, retorted, and shown on opposite sides, by changing the subject into the attribute, and the attribute into the subject.

There are conversions of arguments, from one figure to another, and also from general propositions to particular ones. Thus Cicero against Antony: "Doletis tres exercitus P. R. Interfectos? Interfect Antonius. Devidere clarissimos vivos? Et quos obvibus vivere Antonius. Authoritas hujus ordinis affixa est? Affixit Antonius."

Conversion, in War, denotes a military movement or manoeuvre, which turns the front of a battle, where the right or left flank was, when either flank is attacked.

Conversion of Diseases. A disease is said to be converted, when new symptoms arise in its progress, which require a different designation, and which either put a period to the original disorder, or, combining with it, alter the physician’s views respecting the proprieties, or the method of cure. Many instances of this kind are familiar; as the conversion of intermittent diseases into continued fevers, or obstructions of the viceria; of hemoptysis into phthisis; of jaundice into dropsy, and the like. Others are more unusual, and unexpected, and deserve to be noticed, because they occasion much perplexity in practice, when they occur, and especially as this subject has been much overlooked by medical writers.

We owe the first observation on the subject of conversion, to Hippocrates, and his annotators. Hoffmann has curiously touched on it, in his short dissertation de morborum transmutatione. Baglioli, though very cautious that it should be treated at length, and though liberal in promises of assistance, confines his recital of facts in a great measure to those of Hippocrates. An express treatise was written on the subject by Rodericus a Calefor, under the quaint title of Que ex Quibus, a work better conceived than executed. And an excellent essay was more recently published by Dr. Ferrar, of Manchester, in the 2d vol. of his "Medical Histories and Reflections," in which the substance of this article will be found.

This subject was formerly arranged under two divisions: when the original disease subsisted after the accession of the second, it was termed a case of epigenesis, or propagation; when the second disease put a period to the first, it was called an instance of metamorphosis, metaplasia, or transformation. But this is a loose distinction, which excludes many cases of conversion. The chief difference between the metamorphosis and epigenesis is, that the relation of the successive morbid appearances, and their dependence upon each other, cannot be so clearly perceived in one case as in the other. It would have been more useful, to have distinguished conversions by their influence on the event of the disease; Some are dangerous, and generally fatal; others, while they terminate the original disorder, conduct to a more speedy restoration of health. Thus, when a continued fever supervenes to pulmonary inflammation, the patient is in great danger, it is gravis malo grava noum accedere; when a diarrheæ supervenes to continued fever, in certain stages, it terminates the fever earlier than the regular course of the disease could have done.

All cases of conversion may perhaps be conveniently referred to the following heads. 1. The supervening disease may be produced by the remote causes of the original disorder: in this case, the action of those causes, after producing its first effect, is prolonged so as to excite a new train of symptoms. 2. The supervening disease may arise from the excess or combination of the symptoms of the original complaint. 3. The state of the habit, produced by the first disease, may give rise to a new disorder. 4. Conversion may happen, from the imprudent suppression of habitual diseases.

1. The application of certain remote causes, may be sufficiently powerful to produce a fresh disease, after the first has been brought on by their action. It is common to find pulmonary inflammation supervene to typhus, by a continuation of the application of cold or dampness, which operate as a remote cause of the fever. On the contrary, from the tendency of the system to inflammation, or from the manner in which cold has been applied, the pulmonary symptoms preceded the fever in some cases, and even run their course, before the fever assumes a regular form. In a fatal case of the conversion of pleurisy into typhus, the left lobe of the lung was destroyed by suppuration. (Luetaud. Hist. Nat. Med. tom. i. Obs. 378.) I have seen, says, Dr. Ferrar, a case of peripneumonia notha end in typhus, and the typhus in mania. He also relates, chiefly from his own observation, the conversion of acute rheumatism into typhus in the first week, a circumstance which we have also witnessed—the conversion of the mild febrifus, or typhus, into inflammation of the pelvis, or villous cost of the limbs;—of erysipelas into typhus;—of dysentery and diarrhœa into continued fever;—of hysteria into epilepsy and insanity, &c.; changes which are not very frequent.

Causes of hysteric convulsions, which belong to the head, are very common sources of error to young practitioners, and sometimes deceive even the most experienced. Sydenham long ago enumerated an ample catalogue of the diseases, the symptoms of which the maniac, hysteria, frequently affixes. This matterly essay, with which Dr. Ferrar appears to have been unacquainted, contains a full disclosure of the conversions of this disorder. The symptoms of apoplexy, paralysis, epilepsy, cough, the ipecac passion, jaundice, stone in the kidneys, and in the bladder, vomiting, diarrhœa, rheumatism, lumbago, &c. have been terminated by the accession of a complete hysteric paroxysm. (See Hystéria.) "We are ignorant," says Dr. Ferrar, who has described a similar variety of hysteric convulsions, "by what laws the body poifilles a power of representing the most hazardous disorders, without incurring danger; of counterfeiting the greatest derangement in the system, without materially altering its movements; of producing madness, confusions of its extravagancies, and of increasing the acuteness of sensation, oppressing the common fenfory. In hysteric affections, all these appearances are excited, which are incompatible with the realitions of every syphilist-maker, who has yet endeavoured to explain the inexplicable. Nature, as if in ridicule of the attempts to unmask her, has, in this class of diseases, reconciled contradictions, and realized impossibilities, with a mysterious veracity, which inspires the true philosopher with diffusion, and reduces the syllymatic to despair."

II. The symptoms of an idiopathic disease may, by their violence, affume the appearance, and require the attention due to a new complaint; or affections of particular viscera, which, in their incipient state, are only regarded as symptoms of general indisposition, may, as they gain ground, extinguish the original disease, or be prostrated beyond it. This head comprehends such a variety of cases, that to treat it fully, would be to give the history of all symptomatic diseases. A few illustrations will suffice.

Dr. Percival mentions, that he had seen an effusion into the cavities of the brain, produced by the succusions of coughing, in a confirmed pulmonary consumption, which effusion terminated fatally, with a previous suffocation, more than a week before death, of all the pulmonic symptoms.
CONVERSION.

It is one of the most perplexing occurrences in medicine, when the supervening disease is produced by a symptom of some latent complaint: when, for example, phthisical symptoms arise in a febrile or gouty patient, who exhibits, at first, no other appearance of those two diseases. Dr. Ferrar saw an instance, in which all the characters of confirmed phthisis pulmonalis were present, that terminated in recovery, upon the patient's coughing up some solid particles, which, upon examination, proved to be chalk-flakes. Dr. Percival relates, that a gentleman of rank was supposed to be in an advanced state, of what is called a galloping consumption, having an incessant cough, an expectoration apparently purulent, continued heats, and night sweats: yet his cure was accomplished by giving wine-and-cream copiously, and by administering doses of histhorn and specia. A gentle fit of the got was produced by this cordial regimen. The fever, cough, and spitting, were progressively diminished, and the health of the patient was soon perfectly re-established.

There is, indeed, a strong resemblance between hysteria and gout, in the power of counterfeiting different diseases, but with this material distinction; that the hysterical representations are commonly void of danger, while those produced by gout are often more dangerous than the simple disorder which they imitate. The hysterical hemoptysis, for example, is seldom productive of bad conseqences, but the arthritic apoplexy, pneumonia, and cardialgia, are much more alarming, and run their course quicker than similar complaints originating from other causes. But these diseases agree in this respect, that the accession of the regular paroxysm puts a favourable period to the irregular symptoms.

The prognostics, in conversions of this second class, must evidently vary according to the fact and degree of the supervening disease, and its favourable action upon the original disorder.

III. The original disease, if acute, when it has run its usual course, may leave the habit in a fertile situation to the production of another disease: or if the original be a chronic disease, such a state of the habit may take place during its continuance, and the accretion disease may be simply superadded, or it may vary the form, or affect the duration of the former.

Continued fevers are converted into different diseases, the production of which admits one general explanation. During the increased action of the circulating system, if any part of the body be originally weak, or have been rendered infirm and irritable by preceding disease, congestion, and its consequences, may be expected there. It is therefore easy to conceive, why one patient should suffer a paralytic affection, another phthisis, or a third nephritis, in consequence of tenacious cafes of phthis. The glaudiar suppurations, consequent on fevers, seem to depend on the same principle; for although they are represented as critical, by the older medical writers, we sometimes see striking proofs of the contrary. The exanthemata are frequently converted into ulcers, which become both chronic and dangerous. The small-pox often produces severe coughs, diarrhoea, and opthalmia. In some rare instances, tumours of the joints supervene, which suppurate and destroy the patient. The pneumatic inflammation attending the measles, is too often converted into phthisis pulmonalis. Glandular swellings, and general dropsy, frequently succeed the scarlatina anginosa. There is a curious case in Dr. Percival's Essays, Medical and Experimental, vol. i. p. 148, of a woman, in whom a conversion of fever took place, first into palsy, afterwards into epilepsy, and then into amaurosis. Fevers often terminate in hysterical disorders, especially in women. Nephritis also is a common conversion of fever; it seldom supervenes with considerable violence, excepting in persons who have formerly undergone it; but when it has been familiar to the patient, a very large quantity of gravel is commonly passed, with extraordinary pain in the state of conversion. The accession of nephritis always extinguishes the fever. Other conversions of fever have been noticed, some of them peculiar to certain epidemics.

Various instances of conversion of diseases, under this head, may be found in the writings of physicians. Jaundice is said, by Baglivi, to be converted to typhomacent; typhomacent, by Dr. Ferrar, to diarrhoea and scrophula; dyspeptic complaints of long standing, to general dropsy; seizes to chronic inflammation of the bowels, and diarrhœa, which generally prove fatal; mania, as observed by Dr. Mead, to fatal epilepsy; and also to a cutaneous eruption, with recovery; &c. &c.

IV. Conversions may arise, when a disease, regular in its usual course, or long familiar to the habit, is violently terminated by improper methods, or suddenly extinguished by accidental circumstances.

Thus epileptic fits have been produced by the retroception of the itch, in consequence of some external application; the epilepsy having refited all the usual methods of treatment, was only cured by producing the itch. Instances of the production of melancholy and madness, by the suppresion of eruptions, or the healing of old ulcers, and habitual drains, are common in practical writers.

The diseases originating from the suppression of the menstrual and humoral discharges are also well explained in different books. Dr. Hoffman's treatise, De Membra tum Temporisation, relates almost entirely to this class of disorders. Tenedious dyspeptic cafes are often converted to cutaneous eruptions, in distinct pimples, of a bright red colour; such eruptions extinguish the complaint in the stomach. Examples of conversions might be multiplied infinitely: but we must here content ourselves with advertting to the important conclusions, respecting the prognostics and cure of diseases, which may be drawn from an observation of those phenomena. The following most obvious deductions have been pointed out and illustrated by Dr. Ferrar.

1. Whenever local inflammation supervenes to an acute disease, it shortens or extinguishes the original disorder. The danger, or falsity of this conversion, appears to depend greatly on the nature of the part attacked by inflammation. In fever, for instance, if it be a conglomerate or conglomerate gland, the process will be favourable, but if the brain, the pleura, or the peritoneum, be inflamed, the danger is increased. In the former case, the cure of the fever may be in a great measure trusted to the supervening disease; in the latter, the progress of the inflammation will demand our chief attention. Thus, however, contra-indications will be avoided, and the safety of the patient will be better consulted, than by the temporizing practice usually adopted on such occasions.

This deduction serves also to explain the action of bilifers, which, by producing local inflammation, imitate the process, and, in proportion to their action, exhibit the effect of this kind of conversion. It explains also the falsity of the gouty inflammation, when it seizes a part not necessary to life.

3. It is far certain, that medicines operate by producing conversions, that we perceive very considerable differences resulting from the use of certain remedies, such as mercury, and we judge of the extinction of the original complaint, in some measure, by the increase and permanency of the
CON

CON

remedial diseased. Thus when we give diuretics, or cathartics, we
endeavour to excite a disease in the intestines, or kidneys; for an extreme increase of natural action, in any
part, is certainly morbid. In like manner, Dr. Darwin has
observed, that some rearrangements of mind cannot be
removed, without exciting an artificial delirium.

3. The convulsion denominated hysterical, when it seizes
the muscular fibre, in cases of convulsion, is always salutary,
and may be regarded, in many instances, as the crisis of
chronic disorders.

4. Internal inflammation, supervening to chronic diseases,
have a left tendency to extinguish the original complaint,
than a similar formation of acute disorders, and is equally
dangerous.

5. Cutaneous eruptions often extinguish dangerous dis-
eases. Excepting the regular exanthemata, such conver-
sions seldom happen in acute disorders. But madness and
melancholy, epilepsy, delirium, protracted after fever, dys-
pepsia, various pulmonary affections, are all observed to be
mitigated, or removed, on the appearance of cutaneous
diseases; especially on the return of those, which, after
becoming familiar, had been suddenly suppressed.

6. As it appears that many conversions are proc Moments,
constituted by nature for the cure of diseases, and that of
the most active remedies operate in a similar manner, we
may not only improve the history of diseases, but the prac-
tice of medicine, by paying closer attention to the con-
nection and operation of disorders upon each other.

With this view of the subject, the most complicated cases will
admit an instructive development, and every additional fact may find an useful place. See METASTASIS.

Conversion of equations, in Algebra, is when the quantity
sought, or any part thereof, being in fractions, the whole
is reduced to one common denomination; and then,
ombitting the denominators, the equation is continued in the
numerators only.

Thus, suppose \( a-b = \frac{a+b}{d} \); multiply all by \( d \),
and it will stand thus, \( da-db=aa+ce+db+db \).

In arithmetic, we use the term proportion by conversion of
ratio, for a comparison of the antecedent, and consequent, in
two equal ratios.

Thus, as there is the same ratio between two and three,
as between eight and twelve; it is concluded there is the
same ratio between two and one, as between eight and four.

Or, according to Euclid (ib. v. Def. 17.), it is the in-
fERENCE, in the case of four proportions, that the first is to
its excess above the second, as the third is to its excess
above the fourth.

E.G. If we have \( - - - - - - - : 6 : 6 : 4 : 3 \).

Then convertendo, or by conversion, \( 8 : 2 : 4 : 1 \).

Or, if we have \( - - - - : 6 : 6 : 4 : 3 \).

Thus convertendo \( - - - - - - - : a-b : c : c \).

Conversion, Centre of. See CENTRE.

CONVERSOS. See CONVERT.

CONVET, a person who has undergone Conver-
sion.

CONVERT is chiefly used in respect of changes from one
religion, or religious sect, to another.

Converts with relation to the religion turned to, are
denominated apostates with regard to that they have relin-
quished.

The Jews, formerly converted to Christianity in England,
were called conversos. Henry III. built them a house in
London, and allowed them a competent subsistence for their
lives; which house was called domus convertorum. But the
number afterwards increasing, they became a burthen to the
crown upon which they were distributed among the
monasteries: and after the expulsion of the Jews under
Edward III. the domus conversorum was given for keeping
of the rolls.

CONVERTS, in a Monastic Sense, are lay-friars, or brothers,
admitted for the service of the house; without orders, and
not allowed to sing in the choir.

Till the eleventh century, the word was used for persons
who embraced the monastic life at the age of discretion; by
which they were distinguished from those devoted in their
childhood by their parents, called aliens.

But in the eleventh century, when they began to receive
into monasteries illustrious persons, incapable of being clerks,
and only destined for bodily labour; the signification of the
word was necessarily changed. F. Mabillon observes, that it
was John, first abbot of Vallombrosa, who first introduced
these brother-converts, distinguished by their right from the
monks of the choir, who were then either clerks, or capable of
becoming so.

CONVERTIBILITY of elements into one another. See ELEMENTS.

CONVERTIBILITY of spirits into one another. See SPI-
RITU AL

CONVERTIBLE Husbaniry, in Agriculture, is that
fort of farm-management in which the land is cultivated,
under the alternate systems of tillage and grafs.

The lands which are the most proper for this kind of
husbandry are those in which the soil is of the more dry and
frangible description, and in which there is a disposition
to take on or produce grafs. Wet clayey soils are confidered by
Mr. Davis as wholly unfit for this fort of management. All
the loamy forts of land which are capable of producing good
turnips, and the rich sandy soils, are particularly fitted to
this method of husbandry. And on many other varieties of
land it may be had recourse to with considerable benefit and
advantage, where proper care is taken in the cultivation;
but it is unquestionably a mode of culture which flands in
need of great attention, in order to conduct it in the most
proper and beneficial manner, both for the land and the
farmer.

It has however been observed by Mr. Nairmirth, in his
"Elements of Agriculture," that "though it is possible
to make drill culture universal, and cultivate the whole
country like a garden, it is doubtful if it would be provi-
dent." It is to be feared that it would be something like the
conduct of a person who consumes part of his capital yearly,
along with his annual revenue. Whatever may be said to
the contrary, all soils certainly suffer some degree of deterio-
ratiou by long, unremitted tillage. When divested of that
cloting with which nature always defends it if undisturbed,
and when turned up naked to abide the force of the blight,
the happy medium of confluence is deranged, its heat par-
ticles carried away in torrents; and it is left a feebly skeleton,
poisoning only the faint semblance of departed fertility. This
is strongly exemplified, he says, in the once fertile island of Bar-
badoes, in the West Indies. It has been said that this island,
no doubt somewhat hyperbolically, since it began to be
cultivated by the Europeans, has loaded more wivels with
produce than would have been sufficient to have carried
away the whole island; and now, it is reported, that the
soil is so exhausted, that no kind of culture or manure can
restore its fertility. We have correspondent accounts from
the county of Norfolk, and other districts, where unceasing
tillage has been practised; the species of crop which has been
most run upon is now less productive than formerly. In short,
there are numerous inuiances within the personal knowledge
of many, that wherever the ground has been long dunged and laboured for cropping, without rest, though the crops may be as bulky, they are generally less productive than they were at an earlier period.

Converted husbandry, or regular alternations of tillage crops and pastures, seem therefore, he says, to be the only system by which the fertility of the country can be preserved and improved. The provisions of a country are not derived from tillage crops alone. A considerable proportion is obtained from the dairy and the flocks. Contrails have been made to show the vast disproportion between the quantity of food obtained from any given extent of land in a cultivated crop, and what the same extent of pasture yields. But it should be remembered, that the fertility of a cultivated field is often acquired by its having lain in pasture. The quantity of food from cultivated crops is not always in proportion to the extent of the land cultivated. The county of Ayr, in the west of Scotland, contains, he says, a great deal of good soil. It is not much more than forty years since he remembers the inhabitants of that county palling in crowds with hares, pack-faddles, and empty bags, to the East, to bring pease and barley, of which they made a kind of bread to serve them in summer. At that time the farmers were under no restraint as to the proportion of their farms, which they might have in tillage. Soon after, a gentleman who had the management of a great estate in that county, made a regulation in the leaves, by which the farmers were bound to have never more than a third of their farms in tillage. Other proprietors adopting the same regulations, it became general: and the farmers were afterwards restricted to plough no more than one fourth. Of late, this country, though not less populous than formerly, sends always a great deal of grain to the neighbouring districts; and instead of empty bags and pack-faddles, sends carriages loaded with cheece to Leith, to be shipped for London. Thus by laying land which has been in tillage, frequently in pasture, the future fertility of the country is enhanced, and its present produce is not diminished.

But it has been stated, he remarks, from high authority, that there is nothing more difficult than to bring old tillage lands to produce good pasture. A person who has been in the habit of attending to the culture of the fields, will have some difficulty in comprehending this position. He will have observed, that when the seeds of any of the grasses are permitted to vegetate on land which has been long under tillage culture, they grow with remarkable luxuriance, if they be not overwhelmed by the growth of weeds in their infancy. If his experience has been of a long standing, he will remember the introduction of clover and rye-grass into this country, and will recollect that the first time these seeds were sown on old tillage lands, the crops of grasses were generally more weighty than any that have succeeded on the same ground. Having found such grounds so much disposed to produce grasses, he will be at a loss to conceive why they should not produce good pasture. As grasses feeds vegetation belt on ground which is of a pretty solid condition, they will sometimes fail, when the texture is too loose, unless that fault has been remedied by early ploughing, or by sufficient rolling, or both. But the belt native grassina (grasses), having an of a great bulk, extending horizontally, are not easily ejected, after they have gained strength, and become unfruitful. In the impulses which have given rise to the above position, the ground must not, he thinks, have been stocked with those perennial plants proper to compose a good pasture. In a long course of tillage, the seeds and roots of the native grasses are worn out and banished: the plants introduced from artificial hay frequently fail in a few years; and the ground is left naked, or stocked only with such coarse weeds as have kept footing in the ground, or had their seeds carried there by winds and birds. But to make tillage grounds bear lasting pasture, they should be stocked with the seeds of such indigenous perennial plants as are known to be adapted to that purpose.

The chief of which are, he says, anthus sobolius, lomum perenne, and alopecurus pratensis, for spring pasture, to be followed by cyphurus crypatus, poa trivialis, &c. The leguminous plants for fall pasture, he adds, are of the genus trifolium, the pratensis, the repens, the lupinum, and the prolum; of the genus ximia, the ericaa and fesum, the laffthys pratensis, &c. If lands which have been long in tillage are stocked with the seeds of the herb, and care taken not to suffer the young plants to be overwhelmed by rank weeds before they get themselves established in the ground, all difficulties will be overcome, and such grounds will be found to yield the most substantial and unfailing pasture.

As all vegetables are composed of the same elements, and nourished by the same kind of juices, it may appear somewhat unphilosophical, in a speculative view, to maintain that the fertility of the soil is preserved by cultivating one species of plants upon it one year, or series of years, and plants of a different species and quality the following.

But it is a generally received aphorism, he observes, that nature delights in variety; and this aphorism is supported by experience in this as well as in other respects. Some kinds of vegetables extend their roots near the surface, others penetrate deeper into the soil, some by overshadowing the earth with their broad leaves render it fruitful and mellow; others, whose naked stalks admit the free circulation of the air, consolidate the soil; some derive the greatest part of their nourishment from the juices lodged in the earth; others draw a considerable proportion from the atmosphere; some, having a longer period of existence, continue long to demand nourishment; others arrive more quickly at maturity, and must be easier supported. Besides, among the various tribes of insecta so feeble in themselves, but to formidable and destructive by their numbers, each has some vegetables which it prefers to others for its food, and refrains to the places where such food is produced; and as they propagate their kind, where their food is found, they must become more numerous, and consequently more destructive, where the cultivation of the same plant is often repeated. There are weeds too, he fears, which bear in this respect some analogy to those insects, and as they cannot be at all times fully eradicated, propagate the more, the oftener they meet with the crop most agreeable to them. By the effects which the growth of different vegetables produce on the soil, the proper medium of confidence is in some measure preserved, the vegetable food better harnessed, and the injuries from noxious insects and weeds somewhat eluded. On all these accounts, the maxim of modern agriculturists, that crops of a different nature and quality should succeed one another, is justified.

But the arguments in favour of alternations of tillage and pasture, are, he remarks, still more urgent. The derangement of that happy medium between extremes of too great friability and compactness, which has endeavoured to shew is essential to the general purposes of vegetation, is the unavoidable consequence of long repeated tillage.

This is always, he contends, in some degree restored, when land is left to rest. If it has been properly treated when in tillage, and well stocked with perennial herbage, when left to rest, it will quickly assume a close cover over its surface, which, from whatever principle it proceeds, experience has always shewn, has a powerful influence in dispersing the foil to fertility. In this state, the waiting to which til-
arget lands are exposed in times of rain; is, he supposes, completely suspended, and the water flows away limpid. While the ground continues covered with a close turf, the root-leaves of the herbage spreading over the surface, absorb and digest the carboic acid of the atmosphere, and, perhaps, also, earthy particles which probably float continually in the air, as before stated. As those leaves are imberced and decay, they are perpetually increasing the bulk of carbon and vegetable mould. The celebrated Mr. Kirwan, indeed, he says, of a different opinion. He supposes, that ground lying in pasture is annually diminishing in fertility, though in a less degree than that from which a vegetable crop is carried off, because a part is restored in the excrements of pasturing animals. But though poor soils which are incapable of producing a close turf over their surface, gain little by lying at rest, it is evident, that every foil, which either from its natural conformation, or from the improvements made on it by proper culture, has attained a close cover of sweet herbage, is perpetually gaining. Whenever the temperature is mild, a continual reproduction is taking place; and all the horizontal foliage, which escapes the mouths of pasturing animals, falls into decay and accumulates on the surface. On breaking up such old pastures a surfaced stratum may be observed, differing in colour and conformation from that which lies under it, the thickness of which is in proportion to the time the ground has lain at rest. What is here stated, is, he thinks, corroborated by the following experiment. Having sometimes observed a kind of turf formed over the hardest stones in certain situations, he collected some of which had grown to more than an inch thick on some flat foles, lying at a damp place, at the foot of a northerly declivity under some trees. It seemed to have commenced with the growth of some of the smaller muflci and algae. On this ground the fucula onha and pea glanca had taken root, and formed a strong turf. After it was dried, he subjected a pound of it to combustion on an iron shovell over a fire till it was reduced to black dust. The residue weighed half an ounce, whereas the greatest residue he ever obtained from a pound of dried peat burnt, was not more than five drams. If such a quantity of mould could thus be accumulated by the grasses growing on a naked rock, may it not accumulate at least in as great a proportion on the foil where the succession of growth is incomparably greater?

It is true, he observes, that some foils by long lying at rest, conduce so much as to incommode the roots of the grasses, and on others the moles prevailed so much as to overcome the effulent herbage, but the fertility of the foil is not thereby diminished. Its present energy is only suspended, while it is acquiring additional vigour for future exertions. When such land is again employed in tillage, the spoils of the turf, together with a great part of what has been consumed by pasturing animals refored in excrements, are turned down and mixed with the foil, by which its conformation is improved, and its thickness and principle of fertility augmented. Hence the tillage crops are plentiful—the cars large and plump—and the produce of one year equal to two or more on land weared out by perpetual turning.

"It must not be overlooked, by what is here or formerly said, that he means to undervalue the operation of the plough. But, as we are studying in what manner the fertility of the country may be preferred and improved, and the greatest quantity of disposable produce obtained at the least possible expense, it is necessary to examine how all these aids which nature offers may be made to co-operate with the artificial means of agricultural improvement, and not blindly expect from mechanical labour, more than it can possibly produce. When barren foils are to be brought from a wild state, it is by mechanical labours only that their obnivousness can be subdued, and the different ingredients properly blended. The turf of old grass ground will frequently require a good deal of mechanical operation to mix it with the earths, and facilitate its putrefaction. But when these, and such other aids as mechanical labour is adapted to accomplish, are obtained, that medium of confidence on which fertility depends will be best preserved by alternate successions of labour and reft. The proportion and order of those successions must no doubt vary greatly according to circumstances. While those where the foil is deep and of the most favourable conformation, and where adventitious manure is attainable, may be much occupied in tillage crops, without fubliming great deterioration; in the more elevated grounds, where the foil is generally less happily conformed, exposed to fewer washings and manure less abundant, a greater proportion of the farm ought always to be in pasture. But in all situations and circumstances, the foil will be benefited by being occasionally at rest, provided care has been taken to lay it down unexhausted, free of weeds, and well flooked with proper grasses. By this system of alternations of tillage and grasses crops, the attention of the husbandman is less dissipated, and his labours more regularly distributed. The live stock fed on his pasture, furnish him with manure to enrich his tillage fields, and the more they are enriched, they are the better fitted to yield an abundant return of grasses, when they come in course to be laid to reft. When ground is brought to yield abundance of sweet grasses it is profitable in pasture, and while it continues so it is still improving in fertility, and becomes more and more adapted to yield plentiful tillage crops. Thus under good management, the fertility of the country may progresively advance, and the disposable quantity of provisions for the use of the consumer, and the net return to the husbandman, perhaps, exceed what the operative and expensive system of perpetual following, and crops without rest, could produce.

"Convertible husbandry is not less superior to perpetual grass. Land which lies perpetually in grass, is deprived of the advantage of having the vegetable substance accumulating on the surface from time to time mixed into the foil. By the working of moles, ants, and other vermin, by the condensation of the foil, by the prevalence of moles and useless weeds, the turf is deformed and the reproduction of sweet pasture diminished. Water is frequently detained on the surface, and chills the growth of excellent herbage, and thus the growth becomes more feeble and slow. In proportion to the decay of excellent herbage, plants which are noxious or unprofitable prevail; the pasture becomes gradually less, and the fertility of the foil is almost useless to the owner and to society, while it remains in that state."

The practice of this husbandry must of course in many instances be highly preferable to the cultivator. See Tillage and Grass.

CONVEX, bending down on every side, as the outside of a globular body.

Convex freezes, leaf, lan, mirror, supertices. See the several subtilitantes.

CONVEXITY, the exterior surface of a convex, i.e. gibbous and globular thing; in opposition to concavity, or the inner surface, when hollow or depressed.

The word is of particular import in catoptrics, and dioptrics; where it is applied to mirrors and lentes; which see. See also Refraction.

CONVEYANCE, in Law, a deed, or instrument, by which lands, &c. are conveyed, or transferred, by the proprietor to some other person. In the diffusion of this subject, it is proper to inquire who may thus alienate and to whom a man may alienate, or the several modes of
of conveyance. With regard to the first inquiry, who is capable of conveying and who of purchasing, the subject of consideration is rather the incapacity, than the capacity, of the several parties; for all persons in possession are prima facie capable both of conveying and purchasing, unless the law hath laid them under any particular dis-
abilities. But if a man has only in him the right of either possession or property, he cannot convey it to any other, left pretended titles might be granted to great men, by which title might be trodden down, and the weak op-
preffed. (Co. Litt. 214.) Yet revocations and vested re-
mainders may be granted, because the possession of the par-
ticular tenant is the possession of him in reversion or re-
mainder; but contingencies, and mere possibilities, though they may be released, or devised by will, or may pass to the heir or executor, cannot be assigned to a stranger, unless cou-
pled with some present interest. (Sheppard's Touchstone, 258, 259, 322. 11 Mod. 152. 1 P. Wms. 574. Str. 132.)

Perfons attainted of treason, felony, and praemunire, are incapable of conveying; from the time of the offence com-
mited, provided attainted follows, for such conveyance by 
them may tend to defeat the king of his forfeiture, or the 
lord of his ecchatch. But they may purchase for the bene-
fit of the crown, or the lord of the fee, though they are dis-
able to hold the lands so purchased, if after attainer, be-
ing subject to immediate forfeiture; if before, to a lease as well as forfeiture, according to the nature of the crime. 
(Co. Litt. 42, 2.) Thus also corporations, religious or 
others, may purchase lands: yet, unless they have a licence 
to hold in mortmain, they cannot retain such purcahse; but 
shall be forfeited to the lord of the fee. Idiots and per-
sons of non-fame memory, infants, and persons under du-
refs, are not totally disabled either to convey or purchase, 
but, ful modo only. For their conveyances and purchases are 
voidable, but not actually void. The king indeed, on 
behalf of an idiot, may avoid his grants or other acts. 
(Co. Litt. 247.) See Idiot. A feme-covert may purchase an 
eflate without the consent of her husband, and the convey-
ance is good during the coverture, till he avoids it by some 
act declaring his dissent. And though he does nothing to 
avoid it, or even if he actually consents, the feme-covert her-
self may, after the death of her husband, waive or disagree 
to the same; may, even her heirs may waive it after her, if 
she dies before her husband, or if in her widowhood the doe 
nothing to express her consent or agreement. (Co. Litt. 3.)

But the conveyance or other contract of a feme-covert (ex-
cept by some matter of record) is absolutely void, and not 
merely voidable (Perkins, § 154, 1 Sid. 1200; and there-
fore cannot be affirmed or made good by any subsequent 
agreement. The sale of an alien boll is also peculiar. — For 
his may purchase any thing; but after purchase he can hold 
nothing, except a lease for years of a house for convenience of 
merchandise, if he be an alien-friend: all other pur-
chases (when found by an inquest of office) being immedi-
ately forfeited to the king (Co. Litt. 2). Papists, and per-
fons professing the popish religion, and neglecting to take 
the oath prescribed by statute 18 Geo. III. c. 60. within 
the time limited for that purpose, are by lat. 11 and 12 
W. III. c. 4. disabled from purchasing any lands, rents, or 
hereditaments; and all estates made to their use, or in trust 
for them, are void. (1 P. Wms. 354.)

In answer to the second inquiry, or how a man may alien 
or convey, we are to ficate the several modes of convey-
ances. A translation, or transfer, of property being ad-
mitted by law, it became necessary that this transfer should 
be properly evidenced, in order to prevent disputes as to the 

fact, or in relation to the persons concerned, or with regard 
to the subject-matter, or with respect to the mode and quan-
tity of the transfer. The legal evidences of this translation 
of property are called the common assurances of the kingdom. 
See Common Assurances.

Deeds (see Deed) which form the property 
of lands and tenements from man to man, are commonly de-
nominated conveyances; and those are either conveyances at 
common law, or such as receive their force and efficacy by 
virtue of the statute of uses. Of conveyances by the com-
mon law, some may be called original or primary conveyances; 
which are those by means of which the benefit or estate is 
created or first arises; and others are derivative or secondary, 
by which the benefit or estate, originally created, is en-
larged, restrained, transferred, or extinguished. Original 
conveyances are the following, viz. Feoffment, Gift, Grant, 
Leaves, Exchange, and Partition; which deed respectively. 
Derivative conveyances are kelode, Confirmation, Surrender, 
Assignment, and Defeasance; which deed under their proper 
titles. For other conveyances, which have their force and 
operation by virtue of the statute of uses, which have been 
derived from it or introduced in consequence of it; see Uses. 
See also Covenant to Stand Seized to Uses, Bargain and 
Sale, Lease and Release, and Revocation of Uses.

A conveyance cannot be fraudulent in part, and good as 
to the rest: for if it be fraudulent and void in part, it is 
void in all; and it cannot be divided. 1 Litt. Abr. 311. 
Fraudulent conveyances to deceive creditors, defraud pur-
chasers, &c. are void, by statutes 15 Eliz. c. 5. 27 Eliz. 
c. 4. See Fraud.

CONVICT, in Common Law, one who is found guilty 
of an offence, by the verdict of a jury. This conviction 
may accrue two ways; either by his confessing the offence 
and pleading guilty; or by his being found so by the verdict 
of his country. Judge Blackstone says, that in the Roman 
republic, when the prisoner was convicted of any capital 
offence by his judges, the form of pronouncing that 
conviction was peculiarly delicate, not that he was guilty, 
but that he had not been sufficiently on his guard, "parum 
cavile videtur."

According to Crompton, a person is also a convict, or 
faii to be convicted, when, after having been outlawed, he 
appears and confesses, or is found guilty by the inquest; 
and he says, moreover, that when a statute excludes from 
clergy persons found guilty of felony, &c. it extends to 
those who are convicted by confession. (Cromp. Int. 9.)

The law implies that there must be a conviction before 
punishment, though it is not so mentioned in a statute; and 
where any statute makes a second offence felony, or subject 
to a heavier punishment than the first, it is always implied 
that such second offence ought to be committed after a con-
viction for the first. (1 Hawk. P. C. c. 10. § 9. c. 41. § 3.) 
Judgment amounts to conviction; though it doth not follow 
that every one who is convicted is adjudged. A conviction 
at the king's suit may be pleaded to a suit by an informer, 
on a penal statute; because while in force it makes the 
party liable to the forfeiture, and no one ought to be pu-
nified twice for the same offence; but conviction may be 
punished to a new suit by the king. (1 Hawk. P. C. c. 10.) 
A person convicted or attainted of one felony may be pro-
fected for another, to bring accessories to punishment, &c. 
(Fitz. Coron. 379.)

Perfons convicted of felony by verdict, &c. are not to be 
admitted to bail, unless there be some special motive for 
granting it; as where a man is not the same person, &c. for 
bail ought to be before trial, when it stands indifferent 
whether
whether the party be guilty or not. (2 Hawk. P. C. c. 15; § 43, 80.) See Bail. Conviction of felony, and other crimes, disabales a man to be a juror, witnesses, &c. Conviction and attainted, &c. are, in our law-books, frequently confounded. On conviction, (or even upon an acquittal when there is no reasonable ground to prosecute, and, in fact, a bona fide prosecution,) for any grand or petit larceny, or other felony, the reasonable expences of prosecution, and also, if the prosecutor be poor, a compensation for his trouble and losses of time, are by statutes 25 Geo. II. c. 35., and 18 Geo. III. c. 19. to be allowed him out of the county fcoot, if he petitions the judge for that purpose; and by statutes 27 Geo. II. c. 3, explained by the same statute 18 Geo. III. c. 102, all persons, appearing upon recognizance or falsus praemunire, to give evidence, whether any indictment be preferred or not, and as well without conviction as with it, are entitled to be paid their charges, with a farther allowance (if poor) for their trouble and losses of time. Moreover, on a conviction of larceny in particular, the prosecutor shall have retribution of his goods, by virtue of the statute 21 Hen. VIII. c. 11. and the construction of this act having been in great measure conformable to the law of appeals, it has therefore in practice superseded the use of appeals of larceny. It is now usual for the court, upon the conviction of a felon, to order (without any writ of retribution) immediate retribution of such goods as are brought into court to be made to the several prosecutors, or else, without such writ, the party may peaceably retake his goods, wherever he happens to find them, unless a new property be fairly acquired in them. Or, if the felon be convicted and pardoned, or be allowed his clergy, the party robbed may bring his action of trover against him for his goods, and recover a satisfaction in damages. But such action does not lie before prosecution; for then felonies would be made up and healed (1 Hal. P. C. 546); and also reparation is unlawful, if it be done with intention to smother or compound the larceny; it then becoming the heinous offence of theft-sbot; which fee.

When a person is convicted of a misdemeanor which principally and more immediately affects some individual, as a battery, imprisonment, or the like, it is not uncommon for the court to permit the defendant to speak with the prosecutor, before any judgment is pronounced; and if the prosecutor declares himself satisfied, to inflict but a trivial punishment. This is done, to reimburse the prosecutor his expenses, and make him some private amends, without the trouble and circuit of a civil action. This, says judge Blackstone, is a dangerous practice, which, though intruded to the discretion of the judges in the superior courts of record, ought never to be allowed in local or inferior jurisdictions, such as the quarter-sessions; where prosecutions for nuisances are by such means too frequently commenced, rather for private lucre than for the great ends of public justice. Above all, he says, it should never be suffered, where the testimony of the prosecutor himself is necessary to convict the defendant; for there the rules of evidence are entirely subverted; the prosecutor becomes in effect a plaintiff, and yet is suffered to bear witness for himself. Nay, even a voluntary forgivenes, by the party injured, ought not, in true policy, to intercept the stroke of justice. "This," says an elegant writer (Beccaria, ch. 45) who pleads with equal strength for the certainty as for the lenity of punishment, "may be an act of good nature and humanity, but it is contrary to the good of the public. For, although a private citizen may dispense with satisfaction for his private injury, he cannot remove the necessity of public example. The right of punishing belongs not to any one individual in particular, but to the society in general, or the sovereign who represents that society; and a man may renounce his own portion of this right, but he cannot give up that of others." Black. Comm. Book iv.

Convict reconvict, he who has been legally presented, indicted, and convicted, for refusing to come to church to hear the common prayer, according to the statutes 35 Eliz. and 3 Jac. I.

This is commonly understood to be a popish reconvict; though any others who refuse coming to church on the same account are as properly denominated reculants.

CONVICTION, in Law. See Convict.

Conviction, in Theology, expresses the full degree of repentance; wherein the sinner becomes sensible of his guilt, of the evil nature of sin, and of the danger of his own ways.

Conviction, summary, in Law, is such as is directed by several acts of parliament, for inflicting certain penalties created by these acts, without the intervention of a jury: the party accused being acquitted or condemned by the suffrage of such person only, as the statute has appointed to be his judge. Of this kind are all trials of offences contrary to the laws of Excise, and other branches of the Revenue, proceedings before Justices of the peace, and the method used by superior courts of justice for punishing contempt by attachment. See Contempt.

Convivium, banquet, in our Ancient Customs, Law-Books, signifies the same thing among the laity as prosecution among the clergy; viz., when the tenant was obliged, in virtue of his tenure, to provide meat and drink for his lord once, or oftener, in the year.

Convivium militare, a military banquet or repast. The repast of Roman soldiers was a particular object of military discipline, which the commanders themselves paid attention to. The soldiers were not suffered to eat alone but by troops, in order to prefer union and good fellowship amongst them.

Conuli, in Natural History, Conuli Kleini, a clas of the Lechinus, in the Mollusca order of Vermes. See Echinus.

Conulus, a genus of the Trochus, in the Tethysea order of Vermes. See Trochus.

Convocation, a general assembly of the representatives of the clergy of a province, summoned by the king's writ to consult of the more weighty affairs of the church, as oft as a parliament is convened to consult of those of the state.

The king's writ is directed to the archbishop of each province, requiring him to summon all bishops, dean, archdeacon, cathedral and collegiate churches, &c.

Upon which, the archbishop directs his mandate to his dean provincial, first citing him peremptorily; then willing him, in like manner, to cite all the bishops, dean, &c. and all the clergy of his province; but directing, withal, that one proc- tor lent for each cathedral and collegiate church, and two for the body of the inferior clergy of each diocese, may suf- fice: which the dean accordingly does.

The place where the convocation of the province of Canterbury has been usually held, is St. Paul's church; whence they have been prorogued to St. Peter's in Westminster, in the chapel of Henry VII. or the Jerusalem Chamber, where there is an upper and lower house.

The upper house, in the province of Canterbury, consists of twenty-two bishops, whereof the archbishop is always presi- dent, who prorogues and dissolves the convocation by mandate from the king: and before the reformation abbots, priors, and other mitred prelates sat with the bishops. All,
at the opening of a convocation, are in their scarlet robes and bands.

The lower house consists of twenty-two dean, fifty-four archdeacons, twenty-four proctors for the chapters, and forty-four proctors, representing the parochial clergy; in all 144.

Each house hath a prolocutor chosen among themselves; and that of the lower house is presented to the bishops. Things are first usually proposed in the upper house; then communicated to the lower. All the members of both houses have the same privileges in freedom from arrest, as the members of parliament have, flat 8 Hen. VI. c. 1. and the proctors of the clergy received wages from their constituents.

The convocation exercises jurisdiction in making canons with the king's assent, (flat. 25 Hen. VIII. c. 19.) This statute which restrains the convocation from making or executing any canons repugnant to the king's prerogative, or the laws, custom, and statutes of the realm, was merely declaratory of the old common law. (12 Rep. 72.) It part of it only being new, which makes the king's royal assent actually necessary to the validity of every canon. To the convocation also belong the examination and censure of liturgical and scholastic books and persons. But appeal lies from their proceedings to the king in council, or to his delegates. In case the king himself be a party, the appeal lies by flat. 24 Hen. VIII. c. 12. to all the bishops assembled in the upper house of convocation. See Court of delegates.

The archbishop of York, at the same time, holds a convocation of the clergy of his province. After the like manner at York; and, by constant correspondence, debates and concludes of the same matters as are debated by that of Canterbury; but they are distinct and independent of each other; and when they used to tax the clergy, they granted different subsidies. In the province of York, the convocation consists only of one house; and on account of the small number of dioceses in this province, each archdeacon elects two proctors.

It has been customary with the convocation, for many years back, regularly to assemble, and to adjourn without proceeding to any business, so that the convocation now exists more in form than for any effective purpose. See Church of England.

In the year 1711, the convocation was assembled with the new parliament; the lower house chose Atterbury for its prolocutor; and both houses concurred in conferring some tenets that favoured Arminism, broached and supported by Mr. Whitton, mathematical professor in Cambridge. The archbishop doubted whether this assembly could proceed against a man for hereby; the judges were consulted, and the majority gave their opinion that the convocation had jurisdiction. Five of them professed the contrary sentiment, which they maintained from the statutes made at the reformation; the queen, not doubting their jurisdiction, expected them to proceed, but their scruples arising, they determined to examine the book, without proceeding against the author, and this was censured accordingly. An extract of the sentence was sent to the queen, but she did not signify her pleasure on this subject, and the affair remained in suspense. Before the queen's death, in 1714, the lower house of convocation had declared, that a book published by Dr. Samuel Clarke, under the title of "The Scripture Doctrine of the Trinity," contained affections contrary to the Catholic faith. They sent up extracts from this performance to the bishops; and the doctor wrote an answer to their objections. He was prevailed upon to write an apology, which he presented to the upper house; but apprehending that it might be published separately, and misunderstood, he afterwards delivered an explanation to the bishop of London. This was satisfactory to the bishops; but the lower house resolved, that it was no recantation of his heretical assertions. (See the article Clarke.) In the year 1717, the proceedings in the convocation turned chiefly upon two performances of Dr. Hoadly, bishop of Bangor. One was entitled "A Prefervative against the principles and practices of the Non-Jurors," the other was a sermon preached before the king, under the title of "The nature of the kingdom of Christ?" the convocation appointed a committee to examine the bishop's two performances; and thus commenced the famous controversy, called "Bangorian," in consequence of a letter written on the subject of the bishop's discourse by Dr. Snape, master of Eton college. The convocation drew up a representation, in which the preservative and the sermon were censured, as tending to subvert all government and discipline in the church of Christ; to reduce his kingdom to a flate of anarchy and confusion; to impugn and impeach the royal supremacy in caufes ecclesiastical, and the authority of the legislature to enforce obedience in matters of religion by civil sanctions. Before this representation could be brought into the upper house, that whole assembly was proscribed by a special order from the king. This measure, however, increased the controversy. A great number of pens were drawn against the bishop; but his chief antagonists were Dr. Snape, and Dr. Sherbick, whom the king removed from the office of his chaplains. The convocation has not been permitted by government to do any business of consequence since this time, but merely to confine itself to matters of form. See Church of England.

The English clergy, anciently, had their representatives in the lower house of parliament; as appears by the record, much prized by lord Coke. Among the freetholders who were present in parliament, we find many of the inferior, secular, clergy; an order of men who were, certainly, too great elimation and account in the state not to have had a share in the legislature, either personally or by representatives. There are not, indeed, any words of fummons now remaining, which require proctors to be sent for them to the parliament of this kingdom, before the 23rd year of Edward I; but from the annal of Burton (p. 355, f.amba. 1255) it appears, that the whole body of the clergy were so represented in the 30th of Henry III. Nor is this remarked as a novelty by any of the historians who wrote in that age; though, being all ecclesiastics, they would probably have thought it more worthy of observation than any event in which the laity alone were concerned. It may be therefore presumed, that, not only the attendance of the inferior clergy in parliament, which is evidently proved by many passages in more ancient historians, but this kind of representation of them had been customary long before. See Borough. In later times, from a desire of independence on the state, to which they were invited more and more by the pope, they gradually withdrew themselves from any attendance in parliament, either personally, or by representatives; so that, after the reign of Henry VI, they are hardly ever mentioned as present there; although in the 1st year of Richard II. the commons had drawn in a petition to the king, "how that before those times many judgments and ordinances, made in the times of the progenitors of our lord the king in parliament, had been repealed and disannulled, because the state of the clergy were not present in parliament at the making of the said judgments and ordinances." After the reformation of religion, in the reign of Edward VI., an attempt was made in convocation to have the lower house united to the house of commons, "according to ancient custom, sed ab antiquo, societate confuerat." It was also proposed to queen Elizabeth, but rejected. The clergy continued to tax themselves in a separate body, till the restoration of Charles II; then after which
CON which they were taxed in the same manner and conjointly with the rest of the commons; and have ever since been represented in parliament by the same persons, which has more embodied them with the laity, and prevents the setting up of a church interefl fufficient from that of the people. It is remarkable, that this very important alteration in the state of the kingdom was made without any law, by agreement with the clergy. (Littleton's Hist. Hen. II. vol. iii.)

In the parliament of Ireland, originally formed on the model of that of England, the clergy continued to be members of the house of commons, till they were excluded by an act of parliament, 28 Hen. VIII. A. D. 1536, because they supported the authority of the pope, and obstructed the reformation of the church. Whilst the clergy continued to grant their own money in their convocations, their grants were not effectual till they were confirmed in parliament. In the 15th century the clergy of England had great influence in all the public councils of the kingdom, and particularly in parliament: they continually resided in the kingdom, and were present in these councils; while the nobles and great men were engaged in warlike expeditions into France or Scotland. Besides all the archbishops and bishops, twenty-five abbots and two priors were summoned to every parliament, and sometimes more; so that the spiritual lords were generally double the number of the temporal lords in the house of peers (Prynce's regifter of writs, vol. i. & iv.) This enabled the prelates to procure singulary laws against heretics, and to secure the immense possessions of the church, together with all her abulf errors and wretched superstitions, from all attacks.

1 Hen. IV. c. 15. 2 Hen. V. c. 7.

CONVOLULUS, in Botany, the tenth natural order of dicotyledonous hypogynous plants, in the family of Jullieu, with the following genera: Calyx five-cleft, most frequently permanent. Corolla regular, commonly with a five-cleft border. Stamens generally five, inserted at the base of the corolla, and alternating with its segments. Style one, or definitely divided; when one, with a stigma either simple or divided; when more than one, with as many simple stigmas as there are divisions. Fruit capsular, often three-celled, more rarely two or four-celled; cells with one or more seeds. Seeds marked with an umbilical eye at the base, somewhat obovate, and affixed below to the central partition; valves free, with their edges adjoining to the angles of the partition; radicle of the arched corollum interior. (Coreolum fluit up by the periferms?) Stems thorny, or more frequently herbaceous; many twining; many effescent. Leaves alternate, very rarely almost opposite, (always simple, Vent.)

This order is nearly allied to the Borraginace and Polemonia, in its regular five-cleft pentandrous corolla, and alternate leaves; but differs from the latter, in having the partition adjoining to the edges, not to the middle of the valves; and from the former, in the fruit not being gynopeltic. Jullieu alludes to it the following genera:

Ventenat has changed the name of the order to convolvulaceae, and has included in it only convolvulus, ipomeza, evolvulus, and ciffampelos; entirely omitting marupa, mouroucoa, retzria, endrachium, nana, hydrolea, and sagonca; and removing cufcuta to his undetermined plants, and dispensia and lceflia to the polemonia, his polemonaceae. La March's natural family of lferons corresponds exactly with the first two sections of Jullieu.

Gen. Ch. Cal. perianth five-cleft. Cor. monopetalous, bell-shaped or funnel-shaped, plaited; border generally spreading, more or less five-lobed. Stam. filaments five, awl-shaped, shorter than the corolla, approximating at the base. Pet. germ superior, rondund; style filiform; stigma simple or bifid. Perir. capsule surrounded by the calyx, rondund; one, two, three, or four-celled; one, two, three, four, or many-valved. Seeds one or two in each cell.

Eff. Ch. Five-cleft. Corolla bell or funnel-shaped. Stigmas one or two. Pericarp a capsule, or dry berry. Seeds one or two in each cell.

Obx. Authors often call the calyx five-leaved, when it is very deeply five-cleft.

* Stems twining.

CONVOLVULUS.

Britain, and most parts of Europe, climbing up hedges in moist ground. Its infested juice, taken in doses of twenty or thirty grains, is a powerful purgative. 4. C. Wheeleri. Mart. 84. Wild. 5. Vahl. Symb. 2. 366. (C. flagitaria folius, Wheelerl; Piek. Phyt. tab. 85; fig. 5; Ipomea flagitata; Poir. It. 2. 160. tab. 3.) "Leaves arrow-shaped, rounded behind, entire; peduncles cylindric, one-flowered." Wholly smooth. Leaves acute; petiole the length of the leaf. Peduncles shorter than the petiole, thicker, bracteate towards the middle, thicker under the flower. Allied to C. sepium. A native of Spain and Barbary. 5. C. comumia. Link. Mart. 3. Defr. 81. Lam. 1879. Wood. Med. Bot. London, 1, 2. 1876. Symb. tab. 1, fig. 5. Morif. Hist. 2. 12. tab. 3. fig. 5. Banh. Fl. 294.) "Leaves triangular-arrow-shaped; peduncles cylindrical, nearly double the length of the leaves, about three-flowered." Root perennial, long, thick, flabby, full of a milky juice. Stems cylindrical, slender, somewhat villous. Leaves alternate smooth, acute; posterior lobes diverging, with a tooth on the inner side of each. Flowers large, purplish white or pale yellow; peduncles solitary; segments of the calyx emarginate; bracts small, awl-shaped, spreading, remote from the flower. Cephal three or four-celled. A native of Syria and Asia Minor. For its medical uses, see SCAMoMY. 6. C. involucratus. Wild. 5. "Leaves cordate-hastate, pubescent; peduncles about three-flowered; calyces bracteate." Stem cylindrical, pubescent-villos. Leaves oblong, obtuse, mucronate, quite entire, pubescent on both sides; truncate at the base, undivided, rather obtuse; petioles villous. Peduncles about the length of the leaves, pubescent. Bracts two at the division of the peduncle, pubescent, oblong, acute; two others at the base of each flower, villous, pubescent, elliptical, rather acute, longer than the calyx, and involving it. A native of Guinea. 7. C. flagitifolia. Smith Prof. Fl. Gr. p. 133. Flor. Cez. tab. 193. "Leaves cordate-hastate, covered with long distinct hairs, angular at the base; peduncles generally one-flowered; capsules hispate." A native of the islands in the Archipelago, in vineyards and cultivated ground. 8. C. fibriceps. Linn. Mantis. 203. Mart. 4. Defr. 80. Lam. 1878. Wild. 6. (C. rupestris; Pallas It. 3. n. 80. tab. R.) "Leaves cordate-acuminate, even-surfaced; peduncles two-flowered; filipes retruse, decurrent." Root annual. Stems from four to six feet long, slender, slightly winged from the decurrence of the filipes, but not two-edged. Leaves ending in a point, which extends to half their whole length, soft, thin, smooth, veined, entire, paler underneath; filipes vertical, small, obtuse. Flowers small, scarcely twice the length of the calyx, whitish or flesh-coloured, fugacious; bracts often wanting; when present, bristle-shaped, sometimes at the division of the peduncle, sometimes on the pedicles; calyx smooth, deeply divided; ligule capitule-doubled. A native of Siberia, flowering in July and Aug. Introducet into England in 1779. 9. C. rupestris. Wild. 7. "Leaves obtusely heart-shaped, oblong, lanceolate, acute; peduncles one-flowered." Stem smooth, but little twining, somewhat shrubby. Leaves two inches long, smooth, slightly hairy underneath, and at the edges, when viewed through a lens. Flowers violet; peduncles almost the length of the leaves; bracts two, awl-shaped, about the middle of the peduncle; calyx-leaves, egg-shaped, acute, a little hairy, corolla flat, five-lobed; plucks a little hairy on the outside. Supposed to be a native of Siberia. 10. C. farinosus. Linn. Mant. 293. Mart. 5. Defr. 79. Lam. 1877. Wild. 8. Jacq. Hort. Vind. 1. 13. tab. 35. Salisb. Par. Lond. 35. "Leaves heart-shaped, acuminate, repand; peduncles three-flowered; stem mea-
ered; shorter than the petiole. "Root perennial. The young branches, petioles, leaves, peduncles, and calyxes, cloathed with a silken fliming down. "Stems indrical, woody, almost smooth. "Leaves broad oval, alternate, acute, entire, nerved, about twice the length of the petioles. "Peduncles axillary, foliary, with two awl shaped bractes about the middle; calyx short; two inner leaves smaller; corollas at least two inches long, funnel-shaped. A native of the Philippine islands. Specimen in the herbarium of Jussieu. 16. C. che- 

nedent at the tip, dilated and toothed at the base; calyx-leaves elliptical, cup-shaped; "Root annual. "Stems bilform, smooth, slightly fleshy, almost fimple. "Leaves alternate, about half an inch long, smooth; petioles about a line long. "Flowers purplish at the base, with a yellowish white border; peduncles axillary, foliary, one-flowered, longer than the leaves, with two small bractes near their summit. A native of the East Indies. Introduced into England in 1775, by Sir Joseph Banks. 20. C. angustifolius. Mart. 89. Defr. 32. Lam. 2030. Willd. 15. (Ipomoea angustifolius; Jacq. ic. 2. tab. 37.) "Leaves linear, halate, obtuse, mucronate, smooth; auricles generally entire; peduncle one-flowered." "Root spindle-shaped, rising about an inch above the surface of the ground, with the appearance of a fnder, simple, erect, leaflets firm. "Stems several, febrly a foot high, a little twining, almost fiple, filiform, weak. "Leaves an inch long, about a line broad, numerous, on very short petioles. "Flowers yellow, longer than the calyx; peduncles axillary, foliary, shorter than the leaves, with two awl-shaped bractes, above the middle, upper half thicker; calyx-leaves connivent, lancet; corolla funnel-shaped; border very open; divisions egg-shaped, obtuse; figma globular, didymous. "Root annual. A native of Guinea and the East Indies. 21. C. arigloleobifoli- lius. Mill. Houltou MSS. "Leaves halate-lanceolate; auricles rounded; peduncles many-flowered." "Root annual. 

stem ten feet high, slender. "Flowers yellow, in small clusters, on long peduncles. "Cajpiles trigonous, three-celled. "Seeds two in each cell. Seeds sent to Mr. Miller from Carthage in New Spain. 22. C. adonifolius. Defr. 82. Lam. 2005. "Leaves halate, linear; petiules in pairs, somewhat filiform; calyx mucrinated." "Stems herbaceous, weak, a little villous. "Leaves alternate, dilant, petioted, entire, smooth, from three to four inches long; petiules about an inch long. "Flowers near two inches long, axillary; peduncles nearly the length of the petiules, smooth, with two small bractes about the middle; calyx-leaves egg-shaped, rough, with sharp tuberces. A native of Senegal. 23. C. japonicus. Mart. 7. Defr. 6. Lam. 2005. Willd. 16. Thomb. jap. 87. (Kosud Kudli vulgo Piraga wo; Kempf. Amen. 589.) "Leaves halate, lancolate, acute; later lobes one-toothed; peduncles one-flowered; stem simple. "Stems filiform, smooth. "Leaves alternate, almost unilateral, petioted, smooth; middle lobe an inch long, lancolate, entire, acute; side ones a little reflexed, shorter. "Flowers axillary, foliary; peduncles nearly as long as the leaves, filiform, smooth; in the calyx egg-shaped, acute, entire, smooth. A native of Japan. 24. C. eretricus. Defr. 7. Lam. 2006. "Leaves cordate-arrow-shaped, obtuse behind; peduncles shorter than the petiole, without bractes. Whole plant, except the corolla, cloathed with short white hairs. "Stems scarcely a foot and a half long, slender. "Leaves alternate, acute. "Flowers white, small; pediules one or two-flowered; segments of the calyx five, two outer ones broader; figmas two, globular, purplish. Native country unknown. Cultivated in the botanic garden at Paris. 25. C. leucanthus. Defr. 8. Lam. 2007. (Ipomea leucantha; Jacq. Coll. 2. 280. ic. 2.) "Leaves heart-shaped, acuminate; peduncles shorter than the petiole. "Root annual. "Stems about four feet high, slender, cylindrical, branched, redish, and somewhat rough towards the bottom. "Leaves alternate, entire, or slightly scolloped, smooth. "Flowers white; peduncles axillary, foliary, an inch long, erect, cylindrical, smooth, one-flowered: calyx leaves mucronate, a little open at the summit, ciliated at the base; corolla funnel-shaped; anthers purplish; figmas two-lipped. A native of America. 26. C. fruticosus. Defr. 9. Lam. 2008. "Shrubby; leaves somewhat heart-shaped at the base, linear lanceolate, petiules short; flowering branches, thick fct with leaves." Root perennial. "Stems three or four feet high, cylindrical, slender. "Leaves not more than two lines broad, sloped at the base, on very short petiules. "Flowers with five purple rays; peduncles larger than the petiules, scarcely the length of the flowers; bractes two, small, awl-shaped, unequal, situated nearer to the flment than to the calyx; calyx smooth; corolla slightly five-lipped. A native of the Canary islands, flowering in April and May. 27. C. dentatus. Mart. 90. Willd. 17. Vahl. Sym. 3. 25. "Leaves halate, smooth; auricles toothed; peduncles many-flowered, mucrinated." "Stems cylindrical, smooth. "Leaves scarcely an inch long, somewhat heart-shaped at the base; middle lobe lanceolate, quite fide; side ones roundish, unequally four or five-toothed; petiules filiform, somewhat mucrinated towards the base. General peduncles spreading, thicker, and a little longer than the pediules; partial peduncles in threes; that in the middle one-flowered; side ones with two or three pedicelled flowers; both mucrinated; rigid; calyx-leaves oblong, obtuse, mucronate, equal. A native of the East Indies, found by Schumacher. 28. C. haf- 

ricles.
CONVOLVULUS.

Peduncles shorter than the petiole, villous; calyx-leaves hairy, acuminate, patulous at the tip. A native of Egypt and Arabia. 29. C. Sonneratii. (C. haitatus; Depr. 11. Lam. 2010. Tala-neli; Rheed. Mal. 11. 113. tab. 55.) "Leaves linear, haitatus-acuminate; an-

icles toothed; calyx-leaves simple." Whole plant smooth. Stems very slender, slightly angular. Leaves about two lines broad, alternate, nearly sessile. Peduncles longer than the flower, slender, one or two-flowered, often bent at the in-

ition of the bracteae, thicker upwards; bracteae two, fissional, situated a little above the middle of the ped-

uncle. Flowers yellowish-white, twice the length of the calyx; calyx leaves egg-shaped, acut. A native of the East Indies, communicated to La March by Sonnerat. 30. C. ofarifolius. Depr. 89. Lam. 2287. "Leaves kidney-shaped, broad, veined; peduncles one or two-flowered." Stems cy-

lindrical, smooth, not much branched. Leaves alternate, large, entire, smooth, firm; petioles about two inches long, channeled. Peduncles longer than the petioles; bracteae from two to four, small, awl-shaped, situated almost close to the flowers; calyx-leaves short, egg-shaped, obtuse, two outer ones smaller; corollas at least two inches long; tubular; tube about half an inch in diameter; border but little open, with five pointed divisions; stigma capitate, didymous. A native of Senegal. 31. C. tilesifolius. "Shrubby; leaves heart-

shaped, rounded; younger ones somewhat tomentous; flower and fruit very large." Stems cylindrical, almost smooth. Leaves alternate, a little orbicular, entire; petioles about half the length of the leaves, channeled. Flowers large; peduncles not more than eight or ten lines long, axillary, li-

tary, one flowered; calyx-leaves short, obtuse; almost round; corollas at least three inches long, almost cylindrical; tube narrow as far as the length of the calyx, afterwards eight or ten lines in diameter; stigma capitate, two lobed. Capsule about the size of a walnut, apparently two-celled. A na-

tive of the Isle of France, and the Cape of Good Hope. Found by Commerson. 32. C. panduratus. Linn. Sp. Pl. 5. Mart. S. Depr. 91. Lam. 2080. Willd. 19. (C. megabririzos; Dill. Exth. 101. tab. 85. 65. 99.) "Leaves, some heart-shaped, entire, others panduriform or three-lobed; peduncles longer than the petiole, about two flowered." Root perennial, thick, spine-like haped. Stems long, flender. Leaves distant, petioled. Flowers large, white, with the bottom of fine purple; peduncles axillary, solitary, from one to three flowered; calyx-leaves short; two outer ones shorter and narrower. Capsule two-celled. Seeds hirsute, one in each cell. A native of Carolina and Virginia, flowering from June to September. 33. C. betonisfolius. Mart. 72. "Leaves cordate-arrow-shaped, acute; peduncles one-

flowered." Stem five or six feet high, flender. Flowers white, with purple bottoms; peduncles long, flender. A native of Africa, cultivated by Miller in 1750. 34. C. bre-

tratus. Mart. 91. Vahl. Sym. 3. 25. "Leaves heart-shaped, almost entire, and three-lobed, hispid, attenuated; peduncles one-flowered; outer calyx-leaves bracteate." Stem thinly beft with short hairs. Leaves two inches long; pet-

ioles shorter than the leaf, pubescent. Peduncles the length of the leaf, foliary; bracteae two, lanceolate, acute, situated a little below the calyx; calyx pubescent; inner calyx-leaves oblong, blunt, her, nerves; outer ones much broader, enclosing the others as between two bracteae; corolla villous on the outside, tender, silky; border five-cleft; stigma capitate, two lobed, found in the E. Indies by Koenig. 35. C. bicolor. Mart. 52. Wild. 21. Vahl. Sym. 3. 25. "Leaves heart-shaped, villous, somewhat angular lobed at the base; peduncles one-flowered; outer leaves of the calyx reflexing 

broad. Stem villos. Leaves acute, mucronate, not att-

uated, nearly equal in length and breadth; one, two, or

three-lobed at the bottom, villous on both sides; ven-

ty villous, hoary, and obscurely veined underneath; the younger ones silky. Flowers white, with a violet purple base; brac-

teae, calyx, and corolla, as in the preceding species. Found in the East Indies by Schumacher. 36. C. Geoffroyana. (C. bicolor; Depr. 62. Lam. 2094.) Hairly, leaves somewhat heart-shaped, three-lobed, hoary underneath; peduncles many-flowered." On a superficial view having the appearance of a bramble. Stems flender, cylindrical; beft, as well as the petioles, peduncles, and calyxes, with blackish points, and hispid with rather long flufh hairs. Leaves alter-

tane, longer than their petioles, clothed with fine re-
cumbent hairs, green on the upper surface, hoary under-

neath; lobes oval, acute, entire. Flowers small; peduncles axillary, solitary; thicker and longer than the petioles, dis-

chotomous; bracteae two, linear, awl-shaped, situated at each division of the peduncles; calyx leaves narrow, acute, rather long. Brought from Senegal by M. Geoffrey. 37. C. tri-

lobus. Willd. 22. Thumb. prod. 25. "Leaves heart-shaped, villous, three-lobed; lobes egg-shaped, acute; peduncles one-flowered." A native of the Cape of Good Hope. 38. C. fabquinjulobus. (C. trilobus; Depr. 64. Lam. 2593. Ipomoea triloba; Liin.) "Lower leaves heart-shaped, three-

lobed; upper ones somewhat five-lobed; peduncles three-

flowered." Root annual. Stems two or three feet long, flen-

der, slightly angular, smooth. Leaves alternate, generally shorter than their petioles; middle lobes of the lower leaves egg-shaped, obtuse, mucronate, smooth; lateral lobes of the upper leaves with a deep sinus, which makes them appear five-

lobed. Flowers purple or violet; peduncles angular, nearly the length of the petioles; pedicels very short, bracteae small, egg-shaped; calyx-leaves half the length of the corolla, smooth, egg-shaped, acut, cunivent; corollas small, cylindrical; bor-

der with five sharp teeth. A native of South America, cul-

.s. 167. fig. 7. Feuil. peruv. 3. 16. tab. 11. "Leaves heart-shaped, three-lobed; lateral lobes toothed-angular; peduncles, somewhat three-flowered; calyxes almost as long as the peduncles, smooth." Whole plant quite smooth, except the petioles. Stem cylindrical. Leaves two inches long or more, glaucous, green underneath, with purplish veins; lobes lanceolate; middle one longer, broader, quite entire, acuminate; lateral ones narrower, attenuated, with a smaller broader lobe at the bottom on each side, rounded 

behind, and furnished with an angular tooth; petioles shorter than the leaf, befit with a few scattered hairs. Peduncles rather than the leaf, thickened at the top; lower ones three-flowered; middle ones two-flowered, uppermost one-flowered; calyx-leaves oblong, somewhat membranous, ending in a bristle; stigma capitate. It differs altogether from C. batatas in the smoothness of the stem, and the form of the leaves. A native of America. 40. C. acuminitus. Mart. 94. Willd. 24. Vahl. Sym. 3. 26. "Leaves heart-shaped and three lobed, attenuated; peduncles elongated, many-flowered; calyxes smooth." Stem with a few minute scattered hairs, prilled close, and visible only with a magnifier. Leaves four inches long, three or more broad at the bafe, three-lobed or entire, quite smooth, befted, acute; lateral lobes lanceolate; middle one egg-shaped, attenuated; petals longer than the leaf. Flower large, bell-shaped, purple with a pale bafe and five pale rays running to the margin; peduncles axillary, the length of the petioles alternate; pedicels about five, an inch and half long; bracteae at the bafe of each pedicle two, lanceolate, attenuated, finely 

nered,
nerved, smooth; calyx-leaves lanceolate, attenuated, tender, finely nerv'd, quite smooth; two inner ones a little shorter,��ga capitata. A native of the island of Santa Cruz in the West Indies. 41. C. carolinus. Linn. Sp. Pl. 6. Mart. 9. Defr. 92. Lam. 2088. Willd. 25. Dil. clth. 100. tab. 84. fig. 98. "Leaves heart-shaped, entire, and three-lobed, villous; calyxes even-surfaced; capsules his- tate; peduncles one or two-flowered." Root perennial. Stems slender, reddish towards the root, hairy at the joints. Leaves alternate, scarcely two inches long, some entire, others like those of ivy; petals about the length of the leaves, slender, channelled. Flowers pale purple, resembling those of C. arvensis; peduncles the length of the pedioles, thicker, axillary, solitary, angular, with a few narrow bract. calyx-leaves egg-shaped, acute, fiercely half the length of the corolla, a little ciliate at the edges with whitish hairs. Capsules round, hairy towards the fimnity, two-celled, three-valved. Seeds two in each cell, black, smooth. A native of Carolina. 42. C. hederaceus. Linn. Sp. Pl. 7. Mart. 10. Defr. 12. Lam. 172. Dil. clth. 99. tab. 83. fig. 96. Gart. tab. 134. fig. 2. "Leaves heart-shaped, entire and three-lobed; corollas undivided; fruit erect." Linn. "Peduncles about three flowers; calyxes stubercled." Lam. Root annual. Stems farinose, cylindrical, dull red, two or three feet high. Leaves alternate, petioled, clasped with fine short hairs. Flowers fine blue, with a pale base; peduncles nearly the length of the petioles, axillary, solitary, hairy; bracteae small; pedicels very short; calyx-leaves rough with numerous long hairs, and small black tubercles; two of them narrower. Capsules spherical, smooth, thin, three-celled, three-valved. Seeds two in each cell, black, smooth. A native of Asia, Africa, and America. 43. C. Dilat. Defr. 22. Lam. 2021. Dil. clth. 97. tab. 81. fig. 93. "Leaves heart-shaped, entire, and three-lobed; flowers solitary, almost filiform." Distinct from the preceding, with which it has been confounded. Root annual. Stems long, slender, hairy. Leaves alternate, elliptic or oblong, pinnatifid underneath; lobes angular; pedicels shorter than the leaves, hairy. Flowers fine blue, with a white base; peduncles villous. Fruit cylindrical, stalked; calyxes oblong, five-cleft, hairy; corolla large, very open, almost entire, supposed to be a native of Africa. 44. C. nil. Linn. Sp. Pl. 8. Mart. 11. Willd. 27. Bot. Mag. 188. C. canescens; Ger. em. 861. fig. 1. C. hederacea angulosa folio; Bauh. p. 295. Dil. clth. 96. tab. 8. fig. 91. 92. Ipomoea hederacea; Lam. J. tras. Thun. Fl. jap. 86. Linn. Tran. 2. 330. C. hederacea; Lam. J. tras. Thun. Fl. jap. 86. Linn. Tran. 2. 330. "Leaves heart-shaped, three-lobed; corollas semi-inconspicuous; pedicels shorter than the petiole." Root annual. Stem eight or ten feet high. Leaves woolly, acuminate, on long pedicels. Flowers deep blue, with purple rays; pedicels two-flowered. Fruit erect. Nil is an abbreviation of Anil, one of the names of indigo. A native of America. 45. C. purpureus. Linn. Sp. Pl. 9. Mart. 12. Willd. 28. Bot. Mag. 113. (C. purpureus folio subrotundo; Bauh. p. 295. Ipomoea purpureus; Lam.) "Leaves heart-shaped, undivided; fruit nodding; pedicels thickened." β. caruleus minor, folio subrotundo. Dil. clth. 98. tab. 83. fig. 95. Smaller, blue-flowered, with roundish leaf. C. folio cordato glabro. Dil. clth. 98. tab. 24. fig. 97. with a heart-shaped smooth leaf. β. cha- tocr; Bot. Mag. 1005. Stems very high; leaves orbicular-heart-shaped; flowers white, with five spots, elegantly shaded with blue and carmine. All the varieties are natives of America. The first is a hardy annual, common in the English gardens, under the name of Convolvulus major. 46. C. oblongus. Linn. Sp. Pl. 10. Mart. 14. Defr. 15. Lam. 2014. Willd. 29. Dil. clth. 98. tab. 83. fig. 95. "Leaves heart-shaped, undivided; stem somewhat pubescent; pedicels thickened, one-flowered, calyxes smooth." Root annual. Stems cylindrical, villous towards the top, three or four feet high. Leaves alternate, acute, green, and smooth above, paler and a little villous underneath; pedioles one or two inches long. Flowers white, with a purple base and yellowish rays; pedicels longer than the petals, slender, lightly pubescent towards the bottom, with two small bracteae. A native of Java, and other parts of the East Indies. 47. C. flavus. Willd. 30. (Evolumus hederaceus; Burm. Ind. 77. tab. 30. fig. 2.) "Leaves heart-shaped, repand, somewhat lobed, with small mucronate teeth; pedicels bivalve, many-flowered." Stem rather smooth. Leaves acuminate, somewhat feebrous. Peduc- mcs much longer than the leaves; upper ones three-flowered; lower ones bivalve; branch with a few pedicels, with a single flower at the division. A native of the West Indies. 48. C. angulatus. Linn. Mart. 207. Mart. 12. Defr. 98. Lam. 2098. Willd. 31. Burm. Ind. 46. tab. 19. fig. 2. "Leaves heart-shaped, pentangular, quite entire, villous; pedicels many-flowered." Stem pubescent. Leaves on short petioles, quite entire, rough with reddish shining hairs. Flowers orange; peduncles the length of the leaves, axillary, solitary, most commonly three-flowered; calyx hairy; segments acute; corollas bell-shaped, three times longer than the calyx. A native of the East Indies. 49. C. Bar- tar. Linn. Sp. Pl. 11. Mart. 15. Willd. 32. (Batatas; Bauh. Pin. 91. Rumph. Amb. 5. 307. tab. 130. C. ra- dice tuberosa eculenta; Catech. Car. tab. 60. Ipomoea Batatas; Lam.) Spanish or sweet potatoes. "Leaves heart-shaped, half-axe, five-nerved; stem hispid, creeping, bearing tubers." Root perennial. Stem cylindrical, peren- nial, hispid, proliferate, creeping; sending out scattered, oblong, acuminate tubers, purple or pale on the outside. Leaves angular, on long petioles. Flowers purple, large, about three together, on a stalk as a head. A native of the West Indies; now it is said to have been introduced by the Spaniards into the Philippine islands. It is now extensively cultivated in the tropical climates of both hemispheres, for the sake of its tubers. They are sweet, fæcid, and esteemed nourishing, and are the common potatoe of our old English botanists. There are several varieties, and probably more than one distinct species. 50. C. maximus. Linn. jun. Sup. 137. Mart. 25. Willd. 33. Vahl. Symb. 3. 268. (C. marginatius; Defr. 72. Lam. 2071. Tur-tah; Rheed. Mal. 11. 109. tab. 53.) "Leaves heart-shaped, acute, smooth; pedicels many-flowered, smooth; stem somewhat hairy." Root perennial, fibrous. Stems cylin- drical, slender, reddish. Leaves alternate, thin, soft, even-surfaced, bordered with red; pedicels rather long, thick, channelled, reddish. Flowers pale red, with a purple base, funnel-shaped; peduncles axillary, solitary, thicker than the branches from which they spring; seven or eight-flow- ered; calyx-leaves short, somewhat acute; stigma capitata, two-lobed. A native of the East Indies. 51. C. biflorus. Linn. Sp. Pl. Append. p. 916. Mart. 16. Willd. 34. "Leaves heart-shaped, pubescent; pedicels very short; corollas with trifol lobes." Root annual. Stem cylindrical, hairy, branched at the base, about the size of C. arvensis. Leaves oblong; pedicels cylindrical, hairy, shorter than the leaf. Flowers white; pedicels hairy, approximating at the base, shorter than the petioles; calyx five-lobed; two outer leaves cordate-oblong; two inner ones linear-lanceolate; the fifth semi-heart-shaped; corolla small, campanulate, quinquefid, plate; lobes trifid at the tip; middle lobe smaller; tube shorter than the calyx; stigmas two, capitate, purple. A native of China. 52. C. gemelus. Mart.
CONVOLVULUS.

Mart. 95. Defr. 71. Lam. 2070. Vahl. Symb. 3. 27. Burm. ind. 46. tab. 41. fig. 1. "Leaves heart-shaped, somewhat villous underneath; peduncles of moderate length, channelled. Flowers in small pedunculate racemes, numerous, situated near the extremities of the branches, often pendant; bractlets very small, awl-shaped, at the foot of the pedicels; calyx-leaves smooth, egg-shaped, elongated, unequal in size; corollas bell-shaped, expanding; stigmas capitate, two-lobed. A native of St. Domingo. 58. C. finesus. Defr. 69. Lam. 2068. "Hairy; leaves heart-shaped, acute; peduncles two or three-flowered; calyx-leaves heart-shaped." Whole plant, especially near the summit, clothed with separate, fine, whitish hairs. Stems slender, cylindrical. Leaves alternate, entire, on longish somewhat villous pedicels. Peduncles shorter than the pedicels, axillary, solitary; bractlets small, awl-shaped; three exterior calyx-leaves broader than the others, heart-shaped at the base, very rough with hairs; corollas campanulate, a little longer than the calyx. Supposed to be a native of China. 59. C. pentandrus. Willd. 37. Jacq. in. rar. 2. 316. Collect. 14. 210. "Leaves heart-shaped, acuminate, smooth, somewhat repand; umbels peduncled, capitate, five-flowered; calyxes ciliate." Root perennial. Stem fibrous. "Flowers nearly sessile. Native country unknown. 60. C. guianensis. Mart. 97. Defr. 58. Lam. 2057. Aubl. guian. t. 136. tab. 52. "Leaves somewhat heart-shaped, mucronate, tomentose; flowers collected into a kind of corymbose head, on very long peduncles." Root perennial. Stems a little woody at the base, cylindrical, villous. Leaves alternate, two inches long, quite entire, veined, nerveless; petiole only half the length of the leaf, a little channelled, tomentose. Flowers pale blue, or whitish; peduncles seven inches long, axillary, villous; pedicels very short, intermingled with filiform bracts; calyxes villous, deeply divided into five lanceolate segments; corollas small; lobes of the border acuminate; stigmas two, reflexed. A native of Guiana. 61. C. capitatus. Mart. 98. Defr. 57. Lam. 2056. Willd. 37. Vahl. Symb. 3. 28. "Hilpid; leaves heart-shaped; flowers capitate, involucrated; peduncles scarcely longer than the petiole." Whole plant, hippid, with long distinct hairs of a dirty white colour, placed on minute tubercles. Stem slender, cylindrical. Leaves from two to three inches long, alternate, acute, entire; petioles nearly the length of the leaf. Peduncles axillary, solitary, with about five fiddle flowers collected into a close head. Involucrums consisting of four or five egg-shaped acute bractlets, of unequal size, generally as long as the calyx; calyx-leaves one third of the length of the corolla, ovate-lanceolate, acuminate, smooth within; corolla hippid on the outside with long hairs arranged in five lines. Cappule globular, shorter than the calyx, even-furred, smooth. Found in the East Indies by Koevery and in Senegal by Geoffroy. 62. C. eritrus. Defr. 112. Lam. 2114. "Leaves heart-shaped, almost smooth; heads of flowers very hisbute, on long peduncles, involucrated; capule even-furred." Stem herbaceous, Specimen in the herbarium of Jaffieu. 63. C. hispidus. Mart. 99. Willd. 40. Vahl. Symb. 3. 29. "Extremely hirsute; leaves cordate-egg-shaped; flowers umbellate; peduncles very short. Leaves from two to three inches long, attenuated, quite entire; petiole half the length of the leaf. Pedicels the length of the peduncle. Calyx-leaves lanceolate, attenuated, smooth within, lax. Corolla smooth. Stigma capitate. A native of the East Indies. 64. C. pareiroflorus. Mart. 100. Willd. 42. Vahl. Symb. 3. 29. (Ipomoea pancrenata; Burm. ind. 50. tab. 21. fig. 3.) "Leaves heart-shaped, acuminate, smooth; peduncles many-flowered; calyxes acuminate, villous." Stem weak, slightly villous at the top.

Leaves...
CONVOLVULUS.

Leaves an inch long; petiole the length of the leaf, filiform, villous. _Flowers_ blue; pedicels the length of the petals; pedicels umbellate; lateral ones sometimes branched; calyx-leaves egg-shaped, acuminate, small; corolla smooth, twice the length of the calyx, five-leaf; stigma bifid; segments revolute. A native of Java. 65. C. _veritissimum_. Linn. 12. Mart. 17. Willd. 43. Brown. Jam. 153. "Leaves oblong, heart-shaped, oblong, naked; pedicels umbeliate, bifid, many-flowered." Leaves rough, somewhat expanded. _Flowers_ blue, small, campulate, not cut; pedicels thinner than the leaf; pedicels often somewhat divided. A native of North America. 66. _C. foliiflorus_. (C. parviflorus; Defr. 66 Lam. 2065. Quamoclit purpurea; foliata Aiton; Lam.) Plum. MSS. 2. tab. 62. Burn. Amer. 83. tab. 94. fig. 2.) "Leaves cordate-oblong, mucronate; pedicels branched, many-flowered, short, appearing verticillate." Distinct from the preceding. Roots the thickness of the human little finger, much branched. Stems very slender, long, branched. Leaves sinuated, slightly tomentose; petals rather short. _Flowers_ purplish, small, campulate, deeply five-cleft, as represented in Plummer's figure; pedicels axillary, shorter than the leaves; pedicels forming a corymb. _Capules_ four-celled. Seeds yellow, angular. A native of St. Domingo, on fly hills, communicated to La Maree by Joseph Martyn. 67. _C. violaceus_. Mart. 101. Willd. 44. Vahl. Symb. 3. 29. "Leaves cordate-egg-shaped, acute; pedicels elongated, bifid, many-flowered; two outer calyx-leaves cordate-egg shaped, acute." Stem, petals, pedicels, and _calyces_ villosus. Leaves an inch long. _Flowers_ violet, with five laciniate pale yellow rays; pedicels four or five times longer than the leaf; pedicels three or five-flowered, with a pair of linear-lanceolate bracts at the base; calyx-leaves tender; two innermost ones only half the size of the others, somewhat membranous, smooth, mucronate; corolla campuliate; _figmas_ two, reflexed. It varies with respect to the hairiness of the leaves. A native of the island of Santa Cruz. 68. _C. aureus_. Defr. 56. Lam. 2055. "Leaves somewhat heart-shaped, acute, naked; flowers collected into a head on a very long petiole." Stem woolly, finely flabellate, firm and grevish near the bottom, twining and somewhat villous towards the top. Leaves near an inch and half long, a little longer than the petals, repenen, smooth, rather glaucous underneath. _Flowers_ azure blue, small; pedicels axillary, solitary, divided at the summit into short ramifications intermingled with small bracts; _calyces_ deeply divided; segments acute. A native of South America. 69. _C. cyllorum_. Defr. 64. Lam. 2063. (C. levis minor; Rumpp. Amb. 5. 451. tab. 158.) "Leaves heart-shaped, oblong, acuminate; pedicels cyrnose; fruit podding." _Stems_ long, slender, cylindrical, almost smooth. Leaves four or five inches long, alternate, petiolate, turned, even-serrated, slightly sinuated. _Pedicels_ axillary, about the length of the petals, branched about the middle into a cyme. _Calyces-leaves_ egg-shaped, obtuse. _Corolla_ long, not very open. _Stigma_ capitate, two lobed. A native of the East Indies. 70. _C. umbellatus_. Linn. Sp. Pl. 13. Mart. 18. Defr. 63. Lam. 2062. Wild. 45. (C. leucosolanthys; Plum. Am. 88. tab. 105. Slosin. Jam. 53.) "Leaves heart-shaped; petals pubescent at the base; pedicels umbellate." Root perennial. Stem herbaceous, cylindrical, filiform, flitt, sub-divided, pubescent. Leaves above two inches long, and as broad at the base, deeply heart-shaped, lanceolate, somewhat sinuated, entire, dark green, shiny underneath; petals three inches long, two with fly-petals at the base a little decurrent on the stem. _Flowers_ yellow; pedicels three inches long or more; partial pedicels three quarters of an inch long, three-flowered; each flower on a pedicel longer than the partial pedicels; two of the calyx-leaves a little shorter than the rest; stigma bifid, globular. _Capules_ two-celled. Seeds one or two in each cell, covered with a velvety down. A native of the West Indies. 71. _C. multiflorus_. Mart. 69. "Leaves heart-shaped, smooth; pedicels many-flowered. Seeds villous, furruginous. Root annual. Stems eight or ten feet high, slender. Leaves shaped like those of _C. icpium_. _Flowers_ purple, on rather long pedicels, growing in bunches. _Capules_ trigonous, three-celled, with one seed in each cell. A native of Jamaica. Linnzeus quotes Plunket's _Alm_. tab. 167. 11. for the preceding species; Miller for the present. 72. _C. tugurium_. Mart. 73. Willd. 46. Forth. Prod. 35. "Leaves cordate-earrow-shaped, acute; stem angular; pedicels tetragonal, one-flowered." A native of New-Zealand. 73. _C. terebinthus_. Mart. 77. Lour. Cochin. 109. "Stem shrubby; leaves cordate-earrow-shaped, smooth; pedicels many-flowered; anthers spiral." Stem large, shrubby, branched, smooth. Leaves alternate, petiolate. _Flowers_ yellow, large, campulate; anthers filiform. _Capules_ two-celled, with one seed in each cell. A native of the woods of Cochinchina. 74. _C. cordifolius_. Willd. 47. Thunb. Prod. 35. "Leaves heart-shaped, halate, toothed; pedicels bifid-umbellate." A native of the Cape of Good Hope. 75. _C. refusus_. Mart. 71. Houll. MSS. "Leaves heart-shaped, acuminate; pedicels two-flowered." Root annual. Stems even or eight feet high. Leaves on very long petioles. _Flowers_ large, of a fine rose colour, on long pedicels. _Seeds_ large, covered with a finely down. A native of Jamaica, cultivated by Miller. 76. _C. bifidus_. Mart. 103. Wild. 48. Vahl. Symb. 3. 30. (C. levis maa; Rumpp. Amb. 5. 431.) "Leaves heart-shaped, oblong, acuminate, very soft underneath; pedicels bifid, many-flowered." _C. levis minor_; Rumpp. 5. 431. tab. 158. "Leaves heart-shaped, lanceolate-oblong, smooth." Stem villous. Leaves from two to three inches long, an inch wide at the base, mucronate; petiole one-third of the length of the leaf, hoary. _Pedicelles_ axillary, solitary; pedicels numerous, somewhat umbellated, oblong, ferruginous, deciduous, with minute seclus at the base instead of bracts. _Calyx-leaves_ pubescent at the base, rounded at the tip, equal. _Corolla_ almost funnel-shaped, three times the length of the calyx, with five flatter villous lines on the outside; lobes acute, bearded at the tip. _Stigma_ capitate, two lobed. _Capules_ egg-shaped, filariated, smooth. It has the habit of _C. umbellatus_, but has no larger brown scale. The variety differs only in the smoothness, and its narrow leaves. 77. _C. malabaricus_. Linn. Sp. Pl. 14. Mart. 19. Defr. 68. Lam. 2057. Wild. 49. (Katta-keleng; Rheed. Mal. 11. 105. tab. 51.) "Leaves heart shaped, smooth; stem perennial, villous." Root perennial. Stem somewhat woody, cylindrical, weak, villous. Leaves alternate, acute, quite entire; petals reddish, thicker than the stem. _Flowers_ yellowish white, with a deep purple base; pedicels axillary, solitary, cylindrical; bractae narrow, situated near the calyx; calyx five-leaved; leaves acute, three outer ones longer; corolla campulinate, open, villous on the outside; _figma_ capitate; two-lobed. A native of the coast of Malabar. 78. _C. calycina_. Mart. 74. Lam. 212. Willd. 50. Forth. Flor. Aust. 77. "Leaves heart-shaped, very acuminate, pubescent; pedicels elongated, umbellate-trifid." A native of the island of Tanna in the South Seas. 79. _C. calamistrata_. Linn. Sp. Pl. 15. Mart. 20. Defr. 65. Lam. 2064. Wild. 51. Comm. Hort. 2. 101. tab. 51. Pluk. Alm. 114. tab. 325. fig. 1. "Leaves heart-shaped, acute, somewhat tomentose;
CONVOLVULUS.

soft; peduncles axillary, about three-flowered, rather long."

Root perennial. Stems woody, twenty feet high or more, cylindrical, a little branched, woolly. Leaves alternate, not deciduous, whitish underneath, on short tomentose pedicels. Flowers purple-violet or pale blue, sometimes white; peduncles axillary, longer than the pedicels, tomentose; pedicels three, rarely five or six, short, intermixed with filiform bracts; calyx very villous, with five deep acute segments; corolla a little villous on the outside; border almost flat; stigma bifid, filiform. A native of the Canary Islands. 80. C. pannosus. Linn. F. Lond. tab. 20. "Stem angular; leaves half-angle-shaped, shiny, with hairs on both sides; peduncles two or three-flowered; tube of the corolla a line and half long; segments somewhat mucronate; pericarp tender, hairy." Leaves pale green, halbarb-shaped, very hairy on both sides, like a piece of woolen cloth. Flowers pale purple, with a darker base; bracts narrow, attenuated; calyx hairy; margin of the corolla and the wedge-shaped folds of its border pubescent; filaments white, covered with a glabrous pubescence towards the bottom; anthers blue; nectarary yellow, with a whitish margin; style white, about three lines long; stigma white, longer than the style, spreading out wide, quite linear, obtuse. Capsule two-celled. Seeds two in each cell. Raised from seeds received from Lirbom by Meffrs. Lee and Kennedy. 81. C. ferrugineus. Willd. 52. Vaill. Eclog. 1. 17. "Ferruginous-downy; leaves heart-shaped, acute; peduncles axillary, four-flowered." Root perennial. A native of South America. 82. C. muricatus. Linn. Mant 44. Mart. 21. Defr. 73. Lam. 2072. 53. "Leaves heart-shaped; peduncles thickened, and, as well as the calyces, even-surfaced; stem muriuncate." Refracting C. purpureus, but the stem has a very even surface, with harmer's pricks scattered over it. Root angular, brownish purple; peduncles often two-flowered; corolla more funnel-shaped than that of C. purpureus. Distinct from ipomoea bona nua. A native of Surat; introduced into England by Dr. Solander; flowering in July and August. 83. C. acuta. Linn. Mant. 42. Mart. 22. Willd. 54. "Leaves heart-shaped; stem keeled on both sides." Stem smooth, winged from leaf to leaf with four to five membranous. Leaves three inches long, smooth, veined, obtuse, quite entire; petals nearly the length of the leaf; pedicels axillary, the length of the petals, thicker, four or five-flowered, villous; pedicels thickened, somewhat umbellled, villous; bracts two, at the base of the calyx, broad, egg-shaped, membranous, mucronate, villous, deciduous; two outer calyx-leaves egg-shaped, villos on the outside, smooth within; mucronate; inner ones only half the size, oblong; corolla twice as long as the calyx, bell-shaped; stigma capitate. A native of Ceylon and Java. 84. C. trigynus. Mart. 104. Willd. 54. Vaill. Symb. 3. 30. "Leaves heart-shaped, acute, somewhat vil- lous; pedicels many-flowered; stem three-keeled." Stem pubescent. Leaves two inches long and more; petiole villous, shorter than the leaf. Peduncle the length of the leaves, three or five-flowered; lateral pedicels often two-flowered; middle one one-flowered, shorter, gradually thickened; bracts at the base of the pedicels, egg-shaped, con- cave, tender, acute, mucronate, colored, pubescent, deciduous; two outer calyx leaves resembling bracts, egg- shaped, acute, mucronate, silky; inner ones shorter, smooth, rounded at the tip; stigma capitate. Nearly allied to the preceding, but the leaves are not obtuse, and the rings on the stem much narrower. A native of the island of Santa Cruz. 85. C. Turpethum. Linn. Sp. Pl. 17. Mart. 23. Defr. 86. Lam. 2084. Willd. 56. (Turpethum; Bauh. Pin. 149. C. zeylanicus alatus; Herm, Lugd. 177.

tab. 178, 179.) "Leaves heart-shaped, angular; stem membranous, quadrangular; peduncles many-flowered." Root perennial, about an inch thick, little branched, branching deep into the ground, throwing out thick fleshy twigs, abounding in a milky juice, which soon hardens into a re- finous substance when exposed to the air. Stems woody and reddish near the bottom, slender, with four decurrent wings, branched. Leaves alternate, crenulate, soft, clothed with a thin whitish down, slightly mucronate; pedicels shorter than the leaves, winged, channelled. Flowers white, re- snowing thofe of C. sepium; pedicules longer than the pedicels, axillary, solitary, triand; pedicels one or two- flowered; bracts two, egg-shaped, at the base of the calyx; two outer calyx-leaves egg-shaped, villous; three inner ones smooth; anthers spiral; stigma capitate, two-lobed. Capsule membranous, gloular-depressed, two-celled. Seeds one or two in each cell, black, angular on one side. A native of Malabar, Ceylon, the Society and Friendly Isles, and the new Hebrides. For an account of the medicinal qualities of the root, see Turbath. 86. C. grandiflorus. Linn. jan. Sup. 136. Mart. 24. Defr. 14. Lam. 2013. Jaccq. Hort. 3. tab. 60. (Munda-vali; Reedh. Mal. 1. 101. tab. 50.) "Leaves corollae-egg-shaped, rather obtuse, quite entire; peduncles generally two-flowered; calyces corymbose; stem and pedicels pubescent." Linn. jun. "Leaves heart-shaped, acute, on long pedi- cules short, one-flowered; corolla very large, funnel-shaped." Lam. Root perennial. Stem woody at the base, cylindri- cal, branched, smooth, about three feet high. Leaves large, with rounded lobes, smooth. Flowers very white, sweet-scented. A native of the East and West Indies. 87. C. speciosa. Linn. Sup. 137. Mart. 26. Willd. 52. C. nervosus; Defr. 87. Lam. 2083. Burn. Ind. tab. 20. 88. C. Samudra-Hoggam; Rheed. Mal. 11. 125. tab. 61. "Leaves heart-shaped, tomentose-filky underneath; pedicels longer than the petioles, umbelliferous; calyxes acute." Hort. Kew. Root perennial. Stem woody at the bottom, pub- escent, branched; branches clothed with a thick white cottony down. Leaves alternate, large, acute, quite entire, nerves underneath; petioles and pedicules tomentous. Flowers purplish, more than two inches long; pedicels five or six, very short; bracts elliptical, longer than the calyx; calyxes small, deeply divided into five egg-shaped segments. A native of the East Indies. 88. C. trinervius. Mart. 27. Defr. 16. Lam. 2015. Willd. 59. Thunb. Flor. Jap. 85. "Leaves heart-shaped, oblong, smooth, three-nerved; stem cylindrical; pedicules one-flowered." Stem filiform, simple, smooth. Leaves about an inch long, opposite, acumin- ate, quite entire, paler underneath; petals linear, smooth, half an inch long. Flowers purplish; pedicels axillary, solitary, or in pairs, very short; segments of the calyx almost bristle-shaped, smooth, half the length of the corolla; stigma capitate, two-located. A native of Japan. Defr. obsevrses, that the angularity of the opposite leaves renders the genus dubious. 89. C. petacum. Linn. Sp. Pl. 16. Mart. 28. Defr. 88. Lam. 2086. Willd. 60. Rumph. Am. 5. tab. 157. "Leaves target-shaped; pedicules many-flowered." Stem, according to Rumphius, sometimes as thick as the human thigh, and climbing to the top of the highest trees. Leaves alternate, large, some- what acute, smooth; pedicels rather long, zig-zag. Flowers white or faint purple, bell-shaped, twice the length of the calyx; pedicules axillary, solitary; calyx-leaves egg-shaped, smooth. A native of Ambon. 90. C. ficundus. Linn. Mant. 43. Mart. 29. Defr. 13. Lam. 2112. Willd. 61. Woodv. Med. Bot. tab. 21. Lam. 11. tab 104. fig. 2. (Bryonia mehoacana nigricans; Bauh. Pin. 298.)"Leaves
egg-shaped, somewhat heart-shaped, obtuse, obliquely repand, yellow underneath; peduncles unflowered. Hort. Kew. Root perennial, thick, blackish on the outside, white within, abounding in a milky juice. Stems numerous, herbaceous, ten or twelve feet high. Leaves smooth, different in shape, lower ones triangular, almost heart-shaped; upper ones more oblong and acute; pedicels long. Flowers reddish on the outside, dark purple within (yellow in the Kew Garden); pedicules axillary, solitary. Seeds covered with a very white cottony down. A native of South America, about Xalapa, between La Vera Cruz and Mexico. For its medicinal qualities, see JALAP. 91. C. macropterum. Willd. 62. (Mouroncova violacea; Audub. gymn. 1. 144. tab. 54. Jull. 133.) "Leaves elliptical, acute; smooth; corollas flat; capulcias two or three-celled, with one seed in each cell." Root perennial. Flowers falsely-shaped. Seeds almost an inch and half thick. A native of Guiana. 92. C. imbricatus. Willd. 63. Defr. 78. Lam. 1876. Pluk. Almag. 114. Phyt. tab. 169. fig. 4. "Leaves oblong-elliptical, obtuse, mucronate, nearly lefle; pedicules longer than the leaf." Root perennial, generally two-flowered. One of the least species of the genus. Stem filiform, a little villous. Leaves alternate, scarcely an inch long, and about three lines broad, entire. Pedicules axillary, solitary; bracteae two, awl-shaped, at the base of the pedicels; corollas small, bell-shaped. A native of Carolina and Virginia. 93. C. Barbadensis. (C. glabrifolium Mill. Mart. 68.) "Leaves ovate-oblong, smooth; peduncles one-flowered; calyxes ten-cleft." Root annual. Stems eight or ten feet high. Flowers purple, large, on long peduncles. Sent to Miller from the island of Barbuda. 94. C. fruticosus. Linn. Mant. 43. Defr. 77. Lam. 1875. (C. mollis; Burm. Ind. 44. tab. 7.) "Leaves lanceolate-elliptical, tomentose-filmy underneath; peduncles about three-flowered: calyx short, hairy." Stems shrubby, smooth. Leaves alternate, petiolate. Pedicules axillary, solitary, about the length of the petioles. Calyx-leaves egg-shaped, whitish, filiform. Tube of the corolla narrow to the top of the calyx; afterwards widened and terminating in a purple border, covered on the outside with white hairs. Capulcias downy. A native of the island of Java. 95. C. tomentosa. Later than the last. Mant. 31. Defr. 93. Lam. 2501. Willd. 65. Sloan. Lam. 55. hift. 1. 134. tab. 68. fig. 2. Pluk. altn. 115. tab. 167. fig. 4. "Leaves three-lobed, tomentose; frimit amunigous. Stem twenty feet high, cylindrical, whitish. Leaves alternate, reenblishing the older leaves of ivy; petioles three quarters of an inch long. Flowers purple; pedicules axillary, solitary, many-flowered, a quarter of an inch long; corollas bell-shaped. Capulcias peltaloid, acuminate, two-celled. Seeds one in each cell, black. A native of Jamaica. 96. C. quinquenervis. Mant. 105. Willd. 66. Vahl. Symb. 3. 31. "Leaves fagitate-egg-shaped, attenuated, smooth, crenate, from what repand; peduncles about five-flowered." Stem slightly pubescent, cylindrical, branched. Leaves tender, hoary; petiole shorter than the leaf. Pedicels the length of the leaves, pubescent. Pedicels in threes, umbolled, lateral ones in the greater number bident, but on the pedicules near the top all simple, bracteae two, linear, at the base of the lateral pedicels; calyx-leaves obtong, obtuse, mucronate, somewhat villous; corolla twice as long as the calyx; lobes broader at the tip; stigma bifid. Supposed to be a native of the island of Bourbon. 97. C. ceratosa. Defr. 74. Lam. 2072. Jacq. ic. rar. 2. tab. 315. (C. Hermanniz; Willd. 67. L'Hert. florp. 1. 67. tab. 32.) "Tomentous; leaves cordate oblong obtuse, somewhat repand; pedicules longer than the petiole; border of the corolla acute." 8. euflos. "Leaves less elongated, appearing bitten here and there at the edge, clothed with a reddish down; flowers larger. Whole plant whitish, soft to the touch. Root perennial, spindle-shaped. Stems about three feet long, not much branched. Leaves alternate, on short pedicels. Flower white, small; peduncles long, zig-zag, with two small awl-shaped bracteae near the top, often two-flowered; border of the corolla slightly emarginated, with five acute divisions. Found in Peru by Dombeu. The variety 8. found at Monte Video by Commeron. 98. C. althoideis. Linn. Sp. Pl. 19. Mart. 32. Def. 97. Lam. 295. Willd. 69. Flor. Gr. tab. 194. Bauhin. Pin. 295. Moris. hist. 2. 13. tab. 3. fig. 10. (C. peregrinus, folio betonicce; Tour. 85.) "Lower leaves heart-shaped, filminated; upper ones pinnatifid; somewhat palmate; peduncles generally two-flowered." Lam. 8. C. Bryoniae-folius; Bot. Mag. 943. Root perennial. Stems a foot and half or two feet high, farmentous, white, cylindrical. Leaves alternate. Flowers reddish, large, very open, almost entire; pedicules longer than the leaves, with two filiform bracteae above the middle. The whole plant cloathed with numerous hairs, so as to give it a silky aspect. A native of the Levan, Africa, and the South of Europe. The variety 8. is a much more robust plant; its leaves have no silkenk or silky whitenev; its flowers are larger and deeper colored. Raised from seeds procured from China, by Ifasa Swainson, eig. in 1802. 99. C. tenuiflorus. Smith Proe. Flor. Grac. p. 134. Pl. Grac. tab. 195. (C. althoideis 8. Linn. 99. Defr. C. althoideis; Bot. Mag. 359. 99. C. aristogatus folis tenuiter incisus; Tour. Init. 85.) "Leaves pedate, filary, remarkably shining; linear lobes obtuse; root-leaves cordate-ferrated; peduncles one-flowered." Found by Dr. Sibthorp in Candia, about Athens and in the isle of Zante. 100. C. alephalos. Lam. 2066. "Hirsute; all the leaves deeply divided, somewhat palmate; peduncles few-flowered, longer than the leaves." A native of the Cape of Good Hope. 101. C. cairicus. Linn. Sp. Pl. 21. Mart. 83. Willd. 70. Bot. Mag. 699. (C. folius lanscatus vel quinquenervis; Bauhin. Pin. 295. Barrel. icon. 319 and 320. C. egyptius; Vellin. 53. 73. tab. 74. Ipomea palmatis; Perdil. Defr. 43.) "Stem shrubby; leaves palmate-cleft, mucronate, smooth, quite entire, but often minutely crenate; hinder leaves two-flowered; filipus palmate; calyxes even surfaced; corollas ribbed underneath; divisions acute." Root perennial. Stems with many slender branches. Leaves alternate; segments lanceolate; pedicels the length of the leaves, with two leaf-like filipus at the base. Flowers violet-purple, large; pedicels the length of the pedicels, axillary, from one to three-flowered; pedicels bracteate about the middle, with two small, egg-shaped, acute scales; calyx five-leafed; leaves short, egg-shaped, acute, concave, smooth, very shining either side; tube of the corolla nearly cylindrical, contracted as far as the calyx; border spreading; filaments unequal; anthers somewhat arrow-shaped; stigma divided into furrowed lobes. A common ornamental plant in the gardens of Egypt. 102. C. quinquenervis. Mant. 107. Willd. 71. Vahl. Symb. 3. 32. "Leaves palmate-quinquelobed, finely ferrinated, obtuse, smooth; axils tomentous; peduncles one-flowered; item smooth." Stem cylindrical. Leaves nerved, finely veined, mucronate; middle lobe scarcely an inch long, lateral ones smaller, and narrower; pedicels an inch long, filiform; filipus two, alternate, petiolate, limbed in fructicule to the leaves. Flowers purple; peduncles the length of the petiole, filiform, without bracteae; calyx-leaves obtuse, obtuse, smooth; stigma capitate, two lobed. A native of the Isle of Santa Cruz. 103. C. caietica. Linn. Mant. 559. Mart. 34. Willd. 72. (C. Ripulatus; Defr. 26. Lam. 2025. C. folius laciniam, vel quinquenervis; Bauhin. Pin. 295. Barrel. icon. 319.) "Leaves pedate, ferrated; peduncles eniform, one.
one or two-flowered; calyxes nutricated. Root annual. A
stem angular, smooth, and even-surfaced. Leaves smooth, deeply
divided almost to the base; segments five, lanceolate,
ferrated or unequally toothed, mucronate by the middle
nerve; lateral ones feebly shorter; two external ones often
broad. Petioles long, channelled, feebly underset; 
diplobus similar to the leaves, but smaller. Flowers small,
white; peduncles axillary, compressed, larger than the
petioles, thickened upwards, with two bracts above the
27. Lam. 1826. "Leaves finely laciniate, somewhat
biinnipinnat; peduncles one or two-flowered; calyx of
the fruit nearly naked." About a foot and half high.
shades perfectly smooth, sometimes cloathed with fine silky
hairs. Leaves slender, cylindrical. Leaves alternate, petioloed.

Flowers white; peduncles slender, longer than the petioles,
axillary, solitary, thickened upwards; bracts two, about a
line and half long, linear, acute, fimbriated near the top of
the peduncle; calyx-leaves egg-shaped, obtuse, mucronate,
a little scarious, sometimes rather villous, especially at the
weight of flowering; corollas campanulate, twice the length of
the calyxes. Seeds black, naked. A native of South America. about
Monte Video. Specimen in the herbarium of Commercon.

There is a variety in the herbium of Thion very villous
in all its parts, especially the calyxes, with the lower
leaves less deeply divided, than the upper. 105. C. virgata.

Leaves petiolate; leaflets acute at the base (rather than petiolated), veined; middle one larger than the others, about two inches long; common petioles with a shorter tendril at the base. Dfr. Pedicels with an ovate-heart-shaped, acuminate, solitary leaf at the base. Vahl. Is it not properly a flipula, which, as the peduncles are axillary, may be thought by one observer to accompany the petiole; by another, the peduncle?) Flowers in a corymb; peduncles a flary, dichotomous near the top, with small awl shaped bracts; calyxes short; segments egg-shaped, two inch; corolla funnel-shaped, tube nearly of the same diameter throughout, not gradually enlarged to the top; border but little widened; ligments capitate, slightly two-lobed. Sent by Collinmion from the Isles of France and Bourbon. On a close comparison it appears certain, that Dufourneaux and Vahl have described the same plant, and have given it the same name, without any knowledge of each other's specimens. 118. C. glaber. Dfr. 193. Lam. 2104. Willd. 81. Ait. guian. 136. tab. 53. "Leaves digitate, in fives; leaflets ovate-lanceolate, quite entire, smooth; pedicels many-flowered." Dfrs. numerous, long, cylindrical, flexible. Leaves alternate. Flowers white; petals axillary, solitary; pedicels long; calyx deeply divided; segments long, firm, smooth, acute; tube of the corolla rather long; border open, with five rounded lobes; stigma two, long, acute. A native of Cayenne. The whole plant is milky. 119. C. arborescens. Dfr. 107. Lam. 2106. "Shubby; leaves digitate; leaflets about eight, linear, very narrow; seeds very hispid." Whole plant, except the seeds, hispid. Stems turmouitous, woody, cylindrical, leaves about an inch long, including the pedicels. Flowers purple, axillary, in small dichotomous racemes, shorter than the leaves; calyx-leaves obtuse, not a quarter of the length of the flowers; corolla cylindrical. Cappiell egg-shaped, five-flowered; the entire plant pubescent. Stems singular. Leaves petiolate; leaflets very narrow, entire. Petioles axillary, short; upper ones sometimes one-flowered. Calyx smooth, with oblong leaflets; stigma acute.

** Stems not twining.**
