1819.
COLLISION, from the Latin Collisio, a breaking, knocking, or dashing together, in Philosophy and in Mechanics, means the meeting, mutual striking, or congress, of two or more bodies, one of which at least is in motion. The collisions of bodies and the results arising from those collisions, form by far the greatest part of the operations of nature, as well as of artificial mechanics; hence the industry of man has spared no pains in the investigation of the laws which regulate those motions, and in the performance of experiments tending to confirm and to illustrate the same. In the theory of collision or percussion, the simplest cases are considered first, and such, indeed, as cannot actually take place in nature; for instance, two bodies are supposed to move equally (that is, each of them, or one at least, to run through equal lengths in equal portions of time) in non-resisting mediums, and those bodies are farther supposed to be either hard, or soft, or elastic. A hard body is that whose parts retain their respective situation or figure in all cases, not yielding to any stroke or percussion. A soft body is that whose parts yield to any stroke, and have no power to recover their original situation; and lastly, an elastic body is that whose parts yield to any stroke, but presently regain their original form and situation. Now, in nature, as far as we know, there are no bodies perfectly elastic or perfectly unelastic; including under the latter name both those that are perfectly hard and those that are perfectly soft. All the bodies we are acquainted with are partially elastic, but in various degrees; nor can their motions take place without meeting with some obstruction. Yet the laws of collision, under the above-mentioned suppositions, being demonstratively deduced from the general laws of motion, which are justly assumed as axioms, determine the phenomena which would take place if those suppositions were real; it being afterwards more easy and practicable to estimate, and to allow for those deviations of practical results from the abstract theory, which arise from the imperfect elasticity of bodies, from resistances of mediums, from friction, &c.

The theory of collision is derived from Sir Isaac Newton's third law of motion, which says, that action and reaction are always equal and contrary to each other. See Laws of Motion.

Definition 1. The respective velocities or celerities of bodies are proportional to the spaces which they describe in a given time. Thus, if a body, A, passes through an extension of 10 feet in one second of time, whilst the body, B, runs through an extension of 100 feet in the same time, then the respective celerities of those bodies are said to be as 10 to 100; or as one to ten.

Def. 2. The bodies are said to strike directly against each other, when in striking, there occurs no reason why they should turn towards one side rather than towards another; so that both before and after the stroke, the motion is in the same straight line, unless it be all destroyed.

Def. 3. In every other case the stroke is said to be oblique. The principal proposition belonging to this theory, considers two bodies that strike directly against each other, and the result is concisely expressed by Sir Isaac Newton in the following words: "the quantity of motion, that is gathered by taking the sum of the motions made towards the same parts, and the difference of those made towards the contrary parts, is not altered by the action of bodies amongst themselves." For the sake of perspicuity we shall endeavour to demonstrate this proposition, by considering the two cases separately.

"Theorem
Theorem I.

If a body, A, (Plate XV. Mechanics, fig. 1.) strike directly against another body, B, which is either at rest, or moving in the same direction, but slower; the sum of the motions in both the bodies towards the same parts, will remain the same after the stroke, as it was before that stroke.

Let CD express the motion of the body A, and EF the motion of the body B; viz. that whilst A moves from C to D, B moves from E to F. Therefore, the sum of the motions is CD plus E F. Now, since it moves with greater velocity than B moves with, it necessarily follows, that A must overtake, and strike against B. And it will appear, that after the stroke the sum of the motions is the same as it was before, viz. CD plus E F. For since action and reaction are equal (3rd law of motion), if A, by striking on B, communicates to it the additional motion FG; it must lose as much itself; viz. DK (equal to FG) must be subtracted from CD. So that after the stroke, CK is the motion of A, and EG that of B; and the sum of those motions is CK plus EG, equal to CD plus E F; for, since FG is equal to DK, add EF and CK to both, and it will be FG + EF + CK equal to KD + CK + EF; viz. EG + CK = CD + EF.

The various cases of this proposition are as follow: If FG is equal to CD, then K and C coincide, and C K vanishes or becomes equal to nothing (as in fig. 2); hence, after the stroke, A will be at rest.

If FG exceeds CD; then K will fall beyond C; and the motion of A will become retrograde or negative (as in fig. 3.) Therefore, the sum of the motions towards the same part is the difference between EG and CK; viz. EG minus CK.

If B falls at rest, then its motion becomes equal to 0, and in that case the sum of the motions is reduced to CD.

Theorem II.

If two bodies, moving towards contrary parts, strike directly against each other, the sum of their motions towards the same parts (which is the difference of their motions towards contrary parts) before and after the stroke, will always remain the same towards the same part.

Let the body, A (fig. 4.), move from C towards D, and let CD represent its motion, whilst the body, B, moves in a contrary direction from E towards F, and let EF represent its motion.

Make DH equal to EF; then C H is the difference of the motions towards the contrary parts, and is, at the same time, the sum of the motions towards the same part; viz. towards G. Now, after the stroke, the same, CH, will be as the sum of the motions towards the same part; viz. towards G.

Let the motion of B, after the stroke, be towards G, and let it be represented by E G. Therefore, the force communicated to B is E F plus E G, that is, FG. But (by the 3rd law of motion) making D K equal to FG, D K will represent the motion lost by A; so that if D K be subtracted from C D, the remainder, C K, will be the motion of A towards G. Now, since D K is equal to FG, and D H is equal to F E; it will be D K minus D H, (viz. K H), equal to FG minus FE (viz. E G). Therefore, since E G is equal to E F, K H will represent the motion of B after the stroke, and C K will represent the motion of A; so that C K plus K H is equal to C H, and is the sum of the motions towards C G.

If F G is equal to C D (as in fig. 5.); then K and C coincide, consequently the motion of A becomes equal to 0.

If G exceeds C D (as in fig. 6.) K will fall beyond C, and the motion of A will be retrograde; but (since F G is equal to D K, and K H to D H) K H will be equal to E G; therefore, taking C K from both, C H will be equal to E G minus C K. But C H was as the sum of the motions towards G before the stroke, and E G minus C K is as the sum of the motions towards the same part; namely, as the difference of the motions towards the contrary parts after the stroke. Therefore, the sum of the motions towards the same part will be the same both before and after the stroke.

Having demonstrated the two simplest theorems belonging to the doctrine of collision, wherein the equality of the motions before and after the stroke has been considered, it is now necessary to examine the direction, the velocity, and the momentum of the bodies after the stroke; and for this purpose the properties of the centre of gravity must be recollected.

But, that property of the centre of gravity, which is more immediately concerned with the present subject, is briefly expressed in the following lines:

If bodies, moving in the same straight line, strike against each other, the state of their common centre of gravity will not thereby be altered; viz. it will either remain at rest, or it will continue to move in the same straight line, exactly as it moved before the stroke. See Center of Gravity.

Theorem III.

Let there be two non claflie bodies (viz. either perfectly hard or perfectly soft); and if one of them move in a straight line, whilst the other is at rest in that line, or is moving in the same direction, but at a slower rate, or is moving in the contrary direction; then those bodies must strike directly against each other, and after the stroke they will either remain at rest, or they will move on together, conjointly with their common centre of gravity. Their momentum, after the stroke, will be equal to the sum of their momentums before the stroke, if they both moved in the same direction; but it will be equal to the difference of their momentums if they moved in contrary directions. Their velocity, after the stroke, will be equal to the quotient that arises from dividing the sum of their momentums, if they both moved the same way, or the difference of their momentums, if they moved contrary ways, by the sum of their quantities of matter.

That, after the stroke, the two bodies must either remain at rest or move on together, is evident; for, since they are not claflie, there exists no power that can effect their separation. With respect to the momentum, it must be observed, that where the bodies meet (by the 3rd law of motion), whatever part of the momentum is lost by one of the bodies, must be acquired by the other; therefore, if before the stroke the bodies moved the same way, their joint momentum, after the stroke, will be equal to the sum of their momentums before the stroke. If one of the bodies was at rest, then, as its momentum is equal to its joint momentum, it will be equal to the momentum of the other body before the meeting. If the bodies moved towards each other, then their momentum, after the meeting, will be equal to the difference of their former momentums; and if in this case their momentums are equal, then their difference vanishes; that is, the bodies will remain at rest after their meeting.

The last part of the theorem is evident; for the momentum of a body in motion is equal to the product of the velocity multiplied by the quantity of matter. See Momentum.
The weights and velocities of the two bodies before their meeting being given, the velocity, after the meeting, may be determined by the following method, which is applicable to the four cases of Figs. 7, 8, 9, and 10. Let A and B be the two bodies, C their common centre of gravity, and D the place of their meeting. Make DE equal to DC, so that the point, D, may be between C and E; then DE will represent the velocity after their meeting; for, since the bodies, after their meeting, move together conjointly with their common centre of gravity; and the centre of gravity has the property mentioned immediately before the third theorem; it follows that the velocity of their common centre of gravity after their meeting, must be equal to its velocity before the meeting; viz. DE must be equal to CD, and is the same as the velocity of the two bodies after the meeting, because, then, they move together with the centre of gravity.

Fig. 7. shows when the bodies move the same way. Fig. 8. shows the body, B, at rest before the stroke, in which case B and D coincide. In Fig. 9, the two bodies move towards each other; and Fig. 10, shows the two bodies moving towards each other with equal momentums, in which case they will remain at rest after the meeting. In all those four figures, the respective velocities of the bodies are represented by AD and BD, and A B is their difference. The respective momentums are represented by the product of the weight of A multiplied by AD, and of the weight of B multiplied by BD. The momentum after the meeting is represented by the weights of both the bodies multiplied by DE.

Example of the computation of the first case, Fig. 7. — Let A weigh 10 lb. and move at the rate of 4 feet per minute. Let B weigh 6 lb., and move at the rate of 2 feet per minute, and let the distance AB be 32 feet. The centre of gravity is found by saying 10 : 32 : 10 : BC = \(\frac{32 \times 10}{10}\) = 32 feet; hence AC = 12 feet. Put BD = x, and AD will be equal to 32 + x. Then the time employed by A in moving from A to D, is equal to the quotient of the space, \(32 + x\), divided by its velocity; viz. \(\frac{32 + x}{4}\). And the time employed by B in moving from B to D, is equal to the quotient of the space, x, divided by the velocity of B, viz. \(\frac{x}{2}\). But, since the bodies meet at D, those times must be equal; that is, \(\frac{32 + x}{4} = \frac{x}{2}\); and by the resolution of this simple equation, we have \(64 + 2x = 4x\); and \(x = 32 = BD\).

Then DE = DB + BC = 32 + 20 = 52 feet; viz. after the meeting, the two bodies will move from D to E, which are 52 feet apart, in as much time as each of them employed in going to D; viz. 16 minutes. Therefore, in order to find how many feet per minute the bodies will run over after the meeting, divide 52 by 16, and the quotient, \(\frac{52}{16}\) is the answer.

The magnitude or quantity of the stroke is deduced from the third general law of motion, and from the nature of the momentum of a body in motion, which is equal to the product of the quantity of matter, or weight of the body, multiplied by the velocity, consequently in the same body the momentum is proportionate to the velocity. The particulars relative to the magnitude of the stroke, are expressed in the following theorem.

**Theorem IV.**

If a body in motion strike directly against another body, the magnitude of the stroke is proportional to the momentum lost, at the concourse, by the more powerful body. Also, when the latter body is at rest, the quantity of the stroke is proportional to the velocity of the former body. — If the second body be moving in the same direction with the first, but at a slower rate, the magnitude of the stroke will be the same as if the second body stood still, and the first impinged upon it with a velocity equal to the difference of their velocities. — And, lastly, if the bodies move directly towards each other, the magnitude of the stroke is the same as if one of the bodies stood at rest, and the other struck it with the sum of their velocities.

Thus much may suffice with respect to the collision of non-elastic bodies. It is now necessary to state the particulars belonging to the collision of elastic bodies; viz. of those whose parts yield to any impression, but frequently recover their situation, by-re-acting the contrary way with a force, which, in bodies perfectly elastic, is equal to the impression or stroke received. There are innumerable degrees of elasticity. See Elasticity.

**Theorem V.**

When two bodies, that are perfect elastic, strike directly against each other, their relative velocity (by which is meant the excess whereby the velocity of the lighter body exceeds that of the flower) will be the same before and after the stroke; viz. they will recede from each other with the same velocity with which they approached before the stroke.

The magnitude of the stroke (Theor. IV.) is proportional to the respective velocities. And in bodies that are perfectly elastic, the restoring force is equal to the compressing one; therefore, if the momentums of the bodies produced a certain compression, the elastic force must re-act on the bodies with equal power; hence the bodies will be forced to recede from each other with the same velocity with which they approached each other.

From what has been stated above, the results arising from the collisions of bodies that are perfectly elastic, may be easily deduced in all the variety of cases in which the two bodies may be conceived to meet. The particulars upon which those results more immediately depend, are, first, that the distances of two bodies from their common centre of gravity are inversely as their weights; (see Center of Gravity and its properties); secondly, that the rate or uniform motion of the centre of gravity of bodies is not altered by the mutual action of those bodies on each other; thirdly, that in bodies that are perfectly elastic, the restoring is equal to the compressing force; and fourthly, that the distances of the bodies from each other, and from their common centre of gravity, are equal in equal times taken before and after the stroke; for in those two cases they move with equal velocities.

All the cases of direct collision of two perfectly elastic bodies are delineated in the figures 11, 12, 13, 14, 15, 16, 17, 18, and 19, in which A and B represent the two bodies; C is their common centre of gravity; D the place where they meet. A D expresses the velocity of A, A B the velocity of B and C D that of the centre of gravity. Hence by inspecting the figures it will be easily discerned when both the bodies are in motion, or one of them is at rest; also their directions, &c. Then the rule for determining the velocities after the stroke is as follows: — Take a point E in the line A B, produced if necessary, so that the distance C E be equal to C D; then, after the stroke, the right line E A will express
express the velocity of the body A from E towards A, and the right line E B will express the velocity of B from E towards B.

In fig. 11, B is larger than A, (which is plainly indicated by the situation of the centre of gravity C), B is at rest, and A strikes against it. In this case, after the stroke, both the bodies will recede from the point D, with the velocities E A and E B.

In fig. 12, A, the larger body, runs against the body B, which is at rest. In fig. 13, the body A is larger than B, and they are both in motion the same way. In fig. 14, A is less than B; the rest in the preceding case. In fig. 15, A and B meet at D, where A remains at rest. In fig. 16, A and B are equal, and after the stroke they recede with interchanged velocities. In fig. 17, the bodies are proportional to their velocities; hence the points C, F, D, and E, coincide. In fig. 18, A remains stationary at the place of congress D. Lastly, in fig. 19, though the bodies A and B meet at D between the points A and B, yet after the stroke they both move towards F.

The numerical computation of these cases may be easily comprehended by the following example, which is adapted to the case of fig. 13.

A and B are two elastic bodies. A weighs 2 lb., and moves at the rate of 8 feet per second. B weighs 8 lb., and moves the same way at the rate of 5 feet per second. The distance A B is 12 feet.

1. To find the place of the centre of gravity C, we have A + B = B + A; C = A; and C = C = C = C = 4, a, d CB = AB - AC = 8.

2. To find the distance BD, put BD = x; and since the distances A D and B D are run over in the same time, the former at the rate of 8, and the latter at the rate of 5 feet per second; therefore we have \( x = \frac{8}{8} + 12 = \frac{5}{8} + 60; \) and \( x = 50 \) B D.

3. If the distance B D; viz. 20, be divided by the velocity of B (viz. by 5); the quotient \( q \) is the number of seconds, during which the bodies moved from their respective places A and B, to the place of their congresses D.

4. EC = CD = CB + BD = 8 + 20 = 28; and EA = EC - AC = 28 - 4 = 24; which being divided by 4 (the number of seconds found above) gives 6 for the velocity of A after the stroke, in the direction from E towards A. Also EB = EC + CB = 28 + 8 = 36; which being divided by 4 (the number of seconds, &c.) gives 9 for the velocity of B after the stroke in the direction from E towards B. So that after the stroke, the bodies A and B will both continue to move the same way, but the former at the rate of 6, and the latter at the rate of 9 feet per second.

It is now necessary to apply the above theory to those cases which really occur in nature, and in the first, since all known bodies are partially elastic, we must shew how to eliminate the results of the collision of such bodies. Thus, let A and B, figs. 20 and 21, be two bodies impinging on each other, as C their common centre of gravity; and D the place of their meeting. Divide AC in a, so that AC may be to AC, as the force compressing the body A, is to the force whereby it strikes C. Also divide BC in b, so that BC may be to BC, as the force compressing the body B is to the force whereby it strikes itself. Take C E equal to C D; then the right line E A will express the velocity of A after the stroke in the direction from E towards a, and the right line E B will express the velocity of B in the direction from E towards D.

In the foregoing paragraphs the distances have been reckoned from the centres of the bodies; but since the bodies must strike with their surfaces, and not with the centres, therefore, when great accuracy is required, the thickness of the bodies must be deducted from the distances. However, when the distances are considerable, and the sizes of the bodies proportionately very small, it is immaterial whether the distances be reckoned from the centres or from the surfaces of the bodies; the difference becoming insignificant.

When more than two bodies move in the same straight line, the computation of the velocity of each body after the various strikes cannot be expressed under any general rules; the variety of cases being too great, and often very intricate: yet when any particular case presents itself, the preceding rules will be found sufficient to determine the particulars; offering to apply the computation to the two bodies which, from the circumstances of the case, appear to strike first, then to one of those, and the next, and so on. But sometimes the equality of the bodies, their being contiguous to each other, and other favourable particulars, render the calculation pretty easy and obvious. Thus, if any number of equal and perfectly elastic bodies lie at rest, contiguous to each other, in the same right line, and another body, equal to one of them, strike the first of them in the same right line, with any velocity; then after the stroke the striking body and all the rest will remain motionless, and the last body only will move with the velocity of the striking body.

If the movements, instead of being equal, as we have hitherto supposed, be either accelerated or retarded, the momentum for each small portion of time, must be reckoned such as belongs to the velocity acquired at that particular moment. In curvilinear movements, the direction of the motion in each point is the same as that of the tangent to the curve at that point. Lastly, if the movements, either accelerated or retarded, be likewise curvilinear (as in the vibration of pendulums); the momentum for each given point must be deduced from the degree of acceleration and from the direction of the tangent, at that particular point. Hitherto we have considered the collision of bodies, which strike directly against each other; that is, in a direction perpendicular to their surfaces, and in the direction of their centres. It is now necessary to apply the theory to oblique collisions; and for which purpose the doctrine of the composition and resolution of forces, or of movements, is already known.

See Composition and resolution of Forces.

Theorem VI.

If a body, perfectly elastic, as A, fig. 22, strike obliquely on C on the firm obstacle B, F, then, after the stroke, this body will be reflected from that obstacle in the direction C E, equal to the angle of incidence A C B.

The oblique forces, A C, B F, being resolved into two forces, viz. D C perpendicular to the oblique, and A D parallel to it; the effect on the plane is the same as if the body had advanced towards it directly from D, and (according to the laws already stated) the body A, after the stroke, would be found in the direction A D. But if the body were to enter into which the original force of A was resolved, this body retains the one represented by A D, since this force was not concerned in striking the obstacle; therefore, after the stroke, the body, A, is actuated by two forces, viz. one represented by D C, equal to A B, equal to E F; and the other represented by E F, equal to D A, equal to D E; hence it must move in the diagonal C E; and since the lines C F, 1.
The forces at B, the force B N is retained by it, whilst the force N D is exerted against the other body. Therefore, the actions of those bodies upon each other is exactly the same as if they moved directly from M and the other from N; hence, the above stated rules of direct collision, will serve to find out whether the bodies, after the stroke, will proceed both the same way, or different ways, and at what rate. But when their velocities have been thus determined; for instance, if it be found, that had the bodies moved directly from M and N after the stroke, the body, A, would have moved as far as O, whilst the body, B, would have moved as far as G; then it must be recollected, that, in the present case of oblique collision, the body, A, has retained the force A M; therefore, after the stroke, the body, A, is actuated by two forces, viz., one equal and parallel to A M, and another which is equal and parallel to C O, in conformance of which this body must run a compound course, which is found thus: Through the centre, G, draw C E equal and parallel to A M; through I, draw I E equal and parallel to C O; then the diagonal C E exhibits the velocity and the direction of the body, A, after the oblique concourse. With respect to the body, B, it has been laid, that at the concourse this body retains the force B N, and that, if the bodies had moved directly towards each other, B would, after the stroke, have moved from D to G. Therefore, through D draw D H equal and parallel to B N, and through H draw H F equal and parallel to D G; and, lastly, the diagonal, D F, will represent the velocity and the direction of the body, B, after the oblique concourse.

If the bodies be perfectly elastic, then suppose it to be found (by the rules for elastic bodies) that, after the supposed direct concourse, the body, A, would have been sent back to Q, in the same time that B would have been sent back to R; it follows, that, after the oblique stroke, the body, A, will be actuated by two forces, viz., one equal and parallel to A M, and the other equal and parallel to C Q; the body, B, will likewise be actuated by two forces, viz., one equal and parallel to B N, and the other equal and parallel to D R; therefore, in fig. 24, draw Q Z through Q, equal and parallel to A M; also through Z draw I Z equal and parallel to C Q; then the diagonal, C Z, represents the velocity and the direction of the elastic body, A, after the oblique stroke.—Again, through R draw the line, R X, equal and parallel to B N, and through X draw the line, X Y, equal and parallel to D R, then the diagonal, D X, will represent the velocity and the direction of the elastic body, B, after the oblique stroke.

Amongst all the cases of collision, we have hitherto omitted to mention the striking of a body upon an immoveable obstacle. This has been done merely because the particulars belonging to it may be easily derived from the consideration of the foregoing cases; it being only necessary to consider this case as if it were that of the collision of two bodies, either elastic or non-elastic, or partially so, and to suppose that one of the bodies, which represents the immoveable obstacle, is infinitely great. There is a difference between the stroke of an elastic body, and that of a non-elastic one, which, not being very obvious, deserves to be mentioned. This is, that the effect of the blow of an elastic body upon another body, as upon a plane, is double to that of a non-elastic body, their masses and velocities being equal. This arises from the elasticity of the former, which, after the stroke, by endeavouring to recover its original figure, acts upon the plane with a force equal to the first motion; whereas a non-elastic body acts only with the first impression. See the article Percussion. Also, if the reader with to see the original investigation of the laws belonging to the collision of bodies, together with any analytical and experimental illustration of the same, he may peruse Dr. Wallis's paper in the Phil. Trans. No. 43; M. Huygens's paper, Phil. Trans. No. 45; Sir Christ. Wren's paper, Phil. Trans. No. 45; Gravæeland's Mat. Elem. of Nat. Phil. edited by D'Aubignier; Gregory's Mechanics, vol. i. chap. v.; and all the best works on mechanics.

COLLIUS, Peter, in Biography, of the college of Milan, flourished in the beginning of the seventeenth century, and was the author of a curious treatise entitled "De Animatibus Paganorum," printed at Milan in two vols, 4to, in the year 1622-3. In this work he decides without hesitation on the future happiness or misery of many virtuous and truly illustrious characters of the Pagan world. His conclusions were founded on conjectures, deduced from a comparative view of their means of divine knowledge, their lives and manners, their opinions and writings, united with the testimony of faith and profane history. He published also a treatise "De Sanguine Christi," and a quarteto volume entitled "Conclusions Theologicae." In them all is a great display of sagacity, accompanied with a good share of talents. Novv. Dict. Hist.

COLLIWILY, in Geography, a town of the island of Ceylon; 50 miles W. of Trincomalee.

COLLUMEN, or CULMEN, a town of Germany, in the circle of Upper Saxony, and circle of Leipzig; 6 miles E.N.E. of Merseben.

COLOBRIERES, a town of France, in the department of the Var, and chief place of a canton, in the district of Toulon; 18 miles N.E. of Toulon. The place contains 1509, and the census 2933 inhabitants; the territory includes 3234 kilometres, and two communies.

COLOCCUS, in Botany, Sloan. See Cordia Colloboca.

COLLON, in Geography, a post and fair town of the county of Louth, Ireland, which is neat and well built; and which has improved considerably under the auspices of the late lord chief baron Bolton, and his son the right honourable John Bolton, the much respected speaker of the Irish house of
of commons, when the union took place. It is 29Irish
miles N. from Dublin.

COLLONCE, a town of France, in the department of
Lampt, and chief place of a canton, in the district of
Geneve; the place contains 1175, and the canton 8347 in-
habitants; the territory comprehends 215½ square
and nine communes.

COLLOPS, in Ancient Geography, an appellation diiin-
guishing two towns of Africa; the one called “Collops
Parva,” appears to have been the same with Colliulian,
situate F. of the Sinus Numidicus; the other, called “Collops
Magna,” was, according to Ptolomy, the same with Colula,
and situated N.W. of the same gulf.

COLLOQUIA, in Ecclesiastical History, a name given
in Switzerland to assemblies of the pontifical Grion clergy.
Each league is divided into a certain number of districtis,
the ministers of which assemble twice every year; and these
assemblies are called colloquia. Each colloquium has its pre-
sident, and each league a superintendent, called a dean.
The supreme authority in spiritual concerns is vested in the synod,
which is composed of the three deans, and the clergy of each
league; the synod assembles every year alternately in each of the three leagues. Candidates for holy orders are
examined before the synod. The necessary qualification for admission into the church, ought to be the knowledge of
Hebrew, Greek, and Latin; but many are ordained without
the least acquaintance with either of these languages.
Formerly Latin was freely used, as well in the debates of the
synod, as for the purpose of examining the candidates;
but at present that tongue is more and more disused, and
German is employed in its stead. See GISONS.

COLLOQUIUM, in Law, (a colloquendo), a talking
together, or affirming of a thing, laid in declarations for
words in actions of slander, &c.

COLLUCIANISTÆ, in Church History, a denomination
given to the Arians, from the martyr Lucian, a presbytery
of Antioch.

COLLUM, in Anatomy. See Neck, and Cervix.

COLLURIO, in Ornithology, the name given by Brissin
to the Lanius Collurio of the Linnean Fauna Suecia;
red backed shrive of English writers.

COLLURIO madagascariensis, of Briffon, the hook-billed
shrike, laniscurvirostris.

COLLUSION, a secret understanding between two
parties, who plead, or proceed, fraudulently, each the other,
the prejudice of a third. This collusion is either
apparent, when it shows itself on the face of the act; or more
commonly, it is secret and artfully concealed by a show of
honesty. This is a practice which the law abhors; and,
therefore, when detected, it makes void all things dependent
upon it, though otherwise in themselves good. Co. Litt.
120, 260. Plowd. 54. Collusion may sometimes be tried
in the same action, wherein the covin is, and sometimes
in another action, as for lands aliened in mortmain by a quale
just in; and where it is apparent, the proof of it is unnecessary;
but when it is secret, it must be proved by witnesses, and
found by a jury like other matters of fact. 9 Rep. 33.
The statute of Westminster 2, 13 Ed. I. c. 33. gives the writ
guale just, and inquiry in these cases; and there are several
other statutes relating to deeds, made by collusion and
fraud. The cases particularly mentioned by the statute of
Westminster 2. are of quale impedit, affije, &c. which one
company brings against another, with intent to recover the
land or advowson, for which the writ is brought, held in
mortmain, &c. See FRAUD.

In the canon law, collusion, in matters of benefices, va-
cates the benefice, and incapacitates the person from holding
any benefice at all.

COLLUTHIANS, in Ecclesiastical History, a religious
sect, which rose about the beginning of the fourth century;
and occasion of the indulgence shown to Arius by Alexander,
patriarch of Alexandria.

Several people being scandalized at so much condensation;
and, among the rest, Colluthus, a priest of the same
city; he hence took a pretence for holding separate assem-
bles, and by degrees proceeded to the ordination of priests,
as if he had been a bishop; pretending a necessity for this
authority, in order to oppose Arius. To his fehlm he
added hereby; teaching, that God did not create the wick-
ed; that he was not author of the evils that befal men,
&c. He was condemned by a council held at Alexandria by
Osiris, in the year 350.

COLLUTHUS, in Biography, a presbyter of Alexandria,
was founder of the temporary Christian sect, at the
beginning of the fourth century, above-mentioned. By
the decrees of the council held by Osiris, Colluthus was de-
posed of the episcopal honours with which he had invested
himself, and the prebends whom he had ordained were
degraded. Colluthus submitted to the decree, and returned
quietly to the duties of his office as a parochial presbyter;
his followers likewise re-united themselves to the orthodox

COLLUTION, Collatio, in Medical Writings, is sometimes
used for the washing of the mouth, particularly, when
done to clean or soften bad or loose teeth; or free the gums,
&c. from ulcers.

COLLVIES, a term which Calcutt and other writers
on the universal deluge have applied to the fluid mafs,
into which, according to their opinion, the flrata of the antedilui-
union earth were dissolved, and their constituent corpuscles se-
parated. See DELUGE.

COLLYBUS, κολλυβος, in Antiquity, the name with what
is now called the rate of exchange.

COLLYRÆ, or COLLYRIDES, a certain ornament
of hair, worn by women on their necks. It was made
up in the form of the small, roundish, cakes, called κολλυρία, or
collvre.

COLLYRIDIANIS, in Church History, a sect, towards
the close of the fourth century, denominated from a little cake,
called by the Greeks κολλυρία, κολλυρίδα, which they offered
to the Virgin Mary.

This sect, it seems, consisted chiefly of Arabian women,
who brought it from Thrace to Arabia, and who, out of
an extravagance of devotion to the Virgin, met on a certain day in the year, to celebrate a solemn feast, and
to render divine honours to Mary as to a goddess; eating
the cake which they offered in her name. St. Epiphanius, who
relates the history of this superstitious ceremony, ridicules it.
They sprung up in opposition to the Antidio-Maroni-
ites.

COLLYRIUM, κολλυριον. This term was formerly
applied to any medicament, solid, or liquet, employed to
restrain defluxions; but it is now entirely confined to wet
applications, topically applied for this purpose in complaints of
the eyes.

COLLYRIUM is also a name given to unguents used for
the same purpose; as unguent of totty, and several others.

COLLYRIUM is also a denomination given, though improperly,
to some liquid medicines used against venereal ulcers.

COLLYRIUM Sanium. See SAMIA TERRA.

COLLY-WESTON Slate, a whftish kind of micaceous
grit
grit stone, which splits into very thin lamina, and is much used for lining buildings in the eastern and some of the midland counties of England; it is the produce of a stratum situated not far in the series from the Calcite or Ketton stone, so well known to builders. In this stratum, particularly near Stonesfield, in Oxfordshire, bones of animals of some unknown kind are frequently found lodged. See Slate.

COLM, in Geography, a small island of Scotland, in the Firth of Forth, six miles S.E. of Dunfermline.

COLMAN, George, in Biography, an English writer, was the son of Mr. Thomas Colman, British resident at the court of the duke of Tuscany. He was born at Florence about the year 1733. He received his school education at Wollminster; and was entered as a student at Christ-church, Oxford, where he engaged with Bonnel Thornton, in writing "the Connoisseur," a periodical of considerable merit, which was afterwards published in four volumes, 12mo. This work is remarkable for the humorous delineations of the manners of the age, and displays classical reading and taste. On leaving the university he entered at Lincoln's Inn, and was in due course called to the bar, but never followed his profession. In 1760, he produced two dramatic pieces which were received with great success, the first was entitled "Polly Honeycombe," and the other "the Jealous Wife;" this last still keeps its place on the stage. In 1764, Lord Bath died and left Mr. Colman a handsome annuity, which was increased on the death of general Putteney, in the year 1767. In conjunction with Garrick, he brought out the "Clandestine Marriage," a comedy of great merit, and which maintains an undiminished reputation. In 1768, he purchased a share of the Covent Garden theatre; this, however, he soon disposed of, and purchased Mr. Fout's theatre in the Haymarket, which he held till his death in 1794, though he had for the four preceding years been incapable of any business, owing to a paralytic stroke with which he was seized in 1789, and which affected his understanding in such a manner as to bring on derangement and idiocy. Mr. Colman translated Terence's plays into a sort of blank verse: also "Horace's Art of Poetry," which added to his reputation as a classical scholar. In 1787, he collected, in three small volumes, a variety of pieces which he had published at different times, under the title of "Verse on several occasions, accompanied with some pieces of verse." Gen. Bosc.

COLMAR, in Geography, a town of Germany, in the duchy of Holstein, five miles S.E. of Gluckstadt.

COLMAR, a large and well built town of France, and capital of the department of the Upper Rhine, seated on the river Fecht, and surrounded by a wall, flanked with towers. It has a fair and four courts of justice. The town contains 13,756, and the canton 14,429 inhabitants; the territory includes 55 kilometres, and two communes: 104 leagues N. of Bâle. The principal trade of the inhabitants of Colmar, who are said to be very industrious, is in corn, wine; and their chief manufactures are those of woollen cloth, calico prints, stockings, hardware, and gun-powder. The district consists of 142 communes or townships, distributed into 13 cantons, and comprehending a population of 144,821 inhabitants. Its whole territory includes 1680 kilometres. It has silver, copper, lead, antimony, arsenic, and beautiful crystalline mines; and also a manufacture of gold and lace. N. lat. 48° 44'. E. long. 7° 23' 11".

COLMARS, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Caflillane; 22 miles N. of it. The place contains 898, and the canton 3585 inhabitants; the territory includes 285 kilometres and five communes.

COLMBERG, or Kolnemberg, a town of Germany, in the circle of Franconia, and principality of Anspach; 9 miles N.W. of it.

COLME, L.A., a river of France, branching from the river, Aa, at Watte, in the department of the Straits of Calais.

COLMENAR, a town of Spain, in Old Castile, on the confines of New Castile, 7 leagues N.W. of Talavera de la Reina.—Alfa, a town of Spain in New Castile, five leagues N.E. of Fucshis.

COLMITZ, a town of Germany, in the archduchy of Austria, four miles S.S.W. of Droffendorf.

COLMORTH, a rectory in the county of Bedford, and hundred of Bartord: the lofty spire of its breast forms a very conspicuous object to the surrounding country. In the Government Trigonometrical Survey in 1799, its situation was determined by observations from Lillby-Hoe elevation, distant 57 617 feet, and bearing 0° 12' 52" S.E. from the parallel to the meridian of Greenwich; and from Liddington elevation 75 914 feet; whence is deduced its latitude 52° 12' 49.5' N. and its longitude 22° 27', or 12° 29.4' W. of Greenwich.

COL.N., a river of England, which passes by Uxbridge and Colnbrook, and runs into the Thames, near Staines, separating the county of Middlesex from Buckinghamshire. The clearness and purity of the water of this river, inflowing almost entirely in springs out of the chalk hills of Hertfordshire, have always been proverbial. This circumstance probably occasioned the cutting, at some distant periods, of two channels many miles in length, for diverting part of its waters across Howllow-heath to Twickenham, and into Ditchie-park; and a very principal part of the design of the Paddington branch of the Grand Junction Canal, in latter times, was for diverting part of its limpid streams, in order to supply the metropolis with water, to which purpose it is admirably adapted.

COLN., a river of Essex, which is navigable from the mouth of the Thames at Mersey island up to the town of Colchester. See Canal.

COLN., a river which runs into the Thames at Cricklade.

COLN.BROOK, a town of England, in the county of Bucks, on the river Coln, with a weekly market on Wednesday, three miles E. of Windfor, and 17 W. from London.

COLNE, a considerable market-town of Lancashire, England, is advantageously situated on a dry and elevated ridge. This place, says Dr. Whitaker, "is unquestionably the colne of the anonymous Ravennas, and was probably never abandoned entirely, in the long and obscure period of Saxon history." At this place, there have been several Roman coins, and other antiquities found. The church is a spacious structure, and appears to have been "refored about the time of Henry VII or VIII." Here are a market on Wednesdays, and two annual fairs. Colne is 218 miles N. of London, and contains 782 houses, with 3026 inhabitants. This town is situated in the hundred of Blackburn, near to the grand ridge on its western side, and also to the Leeds and Liverpool canal, and to the famous Forth-tunnel upon it. It was once an object of contemplation to construct a branch of the Rochdale canal to this town; but it was never accomplished. Whitaker's History of Whalley, 4to. See Canal.

COLNUD, de Cayanne, of Buffon, in Crustology, the bare-necked crow, corvus nudus.

COLOMBAUDE, the name given by Buffon to matailla atricapilla, or black cap.

COLO, in Geography, a town of Poland, in the palatinate of Kaliceh, 20 miles N. of Kaliceh.

COLO, in Ancient Geography, a Roman colony, near the city...
city of Constanza, in the kingdom of Algiers, in Africa: the ruins of it now remain, having a castle on a very high rock towards the sea coast, with a garrison, under the command of an aga, under the protection of which is a small French factory, that deals with the Moors for hides, wax, and wool. The mountains of Col, around with a large and fierce kind of monkeys, which the Moors have the art of catching with great facility.

COLOBI, a people of Africa, placed by Ptolemy in the Troglytine region.

COLOBIUM, a region, from which, I suppose, among the Arabs, an upper garment, without sleeves, longer than the tunic.

COLEOMA, in Medical Writings, is used for the pre-terminary growing together of the lips, or eyelids, or for the adhesion of the ears to the head.

COLEONOMRON, in Ancient Geography, a promontory of Ethiopia, near Egypt, placed by Strabo and Ptolemy in the Archil gulf.

COLEOBA, a town of Spain, in Bética, placed by Piny in the district of Hipparia; now Triabena.

COLEBRASUS, a town of Asia, situate in the interior part of Cilicia Montana, which, according to Ptolemy, was a country of Pamphylia.

COLOCASIA, in Botany, Cl. See Arum Colocasia.

COLOCASITES, in Ancient Geography, an island of the Red sea, on the coasts of Arabia, a country of Ethiopia, according to Piny.

COLOCOLO, in Ornithology, a name given by the people of the Philippine islands, to a bird called also there affili, and by some authors the water raven, corvus fluviatilis. This bird, as it is described in the Philosophical Transactions (n. 285), is of the shape of a common raven, but is truly an amphibious bird, living more of its time under water than in the air; it is black in colour; its neck is remarkably long, and it feeds on fish, which it hunts under water, as they do on land; it feeds likewise on frogs, serpents, and shell-fish. It is common to see it under water in clear rivers, where it seems perfectly at ease, and runs about with great swiftness; at times it comes up to the surface, and dries its wings in the air and sunshine. It is understood by naturalists pretty generally, that the colocolo of the Philippines is not other than the common corvus, pelecanus cor- ba, a bird known to inhabit most parts of the world, and to delight especially in maritime situations, or in marshes, and other watery places, near the sea-coast.

COLOCYNTHIS, COLOQUINTA, Bitter Apple, in the Materia Medica. The colocynthis is a species of gourd (cucumis colocynthis, Linn.) brought from Aleppo and Cyprus, of a globular shape, about the size of the fig, white, smooth, of a fungous texture, divided internally into large cells, which contain a number of oblong seeds. The pulp, which is the part used medicinally, is intensely bitter, nauseous, and astringent. It contains a remarkably large portion of mucilage so as to render slimy a considerable quantity of water when boiled with it; and, on this account too, the spiritsuous tincture is too thick to pass through a paper filter.

The colocynthis, taken in substance, without any mixture or preparation, is one of the most violent purgatives that we are acquainted with, producing, when in a large dose (that is, when more than eight or ten grains), very severe griping pains, and often a discharge of blood, and leaving for some days intervals resembling those of dysentery. It is said, too, to act upon the bowels when applied externally to the abdomen.

The activity of the colocynthis renders it a valuable medi-
C O L

Cologne, in Geography, an arch-bishopal electorate of Germany, in the circle of the Lower Rhine. divided into several districts by other electates, and deriving its name from the city of Cologne. It was a bishopric in the year 343, and, in 799, was erected into an archbishopric by Charlemagne. In the ancient constitution of Germany, the archbishop was the actual head of the Holy See, and arch-chancellor of the sacred empire for Italy. He gave his vote after the elector of Treves, and sat at the right hand of the emperor, at assemblies held in his own diocese, in Gaul, or in Italy. The metropolitan church and chapter, which is composed of 25 canons, and 36 dignitaries, are at Cologne. Since the French revolution, and the subsequent arrangement of its territories, Cologne is a district of Roer, or Ruhr, comprehending 10 cantons, viz. Cologne, Bergheim, Brühl, Dormagen, Eifel, Juliers, Kerpen, Lechbach, Wayden, Zulpich, which include 294 communes, 1757 kilometers, and 357,215 inhabitants. Although this electorate is reckoned one of the most fertile countries of Europe, the bigotry, ignorance, and idlenes of its inhabitants, who are mostly Roman Catholics, prevent its deriving those advantages from its productions, and particularly its commerce, which might reasonably be expected.

Cologne, the capital of the archbishopric above mentioned, and formerly one of the free and imperial cities of Germany, in the circle of Welphania. It was taken possession of by the French in 1794, and is now the capital of the district that bears its name in the French department of Roer, and is said to contain 38,344 inhabitants. Cologne is situated, in the form of a crescent, on the banks of the Rhine, and fortified in the ancient manner; but its walls are in so decayed and tottering a state, that they are incapable of affording it any defence. The whole of its length, along the river, is about 32 miles, two-thirds of which space is uninhabited; several of the squares and streets more resembling a field, or an uncultivated garden, than parts of an inhabited city. In traversing its environs one may observe more than 150 miserable farm-houses, with gardens, which furnish the city with all sorts of greens, butter, cheese, milk, &c. The streets are narrow, winding, and gloomy, and most of the houses are very high, old, and ruinous; and yet this city is said to contain, within its comports, more churches, chapels, and monasteries, than there are days in the year. The Roman Catholic university scarcely merits the appellation. The number of beggars that disgrace its police is very great, and it is said, that the propriety to idlenes, glutonry, and begging, which prevails throughout the city and adjacent country, is encouraged and encouraged by the example of the different orders of monks; whose chief object is to keep the people, who, with the exception of a few Protestant families, are Roman Catholics, in a state of ignorance and superstition. Two thirds of the inhabitants are either professed beggars, or con-fidiants. The other third consists of a few patricians, mechanics, and mechanics, on the produce of whose excursions and industry the red wine.

Cologne, upon the whole, is at least two centuries behind the other parts of Germany, with regard to improvement in the arts and sciences. Although no city in Germany is more favourably situated for commerce, the natural bigotry and idleness of the inhabitants lead them to forego the benefits which their situation awards them; and their trade has dwindled away to the manufacture of a few ribbons, stockings, lace, and tobacco. The vessels that may be always seen in the port of Cologne are very numerous; the quay, more than 18 mile long, is continually crowded with ships; but the goods on board are almost wholly the property of foreign merchants. About a fortnight before the fair at Frankfort begins, there is a great concourse of these merchants at Cologne, who repair daily from thence to Frankfort, by means of two commodious vessels containing from 150 to 200 passengers, every other day during the fair. The Jews were expelled from Cologne in the year 1485, and from that remote period not one of them has ever obtained leave to settle there, or dared even to enter the city without permission of the magistracy. Under the old police, if a Jew came into the city, he was accompanied by a guard during his stay, and obliged to pay a duty for every hour of his continuance there. In the year 1618, the Protestants were all expelled, but some years after they obtained permission to return. The magistrates indeed gave them leave to erect a place of worship, which was destroyed by the infuriated mob as soon as it was finished. Since that event they have erected for themselves several handsome churches at Milheim, three miles from Cologne, on the right bank of the Rhine. The trifling commerce of Cologne has been confined to a few Protestant families ever since the period of their return, who, it is observed, are the only opulent inhabitants of the place. The wealth of the churches at Cologne, at least before it was taken possession of by its new occupiers, was immense, particularly that of the cathedral. These churches are repositories of various relics that are held in high estimation by the superstitious Catholics. The theatre is a roomy building, but not elegant. The town-houses are irregular edifices, awkward and a ruinous state. The arsenal occasions part of a very narrow street; its contents are chiefly ancient arms, not proper for modern use; and the building itself is in a state of decay. The dealers of Nuremberg and Augsburg bring their toys in large quantities to Cologne for exportation to Holland, England, and America. The Spaniards and Portuguese carry on a very profitable trade with them in both the Indies. The inhabitants of Cologne derive a very considerable advantage from the importation of coals out of the adjacent countries of Berg, the electorate of Treves, the principalities of Saarbruck, and duchy of Luxemburg, which come by the Saar down the Moselle and the Rhine, and supply the want of wood fuel, that is very scarce about Cologne. Some of these coals are round and large, and another sort consists of dust, which is mixed with clay and water, and formed into small cakes, manufactured in summer; and which, being gradually hardened by the heat of the sun, are stored up in large magazines erected for that purpose. These coal-cakes are sold at 10 livres (about 1/2 English money) per hundred; and it is said, that 100 of them will go as far as three bushels. Near this city some pseudo-volcanic remains have been traced, which are thought to be such as are mentioned by Tacitus at the close of the 13th book of his Annals, the effects of an eruption which ravaged the country of the Juoves, N. lat. 50° 55' 21". E. long. 6° 52'.

Cologne, a town of France, in the department of Gers, and chief place of a canton, in the district of Lombe; 8 leagues E. of Auch. The place contains 769, and the canton 6096 inhabitants; the territory comprehends 1175 kilometers, and 17 communes.

Cologne Earth, a substance used in painting, as a water colour, much approaching to amber in its structure, and of a deep brown. It has generally been esteemed a genuine earth, but has been discovered to contain a great deal of vegetable matter, and, indeed, it is a very singular substance.

It never constitutes an entire stratum in the earth, but is lodged among other strata in large flat detached masses. It is moderately dry, while in the earth, and of a soft crumbly
crumbly texture. When dried, it is of a deep, dusky brown, of a very close, compact, and fine texture, and very remarkably light; it is of a smooth, even surface, dry, but not hard to the touch, crumbles easily to pieces between the fingers, and slightly stains the hands: it adheres firmly to the tongue, but not at all resembling the allergicity of the bones, or any thing else of the mineral kingdom, but plainly resembling the tale of oak bark. It makes no effervescence with acids; if thrown into water, it swells on the surface, till thoroughly wetted: and if brought into contact with burning coals, it takes fire and burns of itself, till reduced to yellowish ashes.

It is easy to discern from this account, that, though this is generally esteemed an earth, and known to the world by no other name, it is no pure native fossil, but contains more vegetable than mineral matter, and owes its origin to the remains of wood which has been long buried in the earth. It is dug in Germany and France; the quantities consumed in painting, in London, are brought from Cologne, where it is found very plentifully; but our own kingdom is not without it, it being found near Birmingham, and on Mendip hills in Somersetshire; but what has been yet found there is not so pure or fine, as that imported from Cologne. Hill's Hist. of Fossils. p. 64. and Dr Colla's Hist. of Fossils, p. 121.

COLOMBO, or Geography, a town of Italy, in the duchy of Tuscany; 6 miles E. of Leghorn.

COLOKITA, or Kolokitia, a town of European Turkey, in the southern coast of the Morea, in a gulf to which it gives name; 25 miles S.E. of Mistra. N. lat. 36° 47'. E. long. 22° 34'.

COLOMAY, a town of Poland, in the palatinate of Red Russia; 5 miles N.E. of Halecz.

COLOMA, in the Materia Medica. See COLUMBO.

COLOMBEL, Nicolas, in Biography, a French painter who was born in 1646, at Sottaville near Rouen, and became the scholar of Le Sueur, under whom he studied several years; he then went to Italy, where he affidulously copied the works of Raffaelle and Nicolo Pouffin; but though he enjoyed every advantage of education, and laboured to form his style upon the model of those great masters, the poverty of his genius ever appeared; and his pictures, though correctly drawn and carefully finished, generally wanted that elevation of thought and striking expression, which can alone give value to historic painting. However, in 1682, he sent four pictures which he had painted at Rome to Paris, and thereby gained sufficient reputation to cause his being chosen a member of the Academy upon his return to Paris in 1694. One of his most esteemed pictures is an "Orpheus playing on his Lyre," in the apartment of the menagerie in the royal palace. He died in the year 1717, D'Argenville.

COLOMBS, in Geography, a town of France, in the department of Paris, and chief place of a canton, in the district of St. Denis; 13 league N.W. of Paris.

COLOMERY, a town of France, in the department of the Meurthe, and chief place of a canton, in the district of Toul; 13 miles S.W. of Nancy. The place contains 8,783 and the canton 12,887 inhabitants; the territory includes 315 kilometres and 32 communes.

COLOMBIEN, De, in Biography. See VALENTINE.

COLOMBIER, in Geography, a town of France, in the department of the Upper Saone, and chief place of a canton, in the district of Voul; four miles N. of Vefoul.

COLOMBIER, Claude De La, in Biography, a celebrated French Jesuit, was born near Lyons, in which city he protected his studies, devoting most of his time to rhetoric and theology. Of the former branch of science he became a professor, and in the latter he was distinguished as a popular and instructive preacher. In this character he was noticed at the court of the duke of York, afterwards James II. of England, being made chaplain and confessor to the cheques, until he was banished under suspicion of being engaged in a conspiracy. He returned to his native country in the year 1684, where he died at the age of 41. Colomiere published six volumes of sermons, which are elegant, pious, and simple; they have been often reprinted. He published also a "Collection of Orations" in Latin, delivered by the author as professor of rhetoric; a volume of "Moral Reflections;" two volumes of "Spiritual Letters;" and "A System and Office for the Solemnity of the Worship of the Heart of Jesus," which the Jesuits employed a considerable time in every Catholic country, as a powerful instrument in favour of the papal cause. Patro, a well known writer, deferebres Colomiere as one who thoroughly understood the most refined of the French language. Nouv. de St. Hil.

COLOMBINI, Cosimo, an engraver of Florence, who engraved a great part of the portraits of painters inserted in the magnificent work of the "Museo Florentino." He flourished about 1574. Strutt. Heineken.

COLOMBONI, Don Angel Maria, a very celebrated painter of miniature and natural history, was born at Gubbio in the year 1608, and at a very early period of life became a monk of the order of Mount Olivet. He made considerable progress in literature, and in the mathematics, and published at Bologna, in the year 1669, a book on sundialling, entitled "Pratica Gnomonica, ovvero Tavole, colle quali si agevolmente può far da se gli Orologi da Sole." But he was not less admired for his miniatures, and for his excellent drawings of herbs, flowers, and birds, which he drew with such talfe and correctness, and finished with such extraordinary deftness and talents, that he was styled the Giovanni da Udine of his time, and the great Guercino used to call him the Raffaelle of his profession. He left two volumes of these drawings of birds, in which not only the beautiful colours and the delicacy of the plumage were admirably represented, but, what was more extraordinary, each appeared exactly in the attitude most usual to it or most characteristic. He spent great part of his life in Bologna, highly esteemed, and died in the place of his nativity in the year 1672. Baldinucci.

COLOMNRARO, in Geography, a town of Naples, in the province of Baflonata; 43 miles S.S.W. of Turpi.

COLOMIES, Paul, in Biography, was born at Rochelle; he embraced the Protestant religion, and followed his friend Isaac Vossius into England, where he attached himself to the cause of episcopacy, and even attacked the party among whom he had been educated, in a work entitled "Theologorum Presbyteriorum Icon," which raised him many enemies. He was, however, rewarded by being made librarian at Lambeth, and reader at the episcopal French church in London. Here he died in January 1702, leaving the reputation of great skill in bibliography. He was author of "Gallia Orientalis," in 4to. which was an account of Frenchmen eminent for oriental learning; of a familiar work respecting Italy and Spain, with many others of considerable note at the time in which he flourished. Bayle.

COLOMMA, Fabius. See COLUMN.

COLON, in Anatomy, from vexo, boldice; is a name applied to the greater part of the large intestine. See INTESTINE.
Col. in Grammar, a point, or character, formed thus (:) serving to mark a pause, and to divide the members of a period. See Pointing. See also Period, Comma, and Semicolon.

Grammarians generally assign the use of a colon to be to mark the middle of a period; or to conclude a sentence less perfect than the dot, or period: but a sentence less perfect than the period, is an expression extremely vague and indeterminate.

Others say, a colon is to be used when the sense is perfect, but the sentence not concluded: but neither is this sufficiently clear and express. Add to this, that in practice, our best writers confound the colon with the semicolon.

F. Builer attempts to fix the use of the colon: but he does not much distinguish it from the semicolon: he prefers the use of either, indiscriminately, and calls them by a common name, intermediate points: as being mediums between the comma, and full point, or period. Their use, according to this author, is to distinguish the supernumerary members of a period. By supernumerary members are meant such as the precedent ones do not raise any expectation of: i.e., such parts as have indeed a dependence on what goes before, even though what goes before has a complete sense, independent hereon: v. gr. "the Augustan age was so eminent for good poets, that they have served as models to all others: yet did it not yield any good tragic poets;" where the supernumerary member, and the use of the colon, are obvious. The most obvious and sensible use of the colon, he adds, is, when the supernumerary member is distinguished by some conjunction: as, notwithstanding, but, except that, unless, inasmuch as, yet, since, the rather as, provided that," &c. Some, indeed, use the colon in the middle of long periods, without any regard to supernumerary members: which custom was probably introduced to mark, that the breath is here to be taken almost as much as in a common period, in the place where the supernumerary period commences. But this, at best, is arbitrary; and the intermediate pointings may always be omitted in a period, if there be no supernumerary member, i.e., if there be no subsequent member, but what is expected from the precedent. As to the occasions where the colon is to be used, rather than the semicolon, there is nothing precise to be said of it; except that the colon shows the supernumerary member more detached, and sets it at a greater distance from the rest; and therefore marks a longer pause than the semicolon.

Accordingly, it seems preferable to use the semicolon before conjunctions adversative, restrictive, conditional, &c., as, "nevertheless, but, excepting that, however, otherwise, provided that." Again, where the supernumerary phrases not only supple the precedent, but depend on them for their regimen, and are, as it were, new parts thereof; there the semicolon seems preferable to the colon: v. gr. "You are regardless of the good works of God, who left thee to a God who is only jealous of your heart for your own happiness; a God who could be equally glorious in destroying you by his justice, as in saving you by his mercy." Or thus: "The discourse consisted of two parts; in the first was shown the necessity of fighting; in the second, the advantages that would redound from it." But this difference, it must be owned, has a dependence on something that influences all the points, and sways the whole doctrine of punctuation; viz., the length, or shortness, of the members and periods: for, when the phrases are long, we point higher than when short.

A latter author, in an ingenious discourse, "De Ratione Intermittendi," marks the office of the colon, and its difference from the semicolon, &c. more precisely; a colon, on his principles, serves to distinguish those conjunct members of a sentence, which are capable of being divided into other members, whereas one at least is conjunct. Thus, in the sentence, "as we cannot discern the shadow moving along the dial-plate, so the advances we make in knowledge are perceived by the distance gone over;" the two members being both simple, are separately by a comma: in this, "as we perceive the shadow to have moved, but did not perceive it moving;" the sentence being divided into two equal parts, and those conjunct ones, since they include others, we separate the former by a semicolon, and the latter by commas; but in this, "as we perceive the shadow to have moved along the dial, but did not perceive it moving; and it appears the grafs has grown, though nobody, ever saw it grow: to the advances we make in knowledge, as they consist of such minute steps, are only perceivable by the distance." The advancement in knowledge is compared to the motion of a shadow, and the growth of grasses, which comparison divides the sentence into two principal parts: but since what is laid of the movement of the shadow, and likewise of the growth of grasses, contains two simple members; they are to be separated by a semicolon; consequently a higher pointing is required to separate them from the other part of the sentence, which they are opposed to; and this is a colon.

Bishop Lowth observes, that a colon distinguishes a member of a sentence, whether simple or compounded, which of itself would make a complete sentence, and so requires a greater pause than a semicolon, yet, is followed by an additional part, making a more full and perfect sense. He adds, that a colon may be also used when a semicolon has preceded, and a greater pause is still necessary, though the sentence be incomplete; and that it is commonly used, when an example, or a freech, is introduced. Intro to Eng. Gram. ed. 1772. p. 207.

Gen. Ch. Cal. five-leaved; leaves linear, coloured on the inside, caducous. Cor. Petals five, with a nectaraceous fascia at the base. Stam. Filaments numerous, inserted into the top of a pentagonal column. Pith. Germ placed at the top of the column, in the centre of the filaments, tetragonal-globular; style longer than the filaments; stigma spher. Peric. Drupe globular, with four wings, opening into four parts. Seeds oval, two in each division of the drupe. Nearly allied to Grewin, and differing chiefly in the structure of the pericarp.

COLONIE, in Ancient Geography, a town of Asa Minor, in the Troade, placed by Strabo at the distance of 140 ferd from Ilium, in the territory of Lampsacus; it was a colony of Milifians.—Alsfo, a town of the name, placed by Strabo near Chrysa; by d'Anville, S. of Troas.—Alsfo, a town, mentioned by Anaximenes, cited by Strabo, and placed in Erythra.—Alsfo, a town of Greece, in Meechis; according to Ptolemy; now Grifco.—Alsfo, a town of Greece, in the Phocide.—Alsfo, the name of a rock, on the bank of the Thracian Bosphorus, over against the Cyanean island, at the entrance of the Euxine sea.—Alsfo, a town of Greece, in Thessaly.—Alsfo, a promontory near the river Lycaus.

COLONEL, the officer who has the chief command of a regiment of horse, foot, dragoons, or artillery. The lieu- tenant.
 Colonel of a regiment of horse, is the first officer in it, and commands it when present. His duty consists chiefly in keeping the regiment complete, in having it composed of men and horses that are fit for service; in taking care to have them well exercised and instructed in the different evolutions, so that they may be able, on all occasions, to form themselves quickly to the ground they occupy or act on, or to the manner in which they may with either to make or receive an attack. In France, Spain, and some other southern nations, colonels of horse have been usually called maistres de camp: But in Germany, and most northern nations, they are called ridefiers.

 Colonel of dragoons. His principal functions are the same as those of a colonel of horse. But he ought to be also in some measure acquainted with the duties of a colonel of infantry, as his men are liable to act either mounted or dismounted.

 Colonel of foot, or infantry. His functions are more extensive and diversified than those of a colonel of horse, as the infantry are employed for a greater variety of purposes, and on a greater variety of services. Colonels of infantry should be well acquainted with fortification, and with field-engineering (which, however, they seldom or ever are); since such a thorough and comprehensive knowledge of their principles, as enables an officer to apply them expeditiously and judiciously, is the belt and fasten guide to the proper formation and arrangement of troops in various situations, and to the advantageous occupation of ground and positions. A colonel of infantry should be particularly careful to maintain union and harmony among his officers, and contentment among his men, to acquire the esteem and confidence of both, and to make himself respected by them; to which nothing contributes more than a steady, uniform, and impartial enforcement of subordination and discipline. He should likewise be peculiarly attentive to the health and comfort of his men.

 Colonel of Artillery; the commander of a battalion of artillery. His duties, when properly understood and attended to, are various and laborious, both in war and peace, and require, in order to be well performed, not only abilities, but also application, knowledge, and experience. He ought to be an able mathematician and mechanic, and should be acquainted with all the duties of an engineer, that are connected with the use and application of artillery in different situations, and to different purposes; the construction of batteries, platforms, field-works, the occupying of positions with artillery, to the best advantage, both as to direct and flanking fires, &c. Whatever situation he may be placed in, or whatever service he is engaged in, he should understand thoroughly what nature and species of ordnance is best adapted to it. He should be acquainted with all the most useful experiments that have been made with artillery in the different nations of Europe; he should know the greatest distance at which balls can be bitter in breech effectually; the different charges of powder, best adapted for different services, and different distances. And he should not only be well acquainted with the wide differences between the ranges of cannon-flies and shells in the air, and those which the parabolic theory gives for them in vacuo, but also be able to approximate, nearly to the truth, the distances to which projectiles will go in the air, thrown with given charges of powder, and given degrees of elevation. In short, he ought to know a variety of things, which few officers of artillery actually do know.

 Colonel of Engineers. See the article Engineers.

 Colonel, lieutenant, is, as has been already observed, the second officer belonging to a regiment, and commands it in the absence of the colonel.

 Colonel General of the French Infantry, or Colonel General d'Infanterie, is an appointment of great trust and authority, which took its birth, or originated, under Francis I. in 1544. It became an immediate gift of the crown, under Henry III. in 1584. It was at first suppressed, because it gave too many prerogatives, and too much power to the person who was invested with it. Under Louis XV. however, it was re-established in 1741, in favour of Louis, the first duke of Chartres. This officer had originally the right of nomination to every commission and place of trust in the infantry. He could order courts martial, and enforce the sentences awarded by them, without any suspension of his power in that respect, by an appeal to a superior tribunal; and he had a company in every regiment of infantry, which was called the colonel general's company.

 Colonel General d' Infanterie de Suisses et Grison. This appointment was not held of the crown; but it was a post always given to a prince. It took its rise in right of office under Charles IX. in favour of the son of the counts of Montmorency, killed at the battle of St. Denis. All the Swiss and Grison troops were subordinate to the colonel general, the captain des cant Sus et de la garde excep'd. He appointed colonels and captains. The succesors of him were chosen by the king, and the officers of the nation, to be included in the promotion of general officers, and enjoyed several other prerogatives.

 Colonel General de la Cavalerie légere et étrangère. This charge, or employment, was created in right of office under Charles IX. It was, however, known before his time, in 1449, under the title of capitaine général de la cavalerie Albaoise." Under Louis XIII. there were two such colonels general, one of the French cavalry, and the other of the German cavalry. Though those general officers enjoyed great honours and prerogatives, the generals of the Roman cavalry, under the emperors, were persons of still greater importance. For they had the same authority over the troops and militia, that the kings and dictators had. The emperors treated them in their regulations and constitutions, as though they were the highest rank, eminence, magnificence, and celebrity. They enjoyed an authority almost absolute, over all military people.

 Colonel General des Dragons, colonel general of dragons. This appointment was created in 1689, by Louis XIV. It was, like the preceding ones, favoured with an attribution of great honours and particular prerogatives.

 Colonel de Troupes Légères, colonel of light troops. This officer ought to be well instructed both by study and experience, in the art of petty warfare, and the management of detachments. For, as he is almost always responsible for the corps confided to his charge, and forced to take advanced positions in an enemy's country, he is of course exposed to be surprised, taken, or at least beaten.

 Colonelle, Compagnie, the first company in a French regiment.

 Colonel, Adam, called the Old, in Biography, a painter who was born at Rotterdam, in 1633, but att reigned and died in London, in 1685. The subjects of his pictures were generally wakes, country fairs, rural subjets, and cattle; besides which, he made several copies from the pictures of the Baffains, with success. He had a son called Adrian Colonli the young, who received instructions from
from his brother-in-law, Van Diek, in addition to the lessons bestowed on him by his father. He frequently painted the figures in the landscapes of Van Dyck, as well as in those of other masters; and sometimes imitated the touch of Saverio Rosa. At other times he produced pictures of history, but more generally those of cattle, conversations, or landscapes. Adrian died in the year 1761, aged 33. Elstington.

Coloni, Cape, in Geography, lies on the W. coast of Atlantic Turkey, N. of the Gulf of Smyrna. N. lat. 39°. E. long. 26° 36'.

Colonia, in Ancient Geography, an episcopal town of Asia, under the metropolis of Scutis; situated in the first Armenia, and called also Tavara.—Allo, an episcopal town of Asia, in Cappadocia.—Allo, a town of Italy, in Etruria.—Allo, a town of the Ile of Albion, in the route from Londinium to Lugwalliam ad Vallum, between Caesaromagus and Villa Paulfini, according to the Itinerary of Antonine. Although our antiquarians are divided about the situation of Colonia, it seems, upon the whole, to be most probable that it was at Calceph-er, on the river Colne, from whence it derived its name.—Allo, a town of the Danuvi, according to Ptolemy, which some, as Camden and Baxter suppose, to have been Coldingham in the Mars, but which was more probably situated at or near Lanark, in Clydedale. See Coldingham.

Colonia, in Geography, a town of Istria; five miles S.S.E. of Rovigo.

Colonia Agrippina Ubiorm, in Ancient Geography, a town seated on the banks of the Rhine; now Cologne. It was built by the Ubii, when they left Germany to establish themselves in Gaul. Agrippina, the mother of Nero, fixed a colony of veterans in this place, and gave it her name in honour of the place of her birth.

Colonia Equeftris, a town of Gallia Belgica, assigned by Piny to the Helvetians; but by Ptolemy to the Sequani. The Itinerary of Antonine marks it under the name of "Equesftris," between Bantus and Lucus Laufatianus. It was also called "Nonundunus," or "Nundunum," but when it became colony, the Romans called it "Colonia Equesftris." It is now Nion.

Colonia Marcia, the town called Cesaris de Pulaeine. Colonia Julia, a town and Roman colony of Germany; now Bonn. Colonia Julia Colfa, a town of Spain, which was a Roman colony; now a village called Xelfa. Colonia Julia Hippetia, a town and Roman colony of Italy; now Umbria; now Spello. Colonia Marcia, a town of Spain, which had the title of Roman colony; now Marchena. Colonia Senecis, a town of Italy, in Etruria, which was a Roman colony; now Scena. Colonia Sepulmonarum Juniorum, a town of Gaul, with the title of colony; now Baziers. Colonia Trigana, now Kohn, or Köln, was situated at a small distance from the Rhine, and about a mile from Cleves. Colonia Ulpi, is now Cleves, which see.

COLONIS, an island of Greece in the Argolic gulf, according to Pryn.

COLONNA, Giov. Paolo, Maestro di Capella di San Pietro di Bologna, in Biography, was the son of Antonio Colonna, alias del Corno, a celebrated organ builder of Brescia. He composed but few operas; indeed, we know of but one, Amleto in Cipro, for the theatre of Bologna, 1602; but he published about the latter end of the 17th century many excellent works for the church, of which P. Martin has given a list, to the amount of twelve, in the second volume of his History of Music.

It was the opinion of the late Dr. Boyce, that Colonna was Handel's model for choruses accompanied with many instrumental parts, different from the vocal. But it must, however, be owned, that Handel has greatly surpassed his model in energy, fire, and vigour of genius. The psalms of Colonna in eightves vocal parts, published at Bologna in 1694, have been very justly admired for their masterly composition. Paolucci has inserted the hymn, "Pange lingua," set in plain counterpoint of four parts, by him, in a manner sufficiently simple and syllabic for the most zealous reformers of church music. His "Sacri lamentationi della fettimana santa, a voce sola," published 1689, contain many pleasing and elegant fragments of pathetic recitative, which we should have admired much more if we had not previously been acquainted with the works of Carissimi, who had anticipated not only all the thoughts of Colonna in this species of music, but almost all those of every composer of the present century. The airs of these lamentations are too short to make much impression on the hearer.

Colonna had a controversy with Corelli in 1685, concerning the consecration of fifths in the fifth movements of the third sonata of his Opera 2da. Every lover of music will be sorry that the charge against Corelli should be well founded; but it must be owned that the base is indefensible in the passage which has been condemned by Colonna, and was not likely to have passed unconfuted, even in an age much more licentious than that of Corelli.

Antimo Liberati, with whom Colonna was in correspondence at the time of this controversy, seems to defend Corelli's violation of the known rule against the consecration of fifths, in a letter written 1635: "Sopra un leggio di quinti," in which he reasons thus: "If a quaver reef, or even a semiquaver, were not sufficient to satisfy the rule against fifths and eighths, a composer writing in many parts would have very narrow limits for the expansion of his genius and fancy, or for varying the harmony." But with due respect for the authority of Antimo Liberati, and with peace to the affections of the gentle Corelli, the passage is unwarrantable, and seems the more inexplicable, as several better basses were easy to find, without altering his design, or destroying the effect of his trebles. It appears that the excellent theorist Berardi had a reverence for the professional erudition of Colonna, by his dedicating to him the seventh chapter of his "Miscellanea Musicale."

COLONNA, Michele Angelo. See Angelo.

Colonna, Marc-Antonio, born from an early age in the service of the Spaniards, and rose to great military reputation. He was appointed by pope Pius V. general of his galleys, and served in the famous battle of Lepanto, gained against the Turks in 1571. On his return he was awarded a triumphal entry after the manner of the ancient Roman conquerors. He possessed several high civil offices, as confidant of Naples, and viceroy of Sicily, and died in Spain in 1584. Moren.
He accompanied his father into Spain, and studied at the universities of Alcalá and Salamanca. Philip II. gave him an annuity, and he was made chamber by Señor V. At the death of the king his patron, he delivered a funeral oration, which he printed. He was henceforth a promoter of literature, and collected a magnificent library. Owing to his great skill in canonical law, and the support which he gave to the claims of the Catholic king, he was made vicar, of Catálica. He afterwards wrote a canonical defence of the pope's conduct in his dispute with the republic of Venice. This and four other letters and harangues he published, and died in Rome in 1568. Moreri.

Colonna, Fabius. See Colonna.

Colonna, Francesco, was born about the middle of the fifteenth century, probably at Venice, and entered young into the order of Dominicans. The work by which he is chiefly known is "Hypnerotomachie di Poliphilo," which signifies the combat of Love in a dream, and the Lover of Poliphilo. It consists of table, history, allegory, architecture, mathematics, &c. and is written in a language compounded of words taken from six or seven different languages. It was printed by Aldus in 1499, and a French translation was published in 1545, and has been several times reprinted. The original and translation have been in great request among collectors of books, as well on account of their rarity, as for the sake of the beauty of the numerous wooden cuts with which the work is decorated. Colonna died at an advanced age, at Venice, in the year 1527.

Colonna, Prospero, a distinguished military commander, was younger son of Anthony prince of Salerno, and born about the year 1452. He engaged in the service of Ferdinand, king of Naples, and after his death, in that of Charles VIII. king of France. When that prince overtook the confederacy of Naples, Colonna, with his cousin Fabrizio, rendered him some signal services, but upon a charge of perfidy, they returned to their former allegiance. Prospero assisted in the recovery of the kingdom of Naples; he was at the battles of Barletta and Garigliano, at which the French were worsted; and he signified his valor and conduct at a variety of sieges and other military actions. In the year 1557, while attempting to defend the province of Amalfi against the French, he was made prisoner, and carried to France, but being liberated, he returned his profession in order to revenge the disgrace that attached to him while a captive. He died in 1575, aged seventy-one, leaving behind him a very high character as a general; he was rather prudent and cautious than formed for remarkable enterprises. Though slow and meditative, he was, by constant vigilance, generally feared from his pride. He was the friend and patron of learned men. Moreri. Robertson's Hist. ch. v. vol. ii.

Colonna, Pompeo, was brought up by his uncle Prospero, and educated by him for literary pursuits. The young man devoted to the profession of arms, and distinguished himself as a military man till he was compelled to assume the ecclesiastical character. He was made bishop of Rieti, and obtained many lucrative benefices. He was, however, little attentive to the duties of his sacred office, and so regarded himself as the deacon that ought to be attached to it, that he accepted a challenge, and tore his cassock to pieces that he might not be prevented from fighting. On a late report of the death of pope Julius II. in 1552, Pompeo joined in raising the cry of liberty, and took possession of the capitol. For this he was deprived of his benefices, but by the interest of his uncle, matters were again accommodated, and in 1557, he was elevated to the rank of cardinal. Still, however, inclined to turbulent measures, his conduct gave his enemies the opportunity of charging him with the intention of putting the pope to death, in order that he might succeed to that high dignity: he was accordingly deprived of his offices, in which he was reinstated on account of some important services which he rendered to the signing pontiff. He was afterwards viceroy of Naples, where he died in 1553. He was esteemed a patron of literature, and wrote a poem "D. Landibus murorum," chiefly in praise of Vittoria Colonna. Moreni. Robertson's Hist. ch. v. vol. ii.

Colonna, Vittoria, a learned lady and poetess, was born at Marano in 1490. At the age of seventeen, she married Ferdinand Francis D'Avalos, marquis Pescara, who, by her influence, was dissuaded from accepting the kingdom of Naples, which was offered him after the victory of Pavia, in order to detach him from the service of the emperor Charles V. After his death, which happened in 1525, she lived in retirement, devoting herself to poetry; she kept up, with much credit to herself, a friendly and learned correspondence with some of the most celebrated literary characters of the age. In 1521, she retired to the monastery at Orvieto, and from thence she went to St. Catherine in Viterbo, but in 1547, she returned to Rome, where she died. Her poems have passed through many editions, and have been printed with the commentaries of learned men. Moreri.

Colonna, in Geography, a town of European Turkey in Dalmatia; 24 miles N. of Spalatro. — Allo, a town of Italy, in the Campagna di Roma; 12 miles from Rome. — Allo, a cape of Naples, on the E. coast of Calabria Ultra. N. lat. 35° 6'. E. long. 17° 56'.

Colonna, in Geography, a town of France, in the department of the Jura, and chief place of a canton in the district of Delphagne. In 1525, it was captured by the French and of Delphagne. In 1525, it was captured by the French and

Colonne, a cape on the coast of the Morea, in the Mediterranean. N. lat. 35° 32'. E. long. 24° 17'.

Colonnossis, in Ancient Geography, a place of Asia, in Lycaonia.

Colonsay, in Geography, one of the islands of Scotland, called the Hebrides. It belongs to Argyllshire, and as it is separated from Oranfay, merely by a narrow channel, which is dry at low water, Colonfay and Oranfay may be considered but one island. Although the inhabitants of the former cannot correctly be termed mountais: they are high, rugged, and covered with heath. The arable land, which consists of about 3000 acres, produces early and tolerable crops, as the soil is light and mixed with sand along the shores; part of this land has lately been converted into pasture, and numbers of black cattle are fed on the two sites. A monastery of Cillertian monks formerly flourished in Colonfay, and the remains of the walls of the abbey gave place some years past to a farm house; a priory attached, stood in Oranfay, where the ruins still remain, and are considered superior to any other religious building in the Hebrides, with the single exception of Icolmilk: there are bucolic fragments of several chapels in Colonfay. The inhabitants make large quantities of kelp from the seaweed found on the coast; and the banks which surround the islands produce plenty of fine coral. The population is estimated at about 720, and the duke of Argyle is the principal proprietor.

Colonsay, Little, an island, and one of the Hebrides, situated between Gometra and Staffa. There are several specimens of basaltic pillars in the Laffer Colorfay, but it has no other inhabitants than one family who attend a few sheep.

Colonum, a place of Greece, in Attica. Here was a forest
a foret, consecrated to the Eumenides. Sophocles, according to Stridas, was born in this place.

**COLONUS**, an husbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year, to plow some part of the lord's land; and from hence comes the word *dewen*, which is called by the Dutch *boer*.

**COLONY**, *Colonia*, is properly a number of persons of all sexes and conditions, transported into a remote province, with a view of remaining there, and for the purpose of cultivating and inhabiting it; but among commercial nations, the term is used in a larger and less proper sense, and applied to the temporary residence of merchants and agents in another country. The word colony originally signified no more than a farm, i. e. the habitation of a peasant, *colonus*, with the quantity of land sufficient for the support of his family; "quantum colonus unus arear poterat." It is derived from the Latin word *colere*, I till or cultivate; hence *colonia*, a husbandman, and *colonia*, a body of farmers, sent to cultivate the ground in a distant country, and, by extension, the place itself. From the Latin the word has passed, with scarcely any alteration, into the modern languages of the west of Europe.

We may distinguish, generally, four kinds of colonies; viz.
1. Those that gave rise to cities or settlements; inhabited a country, where the people are become too numerous, so that they cannot any longer conveniently subsist together. Such colonies were established by victorious princes and people, in the middle of unpeopled nations, to keep them in awe and obedience.
2. Those that are formed by emigrants, driven from their native country by oppression and persecution to seek a foreign settlement, and to subsist by agriculture, and afterwards by commerce. Such colonies were called "colonies of commerce," because trade is the sole object and occasion of them.
3. The first class we may refer the colonization which took place in the earlier ages of the world, and which served to disseminate the human race, first through the various regions of the earth, and afterwards through other more remote parts of the globe. At this early period colonization was of course more frequent than it is at present. The increase of a tribe beyond the limits of a comfortable subsistence upon the lands which were occupied, would be a sufficient motive for inducing the younger members of the society to remove from the prospect or actual pressure of want, to some unoccupied territory. Some antiquaries, however, are of opinion that soon after the deluge, when the descendants of Noah became numerous, a division of the ancient continent and its adjacent islands was made, probably by lot, among the heads of the several families. This opinion seems to be in some measure supported by the authority of Moles, who says, (Gen. x.) on mentioning the children of Eber, that the name of one of them was "Peleg" (division), for in his days was the earth divided. (See Dispersion.) However this be, the gradual extension of the habitations of mankind must have corresponded with their increase; and it seems to have been unrestrained by claims made upon the uncultivated spots. But this unlimited right of disposition has long since ceased in most parts of the world; and hence it has become necessary for colonists, who seek new scenes for their labours, either to unite with the natives as friends, or to subdue them by conquest, if the colony is founded upon hostile principles. At a subliterate period, the different states of ancient Greece, such were Athens, Sparta, Corinth, and Argos, polled territories of very limited extent; and the increase of population gave rise to various emigrations from all those states. The colonies of the Dorians settled chiefly to Italy and Sicily, which, in the times preceding the foundation of Rome, were inhabited by barbarous and uncivilized nations; those of the Ionians and Eolians, the two other great tribes of the Greeks, to Asia Minor and the islands of the Aegean sea, the inhabitants of which seem at that time to have been pretty much in the same state as those of Sicily and Italy. The emigrations now mentioned, and some others of a similar nature, were undertaken by private individuals, with no authority from the government; and as they were generally directed towards distant and transmarine settlements, they remained but a flight connection with their original countries. The parent state, indeed, considered the colony as a child, at all times entitled to great favour and indulgence, and owing in return much gratitude and respect; but, moreover, considered it as an emancipated child over whom no direct authority or jurisdiction was claimed. The colony settled its own form of government, enacted its own laws, elected its own magistrates, and made peace or war with its neighbours as an independent state, which had no occasion to wait for the approbation or consent of the parent city. The colonists, indeed, remembered the land of their fathers with filial affection and respect; they honoured its gods, by offerings of first-fruit to their temples; they retained a predilection for its customs and laws, as well as its religion and language; they yielded to its citizens the place of distinction at public games, and to its priests the holy honour of first inspecting the entrails of sacrifices. In war they generally followed the fortunes of the metropolis, as allies upon equal terms; but as they were perfectly independent, received no protection from her, and often equalled her in resources, they always refused to come forward as auxiliaries, when unfair terms were proposed. Thus, the Sicilian colonies refused to admit an Athenian army into their territories, for the purpose of retaking, on an expedition; and, in the Persian war, the republic of Syracuse, when intreated by the Lacedaemonians to aid the common cause, refused to lend any assistance, unless their chief magistrate, Groton, were allowed to command the united forces. Sometimes the parent country, conscious of her superiority and strength, attempted to exact from the colonies, as matter of right, the usual marks of filial attachment. Thus, Corinth was defied by her colony at Corcyra, for her inferiority of wealth and trade; and the endeavour to obtain by force, the usual tokens of remembrance. The colonists appealed to Athens, which took their part, and retained them as useful allies, especially during the Peloponnesian war. Pothidae, another Corinthian settlement, took the part of Athens, until her impolitic tyranny urged it to throw off the yoke, and appeal to Sparta and Corinth. After a long and severe struggle, the Athenians were successful; sent new colonies to occupy the confederated and vacant lands; continued their oppressive government; and retained their dominion over Pothidae, until the invasion of Philip. When the progres of Cyrus exposed the Atlantic colonies of Greece to extreme danger, they in vain applied to Sparta for assistance; and, being soon conquered by the Persian monarch, they remained in subjection, until the victories of Ptolemy and Myrace restored them to freedom; but despairing of long maintaining their independence, they formed a compact alliance with Athens, who availed herself of the opportunity of a general alarm, to propice an universal contribution from all her colonies and allies, for the great purpose of reifying the Persian power. We might cite many other instances to exemplify the independence of the Grecian colonies on the states from which they originated. Nevertheless, the benefits in point of civilization resulting to barbarous countries from colonies of private adventurers, migrat-
grating from countries more advanced in the knowledge of these arts which mitigate the condition of human life, have entailed honour on those who imparted them, and claimed returns of respect and gratitude from those on whom they were bestowed. From this mode of colonization, reciprocal advantages have been derived. The natives already in possession of the country, to which colonies have migrated, are benefited by the introduction of new arts; while, at the same time, the adventurers receive the reward of their knowledge, valour, and conduct, by the superior degree of influence which they acquire beyond what they would have possessed if they had remained in their own country. Thus individual adventurers, who have fitted out expeditions at their own charge, and conducted colonies to a permanent settlement by their own skill and valour, have, in some memorable instances, attained even to supreme authority. This seems to have been the case with regard to the colonies anciently established by ΑΑαίδαεδας in Sicily, by Inachus in Argos, by Cerecos in Attica, by Janus in Italy, and by Cadmus at Thebes in Greece. From the devastation in which the memory of these adventurers, who were mostly of Egyptian origin, were held, it is evident that they had imparted into the countries where they settled great and important improvements. The great literary renown which Athens acquired in progress of time has rendered us better acquainted with its early history; so that we can form some idea of its primitive laws. The regulation of the connexion between the cities is recorded as being due to Cerecos; from whence some etymologists, as Euclitomithi, deduce the origin of the appellation ΑΑαίδαεδας, by which he was distinguished. The collection of the inhabitants into towns and villages, is said to have been an improvement of his immediate successors, who, it is probable, also introduced the regulation of local jurisdictions, and the division of the land in property among the then existing heads of families, to be inherited by their descendants. This seems to be, in fact, the main foundation of perfect civilization, by introducing this inequality of condition, as some of the families increased or prospered more than others, which, notwithstanding the reverses of some speculative politicians, is absolutely necessary to civilized life. This mode of colonization is seldom attempted in more modern times, because the maritime nations of Europe have laid claim to all heathen lands which their subjects discovered, and have prevented even their own subjects from endeavouring to ameliorate the condition of these countries, by attempting the formation of independent Christian states. The Jesuits had, indeed, formed a considerable establishment for the improvement of the natives in South America; but it gave umbrage to the Portuguese government, and the neglect of military affairs rendered the overthrow an easy undertaking. The Moravian brethren have similar settlements in the most northern parts of America and Europe, where the inhospitableness of the climate is such, that the country is not worth contending for. The establishment of the Macedonian dynasties in Asia and Africa; and, in later times, that of the northern tribes in the southern parts of Europe and of Asia, are signal examples of this mode of colonization. It is notorious, that it was for the establishment of colonies, referred to the first class above-mentioned, that, during the declension of the Roman republic, those torrents of barbarous nations, infusing, for the generality, of the north, overran the Gauls, Italy, and the other southern parts of Europe; and, after several bloody battles, divided it with the ancient inhabitants, and blended their own habits and manners with those of the nations which they subdued, or in which they obtained either temporary or permanent settlements.

To the second class of colonies belong those of a military nature, which served as guards or garrisons, for the maintenance of a conquered country. The Romans reverted to this mode of colonization more frequently than any other nation; and added, to the original motive, that of providing retreats for the aged and worn-out soldiers; as also for the settlement of the poorer classes of Roman citizens. Nor were the interests of the rich forgotten, in the establishment of Roman colonies. The spirit of the Roman laws having refrained the mercantile classes to their proper rank in society, the capital accumulated by their commanders during the long continued and widely extended succour of the Roman republic, was of course invested in land. The extent of Italy was too small for the capital, thrown, by this means, into agriculture; and the capitals were therefore obliged to seek new lands, on which it might be employed. It appears that the eastern shores of the Mediterranean sea were, at the time of their falling under the Roman dominion, in the highest possible state of cultivation. The provinces settled on these shores, were, therefore, the scenes of oppression rather than of improvement, and the plunders, accumulated there, transferred to Gaul, and other western provinces, to be employed in the purchase and improvement of land, or in the support of those who resided there. The high rate of interest allowed by the Roman laws, made it also far better to employ money in loans than in commercial speculations, which cannot be supped, in the restricted and degraded state of Roman commerce, to have yielded the same profit as the former. Senea, the philosopher, is said to have had, at the time of his death, no less than 600,000 &. flowing due to him from the colonists in Britton; the sudden calls in of which produced a rebellion. Besides, Rome, like most of the other ancient republics, was originally founded upon an Agrarian law, which divided the public territory in a certain proportion, among the different citizens who composed the state. The course of human affairs, by marriage, by succession, and by alienation, necessarily deranged this original division, and frequently threw the lands, which had been allotted for the maintenance of many different families, into the possession of a single person. To remedy this disorder, a law was made restricting the quantity of land which any citizen could possess to 500 jugera, or about 352 English acres. This law, however, was neglected or evaded, and the inequality of fortunes went on continually increasing. The greater part of the citizens had no land, and without it the manners and customs of those times rendered it difficult for a freeman to maintain his independency. The people, therefore, became clamorous to get land, and the rich and great, we may readily imagine, were determined not to give them any part of theirs. To satisfy the unquiet and clamorous people, it was frequently proposed to found out a new colony. Accordingly, Rome assigned them lands, generally in the conquered provinces of Italy, where, being within the dominions of the republic, they could never form any independent state; but were, at least, merely a fort of garrison, which, though it had the power of enacting by-laws for its own government, was at all times subject to the correction, jurisdiction, and legislative authority of the mother city. The founding out of a colony of this kind, not only gave some satisfaction to the people, but often established a fort of garrison, too, in a newly conquered province, of which the obedience might otherwise have been doubtful and precarious. Some of these colonies were of a civil, and others of a military nature. In their manners and internal policy, the colonies formed a perfect representation of their great parent; and they were soon endeared to the natives by the ties of friendship and alliance; they effectually diffused a reverence for the Roman name, and a deference, which was felicitous and dom.
COLONY.

don disappointed, of sharing, in due time, its honours and advantages. A Roman colony, whether we consider the nature of the establishment itself, or the motives for making it, was altogether different from a Greek one. The words, accordingly, which, in the original languages, denote those different establishments, have very different meanings. The Latin word, colonia, signifies simply a plantation. The Greek word αυτοικία, on the contrary, signifies a separation of dwelling, a departure from home, or a going out of the house. In conformity to this distinction of names, we may observe, that the colonial settlements of the Greeks were planted in distant countries, and amongst barbarous tribes. They were either planted on the coasts of Greece, or in the states immediately in the neighbourhood, which had already been well peopled, but in Gaul, Sicily, and the south of Italy; in Greece and Egypt; in Illyria and Asia Minor. The Roman colonies, on the other hand, were at first planted in the immediate vicinity of Rome. During the second Punic war, the city was surrounded by no fewer than 50 establishments of this kind; which served as so many garrisons or advanced posts for her defence. Ancient authors mention no less than 164 colonies settled in Italy, from the foundation of Rome to the death of Augustus; whereas those planted in all the provinces were only 199. From this consideration it appears, that the Italian colonies were materially different in their constitution and uses from the colonies of the provinces. The emigrations from Rome to the conquered towns and lands of Italy, and afterwards of the foreign provinces, were the operations of war and plunder. Whenever an Agrarian division of conquered territory was proclaimed, the discontented citizens presented themselves in a body; and if a sufficient number did not offer to form a legion for retaining the conquest, which they called a colony, the deficiency was supplied from all the tribes by lot. As this system of conquering policy was efficacious at first, until the whole of Italy had been subdued no emigration ever took place to any transmarine, or transalpine countries. Among the Romans there were two kinds of colonies: those sent by the Senate, and those that were military, confounding of old soldiers, broken and disabled by the fatigues of war, who were thus provided with lands, as the reward of their services. The colonies sent by the Senate were either Roman or Latin, i.e. they were composed of Roman or Latin citizens. The colonies of Roman citizens had the right of suffrages, and could reclaim the rights of citizens whenever they chose to remove to the capital. The Latin colonies lost their rights for ever, nor had they any right of suffrages without an express permission. According to Ulpius (lib. i. D. de Cens.), there were other colonies, which had little more than the name; only enjoying what they called jus Italicum, i.e. they were free from the tribute and taxes paid by the provinces; such were the colonies of Tyre, Berytus, Helipolis, Palmyra, &c. Between all the Roman colonies and the metropolises, there subsisted the closest connexion. The form of colonial government was modelled upon that of Rome. The laws, if not changed at once, were gradually moulded by the spirit of the Roman jurisprudence; the officers were almost all sent from the capital; the mandates of the republic were more promptly obeyed in the provinces than in the city itself;—in a word, the establishments which have been called colonies, and, compared to those of modern times, or of the Greeks, were military stations; garrisons, placed in conquered countries; advanced posts of a great army, of which the commander in chief held his head quarters in Rome, and occasionally made a progress through the different cantonments. From these settlements taxes were levied, according to a census; and, after paying the expenses of their own government, they transmitted a revenue to the Roman treasury. Men were raised for the Roman army according to a muster-roll. When the grandeur of the Roman name extended across the ocean and the Alps, the rights of citizenship became valuable, as the title to power, honours, and plunder. The allies, or colonial and provincial settlements of Italy, then demanded the communication of this privilege; and the refusal produced that "Social war," which may be justly deemed the end of the regular republican constitution. In consequence of the Julian law, which terminated this war, of other laws afterwards passed at the states of Italy, whether allies, colonies, or pretorians, obtained the full rights of Roman citizens. Until the year A.D. 65, no colony but one, which never flourished, had been planted beyond the confines of Italy. The military colonies, introduced by Sulla, and much favoured by Augustus, were remarkable only for a form of government more entirely military than that of the other settlements. All were equally subordinate to the central government, and equally obedient to its decrees.

The first foreign colony which the Romans planted was in Carthage, A.U.C. 710, when Julius Cæsar formed the plan of refounding that defeated city by means of a colonial establishment. The first colony planted in Italy was that of Cæsarea, A.U.C. 4. The practice of sending Roman colonies to the provinces, where they did not enjoy all the privileges of the Italian colonists, was very common after the experiment of Julius Cæsar. He himself transplanted 80,000 citizens in this manner. (Sueton. in Jul. Cæs. c. 42.) After the time of Augustus, who planted 28 colonies in Italy (Suet. in Octav. c. 45.), the custom of planting Italian colonies seems to have been abandoned. His successors did not plant as many as 20; and preferred forming those settlements beyond seas. Livy does not even mention a transmarine or transalpine colony, although he constantly relates the foundation of those in Italy. Dacia and Britain, the most difficult and insecure of the Roman conquests, had only, the former four, and the latter five, Roman colonies. Twenty-five colonies were settled in Spain; and Africa, the most peaceable of all the Roman possessions long before the downfall of the commonwealth, received, after the usurpation of Julius Cæsar, no less than 57 colonies, exclusive of Egypt. From these circumstances we may be led to conclude, that the Italian establishments were founded with different views, and in a different age of the Roman history, from the settlements in the provinces. M. Vaillart has filled a volume in folio with medals struck by the several colonies, in honour of the emperors who founded them. The ordinary symbol they engraved on their medals was either an eagle, as when the western limits were distributed in the colonies; or a labarum holding a plough drawn by a pair of oxen, as when the colony consisted of ordinary inhabitants. On all the medals are seen the names of the Decemvirs, who held the supreme rank, and had the same authority there as the consuls had at Rome.

In the political relations of the Roman settlements with their parent city, there is some resemblance to the political relations of modern colonies with their mother countries. But in the policy of a state so neglectful of every thing except war, we cannot expect to find any parallel to those commercial views, by which the plantation of modern colonies has been undertaken, and their connexion with the European governments maintained. The objects of the Romans, in planting their colonies, were conquest and plunder; so that detachments of emigrants incorporated with, and governed, the old possessors of the soil. In modern
modern times the chief objects have been trade and agriculture; the most important settlements have been made in defunct countries, or districts, where ancient inhabitants were extirpated by the first settlers. In this respect, then, the Roman colonies rather bear a resemblance to the Asiatic establishments of modern Europe; but they differ from these, too, in the structure of their government. The constitution of the Italian colonies was formed upon the Roman model, and varied with its changes. The provincial governments of Hindooslan, and the islands of the Indian ocean, very little resemble those of their European masters, and are rather allied to the spirit of the oriental legislation. The provincial governments of the Roman transmarine territories here, in every respect, the same kind of relation to the metropolis, which the East Indian establishments do to the states of Europe. The inhabitants retained, in a great degree, their own laws; they were ruled and oppreseed by a Roman magistrate, and an army, composed partly of Roman, partly of native troops; their country was the scene of every criminal excess in politics and manners, and the source of large supplies to the plunderers of the world.

The species of colonies now described is not restricted to the Romans, but it has been adopted by almost every nation, both ancient and modern, with very little variation. To it we may refer the establishment of the Normans in England, and of the English in Ireland. In a still later period, the Portuguese and Dutch have established themselves in India; but the English East India company have, on the contrary, repressed, as far as possible, the colonization of the countries they possess there, as these directors observe that "the energy of the European character becomes obliterated in the course of a few generations."

The commerce of Carthage, together with her extensive continental possessions, enabled her to provide for her increasing population at home. The want of an outlet for inhabitants formed no part of the motives that induced the Carthaginians to settle foreign colonies. Their colonial establishments, indeed, were mostly founded in the same manner with the transmarine and transalpine provinces of the Romans—conquered countries, retained in subjection, from ambition and pride, by means of a Carthaginian governor, and a few followers, prompted by idleness, or the love of change, or the desire of distinction to follow in his retinue. However, the relations of the new establishments with the mother country were different; in several respects, from the relations which connected the distant parts of the Roman dominions with the metropolis. The Carthaginian colonies were, in reality, trading correspondents to the mother country; and should have found a place under the 4th class of colonies rather than here, if they had not been immediately connected with the Roman. It is probable that the Carthaginians received the surplus of the rude produce of Sicily, Sardinia, and Spain, which Africa did not yield, and exported thither those manufactures, which would naturally be raised in a country fully peopled, and long habituated to traffic. From the superiority of their navigation too, the skill of the Carthaginian merchants, their connexions long established with the Levant, more particularly with the great emporiums of the East, Tyre and Smyrna, and from the greater trading capitals of those rich nations; they would more likely furnish the colonies or provinces with Asiatic commodities, of which Carthage would be the natural entrepot for the countries to the west of the Mediterranean. History has preferred two topics of commerce and navigation between the Carthaginians and Romans, conceived in the true spirit of the modern colonial policy; for which see Polyb. i. iii. c. 22.; or Brougham's Colonial Policy, &c., vol. i. p. 21, &c.

In this connection we might mention another species of external colonies, produced by the disproportion of weaker states by those who are stronger, in order to extend their borders, or to profess some advantageous situations for trade, or for war. The bigotry of the Europeans, at the time of the discovery of the West Indies, led them to look upon the natives of those countries in a very unfavorable and contemptuous light, on account of their being heathens and idolaters, and made them hearken to the measures which the constitution of their own country, so that they could not but obtain the object of their wishes. The great disproportion also in the numbers of the invaders and of the natives, in some measure, impelled the Europeans to adopt the most feasible methods, to perpetuate the terror which the natives had originally manifested at the effects of their firearms. The consequence of those feelings was, that the natives of most of the islands were soon exterminated, except in some very small ones which the Europeans left unnoticed. On the continent, however, the natives fled, as they have there sufficient space to retire from the neighbourhood of their visitors.

To the third class belong those colonies that have been formed by refugees from countries, in which they were oppressed or persecuted. Thus the emigrants, who fled from the religious broils in which France, the Low Countries, and Germany have been involved, found safety in England, and introduced many of those manufactures and arts, which have contributed to the commercial supremacy of Great Britain. Newcastle, Canterbury, and even some of the most populous parts of the United States, have been founded from the productions of their inhabitants to those colonies; and, in like manner, part of Pembrokeshire, in South Wales, has been peopled by a colony from Flanders. The colonies of North America were originally planted by men who had quitted their native country, either from a love of civil and religious liberty; or from a desire to better their fortunes, by laying out a small capital in the improvement of land; or from the necessity of finding employment in a country where labour bore a high price. Anxious only to live in peace and freedom, with a competency for themselves and their families; these men centered all their views in the spot to which they removed their fortunes and perils; they gave up for ever the thoughts of returning to the countries which they left behind them; and transferred to their new homes all those ties which had formerly bound them to Europe. The woods of the northern continent were cleared by men of small capital content with a living profit, attached to the soil, which owed its cultivation to their labours, and entertaining no idea of removing from it. By degrees the influence of local attachment binds them to a spot, which need not have made the object of their choice; and in process of time the desire of depositing their bones in a country which had received and cherished them, succeeded to the obliterated partiality for the place of their birth. The first settlers of all the colonies of N. America were men of irreproachable characters, though not very enlightened in their views, or polished in their manners. Many of them fled from perfection; others on account of an honourable poverty; and all of them with their expectations limited to the prospect of a bare subsistence in freedom and peace. The greater part of them viewed their emigration beyond the Atlantic, as a taking up of the crofs; and bounded their hopes of riches to the gifts of the Spirit, and their ambition, to the desire of a kingdom beyond the grave. A set of men more confident in their doings, or simple in their manners, never founded any commonwealth. It is, indeed, the peculiar glory of N. America, that, with a very few exceptions, its empire was originally founded in charity and peace. In process of time, however, new emigrants
grants flocked to this extensive country, as it became more
open and improved, whose views, principles, and character
were very different from those of the first settlers. Many of
them were persons in very indigent circumstances; they were
different sects, or of no perceptible religion at all; and of
different nations, though the English greatly predominated.

Some of them were convicts, who after confinement in goals
were banded for their crimes; many of them persons of dif-
ferent fortunes, to whom every place was equally uninviting;
out of which indigent, indelicate, and region was acceptable, that offered them a shelter from the
consequence, or the voice of public indignation. But
a change of scene would naturally produce some salutary ef-
fect upon characters the most diffluent. This mixture of
various population was soon blended, by the influence of those
simple manners that are formed by an agricultural life, into
one nation of husbandmen, whose character has communicate-
d itself, in a great degree, to the most profligate of those
whom compulsion or defpair from time to time introduced.

While purity of manners was in this way preferred, that
format of principles in religion and policies was maintained,
which had so eminently contributed to the establishment of the
colony. Sentiments of freedom might find an asylum in
America; when, even in Switzerland, it should no longer be
lawful to think beyond the rules. Nevertheless, the circum-
stances of the N. American colonies produced some other
effects not quite so favourable, upon the table, and in what,
common conversation, we call the manners of the people.

The solitary nature of agricultural labour, and the feeling
of the husbandman's reliance, surrounded only by his own
family and servants, are very iminial to all arts of refine-
ment, and to every ornamental accomplishment; whilst the
settlers of the new colonies were occupied with the use-
ful, they neglected the agreeable arts of life; and vol-
untarily threw themselves back some centuries, in most
branches of civilization, instead of prosecuting the improve-
ments of those branches, from the point to which the
mother country had brought them at the era of their emi-
gation. In consequence of their peculiar circumstances
and occupations, the Americans have always polished a nu-
merous, virtuous, and athletic peafantry; but they have
numbered few fine artists, or accomplished orators; and, in-
deed, an ingenious writer, to whom we are much indebted
in the compilation of this article, proceeds so far as to ob-
serve, with a latitude of expression scarcely allowable, that
' the word American has never yet (so far as I know) been
coupled with either poetry, or painting, or music.' The
history of manners in N. America, says this writer, is the
general history of manners in every new community, of
which agricultural industry forms the basis. The peculiarities
(perhaps accidental), which marked the situation and
habits of the first settlers, have likewise produced some effect
upon those of their descendants, without in the least modi-
fying their character as an agricultural nation. The love
of civil and religious freedom was connected with an anxious
attention to all matters of controversy, whether in politics or
in faith; and as the settlers were equally incapable of
understanding either, so they were chiefly captivated with the
more abstruse of the two sciences; and affected great
depth in the things appertaining to grace, spirit, incarnation,
and all the sublime mysteries of the Christian dispensation.
These fruitless speculations were the only literary inher-
ance which they transmitted to their children. But al-
though they had left the old world for the fake of liberty
of conscience, they too soon manifested what they under-
good by liberty of conscience. By that term they meant
(like many other advocates of liberty) the propagation of
their own peculiar tenets; and they shewed that they only
wanted the power to propagate their creed (like their
European oppreifers) by that method of mental perfusion
which consists in burning the body. They allowed
very man entire liberty of conscience, provided that he used
that liberty in adopting their own librand of faith. Ac-
cordingly, while in Old England the spirit of fanaticism was
operating the downfall of government, and mingling itself
with every pursuit of the age, to the universal debauchement
of manners and sentiment in New England, the crosses were
perfected by the impulses of the inward light; or parties were formed, and armies marshalled, and millions led
by the subtle principles of a metaphysical theology.

The Plymouths and Sydney's had no parallels to temper the
unclassical rage of the American bigots; and even the
Cromwells and Bradfaws found but poor representatives in
the stupid fanatics of Bolton and Salem. Long after the
mother country had reinknighed, for ever, the acts of perfec-
tion, they found votaries in the constituted authorities of the
colonies; and the northern states at the end of the 17th cen-
tury, afforded the disgraceful example of that spiritual tyrany,
from which their territories had originally served as an
asylum. The century, which has just elapsed, moderated
this odious spirit; but to this day, the northern states are
chiefly distinguished from the others, by a taint of religious
bigotry; as the character of the middle states is modified
by the greater mixture of different nations, which have contrib-
uted to people them; and that of the southern
magnitudes, by the admixture of negro flavors. In the mid-
dle states, the mercantile spirit has gained more ground than
in any of the rest; the diversities of race have rendered the
sentiments of patriotism, and the love of liberty, less ardent;
while the variety of religions has prevented the introduction
of that fanaticism, of which we have traced the effects in the
north. In the southern states the contrast of servitude has
mangled an aristocratical spirit with the manners of simple huf-
bandmen; and the climate, by promoting the growth of an
article, belonging to the clafs of luxuries, has given rise to
a species of agriculture bordering upon the great gains and
uncertain prospects of commercial speculation. In all the
colonies, however, of the northern continent, a respectable
national character may be said to prevail. If their inter-
course with the mother country would have had no tendency
to civilize or adorn her, it could certainly have in no
degree contributed to the corruption, either of her moral or
political habits; and the most rapid interchange of popula-
tion could only have tended to embellish the American so-
ciety and to vary its accomplishments, while it rendered a
service to the British manners, by the intercourse of a mid-
mingle and virtuous people. Unfortunately, the very cir-
cumstances which necessarilv led the foundation of those
habits and that national character insulated the population
of the country from that of the old world. The colonics
were stationary for the same reason that they were respect-
able; and the circulation of its inhabitants, with all its ef-
fects upon both parts of the empire, has been maintained
and accelerated in other colonies, placed in circumstances
which rendered those effects unfavourable, at least to the
mother country. For the change that has taken place with regard to the principles and manners, the religion and liberty
of the several colonies of N. America, since they have ac-
quired a new government, and been formed into the United
States; see this article, and also an account of the several
states themselves under their appropriate titles.

The fourth clafs of colonies comprehends those that are
denominated commercial, and which have been establisht at
different periods, by the English, Dutch, French, Spaniards,
Portuguese, and other nations; and which are still maintained, in a greater or less degree, with a view of keeping up a regular intercourse with the natives, or of cultivating the ground, by planting sugar-canes, rice, indigo, tobacco, cotton and other commodities. See Charter Government.

The principal of this kind of colonies are those that have been established in North and South America; particularly Peru, Mexico, Canada, Virginia, New England, Carolina, Louisiana, Hudson's bay, the Antilles islands, Jamaica, Domingo, and the other islands of the West Indies, &c. in Africa, Madagascar, the cape of Good Hope, cape Verd, and its islands, and all the coasts extended thence as far as to the Red sea; and likewise in Asia, the famous Batavia of the Dutch, and Ceylon; Goa, Din, of the Portuguese; and some other less considerable places of the English, French, Danes, and other nations, in the East and West Indies.

The establishment of the European colonies in America and the West Indies, if we except those of North America to which we have already alluded, did not originate in necessity; but it was the result of ambitious and interrelated views. The Dutch, indeed, may plead in favour of the extension of their own settlements and commerce, that the colonial system is necessary to their subsistence and prosperity. Their territory is small, and generally undistinguished by its fertility; and therefore they have recourse to the necessaries of life to the ports of more fruitful and less populous countries. Habituated to industry, and excelling other nations in nautical skill, instead of confining themselves to the exchange of their own manufactures for the rude produce, or the manufactures of other nations, they employed themselves in circulating the produce and manufactures of other countries; and, more attentive to this occupation than to the arts of working up the produce which they imported or raised, they became merchants, not of farmers or manufacturers, but of fisher men, merchants, and sailors. Constrained by other circumstances belonging to their country, when compared with other nations, they were obliged, by the disadvantage of their situation and the oppression of their Spanish masters, to put forth every possible effort of fortitude and perseverance. By industry, frugality, and labour, these people not only raised and improved all their contemporaries in riches and naval skill, but amassed a much greater share of wealth, and gained a more formidable influence over the destinies of the world, than so small a tribe ever acquired in any age. Their steady attachment to the principles of freedom and toleration served as a concurring mean of their advancement and prosperity. The necessary consequence of extensive eminence, acquired by a people who have not a proportionally great territory, is, that the means of advantageously employing their capital will become gradually more and more difficult; the profits of its employment more confined, and its accumulation more slow. Such a people will naturally seek some new openings for settlement or commerce, by acquiring territory in distant quarters of the globe. Should they fail in this way, the over-flowing wealth of the nation must infallibly emigrate, as it were, into the service of foreign countries, where the profits are greater than they are at home. Hence we find that the Dutch became, in a sense, the brokers of Europe; and that they advanced sums to foreign states and their subjects, which were enormous. It is probable, says an ingenious and accurate writer, (Mr. Brougham), that the Dutch have frequently been creditors, at one time, to the amount of much more than 500 millions sterling to their own government, and to foreign states, of which we may reckon two-thirds in foreign loan: an immense sum of for- plus capital to have been accumulated by a nation possessed of no greater territory than the principality of Wales, without any good harbours, or any natural produce fit for exportation; a territory, 120 times less extensive than the European dominions of Russia, which is constant running in debt with all the world! A people possessed of such an overflowing capital, was, of all people, that which flood the most in need of foreign colonies; and this for two reasons:—in order to obtain a new opening, of whatever kind, for the stock which could not be employed at home, or which, for want of this employment, was drawn into the service of foreigners; and in order to secure the possession of this opening at all times under its own command. The acquisition of colonial possessions is the only means by which the United Provinces can possibly avoid the decline of their importance, and preserve the dignity of their public and private credit; and supply their national deficiency of territory by the cause of their inutility, as it was the cause of their rise and progress. An opening for capital may then be obtained always under the command of the state. The possession of colonies must be as advantageous to the community of the United Provinces as agreeable to individual capitalists and adventurers. It has certainly preferred the commercial existence of the republic for a long series of years, and enabled this ancient state to retain its place among the great powers of Europe instead of being swallowed up by its neighbours, or reduced to a few fishing villages. No nation of Europe depends so much upon colonial policy as Holland; nor is any thing more certain, in each member, by the slightest variation of colonial affairs. See Dutch East India Company and Dutch West India Company. The whole return of the Dutch colonies, above 20 years ago, was calculated (says Mr. Brougham) at 24 millions of florins—exported in 150 vessels, navigated by 4000 men, and paying, in freight, 4 millions 5 hundred thousand florins—commission and freight, 2½ millions. The Dutch merchants exported to them merchandise (including negro slaves) to the value of 6 millions. The most unfortunate circumstance in the colonial policy of the Dutch has always been their bad treatment of slaves. (See Negroes and Slaves.) The colonies of Holland have also suffered, in general, from the importation of negroes being too scanty to answer the demands of the proprietors. Upon the whole, it is observed by the writer so often cited in this article, that in no country is there a great demand for new colonies as in the United Provinces. To no part of Europe are colonial possessions so valuable; none would be so irretrievably ruined by their loss; none would be so much benefited by their extension.

The views of Spain in its colonial establishments were directed from the beginning of their connection with America to the pecuniary advantages likely to result from them. In consequence of the representation of Columbus, the council of Castile determined to take possession of countries of which the inhabitants were incapable of defending themselves. The pious purpose of converting them to Christianity sanctioned the injustice of the Dutch. But the hope of finding treasures of gold there was the sole motive which prompted them to undertake it; and to give this motive the greater weight, it was proposed by Columbus, that the half of all the gold and silver which might be found there should belong to the crown. This proposal was approved of by the council. The tax was easily paid whilst the defenceless natives were plundered; but as they were stripped of all that they had, which, in St. Domingo, and the other countries discovered by Columbus, was completely done in fix or eight years; and when it became necessary to dig for it in the mines, it was impossible to pay the tax. The rigorous exaction of it occasioned first the total abandonment of the mines of St. Domingo, which have never been wrought since; and it was afterwards reduced, by successive defalcations, to a tenth part of the produce of the gold mines.
miles. The tax upon silver, which was a fifth of the gross produce, was reduced to a tenth in the course of the last century. All the other enterprises of the Spaniards in the New World, subsequent to those of Columbus, seem to have been prompted by the same motive. It was the sacred thirst of gold that carried Ochoa, Nicuesa, and Vasco Núñez de Balboa, to the isthmus of Darien, that carried Cortez to Mexico, and Almagro and Pizarro to Chili and Peru. Impelled by the prospect of immense gain to establish colonies in foreign countries, the first object of the Spanish monarchs was to secure the productions of these colonies to the parent state, by an absolute prohibition of any intercourse with foreign nations. They took possession of America by right of conquest; and, having reason to apprehend the loss of their infant settlements, on account of their feebleness, their extent, and the reluctance with which the vanquished nations submitted to their dominion, they guarded, by every possible method, against the intrusion of strangers. As their possessions were extended, the spirit of jealousy and exclusion increased; and, in order to their greater security, a zymelom of colonizing was introduced, to which the history of mankind afforded no parallel. In the ancient world, as we have already seen, colonies were of two kinds; either migrations from a country overlocked with inhabitants, or military detachments, stationed as garrisons in a conquered province. The colonies of some Greek republics, and the swarms of northern barbarions which settled in different parts of Europe, were of the first kind; and the Roman colonies were of the second kind. In the former, the connection with the mother country quickly ceased; and they became independent states; in the latter, the dependence continued, because the separation was not complete. The Spanish monarchs, in their American settlements, took what was peculiar to each, and fudied to unite them. By sending colonies to regions so remote, by eflablishing in each a form of interior policy and administration, under distinct governors, and with peculiar laws, they disjoined them from the mother country. By retaining in their own hands the rights of legislation, as well as that of imposing taxes, together with the power of nominating the persons who filled every department, civil or military, they secured their dependence. At first, as we have already observed, the precious metals were the only objects that attracted their attention. Afterwards they sought for such productions of the climate as, from their rarity or value, were of chief demand in the mother country; and they forbade the establishment of several species of manufacture, that were likely to interfere with those of the mother country. Their clothes, furniture, instruments of labour, luxuries, and even a considerable part of the provisions which they consumed, were imported from Spain. In return, the colonies supplied the produce of their mines and plantations, which was conveyed only in Spanish bottoms. The commercial intercourse of one colony with another was either absolutely prohibited, or limited by many jealous restrictions. All that America yields flows into the ports of Spain; all that it consumes must likewise from them. No foreigner can enter its colonies without express permission; no vessel of any foreign nation is received into their harbours; and the pains of death, with confiscation of moveables, are denounced against every inhabitant who presumes to trade with them. Thus the colonies are kept in a state of perpetual pupilage; and by the introduction of this commercial dependence, a refinement in policy, of which Spain fet the first example to the European nations, the supremacy of the parent state has been maintained over remote colonies, during centuries. Several maxims were also adopted and enforced with regard to the restrictions of settlers, the rate of property, and the ecclesiastical policy of the colonies, which, it is evident that the Spanish monarchs, professing a country fifteen times more extensive than Holland, of innegably greater fertility, enjoying all the benefits of the finest climate in the world, surrounded with natural barriers of defence, and blessed with every advantage of situation which can facilitate commercial intercourse, and yet maintaining not much more than one-fourth of the Dutch population, are evidently independent of colonial possessions. All the induftry, skill; and capital of the natives, may find ample employment in raising, manufacturing, and circulating the produce of the soil, or in exchanging the superfluous part of that produce for the commodities which abound in other countries. But, though it would have been founder policy in the Spanish government to have promoted a spirit of industry at home, than to have established distant colonies, yet it cannot be denied, that she has received very great benefits from them, and, in their nature and value, as more than counterbalance the injury they have occasioned. At the period of their first establishment, the interior industry and manufactures of Spain were so prosperous, that, with the produce of these, she was able both to purchase the commodities of the New World, and to answer its growing demands. Under the reigns of Ferdinand and Isabella, and Charles V., Spain was one of the most industrious countries in Europe. Her manufactures in wool, and flax, and silk, were extensive, as not only to furnish what was sufficient for her own consumption, but to afford a surplus for exportation. When a market for them, formerly unknown, and to which she alone had access, opened in America, she had recourse to her domestic store, and found there an abundant supply. By this new demand, furnishing answerable employment, the spirit of industry must have been enlivened and encouraged; and the manufacture, population, and wealth of Spain might have gone on increasing in the same proportion with the growth of her colonies. However, by the great and sudden augmentation of power and revenue, which the possession of America brought into Spain, sober plans of industry were overturned, and opulence, rapidly acquired, produced a taste for what is wild and extravagant, and daring in business or in action. The genius of Charles V. in some measure counteracted the pernicious influence of this inundation of wealth and of the subsequent interruption of it; but under Philip II. its effect, both on the monarch and the people, became conspicuous. Philip, poising an extravagant opinion of his inexhaustible resources, and, at the same time, an ambition connected with moderate talents, thought himself equal to any undertaking. Accordingly he waged open war with the Dutch and English, encouraged and aided a rebellion in France, conquered Portugal, and maintained armies and garrisons inItaly,Africa, and both the Indies. Thus Spain was drained both of men and of money. Under the weak administration of his successor, Philip III., the vigour of the nation declined, and the bigotry of the monarch expelled near a million of his most industrious subjects; so that early in the 17th century, Spain felt such a diminution in the number of her people, that from inability to recruit her armies, she was obliged to contract her operations. Her flourishing manufactures were fallen into decay. Her fleets, which had been the terror of all Europe, were ruined. Her extensive foreign commerce was lost. Agriculture was neglected, and one of the most fertile countries in Europe hardly raised what was sufficient for.
for the support of its own inhabitants. In proportion as the population and manufactures of the parent state declined, the demands of her colonies continued to increase. The rage of emigration prevailed, and the strength of the colonies was augmented by exhausting that of the mother-country. The emigrants depended upon Spain for almost every article of necessary consumption. But Spain, thinned of people and delirium of industry, was unable to supply the increased demands. She had recourse to her neighbours; and the manufacturers of the Low Countries of England, of France, and of Italy, which her wants called into existence, or animated with vivacity, furnished in abundance whatever she required. In a short time not above one twentieth part of the commodities exported to America was of Spanish growth or fabric. All the rest was the property of foreign merchants, though entered in the name of Spanish; so that the trade of the New World may be said hitherto not to have belonged to Spain. Before it reached Europe, it was anticipated as the price of goods purchased from foreigners. Thus the possessions of Spain in America have not served as a source of population and of wealth to her, in the same manner as those of other nations. From the close of the 16th century she was unable to supply the growing wants of her colonies; and the pernicious effects of this disproportion between their demands and her capacity of answering them, were farther aggravated by the mode in which she endeavoured to regulate the intercourse between the mother-country and the colonies. Such was the monopoly at which she aimed, and which she wished to maintain, that she did not sell her trade with her colonies in an exclusive company; a plan which had been adopted by nations more commercial, and at a period when mercantile policy was an object of greater attention, and ought to have been better understood. The Dutch gave up the whole trade with their colonies both in the East and West Indies, to exclusive companies. The English, French, and Danes, have imitated their example with respect to their East-Indian commerce; and the two former have laid a similar restraint upon some branches of their trade with the New World. The wit of man cannot, perhaps, devise a method for checking the progress of industry and population in a new colony, more effectual than this. From this error in policy Spain was preferred, probably by the high ideas which the early formed concerning the riches of the New World. Gold and silver were commodities of too high value to veil a monopoly of them in private hands. The crown retained this shining branch of commerce; and in order to secure it, enjoined the cargo of every ship fitted out for America to be inspected by officers at Seville, and then to receive a license for the voyage; and on its return, that a report of the commodities which it brought should be made to the same board, before it should be permitted to land them. By this regulation all the trade of Spain with the New World centered in the port of Seville, and was brought into a form, in which it has been continued with little variation, almost to our own times. See GALEONS and FLOTA.

The trade of Spain with her colonies being thus restricted, was conducted on the same principles which directed that of an exclusive company; and the whole of it was exported by a few wealthy houses, formerly in Seville, and since the year 1720 in Cadiz; there, by combinations easily formed, prevent that competition which prevents commodities at their natural price; and, by acting in concert, to which mutual interest prompts them, they may raise or lower the value of them at pleasure. This restraint of the American commerce to one port, not only affects its domestic list, but limits its foreign operations. In these circumstances, and whilst the evils resulting from them found no effectual remedy, Spain, with dominions more extensive and more opulent than any European State, puffed neither vigour, nor money, nor industry. At length the violence of a great national conventionrouzed the lumbering genius of Spain. As soon as the Bourbons acquired possession of the throne, it was the first object of Philip V. to prohibit the admission of foreign vessels into any port of Peru or Chile; and a Spanish squadron was employed to clear the South Sea of intruders, whose aid was no longer necessary. After the treaty of Utrecht, which terminated the war, new embarrassments occurred in consequence of the amities, or contract for supplying the Spanish colonies with negroes, conveyed to Great Britain, as the price of peace; (See ASSIST) and the additional privilege of sending annually to the fair of Porto-Bello, a ship of five hundred tons, laden with European commodities. By the operations that succeeded these grants, and by the activity of private interlopers, almost the whole trade of Spanish America was engrossed by foreigners. Guardia collars, and regular ships were introduced. (See each of these articles.) Since the reign of Philip V., sentiments with regard to commerce, more liberal and enlarged, began to spread in Spain. At length Charles III. in 1764, appointed packet-boats to be dispatched on the full day of each month, from Corunna to the Havana, or Porto-Rico. From thence letters are conveyed in smaller vessels to Vera-Cruz and Porto-Bello and through the kingdoms of Terra Fomé, Granada, Peru, and New Spain. Other packet-boats sail regularly once in two months, to Rio de la Plata, for the accommodation of the provinces to the east of the Andes. With this new arrangement for conveying speedy and regular intelligence, a scheme of extending commerce has been more immediately connected. Each packet boat is a trading vessel, and is used for facilitating the exchange of Spanish produce, for an equal quantity of that of America. This was soon followed by a greater degree of enlargement. In the year 1765, Charles III. laid open the trade to the windward islands, Cuba, Hicpanion, Porto-Rico, Margarita, and Trinidad, to his subjects in every province of Spain. He reduced the duties on goods exported to America, to the moderate tax of fix in the hundred, on the commodities sent from Spain. He allowed them to return to any port at pleasure. This ample privilege was afterwards extended to Nornifranza, and to the province of Yucatan, and Campuchey. Such have been the benefits experienced from the relaxation of the ancient yolk of commerce between the mother-country and her colonies, that Spain has been induced to permit a more liberal intercourse of one colony with another. In 1774 Charles III. published an edict, granting to Peru, New Spain, Guatemala, and Granada, the privilege of a free trade with each other. The towns to which Spain has granted the liberty of trade with any of her colonies, are Cadiz and Seville, for the province of Andalusia; Alicant and Cartagena, for Valencia and Marcia; Barcelona, for Catalonia and Aragon; Santander, for Cantile, Corunna, for Galicia; and Gijon, for Asturias. These are either the ports of chief trade in their respective districts, or those most conveniently situated for the exportation of their respective productions. Prior to the allowance of free trade, the duties collected at the Cadiz-honfe at the Havana, were computed to be 104,725 pesos annually. During the five years preceding 1774, they rose at a medium to 308,600 pesos a year. In Yucatan, the duties have risen from 8,000 to 15,000. In Hicpanion, from 2,500 to 5,000. In Porto-Rico, from 1,500 to 7,000. The total value of goods imported from Cuba
Cuba into Spain, was reckoned, in 1774, to be 1,500,000 pesos. From another statement, it appears, that the exports to Spanish America in 1778, were made in 170 ships; were worth about 74 millions of reals vellor, and paid above 3½ millions of duty. The imports from thence, in the same year, were made in 130 ships, valued at 74½ millions, and paid nearly 3 millions duties. In 1785, the value of the exports had risen to above 300 millions, and of the imports to above 834½ millions. The duties upon these exports and imports exceeded 55 millions. This rapid increase can be ascribed to nothing but the effects of the free trade; and notwithstanding all the clamours raised by the Cadiz merchants, we find that this city was the first to enjoy the advantage of the change; for the imports of Cadiz from America, in 1788, were three-fourths of the whole colonial imports; and the exports of Cadiz thither were considerably above two-thirds of the whole colonial exports.

Spain has likewise directed particular attention to the interior government of her colonies. For an account of the Philippine colony, see ACAPULCO and MANILA.

The revenues which Spain derives from America, arises from taxes of various kinds, which may be divided into three capital branches. The first contains what is paid to the king, as sovereign of the New World; to this belongs the duty on the gold and silver raised from the mines, and the tribute exacted from the Indians; the former called "the right of figueroa," and the latter "the duty of vassalage." The second branch comprehends the numerous duties upon commerce, which are very minute and oppressive. The third includes what accrues to the king, as head of the church, and administrator of ecclesiastical funds in the New World. In consequence of this he receives the first-fruits, annats, spoils, and other spiritual revenues, levied by the apostolic chamber in Europe; and is entitled likewise to the profit accruing from the bull of Crusade, which fee. The whole amount of the net public revenue of Spain, raised in America, is stated by Dr. Robertson as amounting to a million and a half sterling. Spain and Portugal are the only European powers which derive a direct revenue from their colonies, as their quota towards defraying the general expense of government. All the advantages, that accrue to other nations from their American dominions, arise from the exclusive enjoyment of their trade; but, besides this, Spain has brought her colonies to contribute towards increasing the power of the state, and, in return for protection, to bear a proportional share of the common burden. The amount of the Spanish revenue, above stated, comprehends only the taxes collected there, and is far from being the whole of what accrues to the king from his dominions in the New World. The heavy duties imposed on the commodities exported from Spain to America, as well as what is paid by those who trade in return; the tax upon negro slaves, which Africa supplies the New World, together with several smaller branches of finance, bring larger sums into the treasury, the precise extent of which Dr. Robertson cannot pretend to ascertain. But if the revenue which Spain draws from America be great, the existence of administration in her colonies bears proportion to it.

The total amount of the public revenue of Spain from America, and the Philippines, from the most recent information stated by Dr. Robertson, is as follows:

Paper exported on the king's account, and sold in the royal warehouses, - - - 300,000
Stamped paper, tobacco, and other small duties, - 1,500,000
Duty on coinage, at the rate of one real de la Plata, for each mark, - - 300,000
From the trade of Acapulco, and the coasting trade from province to province, - 500,000
Affitto of negroes, - - 200,000
From the trade of Mâthi, or herb of Paraguay, formerly monopolized by the Jefuits, - 500,000
From other revenues formerly belonging to that order, - - - 400,000

Total 13,000,000

Deduct, half, as the expense of administration, and there remains net free revenue, - 6,500,000

From the above detail, and upon a general view of the subject, it appears to be absurd to deny, that Spain has derived very great benefits from her colonial possessions. Nevertheless, many very enlightened men have maintained, that the downfall of the Spanish power has been owing, in a great measure, to the extension of dominion which followed the discovery of America. To this purpose an appeal has been made to the authority of Dr. Smith, the well known and much approved author of the "Wealth of Nations," "That the monopoly," he observes, "of the trade of populous and thriving colonies is not alone sufficient to establish, or even to maintain, manufactures in any country, the examples of Spain and Portugal sufficiently demonstrate. Spain and Portugal were manufacturing countries before they had any considerable colonies. Since they had the richest and most fertile in the world, they have both ceased to be so." However, Mr. Brougham has remarked, that the tenor of this observation is confined to the statement of a fact which cannot be denied, that the period of the decline which the Spanish and Portuguese manufactures have experienced, coincided with the period of the Spanish and Portuguese colonial greatness. But the whole argument proceeds upon a view of the subject, formerly discussed, that colonial monopolies in general have been hurtful, from their effects on the wealth of the mother-country. Mr. Brougham has accurately examined this subject; and in the prosecution of his inquiry, he has shewn, in what manner the prosperity of Spain has been influenced by the discovery of America; and he has investigated the question, whether the acquisition of rich and extensive colonies can be charged with having caused the decline of the mother-country, and whether, in short, any bad consequence whatever is imputable to this augmentation of empire.

By those who have maintained, that Spain has been materially injured by her colonies, it has been alleged, that by an immoderate extension of territory, the Spaniards have been led to the neglect of the territory, which they formerly possessed. But although Spain, and also Portugal, may have feebly suffered in this respect, it is seldom, if ever, that, from the nature of colonial power, any such consequences can arise to the mother-country from the possession of the most widely spread colonial dominions. In the case of Spain especially, whatever neglect there may have been in the management both of the mother-country and the colonies, the mal-administration of both parts of the empire must evidently have arisen from other causes besides their being united under one crown. Farther, the vast outlet to population which the Spanish colonies
 Colonies afford has been thought by many to be detrimental to the mother-country. They allege that the population of Spain has been drained by the demands and temptations for men which the colonies afford. Our author suggests a variety of considerations that tend to invalidate this objection. The indolent and adventurous, the nobles and soldiers of fortune, and men of considerable property, were the principal emigrants at the first settlement of the Spanish colonies in America; as conquest or plunder, and mining in search of the precious metals were the only modes in which wealth was then sought. Besides, the drain of emigration has been chiefly confined to the population of the maritime provinces of Spain; as the annual amount of the emigration in different periods, cannot be estimated very high. It has been said that the rage for emigration to America was so much abated in a short time after the discovery, chiefly by the ruin of many who flecked thither, that in the year 1550, there were not above 15 thousand Spaniards in all the New World. From other documents it has been inferred, that the whole amount of those who have emigrated to the Spanish colonies, during a period of three centuries, does not exceed 500,000. The drain of the Spanish population must therefore be wholly inadequate to account for the decline of the Spanish resources, and the flow of the Spanish population. It is no less censurable to imagine that the capital which has been drawn to the colonial agriculture and mining, can have impoverished the mother-country in any considerable degree, than to suppose that the colonial emigration has drained her population; and it is, therefore, to causes different from the emigration of inhabitants, and of capitals, that we must attribute the depopulation, the indolence, and the poverty of Spain. In order to account for the depopulation of Spain we may recur to the ravages of the plague, which, during three centuries, was more fatal than the conquest of the colonies. The conquest of the colonies, in the middle of the 14th century, carried off two-thirds of the whole population of the peninsula, and which about three centuries afterwards, destroyed 200,000 persons in the southern provinces;—to the destruction occasioned by dearth and famine;—to the cruel and infaile policy of Ferdinand, who, as an expression of gratitude to God for the successe of his arms, expelled from his dominions the whole tribe of Israel;—to the still more bloody and impolitic measures of his successor, who, about a century afterwards, drove out all the Moors, and unites the western races;—and to the constant persecutions and rebellions of those two classes during the interval between the great and general expeditions, which produced the effect of suddenly eradicating from the kingdom all the industry and skill which had raised it to such a pitch of opulence and glory. The number of the Jews, who, in the year 1492, were butchered or driven out, is reckoned by some authors at 800,000 persons, by others at 800,000 families; and the number of the Moors driven away by the edict of 1609, cannot be computed at less than a million. The best informed writers flate that of the editions and intervening intervals, have amount ed to between two and three millions; confining of the most useful and valuable part of the community. We might enumerate other causes of the decline of Spain, arising from restrictions and impotts, and a miserable system of law and politics, both at home and in the colonies, which operated much more fatally than the acquisition of colonial dominions, and which, indeed, counteracted any benefit they might otherwise have afforded. It is surely a proof, says Mr. B., that the downfall of a country was not caused by its colonial possessions, but by some evil in the national policy common to all its branches, when we find that the era of adversity was common to both the contiguous and remote provinces, and that the same circumstances which raised up the colonies,
foreign conquest, may convince us of the important relations which the provincial wealth and power of this nation must have formerly borne to its whole resources. The East Indian possessions of Portugal, during the 16th century, threw into their hands the whole commerce of Asia, which, long before the discovery of the passage by the Cape of Good Hope, had formed one of the greatest trades carried on between any two parts of the world; had enriched and refined the whole European empire of Rome, and raised the inconsiderable republic of Venice to a degree of power formidable to all the great nations of the continent. The same commerce, divided among several states, has, since the downfall of the Portuguese dominions, fabulously enriched all those nations, and continues to form a very great part of their extended trade. We may judge, in some degree, of the extent of the trade carried on by the Portuguese in their Asiatic settlements, some time after their eastern empire had begun to decline from the completion of the English and Dutch, by a single fact. In the year 1611, the English company's servants, in one of their voyages to Surat, found a single Portuguese merchant fleet, consisting of 240 sail, bound for one place, and destined only for the commerce of the northern and most thriving settlements. (Anderson's Hist. of Commerce, ii. 245. 263.) The African and Asiatic provinces, however, must be considered as conquered territories, held in subjugation by a few troops and squadrons of ships; not as colonies peopled by emigrants from the mother country, or by a race in which those emigrants and their descendants bore a considerable proportion. Of these vast dominions the Portuguese were nominal possessors; the treasure and blood of the metropolis were wasted in wars with the native powers, and the relations of commerce were on every occasion postponed for those of conquest and dominion. Those circumstances have eventually proved fatal to the Portuguese dominion in the East, which has at length been transferred to others powers of superior policy and strength.

The Portuguese trade with India, though rigorously confined to the subjects of the mother country, was never put into the hands of an exclusive company, incorporated by charter, except for a short time, about the year 1731, when the experiment was un successfully tried. The sovereign granted, from time to time, privileges of sitting out vessels, under limitations, to private co-partners and individuals, who thus enjoyed a monopoly of the supplies required both by the Asiatic and European provinces. The monopoly had been generallyotted in the crown, until the year 1752, when it was fixed to be abolished; but several important articles still continued subject to the royal privileges, and could only be bought in India and sold in Europe on the king's account. From the splendid pre-eminence which the Portuguese trade with India once possessed, it has sunk to a few annual voyages, in consequence of the reduction of the Portuguese empire in the East, and the bad management of the trade and settlements that still remain. With a view to its revival, new exclusive grants have been made to mercantile adventurers in Europe, and an exclusive company has been established at Goa (the chief East Indian settlement) for the management of the whole trade with Chins. These abundant measures have taken place since the year 1752, when the evil perceived to arise from monopolizing policy, induced the sovereign to abandon several of his exclusive rights, and to pretend that the East Indian commerce was thrown open. While the Portuguese conquests were rapidly subsiding each other in the East, the discovery of Bengal, opened a new field of exertion in the West. Brazil, however, compared with Asiatic conquests, was regarded with indifference, and slowly peopled by malefactors, and by those whom the perverting spirit of the times drove, from the mother-country. Among the emigrants of this period, sacrificed to the cruel bigotry of the inquisition, was a great body of Jews, who carried over with them to the colony the skill and industry with which they had enriched and strengthened the European dominions of Portugal. Under their cultivation the natural wealth of this fruitful territory began to appear, and by degrees to attract the attention of government. All the Portuguese subjects, who chose to settle in Brazil, were permitted to subsist large tracks of country, and to hold them as fiefs of the crown, with absolute power over the natives whom they had conquered, and with all the prerogatives of royalty, except capital jurisdiction, coinage, and tithes, which were invariably referred to the sovereign. These great territorial lords thus acquired an almost absolute authority, over domains often extending 40 or 50 leagues along the sea-coast; and generally leased out parts of their possessions to sub-fiefolds for terms of 2 or 3 lives. This arrangement immediately attracted to the colony a number of adventurers and opulent persons from the mother country. The importance of this colony, in consequence of the whole territory of Brazil, and the cultivation of various useful articles, gradually increased; and its traffic with the parent state, would have proved a great mutual benefit; if an erroneous policy had not confined it to a few ports in each part of the empire. Annual fleets from Lisbon and Oporto alone were permitted to carry on this rich commerce, under regulations similar to those of the Spanish fleet and galleons. Four emporiums, viz. Olinda, St. Salvador, Paraiba, and Rio Janeiro, were appointed for the designation of thefe squadrons, and the supply of the whole colony. The 18th century opened with a discovery of gold and diamond mines; and since that period many regulations have been adopted, which have proved pernicious both to the colonies and to the parent state. Companies were established at Peru, Fernambuco, and Maraguan, which did not long survive the downfall of Pombal, the Portuguese minister: there have ceased to exist above 20 years, after proving highly injurious to both the mother country and the colony during an equal period of time. A new and more liberal system has been introduced; but the royal monopolies still exist in their full force, and obstruct the growth, as well as the circulation, of the most valuable staple produce which Brazil supplies. Since Portugal has experienced the irretrievable loss of her rich East Indian commerce, and a diminution of the traffic formerly carried on with Africa, Brazil is of great importance to her. This colony is better governed and peopled than any of the Spanish dominions; its proximity to Africa and connection with the Portuguese settlements there, afford great facility in the increase of its cultivation, by means of negroes; the possessions of Brazil gives Portugal considerable weight in the Continental politics; and the possession of this noble colony, besides yielding a clear revenue to the mother-country (above one-fourth of the whole national income) is the source of a great proportion of her whole commerce—the imports from them being nearly equal to the whole imports from the other countries of Europe.

The colonies of Sweden and Denmark, are too insignificant to influence, in any considerable degree, the prosperity of the parent states, and bear a less proportion to the whole imperial resources than those of any other nation. The exclusive companies, which for a long series of years monopolized all the colonial trade of both these countries, have been peculiarly injurious. See Company, Dominions, and Swedish.
For an account of the colonies of France and England, the limits of our article oblige us to refer to the article France and England, West Indies, East Indies, and Company, and the several individual islands of the West Indies.

There are some other kinds of colonies, besides those above enumerated, of which we shall give a brief account. Conquered subjects or prisoners of war have been sometimes removed to particular and distant places, either for safe custody, or for the cultivation of waste lands. The ancients more frequently practised this species of colonization than the moderns, who prefer exchanging the prisoners on each side. The Romans, in particular, were constantly accustomed to remove the more active and daring nations to a distance from their native abodes, and to oblige them to reside in some select place which was probably less defensible than their own country, and where, of course, they would be more under command. We are not, however, without some examples of this kind, even in our own times. The Maroons, or remnant of the Spanish slaves, who had been relinquished by their masters, and left on the island of Jamaica, when the Spaniards were expelled by the English, after having long gallantly refitted the forces brought against them, at last submitted to one of his majesty's officers, upon condition of not being sent off the island. To this submission they were induced by the fear of a new species of warfare with which they were threatened, viz. the use of blood-hounds to discover their retreats. But the legislative assembly of the island not only refused to pay the Spanish police-runners their stipulated bounty, but also took advantage of some unavoidable delays in the performance of the treaty to annul it altogether, and to transport the Maroons to Nova Scotia, whence they were afterwards removed to Sierra Leone. On account of this flagrant act of injustice the commanding officer of his majesty's troops indignantly refused a hand- some reward, which the assembly offered him for his services in putting an end to a war which had been so long protracted. See MAROONS.

Another kind of colonization is the removal of convicted criminals, or of debtors, to some desert spot, in order to work the mines, or break up the land, and thus prepare it for more respectable colonists. The Russians use this mode of colonizing their vast lands in Siberia. But the most interesting colony of this description, particularly to Englishmen, is that of New Holland, which lies—Also Botany Bay and New South Wales.

Great sums of money have been, and still are, annually expended on this colony, but it has hitherto languished; partly from the disproportionate number of the sexes, and the idle habits of the convicts, but still more from some radical defects in its administration, many parts of which render it more like a mere job for contractors and agents, than a well regulated system for the gradual reformation of the criminals, and for rendering them useful subjects in future. The dilations also which have taken place among the officers there, cannot but have tended to injure the colony. These dilations seem to have originated in some measure from the governor being always a naval officer. The abridgment, for such we must esteem it, of a naval officer commanding in chief on shore, merely because he went to the place by sea, is fully equalled by several others, which demonstrate how inadequate to the undertaking were the framers of the system by which the colony is regulated.

During the first ten years, viz. from 1787 to 1797 inclusive, the number of convicts sent to New South Wales was 5765 men and women, and 93 children, being in all 5855 persons. The expense of transporting, feeding, and governing them, during that period, amounted to 1,087,250l. being above 177l. for each, exclusive of the expenses previous to their embarkation.

The number of convicts remaining was as follows:

- Men convicts in the settlement - 2715
- Women - - 939

Convicts sent out in 1796 and 1797:
- Not arrived - - 605

Total - 3802

So that a large of 2849 convicts had been confined in this short period; an evident proof of the most gloomy mismanagement. On the first of September, 1798, the agricultural state of the colony was as follows:

- Acres of land in cultivation - 1700
- Thores - - 14
- Black cattle - - 130
- Sheep - - 197
- Goats - - 111
- Swine - - 59

The later accounts which have been received are equally unpromising. The spirit of dilution has increased, and spread itself to every rank; so also has the depravity of the convicts, in consequence of their not being separated, and placed under the control of steady persons who have an interest in watching over their moral improvement. Indeed, the misfortunes of the convicts increased by fellowship, and even many of the free settlers have, from the force of evil example, acquired the same bad habits. The quantity of land cultivated on the public account is too great, and the numerous public works absorb the labour of the convicts, and leave but few of them to be hired out to settlers. These circumstances, together with the ill selection of the convicts, and of the settlers, as to their former employments, contribute to the want of success in the colony.

It certainly is not improper to fend, as matter of favour, criminals to remote and desert places to procure their own livelihood, furnishing them at first with a few necessaries, and then leaving them to their own industry; or to supply the free settlers in those places with convicts for servants, in order to give them from the heavy expense incident to their procuring servants from a distance. But the idea of transporting large bodies of criminals to an immense distance, and employing them, under a strong guard, in public works, where few such works can possibly be wanted, and in cultivating land in the produce of which they have no interest, does not seem to have been happily chosen, or very promising, even in theory; and we may add, that practice, upon a very extensive scale, has completely flown its object.

The Romans, it is true, transplanted their prisoners of war to distant countries, and employed them on public works; but those works were carried on in well inhabited countries, and were designed for the facilitation of the intercourse between the several parts of the empire, or for adorning the cities with marks of the Roman grandeur.

We believe, however, that the colony of New South Wales might be made to answer much better, if a few simple regulations were adopted, and particularly if the employment of so many convicts on account of government was abolished, and the convicts left more to their own industry.

It was formerly observed in Virginia, that the colony languished so long as the cultivation of the ground, &c. was carried on as a public concern, but that it immediately began

to flourish when the lands were divided, and every one left to shift for himself.

The want of capital and experience among the majority of the convicts, forms no objection; as, by furnishing those accustomed to husbandry, gardening, or useful trades, with the necessary fees and tools, and a very sparing allowance of provisions, to be gradually diminished, there can be no doubt but that, in a very short time, they would not only be able to repay the advances made them, with interest, but also pay a gradually increasing rent. As to those bred to no profession useful in the colony, they might be let out by auction, for a year at a time, until they had acquired sufficient experience; and a fourth part of their wages might be deducted and laid by, to form a stock when they were capable of using it, another part being paid into some benefit society.

Hitherto we have spoken of external colonies, or those in which the colonists recede from their mother-country, and establish themselves in foreign land, without, however, submitting to their form of government.

It now remains to treat of those colonies in which large communities of foreigners are, for some particular reasons, permitted to enter and settle in a country; which colonies differ from those founded by private adventurers, only because they do not so strongly affect the political system of the country.

The Ruflian government, having immense tracks of waste lands, some of which are advantageously situated for mines or for commerce, has, as we have already said, bellowed great attention in endeavouring to people those tracks, as well by foreigners as by natives. The Prussian government has also induced the same laudable attention to the improvement of the waste lands in its possion; and it even went so far as to require from the Poles a tribute of marriageable virgins, with a stipulated portion for each.

To this species of colony belongs what is usually called the Babylonian captivity of the Jewish nation, and which is erroneously supposed to have been a removal of the whole nation in a state of slavery; whereas it evidently appears, from their own records, that it simply meant the residence of the Jewish chiefs, and of their priests, at the court of the king of Babylon. The number of persons carried off by the king himself, was (2 Kings, xxiv.) only 10,000; a number surely applicable only to the higher classes. The officers which many of them held in the Babylonian court, and subsequently in the Persians, are a proof, that although they were, for obvious political reasons, required to reside at court, their situation there was perfectly honourable. It is probable, however, that their removal might occasion the gradual emigration of a number of other families, who followed them for the sake of employment, and spread over the Babylonian dominions; as their number was found to be greatly encresed, when they were allowed by the Persians to return. They then amounted (Nehemiah, vii. Ezra, i.) to 49,697 persons.

Many other instances may be found, both in ancient and modern history, of this importation of people. The conquered Greeks filled the capital of the Roman empire, and, by the virtuosity of their talents, acquired the same influence over the masters of the world, as the modern French, (who frequently boast of their Grec origin) have over the fashionable part of our own country. By means of this influence, they introduced among the Romans all the vices for which they were notorious; and to the baneful effect of their influence, we may judiciously attribute, in great measure, the downfall of the empire, since they introduced a love of dissipation, and of slowy, but trifling acquisitions, instead of the more solid attainments which were required, before they contaminated the public mind.

The importation of slaves into a country, may be regarded as a kind of internal colony of the most important, because dangerous nature. When the slaves are numerous, they are not only retained in subjection with difficulty, being in general far superior in bodily strength but they are also of very doubtful fidelity, and ever ready to join any invader, or to flock to the standard of any military adventurer. There is yet still greater danger in an independent state exists in the neighbourhood, and particularly if it should consist of revolted slaves (as has lately happened in St. Domingo), because the greater energy of an independent government enables it to prosecute any ambitious designs of conquest with decided advantage over a delegated authority.

It is, therefore, highly politic that slavery should be constantly permitted in any country; and, although, for the sake of bringing labourers to any particular spot, it may be tolerated at first, it is the bounden duty of every state to take decisive measures to convert the slaves, by degrees, into free subjects, and to put a stop to the importation, as soon as the colony has obtained a certain population, and further to take some steps in order to liberate the slaves already imported, or at least to make their servitude free at a certain age. Thus it will be requisite for the colonist to attend to the welfare of his present flock, and to introduce talk-work, whereby he will be changed, in time, from a commercial capitalist, or a needy planter, into a landed gentleman. He will then be solicitous only for his rents, and deprecate the idea of keeping more land in hand than is necessary for the support of his establishment, or to serve as an example of perfect cultivation and grazing to his tenants, to the most indolent of whom he might furnish capital and favourable leaves, in order to enable them to improve his own land.

To a neglect of this salutary precaution, we may attribute the present dangerous state of the Dutch and English colonies in the West Indies, since, notwithstanding the length of time that they have been established, the state of society in them is as crude and semi-barbarous as it was at the time of their being first settled.

It was probably owing to a similar neglect that the western provinces of the Roman empire were so speedily subdued by the northern adventurers. The Roman provincials, like the planters in the West Indies, seem to have had little repugnance to a change of masters; partly because the resident planters were thus relieved, at least for some time, from the claims of their creditors; partly because the agents were enabled, in many cases, to convert the plantations to their own benefit; and, lastly, because both were equally afraid that, in case the war was protracted, they should lose their slaves. See Slaves.

As to their intrinsic nature, colonies are either agricultural, which grow within themselves the principal articles of their food and subsistence; or they are commercial, which depend upon other countries for the necessaries of life, and devote themselves to the traffic of a few staple commodities. The northern states of America and the Bermuda islands are so many instances of agricultural colonies; while the West Indian islands, together with Virginia and Maryland on the continent, are examples of commercial colonies.

In respect to the advantages or disadvantages of external dependent colonies, no person has more thoroughly con-
dered the subject than Mr. Brougham, in his elaborate treatise "On the Colonial Policy of the European Powers." The adoption of all the positions advanced by that ingenious writer, may indeed be somewhat hazardous; especially if we consider the great degree of doubt and uncertainty which hangs over all political speculations, on account of the difficulty, and still more the danger of making experiments on those subjects; to lay nothing of the want of means for ascertaining whether the effects are ascribed to the right causes, when (as is usual in human affairs) so many causes concur in producing those effects.

The first advantage arising from colonies is, as has been said, the extension of the home trade; for such in fact the trade between the mother-country and the colony may fairly be considered, because the whole of the profits is retained within the state; whereas in foreign trades, one of the profits, either that of the buying, or of the selling merchant, goes to enrich a foreign state. The trade of a colony also produces a considerable augmentation of the mercantile navy of the mother-country, and, at the same time, as the ships and their crews are constantly retained within the power of the state, there is far less danger of the sailors being enticed into foreign service, than if part of their time was spent in foreign ports. The European nations have anxiously endeavoured to confine the trade of their colonies to the merchants of the mother-country by positive regulations; but Mr. Brougham thinks this solicitude is absurd and even nugatory. Merchants will, in all countries, prefer dealing with their own countrymen, with whom language, laws, and habits of thinking they are acquainted. And this is more especially the case in commercial colonies, as they require in general such large advances of capital, that few persons would be inclined to invest sums upon private foreign security.

But the greatest utility of colonies, is the ascertaining an opening for the employment of the superfluous population of the mother-country, which must otherwise either emigrate to the neighbouring foreign nations, or die of want at home. The inhabitants, indeed, of agricultural colonies, are in general stationary, and, as it were, lost to the mother-country; but these colonies only attract those who cannot get employment at home, or in the commercial colonies, or those who are in such desperate circumstances that they are obliged to fly from home to avoid the hardships of their creditors. Commercial colonies, on the other hand, have for the most part only a temporary population, as the colonists, after spending a part of their time in the colony, generally return home with their fortunes improved, and carry with them, to the mother-country, the same spirit of improvement to which they owed their success in the colony.

Commercial colonies have a further advantage, in furnishing employment for those large capitals which would otherwise be employed upon the more distant foreign trades, or lent to foreign states.

We shall now say a few words respecting the disadvantages arising from the possession of colonies; these are so great that the economists have loudly declaimed against the utility of forming such establishments; but they have committed a fundamental error, in considering colonies as foreign states. They ought rather to be considered as mere extensions of the parent state, into regions adapted to the production of articles which cannot be raised at home. A circulation of inhabitants is kept up by the commercial intercourse between the colony and the mother-country, and also by the weaklings incident to parts remote from the seat of government. So that, as the colonies require, at all times, the fostering care of the mother-country, they are generally filled with the troops of the parent state and their followers, and the ports are constantly referred to by its shipping, both mercantile and warlike. It were needless to infilt upon the powerful attractions resulting from their common origin, their identity of language, and their similarity of habits in thinking; as the effect of these, in producing a good understanding among nations, must strike the most inattentive observer.

One of the principal disadvantages of colonies, is the wars into which they seem to draw the nations which possess them. But although it is certainly true that external commercial colonies draw, in the present times, generally the force of war from one of the belligerent powers as polishes them, it is not always that they are the causes of the war; for as they increase the frontier to be defended, those nations which possess them will be less ready to engage in hostilities; and it is the weakness of the colonies, (on account of their deficient population preventing the raising of regular troops in them), that is the principal cause of the enemy chusing rather to invade them, than to force his entry into the parent state. The want of a powerful landed interest, in colonies of this nature, tends also to attract the hostilities of the enemy, as the possession of them is seldom disputed with the obstinacy which marks the resistance to invasion in old settled countries; the defence being limited to the small number of troops which the parent state can spare without endangering her own safety, and whose exertions are impeded by the mixture of an ill disciplined militia, and of volunteers, unacquainted to service, and deploring their fate in being forced from their own homes.

This unfruitful of external colonies, which are always underocked with inhabitants, to contribute supplies of men for the general defence of the state, is usually considered as a disadvantage; but it cannot in reality be deemed to be one of much consequence. Even in the parent state itself, it is only in those manufacturing districts that produce articles, the demand for which is variable, that the recruiting service meets with success; in those where agriculture prevails, or in which a staple commodity is manufactured, that service is in general unsuccessful. It cannot, however, be of any consequence, in regard to the general population of the empire, whether the mother-country supplies soldiers, or whether they are raised in the colony, and their place supplied by fresh settlers.

It is only the total want of supply, both in the planting and subsequent management of the English colonies, that rendered them at first, and still keeps several of them expensive burthens to the mother-country; as those of other countries not only pay, in general, their own expences, but also furnish a surplus revenue for the service of the empire.

It will appear, from what we have already said, that a great difference of political strength subsists between agricultural and commercial colonies. The former are much stronger internally, and capable of affording, with their own resources, a more obdurate defence to the attacks of the enemy. But this strength renders them refractory, and difficult to be controlled; hence they require either early restraint, and the observance of a strict discipline, or they must be relinquished as dependencies, and incorporated into the mother-country, as has recently been found necessary in respect to Ireland. On the other hand, although the weaknesses of commercial colonies renders them much more dependent on the state to which they belong, yet, from the debts with which they are in general loaded, they are ever ready to submit to any invader; especially if the change can be made to a state, where the merchants possess larger
Larger capitals than those of the flate to which they have already been subjected; as this affords them a hope, not only of being released for some time from the claims of their ancient creditors, but also gives them reason to suppose they may be able to procure still greater credit from their new masters. Every person acquainted with West Indian affairs must acknowledge the truth of this remark; and with respect to other parts, we have, ourselves, twice experienced the facility and even eagerness with which the Cape of Good Hope was surrendered to us.

The want of mercantile capital, which our enemies in the West Indies do not as yet possess, is the principal security we have that those colonies will rather chafe to remain under our dominion than fall into the hands of other powers, as they would, in that case, be obliged to diminish their cultivation in consequence of the diminution in the advances made by the merchants upon their future crop. And as to any attempts at independence, the mother-country has a considerable security in the precarious situation of the inhabitants, in consequence of the number of their slaves and the discontent that generally prevails among them. This latter circumstance, might, by those who think the possession of colonies, and the monopoly of their trade, are of great benefit to a nation, be thought to afford a good argument against the abolition of the slave trade, as tending indirectly to lefen the dependency of the colonies. But we may remark, that the greater strength of the colonies, arising from their internal improvement in consequence of the abolition of the slave trade, would make more than counterbalance the danger of their revolt, as they would, in consequence of such strength, run less hazard of falling into the hands of an enemy. And the event of the American war has fully proved, that even in the case of the colonies revolting, when they had acquired sufficient strength, the commercial intercourse between the two countries would continue, and probably rapidly increase; so that the government would, at the worst, lose only an expensive incumbrance. It can only be by the influx of foreigners, belonging to a mercantile nation, in such numbers as to acquire a preponderance in the state, so as to alter the fundamental laws and language of the colony, that any great change in its commercial relations would be effected.

The most serious disadvantage of colonies, is that they divert the capital of the nation from the improvement of the mother-country; although this improvement is certainly the most advantageous employment in which the capital of any nation can be engaged. It has indeed been asserted, that the labour of one man on the continent of America, produced more to the state than four at home; but this must be regarded as the mere rant of visionary politicians, being totally unfounded and absurd in the highest degree; for the subject at home being directly taxed, must yield far more revenue than those in the colonies, who are in general only indirectly taxed to the common service of the empire, by the cullums levied upon the commercial intercourse of the two countries. The fame perons asserted that each white person in Virginia and Maryland, took off from ten to twelve pounds a year of the growth or manufactures of the mother-country. But the cullum-horse books are sufficient evidence that this calculation was much over-rated; for the exports to those colonies were never more than 300,000l. a year, and therefore, allowing them to contain, as was stated, 120,000 white persons, the consumption of each person was only 1l. 13s. 4d. a head. The whole of the exports to America, when at the highest, was only about 834,000l. a year; and this tends to shew that it is better to retain the industry of the inhabitants of any country within its own sphere, and encourage the cultivation of the wakle lands, than to divert it to distant colonization. It may, however, be sometimes necessary, as a measure of precaution, to secure the possession of distant places, when it is known, or suspected, that the usual enemies of the state intend to colonize them; but it is extremely improper to foster these distant colonies at the expense of the mother-country, as is done in respect to the British colonies. When an old settled country is improved to the highest, then, and then only, can it be necessary to provide outlets for the employment of the surplus capital of its subjects, by conquering, or purchasing some poor country, with a view to its improvement.

As to internal colonies, the encouragement of foreigners, and especially the importation of foreign slaves, must, in general, be regarded as errors in politics. The procuring of a flock of labourers in the first stage of breaking up a new and uninhabited colony, the introduction of new manufactures, or of new commercial relations, can alone justify such measures. And surely it is far better to endeavour to attain these ends by other means. The removal of idle and disorderly persons from great cities, the finding out intelligent travellers into other countries, the encouragement of experimental philosophers and chemists, together with the apprenticing of clever youths to merchants in foreign countries, would probably be equally efficacious. See Smith's Wealth of Nations, B. iv. chap. 7. Robertson's Hist. of America, vol. iii. Brougham's Inquiry into the Colonial Policy of the European Powers, 1803, vol. i. and ii. passim. Paley's Principles of Moral and Political Philosophy, vol. i. p. 381. Edwards's Welh Indies, vol. ii.

Colony of Bees. See Hive.

Colony, or Colône, a town of HindooLAN, in the cercir of Guntoor, which possesse a diamond mine on the southern bank of the Kilinah, and not far from Condavar.

Colopena Regio, in Ancient Geography, a country of Asia in Cappadocia; Seballeas and Seballe are towns of this country.

Colophon, a town of Asia Minor now Attaleia, or according to others, Belvixdr. It was one of the chief cities of the Indian league, fated near the Ica, and not, as Piny calls it, an inland city, in the small river Haleus, N. W. of Ephesus and S. S. E. of Smyrna. It was founded by Moplius, grandifico of Tircias, and, in process of time, Damacliten and Promether, sons of Codrus, conducted a colony hither. It was deforced by Lyimachus, and its inhabitants were sent to people Ephesus; but after his death it was rebuilt in a more convenient situation. The Colophonians were such excellent horsemen, that those, for whom they declared themselves, were sure of victory; whence the trite proverb "The colophonion addere, i.e. to put the last hand to a work, or successfully to terminate it." Colophon was the birth-place of Nicedor, and one of the seven cities that claimed Homer, who lived there some time, as Herodotus informs us. The ancients mention a famous grove and temple of Apollo Darius in the neighbourhood.
behood of this city; whence some have said that he derived this appellation, though others say that he was so called from a mountain bearing that name. The small town of "Notium," on the same coast, often mentioned by Livy, belonged to the Colophonians, and the Romans allowed it the same privileges, which they granted to Colophon itself. Piny informs us, that they collected in the vicinity of Colophon, a resin of a yelowish red colour, which being bruited, emitted a throng odour; and hence some have derived the name of Cyccoliun, now frequently called "Spanish wax," or "Grecian resin," as it is brought from one or the other of those countries. Its episcopal see was subject to the metropolis of Ephesus.

Colophon, a town of Greece in Epirus.

Colophon, in Botany, Commenrs. See Bursa paniulata.

COLORS, in Geography, the name given by Dion to a river of Pannonia, called Colupa, by Strabo.

COLORQUINTIDA, in the Materia Medica. See Colorcynthia.

COLOR, in the Ancient Muses. See Colours.

Color rubra; see Indigo Color.

Color aurea; see Indigo Color.

COLORADO, in Geography, a river of New Mexico, in the south-western part, which flows into the northern part of the Vermillion sea, or gulf of California, called by D'Anville colorado de los maitres. The course of this river, which is generally from N. E. to S. W. sometimes W. may be computed at 650 British miles. It is called Rio Colorado, or Red river, because the waters acquire that colour from the red clay on which the rains fall. Its stream is deep and copious, and capable of considerable navigation. The neighbouring savages, who swim adrift by a peculiar artifice, are denominated zonmaratopithec, which fe. This river is joined from the east by a large river, called Gila, which, however, is everywhere fordable. The country between these rivers is said to be an upland desert, without water or pasture. On the other side of the Colorado, the country is said to be very fertile, and the natives rather fond of cultivation. It is thought that considerable rivers also join the Colorado from the west, flowing from the same chain of mountains that supply the sources of the Rio Bravo, in lat. 49°. Among these, the Zuniga, or New Mexico, is the most lengthened stream, and may therefore be regarded as the Colorado itself. On the west of the Colorado, the river of Mitytas, and that of Pyramids, have embaracling terminations, perhaps in the same lakes, or, perhaps in the Colorado. In lat. 39° W. long. from Madrid, 110° 31', there is a large lake without a name, which receives two considerable rivers from the east, one of which is called Lencara. From lat. 42° to 43°, and under the same meridian, extends another lake, which, though not fully explored, is said to be that of Impariciones, where the fathers Velas and Ictalinestimate their discoveries, and the amount island knowledge of the Spaniards. If, indeed, the Spaniards have explored that part of the country, they conceal their informant.

On the west of the same chain, from which springs the Río Bravo, are two rivers, which probably join the Balantun: and it appears that the eastern river of Colorado has been confounded with another river of the same name, with the epithet of Nichteus, which probably joins the Atlanza or Alahabas. See Colorado or River Ranco, fra.

Colorado, a river of New Mexico, which runs into the Bay of St. Bernard, in the gulf of Mexico.

Colorado, Riviere Rouge, or Red River, a river of North America, in Louisiana, which runs into the gulf of Mexico, or rather joins the Mississippi river, before it falls into this gulf, some miles above New Orleans.

COLORADOS, Los, a numerous cluster of small islands or rocks, near the N. W. coast of the island of Cuba.

COLORATURA, in the Italian Music, is used to denote all sorts of variations, trillos, diminutions, &c. that can render a song agreeable.

COLORBASANS. See Colorbassians.

COLOREDO, in Geography, a town belonging to the state of Venice, in the country of Friuli; seven miles N. W. of Udina.

COLORETTI, Matteo, in Biography, was born at Reggio, in the year 1611, and is spoken of by Tirabolchi and the abbe Lanzi, as a most excellent painter of portraits.

COLORIFIC earth, in Mineralogy, a rush or tube of earth, in the arrangement of Kirwan, described by him as strongly staining the fingers. Of these he enumerates four families, viz. red, yellow, black, and green; the red the redder, or rubricae Rubris. Rothol. L. o. 973. Of dark cochineal red colour, or intermediate between brick and blood red, having neither luster nor transparency; fracture, earthy, sometimes conchoidal; fragments, 1/2 hard, 4/5 gr. incon siderable; adhering pretty strongly to the tongue; feeling rough; assuring a polish from the nail; strongly staining the fingers; falling immediately into powder in water, and not becoming dextrileae; not effervescing, nor easily dissolving in acids. When heated to reduce, cracking and growing black; at 155° the specimen (Lefke, o. 975) melted into a dark greenish yellow frothy enamel. It differs from red ochres only by containing more argil. The red colour proceeds from oxygenation, and the absence of acid. The mere air of water is expelled by heat, the browzer it grows. The yellow, Gellebarde, Lefke, o. 1029, is of an ochre yellow colour; as to luster, externally it often hath some globs, but internally none; transparency, 0; fracture earthy, often inclining to the conchoidal; fragments, 0; hardness, 3/5 gr. incon siderable; adhering strongly to the tongue; feels smooth, or somewhat gritty; takes a high polish from the nail; strongly stains the fingers; in water it immediately falls to pieces with some hissing; and afterwards to powder, without diffusing itself through it; does not effervesc with acids, nor is easily soluble in them; heated to reduce, it cracks, hardens, and acquires a red colour, and given a red earthy ash. At 155°, Mr. Kirwan melted the specimen, Lefke, o. (1029) into a liver brown porous porcelain mass. This yellow earth differs from ochres only in containing a greater proportion of argil; the yellow colour proceeds from the calc of iron, highly oxygenated, and probably containing both water and sand. Those earths which contain a large proportion of iron, have rather an orange colour. According to the analysis of M. S腳 of Paris, who has the merit of referring to his countrymen the immense doses acquired by the Dutch on converting this yellow earth into what is there called "English red," it contains 50 per cent argil, 45 per cent of iron. 5° water, acidulated by vitriolic acid. Mem. Par. 177, 318. The 3d family, or black, black chalk. Schwaz--Krack, Z. en, Schiffer, Lefke, o. 972. Pierre noire du Brisson, p. 15 is of a greyish black colour; luster, 0; transparency, 0; fracture imperfectly curved flat; fragments, 1 partly fe. partly long foliary; hardness, 3; 10 gr. 2114. by Kirwan's trial by Brinson, 2185 before absorption of, 2.77 after absorption of water; adheres slightly to the tongue, feels smooth, affords a polish from a knife, gives a black streak, and marks black in wa-

COLORADO.
ter does not readily moulder, but if taken out cracks in a short time; does not effervesce with acids, nor easily dissolve in them; heated to redness, it cracks and becomes reddish grey; and contains somewhat vitriolic. The 4th family, green, Lefke, o. 013, is of a greyish green colour; found generally in lumps in the cavities of other rocks, or externally invading them; lube, o; transparency, o; fracture, earthy, sometimes uneven, sometimes verging to the conchoidal; fragments, 2; hardness, from 6 to 7; fp. gr. 20,017. Sometimes feels smooth, does not assume a polish from the knife, nor adhere to the tongue, nor stain the fingers, nor mark while dry, and when wet but lightly, in water it often crumbles after floating about half an hour; does not effervesce with acids, nor is easily soluble in water; heated to redness, it cracks and becomes of a dark red earthy colour; at 147°, the specimen (Lefke, o. 013) melted into a black compact glass, resembling that of basalt; which shows it to consist of felsic, argill, iron not much oxygened, and oxyz of nickel, from which the green colour is derived, besides water. Kirwan’s Elem. of Mineralogy, vol. i.

COLORINA, or Colarina, in Ancient Geography, a town of Arabia Felix. Ptolemy.

COLORATION, or Coloration, in Pharmacy, a term applied to the several changes of colour which bodies undergo in the various operations of nature, or art; as by fermentations, lotions, cocations, oxidations, &c.

COLORITES, in Ecclesiastical History, a congregation of Angullin monks, instituted about 1530, and so called from Colorita, a mountain near Marzento, in Calabria, where a church was erected to the Virgin Mary.

COLORNO, in Geography, a town of Italy, in the Parmesan; 7 miles N. of Parmo.

COLOR, a town of Transylvania; 4 miles N. of Colofte.

COLOR Salt Mine, in Hungary; the stratum of rock salt in this famous mine, is of the enormous thickness of 60 fathoms; the diameter of the excavation made therein by the miners, is 50 fathoms. “Born’s Hungary,” p. 140, 143.

COLOS, See Colos.

COLOSSAL COLUMN. See Column.

COLOSSI, in Ancient Geography, now Chonos, or Konos, a city of Phrygia Major, in that part called Paeanien, seated on an eminence, on the south side of the Meander. It was built by the river Lyces, near the place where, according to Herodotus (I. vii. 620), it begins to run under ground, as it does for five furlongs before it rises again, and flows into the Meander. This city was situated at an equal distance between Laodicea and Hierapolis; and to this place thebes came in his expedition against Greece. All thee three cities perished by an earthquake, says Eusebius, in the 10th year of Nero, or about two years after St. Paul’s epistle was sent to the Christians at Colosse. The government of this city was democratic, and its first magistrate bore the title of archon and prexer. This city, having been forcibly transferred to the Ptolemies by the Macedonians, paled afterwards to the Salamis. After the defeat of Antiochus III. at the battle of Magnesia, it became subject to Eumenes, king of Pergamos. And when Attalus, the last of his successors, bequeathed his dominions to the Romans, this city, with the whole of Phrygia, formed a part of the praefectural province of Asia, which division subsisted till the time of Constantine. After the reign of this prince, Phrygia was divided into Phrygia Paeanien, and Salutaris, and Colosse was the fifth city of the first division. It afterwards took the name of Chonos, or Konos.

COLOSSIANS, Epistle to the, in Biblical History, a canonical epistle, addressed to the Christians at Coloss by the apostle Paul, and conveyed to them by Tychicus and Onesimus, towards the close of St. Paul’s first imprisonment at Rome, which was about the year of our Lord 63, or the 9th of the emperor Nero. As Timothy joins with the apostle in the salutation at the beginning of this epistle, he was still at Rome, and not yet sent away to Philippi; and here Dr. Lardner concludes, that this epistle was written about the same time with that to the Philippians, in the year 62, and some time before the end of it. Although it appears from this epistle, that a Christian church was established at Colosse; we have no account by whom, or at what time, it was founded. Some have concluded from chap. ii. 1, that St. Paul had never been there himself. It is not, however, improbable, though no mention occurs of this fact in the history of the Acts, that the Colossians might have been converted while Paul resided at Ephesus, considering more especially that he spent no less than three years in that city, and preached with so much success, that St. Luke tells us, (Acts, xix. 20.) that “all they who dwelt in Afa heard the word of the Lord, both Jews and Greeks.” (See Acts, ch. vi. xvi. 23.) Dr. Lardner, arguing from the testimony of Theodoret (tom. iii. p. 342, 343.), who lived in the 5th century, alleges a variety of considerations, inducing him to think, that the churches of Colosse and Laodicea, had been planted by St. Paul, and that the Christians there were his converts. Of these he shall only mention the three following, viz.: that the apostle was twice in Phrygia, in which were Colosse, Laodicea, and Hierapolis (Acts, xvi. 6); that he does not, in effect, or even expressly say, that he had dispersed the gospel to the Colossians (Epist. ch. ii. 14—15); and that from several passages which occur in this epistle, it appears, that the apostle is not writing to strangers, but to acquainted, disciples, and converts.

The Christians of the church at Colosse seem, from the honourable testimony that is born to them in this epistle, to have maintained an honourable character for their party, and the zeal they discovered for the gospel; nevertheless, we find, from the cautious addressed to them in the second chapter, that they were in some danger of being drawn aside by the futilities of the Heathen philosophers, and the inducements of certain Jewish zealots, who insinuated upon the necessity of conforming to the ceremonies of the Mosaic law. Accordingly, the grand design of this epistle is to exalt the Colossians, by the most persuasive arguments, to a temper and behaviour worthy of their sacred character, and to secure them from the influence of those Pagan sophists, or Jewish bigots, who would seduce them from the purity of the Christian faith.

COLOSSUS, a statue of enormous or gigantic size. The most eminent of this kind was the colossus of Rhodes, one of the wonders of the world, a brzoan statue of Apollo, so high, that ships sailed with full sails below its legs. It was the workmanship of Chares, a disciple of Lydippus; who spent twelve years in making it: it was at length overthrown by an earthquake, B. C. 224, after having stood about sixty-six years. Its height was a hundred and five feet; there were few people who could encompass its thumb, which was said to have been a fathom in circumference, and its fingers were larger than most statues. It was hollow, and in its cavities were large stones employed by the artificer to counterbalance its weight, and render it steady on its pedestal.

On occasion of the damage which the city of Rhodes sustained by the above-mentioned earthquake, the inhabit-
ants sent ambassadors to all the princes and states of Greek origin, in order to solicit his assistance in repairing it; and they obtained large sums, particularly from the kings of Egypt, Macedon, Syria, Pontus, and Bithynia, which amounted to a sum five times exceeding the damages which they had suffered. But instead of setting up the colossus again, for which purpose the greatest part of it was given, they pretended that the oracle of Delphi had forbidden it, and converted the money to other uses. Accordingly the colossus lay neglected on the ground for the space of 834 years, at the expiration of which period, or about the year of our Lord 653, or 672, Mosæus, the 6th caliph, or emperor of the Saracens, made himself master of Rhodes, and afterwards sold their statue, reduced to fragments, to a Jewish merchant, who loaded 900 camels with the metal; so that, allowing 500 pounds weight for each load, the brass of the colossus, after the diminution which it had sustained by rust, and probably by theft, amounted to 720 thousand pounds weight.

Some critics observe, that the colossus of Rhodes gave its own name to the people among whom it stood; and that many, at least among the ancient poets, call the Rhodians Colossians: hence they advance an opinion, that the Colossus in scripture, to whom St. Paul directs his epistle, are, in reality, the inhabitants of Rhodes. Of this sentiment are Suidas, Caepine, Munzer, &c.

The basis that supported it was of a triangular figure: its extremities were furnished by sixty pillars of marble. There was a winding stair-case to go up to the top of it; from whence one might discern Syria, and the ships that went to Egypt, in a great looking-glass that was hung about the neck of the statue. This enormous statue was not the only one that attracted attention in the city of Rhodes. Pline (I. xxxiv. c. 37.) reckons 100 other colossi not so large, which rose majestically in its different quarters. Besides these, there were to be seen five others, the work of Briesis, and representing divinities. Among the antiquities of Rome, there were seven famous colossi: two of Jupiter, as many of Apollo, one of Nero, one of Domitian, and one of the Sun.

COLOSTRUM, or COLOSTRA, in Medicine, the first milk of any animal after bringing forth young, called in common bovdings. It is remarkable that this milk is generally cathartic, and purges off the meconium; thus serving both as an aliment and medicine.

The same name is likewise given to a diseased which this thick coagulated milk sometimes occasions.

An emulsion prepared with turpentine, dissolved with the yolk of an egg, is sometimes also called by that name.

COLOSVAR or CLAUSENBOURG, in Geography, the Zungua of the ancients, by the Hungarians called Kolosvaar, and in Latin Claudiepolis, a town of Transylvania, seated on the first branch of the river Samos, and surrounded by an ancient thick wall, where the states of the province usually assembled. The university was suppressed in the year 1782. The Unitarians, who formed one of the sects received in Transylvania, established their principal seat in this place: 255 miles E.S.E. from Vienna, and 45 N.N.E. from Belgrade. N. lat. 48° 37' E. long. 22° 21'.

COLOT, GERMAN, in Biography, a famous lithomith of the 15th century, practised surgery at Paris, during the reign of Lewis IX., from the year 1261 to 1283, and was in great favour with that prince. He was the first regular bred surgeon who practised lithotomy. The operation before his time had been engrossed by persons practising no other part of surgery. Regular practitioners had probably been deterred from interfering in the business, from reverence to the authority of Hippocrates, who obliged his disciples to swear they would not perform the operation. "Nec vero calculo laborantes fecabo," He ingratiated himself with some of the itinerant practitioners, law them perform the operation, and began with cutting dead bodies. Having communicated his ideas to the physicians of the court, they obtained leave from Lewis, that he might operate on a condemned criminal, who was attacked with the stone in the bladder. The criminal confuted, on the condition promised, that he should be pardoned the crime he had committed. The operation was successfully performed, the patient recovering, it is said, in fifteen days. Colot obtained great reputation by the cure, which was rewarded by a pension from his sovereign. The time of his death is not known.

COLOT, LAURENCE, a defendant of Germain, from whom he acquired the art of cutting for the stone, was in great reputation, in the early part, and to the middle of the 16th century, for his skill in performing the operation, by what is called the greater apparatus. By this method the urethra and neck of the bladder are necessarily cut through, which subjected the patients, not unfrequently, to fistula, and other inconveniences, yet by his dexterity in operating these accidents were often avoided, which gave him so much credit, that he was sent for to visit patients in Flanders, and other distant countries. To retain him in France, Henry II. made him his surgeon in ordinary in the year 1550, rewarding him with a pension, adequate to the loss he sustained, by being prevented visiting patients in foreign countries. He also crested for him the poll of lithomith to the royal family, which was continued to three of his descendants. Philip, the last of them, died in 1616, aged sixty-three years.

COLOR, FRANCIS, son of Philip, appears to have inherited, with the name, the skill and dexterity of his ancestors, in performing the operation of lithotomy. He left a treatise on the operation, which was published in 1727, under the title of "Traité de l'opération de la taille, avec des observations sur la Formation de la Pierre, et les Suppressions d'Urines," 12mo. Paris. In this work he gives a short history of the method of operating by the greater apparatus. It was invented, he says, by John de Romanis, a physician of Cremona, Italy, in 1525, and by him communicated to Marianus Sanetius, who instructed Octavian de Via, a surgeon at Rome. Marianus published, in 1535, "Libellus Aureus, de lapide et Vesica per incisionem extra hendo," Svo. Venet. Of Octavian de Ville, who was several times called to France, to perform the operation, Laurence Colot is supposed to have obtained some valuable information on the subject, which contributed much to the celebrity he afterwards enjoyed. The method of operating by the greater apparatus has been long since abandoned for a more simple and easy operation, therefore called, by the latter apparatus, first discovered, Mr. Sharp says, by Mr. Foubert, an ingenious French surgeon, but much improved by Mr. Chefield, in which the urethra and neck of the bladder are avoided by the operator; with Francis Colot, the celebrity of the family, seems to have been extinguished.

Eloy Dict. Hill.

COLOUR, or COLOR, from the Latin, color, in Philosophy, means that property of bodies which affects the sight only; thus the grass in the fields has a green colour, blood has a red colour, the sky generally appears of a blue colour, and fo forth; nor can those colours be distinguished by any of our other senses, besides the sight. The variety of colours, as they are presented to us by the substances that
surround us, is immense, and from them arises the admirable beauty of the works of nature in the animal, in the vegetable, and in the mineral kingdom, or, more properly speaking, in the universe. The science, which examines and explains the various properties of the colours of light and of natural bodies, and which forms a principal branch of optics, has been properly denominated _chromatics_, from the Greek word, _χρώμα_, which signifies _colour_. We shall, however, rate this theory in the present article, as being much more obviously recurred to by those persons who wish to be informed on the subject. A distinct idea of what is meant by the word _light_, may be easily formed by its contrast with _darkness_, which is a privation of light. With our eyes shut, we have _darkness_; if we open our eyes, whatever we perceive through them is occasioned by the agency of light, and the various colours of bodies are parts of that light.—It has sometimes been pretended by certain ignorant persons, that they could distinguish colours by the touch; but the testimony of divers intelligent persons, who have had the misfortune of being blind, in consequence of which their touch has, from necessity, become very exquisite, has constantly contradicted those vain affections. Besides, it will appear from the following theory of colours, that to differentiate colours by the touch is utterly impracticable. There are indeed certain pigments of common use in painting, which, either from their roughness, smoothness, unctuosity, or other quality, may affect the touch, and with a little practice a person may learn to distinguish the feel of vermilion which looks red from that of lamp-green, which looks green, and so forth; but this is not the art of distinguishing colours by the touch. It is only the art of distinguishing certain peculiarities of surface. In fact, if two pigments exactly of the same texture (and several such there are) but of different colour, be presented to the fingers of a man with his eyes shut, he will pronounce them to be exactly of the same colour. The questions which naturally occur to the human mind in the contemplation of colours, are, whence do they derive their origin?—Are they produced by the coloured bodies themselves, or by something external?—Do they move from the coloured bodies to our eyes, and strike upon them, or enter them; or are they owing to some medium interposed between the various bodies of the universe?—Are they material or not?

The ideas entertained by the ancients concerning the nature of colours, were mostly wild and absurd; nor has the present theory, imperfect as it is, been formed without an innumerable variety of experiments, observations, and the convicing investigations of a great many ingenious persons. The followers of Pythagoras called colour the superficies of bodies; Plato considered it as a flame issuing from them; Zeno called it the first configuration of matter; and Aristotle said it was that which rendered bodies actually transparent. We need not add a formal refutation of those extravagant ideas, which were the mere off-spring of the imagination, unsupported by experience and by reason. The philosophers of those times paid little or no regard to experiments; hence they made no discoveries or improvements worthy of being recorded. A long and unprofitable period of nearly 2000 years elapsed, from the commencement of philosophical study in Greece, until about the time of Descartes, when the revival of learning in Europe renewed with additional vigour the enquiries concerning the nature of light and colours. And it is curious to observe by what small steps, and what circuitous ways, any useful discoveries were made. See Priestley's history of vision, light, and colours. Descartes considered colour as a modification of light, and he attributed the difference of colour to the prevalence of the direct or rotary direction of light. Grimaldi, Dechales, and others, supposed that a certain elastic medium of a peculiar kind filled the universe, and that the differences of colour depended upon the quick or slow vibrations of this medium. Rohault imagined that the different colours were produced by the rays of light entering the eye at different angles with respect to the optic axis. And Dr. Hook imagined that colour is caused by the vibration of the oblique or uneven pulse of light; which being capable of no more than two varieties, he concluded there could be no more than two primary colours. Such were the ideas of philosophers respecting the nature of colours, when Sir Isaac Newton began to examine the subject in his cautious experimental manner, by which means, about the year 1666, he discovered the foundation of a theory of colours, which has been fully adopted and admired by his contemporaries, as well as by the present succeeding generation. Rays of light issuing from a luminous object, proceed in straight lines as long as they pass through a uniform medium. If they meet with a transparent medium of different density, they will also proceed through it in straight lines, provided they enter that medium in a direction perpendicular to its surface, otherwise they are caused to bend their course, so that beyond the aforesaid mentioned surface they proceed in straight lines also; but these straight lines form a certain angle with the straight lines of their direction before they entered the last medium. The bending of the rays is called the _refraction_ of light, and the angle that has been just mentioned is called the angle of refraction. See _Refraction_. Newton, having presented a glass prism, or kind of wedge, to the light of the sun, which ented a dark room through a small hole, found not only that the rays were bent from their course, viz. refracted, but he likewise observed that the image of the sun was thereby considerably elongated; and this elongation of appearing of a uniform bright white light, was resolved into a series of colours, which exactly resembled the colours of the rainbow. This elongation of the solar image thus formed, is called the dispersion of light. These colours pass from one to the other by very small, and altogether imperceptible gradations; so that it is impossible to say where one begins and the next ends. Various methods have been tried for the purpose of rendering the colours of this prismatic spectrum more limited and distinct; none, however, has been attended with complete effect. The following seems to be the best method. Let the light of the sun pass through a hole of about one-tenth of an inch in diameter, into a dark room. Place a screen at a little distance from the hole (for instance six or seven inches) within the room; and let the middlemost part of the light pass through a similar hole in the screen; the object of which is to prevent, in great measure, the scattered light or penumbra, on the sides of the spectrum. Let the light then fall perpendicularly upon a convex lens; at the distance of about 10 feet, by which means a defined image of the sun will be formed upon a screen placed at the focal distance of the lens. Now, if a prism be placed close to the lens, so that the light, after having passed through the lens, may pass through, and be refracted by, the prism; then a coloured spectrum will be formed upon the screen. The long sides of this spectrum are very well defined; but its narrow terminations are semicircular, and its whole length consists of circular coloured images of the sun intermixed with each other, especially about the middle or axis of the spectrum; yet the most prominent colours are more distinguishable from each other, especially towards the sides of the spectrum, so that their boundaries may be marked with tolerable accuracy. The glass prism fit for this experiment must be well formed,
and free from veins, scratches, bubbles, &c. Those principal colours are seven in number, viz. red, orange, yellow, green, blue, indigo, and violet. They do not occupy equal spaces in the spectrum; but for the proportion of their breadths, and likewise for a more accurate description of the prismatic experiments on light, see the article REFRACTION.

The above described experiment with the glass prism gave Mr. Isaac Newton reason to conclude that the white light of the sun consisted of seven colours, which had different powers of being refracted, so that the red rays were refracted least, the orange a little more, the yellow still more, and so on; hence the image of the sun was converted into an oblong variegated spectrum. In confirmation of this theory Newton instituted a variety of other experiments, which were attended with remarkable results, and the principal of them are as follows:

If the light which has been refracted and dispersed by a prism, be received again upon another prism which must be situated in a direction perpendicular to that of the former: the spectrum will by that means be removed from its original situation into a lateral one; but its breadth and its colours will remain unaltered. Now if the elongation of the beam of white solar light, and its resolution into different colours, were a modification of light produced by the prism only; then the second prism ought to expand the spectrum in breadth, so as to form a quadrilateral figure of equal sides; but instead of that we find that the colours and their breadth remain unaltered.

If the refracted and dispersed beam of solar light, be received upon a concave reflector, the different coloured rays will be reflected to a focus, where they will form a white or colourless image of the sun. But if any of the colours be stopped by the interposition of a wire, or other slender and opaque body between the prism and the reflector, then the image will become coloured with some mixture of colours. This proves that white light consists of coloured rays, intermixed in a certain proportion, and that by a mixture of the rays of the seven primary colours in that due proportion, white light is produced. Therefore, white arises from a certain mixture of colours, and blackness arises from a stoppage or absorption of all colours. This property of light and colours, may be familiarly illustrated by the following experiment: Divide the flat surface of a wheel, or the upper flat surface of a top, such as boys use, by means of links going from the centre to the circumference, into seven parts, having the same proportion that the breadths of the colours have in the prismatic spectrum, and let those portions be painted respectively with the seven colours. This done, if you spin the wheel or the top, so as to cause it to turn very fast, in the light of the sun; you will find that the painted surface will look white; for by the quick motion of the wheel, the impression of the colours in the eye become mixed, and of course they form a white light. Stop the wheel and the seven colours will appear very distinct.

If, when a spectrum is formed by the light which has passed through a prism upon a screen, a small hole be made through the screen, and the rays of one colour only be permitted to pass through it on the other side of the screen; then whatever is viewed in that homogeneous light, will appear of that particular colour. Thus, if the red light only has passed through the hole, then blood, or grass, or milk, &c. viewed in that light behind the screen, will all appear red; excepting that the blood will appear of a brownish red colour, or the grass or the milk. If the blue light only has been transmitted through the hole; then the above-mentioned substances will all appear blue; and the like may be understood of the other homogeneous colours. This proves that the colours, which seem to proceed from coloured bodies in general, do not belong to those bodies, but are the component parts of the white light, in which those bodies are viewed, and that certain bodies have the property of absorbing some of those coloured rays of the white light which falls upon them, and of reflecting others. Thus, grass reflects the green rays and absorbs the red, hence, the green rays coming to our eyes, render the appearance of grass green; thus blue absorbs every other coloured ray excepting the red, and so forth. Black bodies absorb all the seven coloured rays, and white bodies reflect them all.

If two holes, at about a foot distance from each other, be made in the shutters of a dark room, and two prisms be used, viz. a prism be placed to receive the light at each hole, two spectrums will thereby be formed upon the screen; and by turning the prisms gently round their axes, the spectrums may be caused to fall one upon the other. Let the yellow of one spectrum fall upon the blue of the other, and at that place the mixture of those two colours will appear green. Let a small hole be made exactly at that place, and that green light will pass through the hole behind the screen, and will form a green circular image upon another screen placed to receive it. Now, if exactly behind the perforation of the first screen, you fix the refracting angle of a prism, then the image upon the second screen will not only be moved from its place, but will appear oblong, with a yellow border at one extremity, and a blue border at the other extremity; for that spot or image of the sun consists of two primitive colours of different refrangibilities. The same thing must be understood of any other colour formed from a mixture of any two primitive prismatic tines; for any two of those colours will form, or rather will look like an intermediate colour; thus, red and yellow form an orange, blue and violet form an indigo, and so forth.

If the experiment be performed with one solar spectrum: viz. a single prismatic colour; for instance the green be permitted to pass through a hole in the screen, and be then received upon another screen, the image will be of the same colour as in the preceding experiment, viz. green, and circular. Now, by placing a prism behind the perforation of the first screen, the green image will be moved from its place, but it will not be elongated nor altered in colour, because this image consists of one uniform primitive colour. (Newton’s Opt. b. i. p. ii. prop. iv.) This remarkable experiment shows, that though a green may be formed from a combination, or any other prismatic colour may be formed from a combination of the two adjacent colours; yet each of these colours in the prismatic spectrum, is a primitive uniform or homogeneous colour.

Notwithstanding the conviction which naturally attends the result of the above mentioned experiments, several persons have supposed that the primitive colours of light are not seven, but three only; namely, red, yellow, and blue; and they have been led to this supposition, by observing that the painters can produce all the other colours, by mixing either all those three colours together, or two of them, in due proportion.

A recent writer of eminence in the philosophical world, (M. C. A. Priestly) has started another theory. He thinks that the primitive colours. (viz. the components of white light) are three in number; but he supposes them to be the red, the green, and the violet; and that the other colours of the spectrum are formed from a mixture of three; that is the yellow from the red and the green, the blue from...
from the green and the violet, &c. See l'Annales de
Clinic, Sept. 1826.

Hitherto we have treated of the formation of colours by
refraction; from which it appears that the white solar light
consists of coloured rays; but whenever that light enters a
transparent medium in an oblique direction, it is caused to
deviate from its rectilinear course; and at the same time its
component coloured rays, are separated in consequence of
their different refrangibility. The next series of facts, upon
which the theory of colours depends, relates to the infusion
of light, it having been found, that the rays of light are
bent in their course, and resolved into their component
colours, not only by refraction, but likewise by merely
palpable by the surfaces of bodies. It seems that the rays of
light are attracted by bodies, when they come within a cer-
tain distance of their surfaces, and that the coloured rays of
white light being attracted more or less, are separated from
each other. A great variety of experiments relating to this
infection of light, were originally made by Newton, and
have, since his time, been instituted by other able philoso-
phers. But, though several remarkable facts have been
discovered; yet the prevalent state of knowledge does not
admit of their being reducible to a single principle, or to
any general and comprehensive laws.

In order to give our readers some idea of this property
of light, we shall now fulfil an experiment related by a
recent anonymous writer; referring then, to the reader to the
article Inflection of Light, for a full account of whatever
belongs to it.

"Across a beam," says the above-mentioned author, "of
folar light, admitted into a dark chamber, through a small
hole in a thin piece of lead, nearly \( \frac{1}{5} \) of an inch wide, I
interposed a hair of a man's head, and receiving the beam
on a screen, or sheet of white paper at a distance, and with
an obliquity convenient for the purpose, I noted the follow-
ing appearances.—At the termination of what may be con-
considered as, and therefore may be called, a shadow, whose
intensity or darkness was not considerable; the following
orders and distincions of colours appeared. First, and
nearest to the dark or black parts of the shadow, might be
seen a dilute blue, changing into a breadth of white light,
followed by breadths of yellow and red. To these succeed-
ed an interval of dilute thade, then breadths of dilute
violet, blue, dilute green, yellow, red; then green dilute
yellow, red; dilute green, red; white, dilute red; and
finally white light. These are the more general orders of
the colours. Of these orders, the three first were suf-
sufficiently obvious and distinct; the last evanescent and requiring
accommodation of circumstances to produce, and attention to
perceive them." Observations concerning the Inflection
of Light, &c. London 1799.

The last of facts that remains to be mentioned, as relat-
ing to colours, consists of the phenomena exhibited by
thin transparent bodies, especially by those of variable
thickness. Every person must recollect to have seen the
bubbles of a solution of soap, or of other thickening sub-
stances, exhibit a variety of colours similar to those of the
folar spectrum, or of the rainbow. These bubbles are no-
thing more than thin veils of the solution, whose thick-
ness varies continually. But a variety of thin solid sub-
stances exhibit the like phenomenon, such as plates of muf-
covy glass, or of tale; thin plates of glass; metallic and
glass plates moistened with a variety of fluids, &c. Newton
took two object glasses of telescopes, one of which was a
plane convex, and the other a double convex one. He laid
the latter on the flat side of the other, and prefixed them
gently. Instantly circles of colours appeared about the
point of contact, which increased and decreased both in
number and in size, according as the lenses were more or less
forcibly pressed against each other. The central spot was
black, and circles of colours appeared round this spot, which
were brighter near it than farther off. Their order, com-
mencing from the black spot, was blue, white, yellow, red;
violet, blue, green, yellow, red; purple, blue, green, yellow,
red; green, red; greenish, blue, red; greenish, blue, pale
red; greenish, blue, reddish, white. (Newton's Optics, b. ii.
p. 1. Ob. sc. iv.) Experiments similar to the above have
also been performed with flat glasses, leaves of various cur-
vatures, and other substances, by other philosophers, such as
Moraldi, Grimaldi, Delisle, Mairan, Mazzoni, Du Tour,
seet. 6. After the above succint account of the principal
experiments that have been instituted, and the various im-
portant discoveries that have been made, concerning
the nature of light and colours; it is proper to observe, that
the subject is not only very far from being exhausted; but
that the theory arising from those experiments and discoveries
is doubtful in almost all its parts. The number of primitive
colours distinct from one another, if such do really exist,
is not quite determinate; the attraction between the rays
of light and other bodies is an hypothesis not clearly un-
derstood; for it is a prevailing opinion with several philo-
osophers, that the rays of light are attracted within a cer-
tain distance, and repelled beyond that distance. The re-
flection of coloured rays from the surfaces of bodies is likewise in-
volved in much uncertainty; it being unknown whether the
reflection takes place at the very surface, or at a little
distance beyond it by force power inherent in bodies, or,
lastly, from some other surface a little within the bodies,
by which supposition is founded upon the hypothesis that all
bodies are transparent, as far as a very small part of their
bulk, which hypothesis is founded upon the observation
that several dense and opaque bodies, when much atten-
nuated, become, in some measure, transparent; and that in
the case with gold leaf, when placed against the
light, appears of a greenish cast.

Notwithstanding this uncertainty respecting the theory in
general, the following particulars seem to be sufficiently
established; namely, that by refraction and infection the
white light of the sun is resolved into coloured light.
Here it may be naturally asked whether the light of other
luminous objects is not resolved, by the like means, into
the fame colours? The observations made in relation to
this particular are not so numerous, nor so exact as might
be wished; it appears, however, that some luminous ob-
jects yield rays of particular colours more abundantly than
of other colours. The abbé Rochon having placed a
prisma before an achromatic telescope, observed through it
the light of the stars; and found that the white light of
Sirius was resolved into an oblong spectrum, which con-
stituted almost entirely of three colours, viz. red, green, and
violet. An indication of yellow was barely discernible
between the two first, and a slight degradation between the
two last. Through Dr. Herchells' powerful telescopes
most of the fixed stars seem tinged with peculiar colours,
viz. some evidently incline to a green, others to a red, and
so forth. The light yielded by particular combinateles is
also tinged with peculiar colours, and the furnace of wine is
a strong instance of this nature; for it common
fact be mixed with the spirit, the light of its flame seems to
be entirely deluxite of red, yellow, and violet, and it is
owing to this peculiarity that children frequently play with
it in order to give a ghastly appearance to the surrounding

P 2 com-
company. When baryc (ponderous earth) is mixed with spirit of wine, its flame is yellow; boracic acid renders it green, and drontian earth gives it a purple colour.

The phenomena of coloured bodies, as they occur to us, in general, may be distinguished into five classes, viz. 1. The colours that arise from evident refraction, such as the colours of the rainbow, of the bubbles of a solution of soap, &c. 2. Tholse of opaque bodies that are fixed. 3. Tholse of opaque bodies that are not fixed. 4. Tholse of transparent bodies formed by the light falling through them. 5. Tholse that are changeable, according to the situation of the eye, like the colours of certain fluids, feathers, flowers, thin lamiae. &c. and the light falling through them.

With respect to this, it must be observed, that a transparent body, like a plate of glass, a drop of water, or the reflection of its surfaces at the same time that it lets part of the light pass quite through its substance. Direct your eyes to the surface of a common glass plate, and see the reflection of an object, as in a looking glass, and if you observe attentively you will perceive two reflected images close to each other, viz. one from the anterior, and the other from the posterior surface. In moist looking glasses, if you place a lighted candle on one side, and view the reflected image of it from the other side, you will generally see a succession of images of the candle fainter and fainter, in proportion as they recede from the principal image. The reason of this appearance is, that since both surfaces reflect, the image formed by the reflection of the posterior surface is partly transmitted to the eye of the spectator, and partly reflected from the anterior surface to the posterior one, the latter of which is again reflected, and so on. Now, in the case of the drops of rain, when they form the rainbow, the light of the sun falling obliquely on the surface of the drop is refracted and resolved into colours, in which state it proceeds through the drop to its farther surface, from which it is partly reflected to the eyes of the spectator. The same explanation is evidently applicable to the colours of the bubbles of soap, thin transparent lamiae, and the like. See RAINBOW.

2. The fixed colours of opaque bodies are in all probability owing to their absorbing some of the coloured parts of white light and reflecting others; their immense variety arising from a mixture of the reflected primitive colours in various number and proportion; but it is impossible to say at present whether that reflection is effected at the very surface, or at some distance from it, either within or without the body; also to what cause the disposition of reflecting certain colours in preference to others may depend upon. Mr. Delaval's experiments seem to indicate that the colour of opaque bodies arises from the light that has passed through a thin layer of transparent coloured particles, and is then reflected by the smooth surface immediately under them.

3. The greatest number of accurate experiments, concerning the colours of transparent bodies, was made by Edward H. Delaval, esq. F.R.S. (See his Paper in the Memoirs of the Lit. and Philos. Society of Manchester, vol. ii.) His experiments were performed with an immense variety of liquids differently tinged by metallic solutions, decocations, and infusions of flowers, rubins, gums, woods, mineral and animal matters. Tholse liquids he placed in phials of flat glass, of a parallelepiped form, with an oblong cylindrical neck. “I covered,” he says, “the bottom, and three of the sides of each of these phials, with a black varnish; the cylindrical neck and the anterior side, except at its edges, were left uncovered.”

In order to examine what colour those liquids would exhibit, either by transmitted or by reflected light, he viewed them through the neck of the phial, or looked into the phial through the side which had been left uncovered by the varnish. But with respect to this latter case, he says, “the uncovered side of the phial should not be placed opposite to the window, through which the light is admitted; because in that situation the light would be reflected from the farther side of the phial, and would be transmitted through the coloured liquid; and it is observable that smooth black surfaces reflect light very powerfully. Now, as it is a principal object in the experiment that no light be transmitted through the liquids, this will be accomplished by placing the uncovered side of the phial in such a direction that it may form a right angle with the window.”

All the coloured liquids, which Mr. Delaval tried in the above-mentioned manner, appeared tinged with their peculiar colours, when viewed through the necks of the phials; but when he looked on that part of the liquid which filled the body of the phial, he perceived no colour whatever, the whole appearing black; which proves an important fact, namely, that transparent coloured liquids do not yield any colour by reflection, but by transfixion only. “If these liquids,” he observes, “are spread thin on any white ground, they appear of the same colours which they had exhibited when viewed in the necks of the phials; as the light reflected from the white ground is, in this case, transmitted through the coloured medium. But when they are spread upon a black ground they afford no colour. The black ground, however, should not be a polished body; as the light reflected thereby would be transmitted through the thin medium on its surface, and be tinged by passing through it.”

Next to the above, Mr. Delaval relates various other experiments which he made with transparent solids, vis. with coloured glasses, which he made on purposes, by tinging the substance of the glasses with metallic and other matters, in imitation of real gems. These coloured glasses exhibited phenomena similar to the coloured fluids. “Having,” this author says, “formed pieces of such glasses, about two inches thick, I included all their sides with black cloth, except at their farther and anterior surface. Each of these pieces of glasses vividly exhibited its colour, when viewed by transmitted light; but when the transmitted light was intercepted, by covering the farther surface, the anterior surface afforded no colour, but appeared black. When plates of transparent coloured glasses, somewhat thicker than window glasses, are viewed by transmitted light, it is well known that they exhibit their several colours. I intercepted the light, which was transmitted through coloured plates, by fixing a piece of black cloth contiguous to their farther surface. The plate, thus prepared, when placed in such a direction that they form a right angle with the window, appear perfectly black; which shows that the coloured particles do not reflect any light.”
It is hardly necessary to observe that wherever light is transmitted through any coloured transparent body, a greater part of it is left, than when that body is quite colourless; for by transmitting one sort of coloured rays more copiously, it flours a great part of the oppositely coloured rays.

Besides these transparent coloured bodies which have been just noticed, there is a vast gradation of others between them and those that are perfectly opaque. Thefe, which are called femaillicular, or femtransparent, exhibit a vast variety of phenomena arising from the various proportion of the opaque and the transparent particles which enter in their composition. Thus some appear of the same colour, whether viewed by transmitted, or by reflected light, others exhibit one colour by transmitted and another by reflected light; others again appear of various colours, according to their thiefefts, &c. See Newton's Opt. l. i. p. ii. prop. 2.

4. The falt paragraph may, in fome measure, tend to illustrate the nature of thofe coloured ficks, feathers, &c. which change their colour according to the angle in which they are viewed, and in which the light falls upon them; other circumstances, however, are concerned in the phenomena of thofe bodies. Thus the furfaces of some of them are very irregular, in consequence of which they reflect with fome of their particles, whilst they absorb moft of the light with other particles; hence, when by a lateral view, the former or the latter are placed out of the direétion of the eye, the colour of the whole appears different from what it does in another point of view. Certain bodies of this fort may likewise be transparent to a certain small depth, in which case they become visible partly by reflected and partly by refracted (confequently decompofed white) light; hence the eye of the fpectator muft, according to its situation, fee fome coloured rays in preference to others. The phenomenon of thofe changeable bodies, meaning with refeft to colour according to situation, are far from being clearly understood; it is moft probable, however, that in them all, the three principal properties of light are concerned, namely, its reflection, refraction, and inflection.

5. In the practice of various arts, wherein colours are concerned, fuch as in dyeing, enamelling, painting in oil or water colours, &c. a change in colour of moft of the materials is commonly observed, which is evidently produced by the action of the air, the fire, the oil, or other agent to which the colouring materials are exposed, and by which they undergo different degrees of chemical alteration in their nature. This obfervation, and a defire of investigating the nature of thofe changes, with a view of improving the practical arts dependant upon them, induced ferveral perfons to try a variety of experiments, and Mr. Delaval, the fame above-menioned gentleman, who invesigated other branches of the prefent {ubject, became one of the greatest labourers in this field of inquiry. Were we acquainted with the nature of thofe particles in bodies which refeft or refraft the coloured rays, and had we a fufficient knowledge of the alterations produced in thofe particles by the action of different agents or reagents, be they oils, acids, air, alkalies, &c. a fuch idea might perhaps be formed of the changes in colour, which muft arise from certain combinations; but as the prefent state of knowledge does not admit the formation of fuch a theory, the whole must reft upon conjecture, and the practical part muft depend upon the reft of particular experiments.

Sir Isaac Newton thought, that bodies refeft and refraft light, by the fame power in different circumstances. Also, that the forces of bodies to refeft and refraft light, are very nearly proportional to the denfities of the fame bodies, excepting that unctuous and fulphureous bodies refraze more than others of the fame denfity. In support of this affection he relates feveral experiments, the refult of which he expreffes in a table, wherein the proportion of the fines which meafeure the refractions of the feveral bodies, the denfities of the bodies estimated by their specific grauity; and their refractive powers in reft of their denfities are flated in feparate columns. Mr. Delaval conceived that the defer fluidities ought, by their greater refractive powers, in like circumftances, to refecf the left refrangible rays; and that fluidities of left denfity, fhould refect rays proportionably more refrangible, and thereby appear of feveral colours in the order of their denfity. Agreeable to this fuppofition he gives infiftances of natural bodies, which differ from each other in denfity, though circumftanced alike in other refpects, excepting in their colour, which colour follows the order of their denfity; the denfity being red, the next in denfity orange, the next to that yellow, then green, &c. In support of this hypothesis Mr. Delaval made feveral experiments with glafs tinged by metallic particles, in which the colour of the glafs, in a great meafeure, corresponded to the denfity, or to the specific grauity, of the metal concerned. But this feries of experiments is not extended to that degree, nor is it conducted with that caution, which a confirmation of the hypothesis demanded. Mr. Delaval alfo intituted similar experiments with coloured liquors, in which he endeavoured to fhew, that by an incification or an attenuation of their particles, their colours may be changed in one order or in the revere. His mode of attenuating thofe liquors was accompanied, as he fuppofed, by the addition of acids, and that of incification, by the addition of alkalies. But however fecutive this hypothesis may at firft finge appear, a strict examination of facts will easily fhew the fallacy of it in almost all its parts, and feveral writers have pointed out fome of its defects, but none better than Dr. Bancroft, F.R.S. in his "Experimental Researches, concerning the Philosophy of permanent Colours," vol. i. chap. i. In this excellent work, Dr. B. fhews that Mr. Delaval has not noticed the change of nature, as well as of specific grauity, which the metals undergo by their being exposed to different degrees of heat, together with the glafs. He also observes, that if, according to Mr. Delaval's hypothesis, the deferft bodies are of a red colour, or approximating to it, platinum, the heaviest of all known metals, ought to be red; whereas it is white, like tin, and the lighteft metals. Also gold, the heaviest metal next to platinum, is much farther removed from the red colour than copper, which is much lighter. With refpect to Mr. Delaval's experiments on coloured liquors, Dr. Bancroft fays, "instead of choofing and employing mechanical means, which alone are fifted to produce thofe effects, and only thofe effects, he has recourse to mere chemical agents, whose actions in the way which he fuppofes must have been almost doubtlefs, though their powers of producing other, and very different effeets from what he fuppofes, is more certain. Mr. Delaval, however, adopting for Isaac Newton's fuppofition, that acids always attend, and alkalies always incificate, prepared what he confidered as a diluving or attenuating liquor; which consisted of water with about $\frac{1}{4}$ part of aquafortis: and when he wanted to lessen the diluving force of this liquor, instead of weakening it by the addition of water (which would certainly have been the most obvious and unexceptionable expedition), he chose to do it, as he fays, by adding a fmall quantity of a solution of potas-
COLOUR.

...it, or some other alkaline liquor, and thereby produced a new composition, the effects of which, in many cases, prove different from those of a mere diminution of the supposed diffusing power of the former liquor. And on the other hand, when he wanted to increase the force of his acid liquor, instead of doing it by a farther addition of aquafortis (obviously the most proper expedient), he recurred to an addition of oil of vitriol, an acid possessing very different properties, and producing very different effects, on a great variety of substances, and particularly on colouring matters; of which we could easily allege hundreds of instances, but shall content ourselves with only mentioning what is well known, that even the strongest and most concentrated oil of vitriol (used to diflodge indigo for dyeing the Saxan blue, &c.) does not destroy, or even weaken, its blue colour, though a very weak nitrous acid, or aquafortis, will wholly destroy it, and convert the indigo to a dirty brown mass, of no use whatever."

For further observations of Dr. Bancroft on Mr. Delaval's Theory of Colours, we refer our readers to his abovementioned work.

But with respect to the practical part of the subject, viz. the art of colouring gluts, porcelain, &c. or the methods of forming pigments, they are requested to consult the articles, Painting, Enamelling, Dyeing, Staining, Crayons, and Pigments.

COLOUR of the clouds, is thus accounted for by Sir Isaac Newton. Concluding from a series of experiments, that the transparent parts of bodies, according to their several sizes, reflect rays of one colour, and transmit those of another; he hence observes, that when vapours are first raised, they are divided into parts, too small to cause any reflection at their surfaces, and therefore do not hinder the transparency of the air: but when they become so copious, in order to form drops of rain, and constitute globules of all intermediate sizes, these globules are capable of reflecting some colours, and transmitting others, and thus form clouds of various colours, according to their sizes. Mr. Melville controverts this doctrine, in its application to the red colour of the morning and evening clouds. "Why," he says, "should the particles of the clouds become at that particular time, and never at any other, of such a magnitude as to separate the red colour?" And why are they rarely, if ever, seen tinged with blue or green, as well as red, orange, or yellow? Is it not more credible, that the separation of rays is made in passing through the horizontal atmosphere, and that the clouds only reflect and transmit the sun's light, as any half-transparent coals would do? For since the atmosphere reflects a greater quantity of blue and violet rays than of the red, the sun's light transmitted through it ought to incline towards yellow, orange, or red; especially when it passeth through a long tract of air: and thus it is found, that the sun's horizontal light is tinged with a deep orange, and even red; and the colour becomes still deeper after sunset." Hence he concludes, that the clouds, according to their different altitudes, may assume all the variety of colours at sunset and setting, by passing reflecting the sun's incident light as they receive it. COLOUR, and Colour Making, in Calico-Printing. The preparation of colours for calico-printing, constitutes one great branch of that beautiful art, and involves in it a series of interesting and important processes. As an art, its operations are not dependent on any other, on those minute differences and changes in the constitution of bodies, which it is the business of chemistry to investigate. Hence that liability to error and uncertainty which, in the hands of the ignorant, pervades many of its processes, though conducted according to long established and approved formulœ.

Our present volume would scarce suffice for the various receipts in which the art abounds; yet, in the following article, we shall endeavour to lay down general principles, rather than more practical directions; convinced, that by presenting our readers with a clear and concise theory, deduced from such practical illustrations, as may be necessary for this purpose, we shall render them a more acceptable service.

The term colour, as used in calico printing, is applied not only to those vegetable, animal, and mineral solutions, which impart their own colour to the cloth on which they are applied, but also improperly to those earthy or metallic solutions, which, poising little or no tincturing properties themselves, yet retain or fix the colours of other substances, when afterwards applied to the cloth. Thus the acetic of alum, or printers' red liquor, when pure, is almost colourless, and only becomes red by the process of dyeing, as will be explained hereafter. The acetic of iron, or iron liquor, in like manner, when used of a determinate strength, is called black colour, and when weaker purple colour, though the cloth impregnated with these solutions becomes black or purple, only as being raised, like the other, in the dye-copper.

1. The colours produced by means of these earthy or metallic solutions (which, in the language of science, are called mordants), form the most valuable and important series, whether considered with regard to the almost infinite variety of shades, or to their solidity and durability. These colours, from the mode in which they are produced, (the mordant being first applied to the cloth, and the colour afterwards raised by dyeing), are called dyed colours.

2. Sometimes the mordant is previously mixed with a solution of colouring matter, and in that state applied to the cloth, so as to paint or stain it, at one operation, and without the process of dyeing. Thus, another class of colours is produced, many of them poising great brilliancy indeed, but much inferior to the former in durability. The colours called chemical, by calico printers, belong chiefly to this class.

3. In the third and last class, we may place all those wherein the colouring matter is simply held in solution by an acid or alkali, and in this state applied to the cloth, without the intervention of any mordant. To one or other of the foregoing classes, may be referred all the colours used in calico printing; with the exception, however, of those solutions of colours which have been produced by calico printers in this country, within a short period, by processes, and upon principles which have hitherto not been made known.

Class I.

The colours of this, as has been already observed, are produced, by first impregnating the cloth with an earthy or metallic solution, or mordant, and raising the colour afterwards by dyeing. In this article we shall confine ourselves to the preparation of the different mordants, and the enumeration of colours they afford, with different colouring substances. The operations of the dye-houses, and the mode of raising the colours in the dye-copper, will be detailed hereafter.

The two great and most important mordants used in calico printing, are those that we have already noticed, viz. the fulminic acid, or acetic acid, and the vitriolic acid, or vitriol, and the aetous solution of alum, or the earth of alum, called red liquor, or red colour, and sometimes yellow liquor.

With these two solutions, either separately applied, and of
The cut into lengths of from eight to ten inches is preferable to any other. It is readily cleaned and more easily taken out of the vat, and returned into it again than misshapen masses fold under the name of old iron. When mule acid is employed, simple heating and washing is insufficient to free it from any fouling: it may have contracted in the vat; but when the pyroligneous acid has been used, it becomes so coated with resin on its upper surface after a second or third solution, as to prolong the period of saturation to twice or thrice its usual length. In this state it must be removed from the vat and heated to redness in oven, through which there is a current of air. The resin is confounded, and the iron by heating is freed from any remains of carbonaceous matter that may adhere to it, and is again ready for the vat.

The only objection to this mode of making iron liquor is the time required to saturate the acid, which to those, whose consumption is very great, or who manufacture it for sale, is oftentimes of importance. Different processes have therefore been devised to remedy this inconvenience, in many of which the saturation is accelerated by means of heat which is applied in various ways, as bell suits the convenience of the manufacturer; but the most expeditious mode is that of precipitating the iron to the acid in a flake of oxidation, by which means the solution is effected immediately. Calico printers have long been in the habit of using an extemporaneous acetate of iron, formed by mixing together solutions of acetate of lead and fulphate of iron. A very pure acetate of iron may be obtained by this means, but the price of acetate of lead renders this mode too expensive for general use. By forming a solution of lead, however, in pyroligneous acid and decomposing it with sulphate of iron or copperas, an iron liquor may be obtained sufficiently cheap to render this process advantageous in many cases, though still more expensive than the ordinary mode. A patent was lately taken out for making iron liquor by a process somewhat similar to this, which, however, we understand has not answered the expectation formed of it. A solution of lead in pyroligneous acid is digested on clear metallic iron. The iron becomes oxidised at the expense of the lead and is dissolved, whilst the lead is precipitated in the metallic state, and may again be used for a fresh solution. All these modes are evidently more expensive than the ordinary one of simple solution of metallic iron in pyroligneous acid, and the only consideration with the manufacturer is, whether this extra expense is counterbalanced by the economy of time or not.

The process adopted some years ago by Mr. Thomson, is perhaps the most expeditious, and next to the common mode, the most economical of any yet in use. It consists in saturating the pyroligneous acid with quicklime, and pouring the clear boiling solution on as much sulphate of iron or copperas as will precipitate the whole of the lime. A calk of iron liquor may be made by this mode in a few hours, and when ready has been taken as to proportion the ingredients so as to produce complete decomposition, it is inferior to no solution whatever in any of its properties.

The processes of the acetous solution of iron fit eminently above all others for the purpose of the calico printer, and having detailed its preparation we shall endeavour to point out in what this superiority consists.

The acetate of iron exists in two states, dependent on the quantity of oxygen combined with the iron. When pure, and recently prepared, it is of a pale greenish hue, but by exposure to air soon becomes tinged with brown. In this state the iron is at its lowest point of oxidation, strongly attractive of oxygen, and if precipitated by an alkali, of a deep green colour. By exposure to the atmosphere, and consequent
COLOUR.

Coarse absorption of air, the solution passes to a deep red brown, and, if concentrated, deposits orange oxyd of iron, and becomes strongly acidulous. With this excess of acid, the solution now becomes permanent; the iron is almost wholly at the maximum of oxygenation; and, when precipitated, of a dark red colour.

The same takes place only in a left degree, and more slowly with the sulphuric and muriatic solutions of iron. Of a pale greenish hue in their recent state, they gradually attract oxygen from the atmosphere, and become slightly red, deposit red oxyd of iron and pass to a state of acidity, at which the solution becomes permanent, and the oxygenation of the iron proceeds no further.

If the solutions, properly thickened with gum or flour, are applied to cloth, the same change takes place, but with more rapidity, from their diffusion over a thin surface, and more complete exposure to the air. The aqueous and volatile part of the solution speedily evaporates, and as the oxygenation goes on, the oxyd of iron is deposited on the cloth, and a portion of acid set free. When this acid is volatile, as is the case with the acetous, and also in a great degree with the muriatic, it is diffipated. The oxygenation of the iron then goes on, fresh portions of acid are again liberated and drawn off till the whole of the solution is decomposed, and the oxyd of iron deposited in the cloth.

When the acid is not volatile, however, as is the case with the sulphuric, the slight portions of acid that are liberated not being drawn off, the oxygenation proceeds more slowly till the excess of acid becomes so great as wholly to interrupt it, and great part of the iron in the operation of rinsing is again carried off the cloth. Another and more serious inconvenience attending the use of the sulphuric solution is its action on the cloth itself. The difengaged acid being in a state of great concentration acts upon its fibres, weakens, and at last destroys them. The same takes place with the muriatic solution also, for though the excess of acid is slowly diffipated, yet it has sufficient time and concentration to act very powerfully, and is, if possible, still more destructive than the sulphuric, since its action is not confined to the part on which it is applied, but from its volatility extends over the whole surface of the cloth.

It is necessary, therefore, that the acid should be not only volatile, but harmless in its action on the vegetable fibre, which conditions are more completely fulfilled by the acetous than by any other solution whatever. From the preceding observations on the properties of the acetous of iron, and the changes it undergoes on the surface of the cloth, may readily be deduced the reasons for that exposure to heat and air which calico printers have, from long experience, found necessary to goods printed with this solution. By exposure to air the iron becomes oxygenated and deposited on the cloth, whilst the heat favours the liberation of the acid, and accelerates the process. From what has gone before it may also be inferred, that the acetous of iron should be used in its recent or green state, since in that state the acetous acid is capable of holding a greater quantity of oxyd of iron in solution, and that consequently after its saturation and removal from the iron, it should not be too much exposed or agitated in contact with the air. On this account, also, it is wrong to pump the liquor in the vats too much when it approaches the point of saturation, since the oxygenated iron is almost all precipitated, and fresh portions immediately dissolved, so that the liquor might in time be rendered quite thick with precipitated oxyd of iron.

The preceding ideas are at variance with the general opinion respecting the state in which the acetous of iron should be employed. All the speculativ writers, and even many well acquainted with the processes of calico printing, recommend the oxygenation of the solution by exposure to air and removal from the iron, as essential to the goodness of the iron liquor. Even Bertholet, in the last edition of his "Elements of the Art of Dying," has fallen into the same mistake, the source of which, and the facts which seem to countenance it, we shall point out in a future article.

It is an object of importance to the calico printer to know the precise strength of his iron liquor, and to be able to ascertain this at all times, with little trouble or chance of error. Great mischief and inconvenience often arise from uncertainty in this respect, especially in the pale shades of purple, which are obtained from madder, with diluted acetous of iron. The hydrometer has been objected to, as indicating not merely the quantity of iron in a solution, but also the essential oil, resin, and mucilage which these impure solutions often contain. This objection, however, only applies where the same instrument and graduation is employed to ascertain the relative strengths of iron liquors, prepared with different acids, as the pyrogallic which contains much effluent oil and resin, and malt acid which abounds in mucilage. In this case the hydrometer may indicate great difference in solutions containing equal quantities of acid and iron, but varying in the quantities of mucilage, oil, or resin. Iron liquor, however, prepared constantly by the same process, and from the same acid, varies little in the relative proportion of its ingredients, that the hydrometer may be used to ascertain its strength in preference to any other mode whatever; provided the necessary precautions are used to correct any error arising from variation of temperature.

In a work of this kind, not illustrated by actual specimens, and without reference to some particular kind of iron liquor, it is impossible to point out the specific gravities of the different solutions required for producing the various shades, we have enumerated. An acetous of iron, of specific gravity 1.047, with madder or logwood, will produce a black, and with weld or sumac an olive, and diluted with, six, eight, or ten times its bulk of water, various shades of purple, drabs, or olives, according to the colouring matter employed. A standard solution of iron once obtained, the necessary strength for producing the different varieties of colour is easily ascertained by actual experiment, and to this we must refer our readers.

When thickened with flour or gum, and tinged with a decoction of logwood or Brazil, the better to enable the workman to observe the progress and state of his work, it forms, as we have before observed, the printers black colour, a purple colour, &c. according to the strength of the solution and the purpose it is intended for. Various ingredients were formerly added to iron liquor, to improve its quality, or vary the hue of colour it produced. Verdigris and copperas were added to the solution intended for black; and alum or nitre to the diluted solutions for purple. These are, however, now almost universally laid aside, as being for the most part useless, and often hurtful: the simple acetous of iron being found to answer every purpose of the more complicated and heterogeneous solutions.

The acetous of alum, or red liquor, is always prepared by the decomposition of alum, by an earthy or metallic salt, since the aluminous earth is not soluble in acetic acid, except in its newly precipitated and minutely divided state. The purest solution, and that which is generally used for the finest and most delicate colours, is produced by decomposing alum with Dutch fusar of lead, generally in the proportion of two parts by weight of the former, to one of the latter. The proportion of the two salts, and also the quantities of each gallon, as used by different calico printers, vary yet

2 with
with little difference in effect. The alun in general predominates so far as completely to saturate the liquor. The printers' alumino-mordant therefore is a compound solution. It is an aceto-sulphate of alumine, consisting of a saturated solution of common alun and more or less acetic acid, according to the quantity of furgar of lead employed. In the neighbourhood of London, the proportions are 6 lb. of alun, and 3 lb. of furgar of lead to a gallon of water: when these are completely dissolved, one ounce of Spanish white is added, and the whole briskly thinned till the effervescence has in great measure subsided. In a few hours the solution becomes clear, and forms a standard liquor from which, by greater or less dilution, may be obtained all the various shades of red, yellow, &c. already enumerated. In the above formula the proportion of alun is somewhat too great. A part of it remains undissolved, or immediately recrystallizes, and falls to the bottom along with the precipitated lead. This excess of alun is however strongly infixed on by many calico printers, as essential to the purity of the mordant, from an idea that the purest part of the alun only is taken up in the solution. This fact however may be readily disproved by employing this undissolved or recrystallized alun on the formation of true mordants, whose purity will be found in no respect inferior to the former. The purity of the alun and furgar of lead, and especially their being free from iron, is of great importance in the preparation of this mordant, and on this account the Dutch furgar of lead is preferred, but its high price renders it too expensive except for the pale reds of light chintz, and other kinds of work, whose great delicacy in the red tints is required. A substitute for it has been found in the solution of litharge in vinegar, or pyrogallic acid, which is afterwards decomposed by the addition of alun, and the excess of acid neutralized by Spanish white as in the former cafe. Great part of the acetic of alumine manufactured and sold under the name of red liquor is prepared in this manner. It is in general used for yellows, dark shades of red, and for those compound mordants into which the acetic of iron enters, and when its purity is of course of little consequence. The acetic of lime has long been substituted with great advantage by the writer of this article for the solution of lead, and its use is becoming daily more known and extended. When carefully prepared, it is far superior to the bell furgar of lead, and the impure solutions answer equally well, for the compound mordants before mentioned. The theory of these processes is the same in all. The object being to obtain a solution of alumine or earth of alun in acetic acid. On mixing acetic of lead, and sulphate of alumine together, a change of state takes place; the sulphuric acid unites with the lead, and falls down in the form of a white heavy precipitate, whilst the earth of alun combines with the acetic acid, and remains in solution. The same takes place with the solution of litharge in pyrogallic acid, which is indeed an acetic of lead, and when the acetic of lime is employed instead of lead, the sulphuric acid and lime unite and form an insoluble powder, which subsides, though less quickly than the other, whilst the acetic of alumine remains in solution above; the addition of the Spanish white is necessary to saturate a small excess of acid which exists in the solution. This excess is taken up by the lime, and immediately converted into acetic of alumine, by the decomposition of a fresh portion of alun.

The acetic of alumine when pure, is almost colourless. It has a slight acetic smell, and when boiling throws off acetic acid in great abundance, and deposits a portion of alumine. When evaporated it acquires a thick gummy consistency, but does not crystallize a property which gives it a decided advantage over common alun as a mordant. It unites readily with gum; but when concentrated and holding much alun in solution, forms with flour a watery pulpy kind of paste, which has little adhesion, and from which the fluid soon separates. The sulphuric salts have indeed all a disposition to injure the thickening quality of flour.

The affinity of cotton for the earth of alun, is so strong as to separate it from its combinations even with the mineral acids. When a solution of common alun properly thickened is applied to cloth, a portion of alumine unites with it, and the acid, which held it in solution, is set free. When this is accumulated to a certain degree, it prevents any further decomposition, and in rinsing carries off the greater part of the earth again. When the acid however is volatile, like the acetous and is dissolved as soon as diffigured, there being no longer any obstacle, the decomposition goes on till the whole of the acetic acid is driven off, and the alumine combined with the cloth. In the infancy of calico printing, and before the theory and constitution of the different mordants was properly understood, a variety of sublimates were added to the solution, some of which are retained to this day. Verdigris in the proportion of two ounces to a gallon, is recommended by many as tending to exalt the hue of yellows, and may in some cases be useful. Corrosive sublimates have been but lately laid aside, and the nitro-muriate of tin was long thought to give finity and brilliancy to reds, when used in a small proportion with the alunino-mordant. In general, however, the aceto-sulphate of alumine is found adequate to every purpose of the calico printer; we shall not therefore, perpetuate error by detailing any of those unmeaning mixtures which are still retained by the ignorant and prejudiced. These two mordants, the acetates of iron and alumine, and their various combinations, are those only in general use in calico-printing, for producing colour of the finest class. This application is so extensive, and the same time so simple, as to supersede the necessity of any other. The solutions of copper are sometimes used as mordants, but they afford colours of little solidity. The solutions of tin have also been employed, but we shall speak of these and other earthy and metallic solutions which have been used with partial success, when we come to treat of mordants in general.

Claf II.

In this class the colours are produced by combining a solution of colouring matter with some earthy or metallic salt, capable of giving it finity when applied to the cloth. The mordant and colouring matter are here applied at once, and the cloth is painted, as it were, or stained, with the colour it is intended to retain, and requires, in general, no farther operation than that of rinsing, to free it from the paste or gum with which it was thickened.

The colour of this class possessed, as we have before observed, in general great brilliancy, but wants that solidity and finity which characterised the colours of the former claf. The union of the mordant with the cloth is weakened by its previous combination with the colouring matter, and not being favoured by heat, as in the former claf: the triple combination of vegetable fibre, mordant, and colouring matter, wants that solidity which is so necessary to constitute what is called a fast colour.

Many of these, however, are sufficiently durable to be partially introduced, and intermixed with other colours of greater durability, and some are indispensably necessary, as no better mode has yet been devised of producing them. When the...
COLOUR.

chemical's art shall have discovered means of giving fixity to colours thus topically applied, the art of calico printing will have arrived at perfection. Systems of colours may then be combined, which are at present incompatible, and the tedious operation of dying and bleaching, with their attendant difficulties, be banished from the art. Nor is the hope so chimerical as might at first be imagined; several of the most useful and permanent colours are of this description, as will be shown hereafter.

We shall content ourselves with describing the leading and most useful colours of this class, giving, at the same time, the theory of their constitution. The mere enumeration of all the varieties that have or may be formed, would be endless, and foreign to our purpose.

Chemical Black.

This is the most useful colour of the class, and one of indispensible necessity in certain combinations of colours, where, for instance, it is mixed with drab, olive, and yellow, railed in the dye-copper with weld quatraron bark, or any similar colouring matter, and where the preface of any substance, such as logwood or madder, capable of producing a full black, would be ruinous to the other colours. A deep olive, approaching to black, might, indeed, be produced, by employing a strong iron liquor, as mordant, and using fumac in the dye-copper; yet as this would bear no comparison in point of intensity with the madder or logwood black, and as the force of the colouring in such course of work greatly depends on contrast, the topical or chemical black, which has all the intensity required, is almost constantly employed. The constitution of this black is pretty nearly the same in all the different forms in life. It consists always of a solution of iron combined with a solution of colouring matter generally of an alritrent nature. On the right proportion of these two solutions, and on their due specific gravity or strength depends, in a great measure, the goodness of the black.

1. If to a decoction of Aleppos galls, in five times their weight of water, made into a palte with flour, a solution of iron in nitrous acid of specific gravity 1.25 be added, in the proportion of one measure of nitrate of iron to eighteen or twenty of the former, a black will be formed fit for almost all the purposes of calico printing, and possessing the chief requisites of this colour, namely, tolerable fixity, and a disposition to work well with the black.

2. In lieu of nitrate of iron, some calico printers employ copperas, in the proportion of one pound to a gallon of the decoction of galls. Half the copperas is directed to be dissolved in the gal-liqour before it is thickened with flour; the remaining half, diffused by heat as much aquafortis as will cover it, is added afterwards. This black has tolerable fixity, but does not work so well as the preceding.

3. Copperas dissolved in various proportions of from four to twelve ounces per gallon, will form, with decoction of galls or logwood, blacks of less solidity indeed than the former, yet applicable, nevertheless, in many cases where the others are not.

The constitution of the two last mentioned blacks differs somewhat from the first. We shall point out this difference, and explain, as concisely as possible, the rationale of the foregoing processes.

When a solution of iron in nitrous acid is added to a decoction of galls, as in the first example, the solution is decomposed, the iron unites with the gallic acid and tannin principle, whilst the nitrous acid is diffused. This is proved by the blackness which the solutions assume immediately on being mixed. The difengaged acid, however, shortly reacts on the new compound, the blackness gradually disappears, and in a few days, if the nitrate of iron has been added in proper quantity, the pale, instead of black, is a dirty olive green. If the proportion of nitrate of iron is greater than this, the change will be effected sooner; and it is high as 2", the pale, when applied to the cloth, will be a bright orange, like the acetite of iron. By exposure to heat and air, this colour generally deepens, becomes grey, and at last a full black. In this state it is permanent, and adheres powerfully to the cloth. These changes of colour depend on the solution of the tannate and gallicate of iron in the difengaged nitrous acid, and the evaporation of the acid when exposed to heat and air on the cloth. This solution of the tannate and gallicate of iron is indeed a essential requisite in the goodnoss of the chemical black. If the difengaged acid is not sufficient to effect this, or if it is in too great a state of dilution, the colour has but a feeble adherence to the cloth; it is not preferred in a state favourable to its union with it, since the combination into which the iron has entered is insoluble in water. It acts merely on the surface, but does not penetrate its fibres, and yields readily in the various operations to which it is subjected. The chemical black, therefore, of the first example is a solution of the tannate and gallicate of iron in nitrous acid.

The black of the second, but more particularly of the third example, differs from the preceding in the circumstance of the iron in the solution being in a less oxygenated state. We may consider this black in its recent state as a mixed solution of green sulphate of iron, and gallic acid, and tannin principle; for the decomposition of the sulphate is not complete till by exposure to air on the cloth the iron becomes fully oxygenated. When this black is recently applied to the cloth, it is of a pale greyish colour, has little fixity, simple rinsing in cold water being sufficient to fetch nearly the whole away. By gradually absorbing oxygen, it becomes deeper, and at last black. The sulphuric acid has no longer any action on it, and is removed in the first operation in which it is immersed in water.

The decoction of galls used for chemical black is variously prepared. Many calico printers infuse the galls cold in casks of vinegar, or pyroglucose acid, suffering them to remain several months, occasionally drawing off the lower part, and returning it on the galls. Others steep them in wine. Both these modes are vicious, particularly the last. Simple boiling in water, till all the soluble matter is extracted is sufficient, taking care to imbibe the galls in a bucket, that when left they may not render the decoction thick.

Grey.

By diluting the chemical black of the first example with once, twice, thrice, &c. its bulk of water, and thickening the solution with gum, various shades of grey are obtained, which require rinsing off in water only, and the deeper shades of which have tolerable permanence.

The theory of these mixtures is the same as of the black, from whence they are derived. On the addition of water to the olive-green solution, mentioned in the preceding article, the colour instantaneously becomes deep purple, approaching to black. This is occasioned by the dilution of the free acid, which being no longer able to hold the tannate and gallicate of iron in solution, lets part of it at liberty, which instantly regains its colour. For this reason already alluded to, this has less adherence to cloth than that in which the solution is more perfect. The addition of a small quantity of nitrous acid effects this. The olive-green colour of the solution is restored, which,
which, by exposure to the air, and consequent evaporation of the acid, disappears, and leaves the tannate and gallate of iron more firmly fixed on the cloth. The complete precipitation of the combination is afterwards effected in the operation of rising off in water.

**Yellow.**

The false or chemical yellows are generally prepared with decoctions of French or Turkey berries, and sometimes with quercitron bark. The latter substance produces pale yellow or straw colour, but does not afford the deep bright orange yellow of the berries. Dr. Bancroft, to whom the public is indebted for the introduction and knowledge of this most useful dyeing drug; indeed, affords the contrary in his work on "Permanent Colours," and has given a receipt for the bark-yellow, which has, however, never succeeded in our hands.

**Berry-yellow.** Boil two pounds of good berries, lightly bruised, in a gallon of water during three hours, taking care to replace, from time to time, the evaporated water with liquor obtained from the second boiling of a former quantity of berries. When the liquor is cool, add to it eight ounces of alum, and if it is intended for the block thicken it with flour. If it is meant for those small objects in printed goods, which are generally touched with the pencil, two ounces of sugar of lead should be added with the alum, and the colour thickened with gum dragon. This yellow is generally passed through lime water as the first part of the operation of mordant; by this means the greater part of the earth of alum, which would otherwise have been carried off in the operation, is precipitated on the cloth, and the colour confiderably heightened.

When this operation of mordant cannot be performed without injury to some other colour, a greater proportion of sugar of lead should be added. This decomposes the alum, and forms an acetate of alumine, which being more readily decomposed by the colouring matter and the cotton than sulphate of alumine, does not require the assistance of an alkaline solution to precipitate it on the cloth.

The proportion of berries above directed is for a full yellow; one fourth or one-third less will form, with the same quantities of salts, yellows of great brightness. Some calico printers add a small quantity of nitrate of copper to the yellows intended to be simply rinsed off without mordant. This heightens the colour, but what is gained in intensity is lost in brightness; for if the solution of copper be added in sufficient quantity to produce any very perceptible effort, it imparts a desire to the hue which is very detrimental. This is the invariable effect of copper in any shape, whether the acetate, sulphate, or nitrate of copper be employed.

**Bark yellow.** For a lemon or straw colour, it will be sufficient to make a decoction of bark by boiling from four to six pounds in as much water as is necessary during two hours, and after evaporating down the decoction to one gallon, add to it two ounces of sugar of lead, and eight ounces of alum. If not limed, the proportion of sugar of lead should be doubled. For yellow greens, Dr. Bancroft directs the addition of both nitrate of copper and nitrate of lime in quantities so great, as near seven ounces of the former to a gallon of colour. Experience, however, though it has done justice to the merits of Dr. Bancroft's discovery of the use of quercitron bark, has not verified the expectations he had formed of it as a substitute for the Turkey berries in the topical or chemical yellow.

The constitution of these colours, whether formed with the sulphate and acetate of alumine, or with the solutions of copper is the same. Alumine, or the earth of alum, and the oxyd of copper, have an affinity both for colouring matter and vegetable fibre. They form the connecting link between these substances, which would otherwise counteract a feeble union. When a solution of alum is added to a decoction of berries or of bark, a light precipitation takes place by the union of a portion of colouring matter with the earth; the greater part however remains suspended or held in solution by the acid of the alum. When applied to the cloth the farther decomposition of the salt is aided by the affinity of this substance for alumine, and, when the acid is volatile, as the acetic for example, by its consequent evaporation. The same takes place with the solutions of copper. The operation of rinsing farther aids the precipitation of the colouring matter and alumine, by thus largely diluting with water; and lastly, when the goods are previously passed through the lime tube, the decomposition is complete, the last portions of earth or oxyd are precipitated, and the colour thereby considerably exalted.

The solutions of tin are capable of forming very bright and beautiful yellows, with decoctions of different yellow colouring substances; but the excess of acid which these solutions necessarily contain, and their powerful action on the cloth, renders their application less general than the preceding. The solution of tin most proper for yellows is the muriatic, and is formed by digesting, in a low heat for several days, the common muriatic acid, or spirits of salt, on fine grain tin. This solution, with bark, a pale and lively yellow, and with berries a yellow bordering more on orange. These spirit yellows, however, as they are improperly called, are seldom used except upon dyed grounds, and of this preparation for such purposes we shall treat at large under the head of Discharged Work.

**Blue.**

The only blue belonging to this class is that produced by combining the colouring matter of logwood with the oxyd of copper. It is but seldom used since the mode of dipping China blue has become generally known; and indeed its want of durability renders it of little value. It may be produced by combining almost any of the solutions of copper with a decoction of logwood.

1. Boil two pounds of logwood in a gallon of water, and to the decoction, thickened with gum, add eight ounces of sulphate of copper.

2. To a decoction of logwood as above, add two ounces of sulphate of copper, and two ounces of verdigrise.

Their colours may either be rinsed off or limed, as best suits the style of work. The theory of these combinations is the same as the preceding.

**Green.**

The chemical or false green is a compound colour, and consists of a mixture of a decoction of logwood and berries, or bark, and a solution of copper. Though fugitive, its use is in some degree authorized by the impossibility of obtaining a green of greater durability that can be applied in figures with the block. The fast green of the calico printers is the product of two operations, and it is of course limited in its application, and tedious in its use. The production of a fast green at one operation, or rather by one application to the cloth, either with the pencil, block, or press, is one of the great desiderata of calico printing.

1. One pound of logwood and two pound of berries boiled together during two hours, and strained whilst hot upon
upon two ounces of sulphate of copper, and two ounces of verdigris, and thickened with gum, form a good and lively green, the hue of which may be varied at pleasure by the increase or diminution of the proportion of logwood. To this same calico printer adds two ounces of common salt, and two ounces of sal ammoniac or acridulous sulphate of potash.

2. To one measure of blue of the first example in the preceding article, add two, three, four, &c. measures of a decoction of bark, made by boiling six pounds as before directed for the yellow, and to which, when reduced to one gallon, two ounces of sulphate of copper, and two ounces of verdigris have been added. The tone of the green depending on the relative proportions of blue and yellow, it is, in general, best to keep the two decoctions separate, to be mixed, when wanted, in such proportions as may best suit the purpose required. The theory of these mixtures is the same as of the blue and yellow already described. To the eye of the more speculative chemist, the addition of common salt and acridulous sulphate of potash in the first example, may appear unnecessary and unmeaning. They indeed affect little, either the hue or fixity of the colour, but experience has proved that this addition facilitates its working with the block, more especially when thickened with gum dragon. The cause of this, in the particular instance before us, is perhaps not very clear. The sulphur falls in general, such as the sulphates of alumina, iron, and copper, are all unfavourable to working, as their solutions, especially when concentrated, neither thicken well with flour nor gum. A saturated solution of copperas cannot be thickened with flour, nor can a strong solution of the aceto-sulphate of alumina, in which the alum is in great excess; even with gum it unites with difficulty. But if to a solution of copperas, which refines to form a paste with flour, a small portion of nitrate of iron be added, the whole forms a good and substantial paste that works admirably with the block; and half a pound of common salt added to the aceto-sulphate of alumina has a similar effect. In the instance more particularly before us, the addition of common salt forms a muriate of copper by the decomposition of the sulphate; but this salt is in too small a quantity to affect the working of the colour very sensibly. The cause of these effects is to be sought for in the very complicated play of affinities, which exist in such compounds, and which future investigation and discovery may perhaps unfold. The speculative philosopher, who is ignorant of the minute details of an art, that involves in it consideration and difficulties, unsuspected in the laboratory, will hence learn to suspend his judgment in deciding on the merits of a formula, till experience shall have proved the inferiority of those ingredients which theory would reject as absurd.

But to return to our subject, there is a wide field open for experiment and discovery in the production of greens, into which logwood does not enter. A calico printer near London, celebrated for his ingenuity and invention in colours of this class, has long employed a green which, from its beauty and durability, when compared with the foregoing colours, indicate the presence of indigo as a constituent part. Prussian blue in a minutely divided state, and mixed with bark or berry-yellow has been employed; but the blue in this case has so little adherence to the cloth, that mere mechanical force, the operation of rinsing and washing is sufficient to disengage it. With one or other of these substances, however, it is likely that greens much superior in beauty, and probably also in durability to those generally in use, might, by a series of patient and well conducted experiments, be readily obtained.

Pink.

The pale, and more delicate shades of red, belonging to this clafs, are chiefly sought after in calico printing. They are employed in giving relief to other colours, the effect of another colour taken in the shade of the colour-maker is exerted in giving them brilliancy and richness of tone. They are chiefly produced from decoctions of Brazil, Nicaragua, or peachwood, and cochineal, fixed, and fixed on the cloth with solutions of tin, rarely with the aluminous mordants, though delicate and lively colours may be produced this way.

The nitro-muriate of tin is chiefly employed, though the relative proportion of the two acids, and their degree of saturation with tin, varies almost with every calico printer. The solution itself, made according to established rules, and with the same properties, varies so considerably at different times, as wholly to alter the nature of its compounds, without any apparent cause of failure. The source of this discordance is to be sought for in the constitution of the solution itself, which, from caufts that we shall endeavour to explain, is subject to considerable variation.

H. R., from the strength or concentration of the acids employed, which are seldom uniform or constant; muriatic acid from the same manufacturer varying often in specific gravity from 1.12 to 1.18, and nitrous acid not less than from 1.15 to 1.23, without reference to the common diminution of single and double aquafortis.

When the specific gravity of the acid is neglected, as is but too generally the case, these differences occasion serious inconveniences in the use of solutions, whose properties often depend on the accuracy of their proportions, and on determinate degrees of saturation.

Secondly, from the impurity of the acids. The muriatic acid of commerce always contains iron and sulphuric acid; if the former exist in any notable proportion, it is unfit for the solution of tin; the presence of the latter is of great importance, though, on the whole, unfavourable to delicate colours. The nitrous acid varies considerably in its purity, being subject to greater or less admixture with the muriatic; the nitre is made from being field-mint free from marine salt. The aquafortis of commerce is, in fact, an aqua regia. This variation of the proportion of muriatic acid in the nitrous, is of the utmost importance, since the properties of the solution eminently depend upon this. With muriatic acid only, tin forms a colourless and permanent solution, one of whose distinguishing properties is, its strong affinity or attraction for oxygen. With decoction of cochineal, it forms a deep and dull purple-coloured precipitate, which, however, gradually loses oxygen, and becomes crimson, especially when exposed on the filter. With decoctions of Brazil and peachwood, it affords crimson precipitate, varying in intensity with their saturation with tin. It decomposes all the combinations of iron with colouring matter, deoxygenating the iron which it carries off, leaving the tin in combination with the colouring matter. Thus a madder black becomes a red on the application of muriate of tin. On this property is founded the art of printing on dyed grounds, of which we shall treat hereafter. With nitrous acid, unless very dilute, tin contracts a very feeble union, and is generally precipitated as soon as dissolved, in a state fully saturated with oxygen. The addition of a small quantity of muriatic acid renders this solution more permanent, provided it be not fully saturated with tin, and the addition of
of larger portions approximates the solution still more to the nature of the former, and renders it capable of supporting a greater degree of saturation. The properties of the solution depend greatly on the proportion of nitrilic acid, and consequent of nitrile of tin contained in it. When small, the precipitate with cochineal is bright crimson scarlet. It does not decompose the combinations of iron with colouring matter, unless the solution be far from saturation, and this effect is then due to the disengaged acid only.

The purity of the tin is another requisite which should be carefully attended to. The fine tin of Cornwall, commonly called grain tin, should be employed. If alloyed with lead, it is wholly unfit for these purposes.

In lieu of nitrilic acid, sal ammoniac and common salt are oftentimes employed to form an aqua regia with nitrous acid. The solution differs little from that formed by a mixture of the two acids, the allowance being made by the portion neutralized by the alkali of the neutral salt.

From this short outline of the history of the substances employed in the formation of the solutions of tin, and of the properties of the solutions themselves, may be deduced such general ideas as will elucidate and explain many anomalous effects in their combinations with different colouring matters, and seem to direct future experiment in the discovery of those minute, but often important, conditions necessary to the formation of particular shades of colour.

The following examples of spirit reds, as they are improperly called by colico prieters, will illustrate some of the preceding observations, and may be considered as specimens of the most beautiful and brilliant colours it is possible to form upon cotton.

1. Prepare an aqua regia by dissolving two oz. of sal ammoniac in one pound of nitrous acid of specific gravity 1.25. To this add two ounces of fine grain tin; decant it carefully off the sediment, and dilute it with \( \frac{1}{2} \) its weight of pure or distilled water.

2. One gallon of water add one pound of cochineal, ground as fine as flour; boil half an hour; then add two ounces of finely pulverized gum dragon, and two ounces of cream of tartar, and stir till the whole is dissolved. When the liquor is cool, add one measure of the preceding solution of tin, to two of the cochineal liquor, and incorporate well by stirring. Apply this with the pencil or block, suffer it to remain in the cloth six or eight hours, then rinse off in spring water. This colour will be a bright and beautiful scarlet.

3. Boil 12 pounds of Brazil chips during an hour in as much water as will cover them. Draw off the decoction, and pour on fresh water, and boil as before. Add the two liquors together, and evaporate slowly down to one gallon.

To the decoction whilst warm add four ounces of sal ammoniac, and as much gum dragon or fencag as will thicken it for the work required. When cool, add one of the solution of tin before described, to four, six, or eight of the Brazil liquor, according to the colour wanted. Boil it to remain from 18 to 24 hours on the cloth, then ruffle off in spring water as before. The colour will be a pale and delicate pink. If it is required deeper, the decoction must be made stronger, and used in the proportion of three or four to one of the solution of tin. Nicaragua or peachwood, though not so rich in colouring matter as Brazil, yields a colour, however, which is, if possible, more delicate and beautiful. The fine pinks produced by certain hoffies, which have for years been the envy and admiration of the trade, are afforded by this fine dye-wood.

These colours require no liming, simple affusion with water being sufficient to precipitate the colouring matter in combination with the tin. The theory of these mixtures is the same as the preceding. They require, however, a greater excess of acid to hold the colouring matter in solution. A decoction of cochineal poured into a saturated solution of tin, occasions an instant precipitation which is not disintegrated, and the greater part of which, if applied to cloth, would come off in the operation of rinsing. It is sometimes necessary to add a small quantity of nitrile of tin to prevent this precipitation, or to correct it when it happens; and sal ammoniac is supposed to have the same effect, probably by engaging the water of the solution.

With the aluminous fults, the decoction of cochineal and Brazil forms colours less brilliant than those we have just described, but which are applicable in cafes where the excess of acid in the solutions of tin is attended with inconvenience.

1. To one gallon of water, add eight ounces of finely ground cochineal, and two ounces of bruised galls; boil half an hour, strain the liquor whilst hot through a fine cloth, upon four ounces of cream of tartar and four ounces of gum, and thicken with gum dragon. This colour requires liming.

2. Upon 3 lbs. of Brazil, and 2 oz. of galls, pour one gallon of water, let them soak some time, then boil two hours, replacing the evaporated liquor with fresh water. Strain through a fine cloth upon 4 lbs. of gum fenegal, and add one pint of the acetate of alumine, described in a former part of this article.

The addition of galls in the two preceding formulæ is supposed to import solidity to the colours in some way analogous to the operation of galling in silk and cotton dyeing, of which we shall have occasion to speak hereafter. Their constitution is otherwise the same as the berry and bark yellows, and most others of this class of colours.

Purple.

1. If the solution of tin directed for the pink in the last article be mixed with six times its bulk of a decoction of logwood poured whilst hot upon four ounces of sal ammoniac, and 2½ lbs. gum fenegal, a bright and lively purple will be obtained, the hue of which varies with the strength of the decoction and the proportion of solution of tin employed.

2. If instead of the solution of tin, the acetate of alumine before alluded to, be used in various proportions of one-sixth, eight, &c. purples differing in shade and intensity will be formed, applicable in some cafes, but possessing less solidity than most of the colours already described.

The constitution of these compounds is the same as the preceding.

Olives.

Olives are variously compounded, according to the colour required.

1. By mixing chemical black in various proportions with berry or bark yellow. The depth and fulness of the olive depends on the quantity of black.

2. By a decoction of logwood added in greater or less quantity to the bark or berry yellow.

3. By the addition of copperas or nitrate of iron to decoctions of yellow or aluminium colouring matters, such as bark, sumac berries, weld, &c. each of these produces a different hue, varying from the green olive to a drab or cloth colour. By mixing these decoctions in different proportions, and by varying their strength, and the quantities of copperas
or nitrate of iron added to each, a multiplicity of shades may
be produced, of which it is impossible to convey any precise
or definite ideas.

These colours may be indifferently thickened with flour
or gum, as best suits the work required, but when nitrate of
iron is added to solutions containing gum, the instant coag-
ulation that takes place must be counteracted by the addition
of a portion of free nitrous acid. This effect arises from the
strong action exerted by metallic oxides, at the maximum
of oxidation, on mucilage or gum. When the decoction
is very concentrated, and contains sufficient colouring
matter to engage the whole of the iron, this effect takes
place in a lesser degree, but with solutions adapted to the
production of the foregoing colours, a coagulation invari-
able takes place, unless counteracted by the presence of a
portion of free acid. Of this action of metallic oxides on
the solution of gum we shall further treat under the article
Gum.

Clas III.

In this class, the colouring matter is simply held in solu-
tion, by an acid or alkali, and in that state applied to the
cloth without the intervention of any mordant.

The most important of these colours, is the alkaline solu-
tion of indigo, which forms the topical or.

Pencil Blue.

1. Prepared solution of pot-asf, by boiling together
7 lbs. of quick lime, and 15 lbs. of pot-asf, in 10 gallons of
water. Decant off the clear liquor, and separate the re-
mainder from the lime by means of the filter. To one
gallon of this solution, add 1 lb. of red arsenic, or orpiment,
and 1 lb. of fine indigo, both previously ground together in
a mill with sufficient water to form a thick paste. Bring
them up gradually to a boil, stirring carefully all the time,
and then withdraw the fire. Thicken the solution with the
best gum fenug, and for the pale shades of blue, dilute
with one, two, &c. measures of gum-water.

The quantities and relative proportions of pot-asf, orpi-
ment, and indigo in a gallon of pencil blue vary considerab-
ly with different calico printers, and within certain limits, it
appears, that the accuracy of these proportions is not of great
importance. Haussman, an intelligent French printer, em-
ployed 15 lbs. of pot-asf, 6 lbs. of orpiment, and 1 lb. of indigo,
to 12 gallons of water; and Oberkampf, proprietor of the
celebrated manufactory of Tony, a thil greater proportion of
indigo. Some printers add brown sugar, and Baneroff
has proposed to substitute this for the orpiment, but with-
out success.

The solution, when recently made, is a yellowish green,
but by exposure to air, becomes gradually deeper, and at
last blue. In this state, it is wholly unfit for use, it contracts
no union with the cloth, and is detached from it in the
first operation of mordanting.

Of the peculiar nature and properties of indigo, we shall
have occasion to treat hereafter, under its proper head, at
present it will suffice to observe, that it owes its colour and
infusibility in alkalies, to a portion of oxygen intimately
combined with it. To render it soluble, therefore, it must
be deprived of this oxygen, by the action of a substance
having a more powerful affinity for it, and the fulminating
of arsenic, or orpiment, is used for this purpose. Sulphate
of iron, has a strong affinity for oxygen, and is employed in
de-oxygenating indigo for certain purposes; but the oxyd
of iron not being soluble in alkalies, the solution of indigo,
formed by it, become quickly regenerated by the absorption
of oxygen, and cannot even be transferred from one vessel
to another. The sulhydure of arsenic, on the contrary being
very soluble in alkalies, precludes the double advantage of
de-oxygenating the indigo, and of retaining it awhile in that
state, till on its application to cloth, it becomes exposed to
the action of atmospheric air, as to regain its oxygen, colour,
and insolubility; and becomes fixed in its original or blue state.

The copper coloured pellicles, which forms on the surface
of pencil blue, and is renewed immediately on its removal,
arises from the abstraction of oxygen, which, in spite of the
action of the orpiment, is continually taking place. Hence
arises that disposition to unevenness, which is the great dis-
advantage of this blue; the unavoidable exposure to air of
small portions of the colour during its application with the
pencil, conferring greater or less portions of indigo, and con-
derably reducing its strength.

Most calico printers boil up the quicklimes with the other
ingredients, thinking its presence not less necessary than the
pot-asf and orpiment; by this means a considerable portion
of the solution of indigo is taken up by the sediment, which
caresl washing does not wholly separate. As the action
of the lime is confined merely to the alkali, which it renders
calcaeous, and capable of acting with greater force on the
other ingredients; it is certainly much more economical to
render the pot-asf caustic before its addition to the indigo.
A considerable waste of colour is by this means prevented,
and the solution may be thickened the moment the emulsion
has ceased without waiting for the deposition, which in the
old mode takes place.

Orange.

The oxyd of iron, when dissolved in acetic acid, forms
one of the most useful and important mordants, as we have
already shewn in the former part of this article. It is also
capable of imparting a very pleasing and permanent colour
to cotton, when applied in solutions of tolerable strength and purity, and forms the orange, buff, and gold
colour of the calico printers.

1. The solutions of iron in vinegar, strengthened by the
addition of copperas may be used, but the purest and
brightest gold colours are obtained from copperas and sugar
of lead, in the proportion of 3 lbs. of the former, and 1 lb.
of the latter, to a gallon of water. When thickened with gum,
and employed undiluted, it affords, when lined, a full strong
gold colour, and with two, four, six, &c. times its bulk of
water, various shades of orange and buff, which render
the action of air, alkalis, and soap; and are neither excited
than impaired by frequent washing. The addition of sugar
of lead, is to increase the strength of the solution. A gallon
of water dissolves about 4 lbs. of copperas. The addition
of a pound of sugar of lead, enables it to take up another
bount nearly, and the strength of the solution may be still
further increased by equal additions of the two last. The
operation of lining is a simple precipitation of the oxyd
of iron on the cloth, and in cases when this cannot be perform-
ed, the proportion of sugar of lead must be increased to
nearly that of the copperas. It is only the paler shades of
orange, however, which are to be obtained this way. The
deep 20.4 colour before named, is not to be procured with-
out the aid of a precipitant. Spanish brown is sometimes
added to a solution of iron, and employed in such a cafe,
but it contracts no union with the cloth, and is readily re-
moved by simple washing and beating. When the orange,
or gold colour, is thickened with flour, a small portion of
nitrate of iron must be added to the paste, for reasons we
have assigned on a former occasion.

2. A beautiful, but fugitive orange, is obtained by boil-

ing
ing half a pound of annotta with th. of caustic potash in a
gallon of water, and thickening the liquor with gum. This
colour acts powerfully on the seizes and blocks, which it
very soon destroys, and on this account, and also from its
want of permanence is seldom used. It may either be simply
rinsed off, or first passed through water rendered slightly
acidulous with sulphuric acid, or what is still better through
alum-water. This operation is the very reverse of liming,
for here the colouring matter to be precipitated, being held
in solution by an alkali, an acid must be employed for that
purpose. The colour by this means is considerably heighten-
ed, and when applied with the pencil, is useful in some cases
where the other colours will support the action of alum-water
without injury.

Borax, and even spirits of wine, are sometimes added to
the alkaline solution of annotta, and are supposed to contribu-
to its strength and fixity, though on what principle it is not easy to discover.

Green.

The oxyd of copper, dissolved in volatile alkali, affords a
delicate and pale green, which is sometimes employed inter-
mixed with other colours. Turnings of copper, or verde-
gris, which is more generally used, may be digested in a
low heat with spirits of salt anisone. Care must be taken
that the heat be very moderate, and the vessel in which the
solution is made, well stopped, the ammoniac will otherwise
be driven off, and lost. When the alkali has taken up as
much copper as it can dissolve, the solution must be thickened
with gum, and applied with the block or pencil. In a few
days the ammoniac evaporates and leaves the oxyd of copper
on the cloth, which must be rinsed to free it from the gum
and impertinent colour.

The blues produced by alternate immersion in copperas
and lime, and also in the solution of indigo, by the same
substances, properly come under this class of colour, as they
are solutions of colouring matter in lime and alkalis. As
the processes by which they are applied, differ however very
materially from all those that have been treating of, they
claim a separate and distinct notice. For the details of these
operations, and the mode of preparing the pastes for bark
and pale blue dipping, and the colours for China blue, we
must therefore refer our readers to the article Dipping
Blues.

COLOURS, in Dyeing.—There are five simple, primary, or
mother colours, used by the dyers: from the mixture where-
of all the other colours are formed; these are blue, red, yellow,
black, and brown colour; each of which fee under their
proper head, Blue, Red, &c.

Of these colours, mixed and combined, others are formed,
which are infinitely various. According to the propor-
tion of the different ingredients that are employed, or the
processes by which they are blended, thus a mixture of
blue and yellow forms green, which is distinguished by dyers
into a variety of shades, according to the depth of the shade,
or the prevalence of either of the component parts. Hence
we have sea-green, peas-green, pea green, &c. &c. Blue and
red form different shades of violet, purple, and blue. A mixture
of yellow and red produces orange. Mixtures of black
with other colours constitute grey, brown, and brown. For
a more particular account of these and other colours; and
the method of procuring and applying them; see the article
Dyeing. See also the preceding article.

The greatest perfection in the art of colours would be to
find the means of preparing the fixed colours without the
use of acid or alkaline salts, which usually subject
the colours to change, or else are apt to prey upon the
cloth, canvas, &c. as we see in verdigrise, the blue and green
crystals of copper, &c. It appears highly probable, that
the Indians, for making the fine bright and durable colours,
which with their chintzes and calicos are famed, make use
of metallic solutions; for some stained calicos, brought
from thence, having been kept 40 or 50 years, the bright
colours have been observed to eat out the cloth, exactly in
the same manner as acid spirits, which diffuse metals, are
found to do.

Since these, then, are the inseasonings attending such
colours, we ought to search for menstrums with which to
extract colours, which are neither acid nor alkaline; and for
such metallic oxides, precipitates, or powders, as will not
loose their colours, by being well washed to get out their
salts; to prepare certain metallic matters, by mere calcu-
lination, or the bare sufficiency of fire; and lastly, to look out
for native colours, wherein no saline matter abounds.

Mr. Geoffroy has given a very curious process for making
two clear, spirituous, inflammable liquids, which differ
very little in taste and smell, and being mixed together give
a fine carnation colour, without any sensible fermenta-
tion.

To make the first of these liquids, put a small handful of
dried red roses into a glass bottle; pour on them rectified
spirit of wine, till it covers them an inch; let this stand
in a cold infusion four or five hours; then pour off the liquor,
which will be clear and colourless, as when put on. The
second liquor is made by dropping into rectified spirit
of wine, a very much of sulphur, by the bell, or spirit of vitriol,
as will be borne in it without giving it any very sensible aci-
dity when tasted. When these liquors are thus prepared,
let a small quantity of the latter be dropped into some of the
former, and the whole will become of a fine carnation colour,
though there is no fermentation, nor any other change per-
ceived in it, but barely that of colour. If instead of this
balsam liquor, there be added to the first a few drops of the
spirit of salt ammoniac, the whole will become green.

Make a slight infusion of galls in water, so as not to co-
 colourful the water; make also a weak solution of green vitriol
in water, so that it may appear colourless; mix these two
colourless liquors together, and an inky blackness is imme-
diately produced; add to this black liquor a little oil of vi-
triol, and the liquor becomes pellucid and colourless again;
then add to this a little salt of tartar, and the whole is black
again.

Put a little bruised camphor into rectified clear oil of vi-
triol; shake the mixture, and it will become black, and
the camphor will be dissolved; add to this a little water, and
the liquor becomes clear, and the camphor is found separated
at top, in its own form, and native whiteness.

Infuse lignum nephriticum in cold water, and pour off the
clear liquor. This held up against the light, appears of a
fine yellow, but viewed from the light, of a beautiful
blue: a little spirit of nitre put to this liquor makes it
loose the power of reflecting the blue rays, and a little
oil of tartar, afterwards added, recovers that power again.

Logwood, infuse in water, gives a red colour. Put to
this a little spirit of urine, and it becomes of a fine purple;
and drop in afterwards a little spirit of salt, and it becomes of
a pale red.

A beautiful blue tincture may be made from filings of cop-
pper, by dissolving them in spirit of urine, hardnose, or the
like. The addition of oil of vitriol destroys the blue colour;
and a little spirit of salt turns it green.

Pellucid oil of vitriol, mixed with pellucid oil of turpen-
tine, produces a thick red balsam. And common oil, mix-
ed with fair water, by means of a little wax, and continued
rubbing,
rubbing, turns into a thick white balsam, called cold cream.

Oil of vitriol, distilled from quicksilver, leaves a white powder behind, which, if water be poured on it, becomes yellow.

Dissolve quicksilver in spirit of nitre, and to part of it add spirit of urine, and a white powder is precipitated; to another part of the solution add oil of tartar, and a yellow powder falls to the bottom.

Dip a new pen in spirit of vitriol, and write with it on common blue paper, and the letters will appear red.

A pelucid folution of fuscarem fuscum being written with on paper, becomes invisible when dry; but the base funes of an infusion of quicklime, and opiment, in water, will render the invisible writing black and legible.

Volatil fable fune ammoniac, which is white, mixed with cryall of copper, which are green, produce a fine purple.

The original and simple, as well as the mixt, colours are producible by mixture. Thus, if the fune's rays pafs through two pieces of glass, the one blue, and the other yellow, and be afterwards received upon a white paper, the colour there seen is green. The dyers make cloths blue with wood, and then turn it green by the yellow herb called lutecola, or dyers' weed. To a yellow folution of gold in aqua regia add a blue one of copper in spirit of urine, and the mixture becomes green. The painters every day prac-

tice this art of producing new colours by mixture.

Metalline and mineral matters are reducible to a considera-
able degree of finhty, or finialuets of parts by fire, or dry calcination, so as to leave them durably polished of their native or adventitious colours. Thus laptops lapis lazuli, by being calcined, becomes the fine rich blue called ultramarine; light ochre, by the same treatment, becomes a light red, or flesh colour, the most useful flesh-colour in painting. Lead, by calcination, becomes durably red, and iron durably brown; but a proper method seems wanting for the dry calcinations of the nobler metals, gold and silver; though, for the use of gilding, these are easily prepared by dipping linen rags in their respective solutions, and then drying, and burning them to ashes, whereby a dry and fine metalline powder is procured.

Colour, in Heraldry, the heraldic colours are nine, and were anciently expræfled by the word tinture. viz. or, argent, azure, gules, fable, vert, puerpur, tenney, and saufingue, and also by precious stones and planets; the auralial colours are blazoned in different terms, according to the rank and dignity of the persons whose arms are designed, as follows:

<table>
<thead>
<tr>
<th>Colour</th>
<th>For Commoners by Tinctures</th>
<th>For Peers by Precious Stones</th>
<th>For Emperors, Kings, and Princes, by Planets</th>
</tr>

For a fuller account of each, see under the respective heads.

Or, and argent are metals, and it is an invariable rule in heraldry not to put colour upon colour, or metal on metal; that is, if the field be of a colour, the charge or bearing must be of a metal.

Colour, in Law, is a probable or plausible plea; though in reality false at bottom; and only calculated to draw the trial of the cause from the jury to the judges: and, therefore colour ought to be matter of law, or doubtful to the jury.

In pleading it is a rule, that a man may be allowed to plead, specially, such a plea as amounts only to the general issue; but in such case he shall be driven to plead the general issue in terms, by which the whole question is referred to a jury. But if a defendant in an affrce action of trespass, be de-

formed for the validity of his title to the court rather than to the jury, he may state his title specially, and at the same time give colour to the plaintiff, or suppose him to have an appearance or colour of title, bad indeed in point of law, but of which the jury are not competent judges. As if his own true title be that he claims by sequestration, with livery from A. by force of which he entered on the lands in question, he cannot plead this by itself, as this plea amounts to no more than the general issue. But, he may allege this specially, provided he goes farther and says, that the plaintiff claiming by colour of a prior deed of sequestration, without livery, entered, upon whom he entered, and may then refer himself to the judgment of the court, which of the two titles is the best in point of law. (Dorfler and Student. 2. c. 57.) Every colour ought to have the following qualities.

1. It is to be doubtful to the jury, as in case of a deed of sequestrance pleased, and it is a doubt whether the land palfeth by the sequestrance, without livery or not. 2. Colour ought to have constancy though it wants effect. 3. It should be such colour, that, if it were effectual, would maintain the nature of the action, as in affrce, to find colour of freehold, &c. (10 Rep. 88, 90, and 91.) Colour must be such a thing, which is a good colour of title, and yet it is not any title. (Civ. Jac. 122.) If a man states his entry for such a cause as binds the plaintiff or his heirs for ever, he shall not give any colour; but if he pleads a defendant in bar, he must give colour, because this binds the possession, and not the title; so that when the matter of the plea bars the plaintiff of his right, no colour must be given. When the defendant entitles himself by the plaintiff, where a person pleads to the writ or to the action of the trial; he who jurifies for titles; or where the defendant jurifies as servant; in all these cases no colour ought to be given. (10 Rep. 91. Trut. 1343.) Where the defendant doth not make a special title to himself or any other, he ought to give colour to the plaintiff. (Civ. Eis. 76.) In trespass for taking and carrying away two hundred oaks of wood, &c. the defendant says, that A. B. was possessed of them, ut de bonis propriis, and that the plaintiff claiming them by colour of a deed after made, took them, and the defendant retook them and adjudged that the colour given to the plaintiff makes a good title to him, and confeceth the interest in him. (Lil. Abr. 275.)

Thus, c. gra. in an action of trespass for taking away the plaintiff's heads, the defendant urges, that before the plaintiff had any interest in them, he himself was possessed of them, as his proper goods; and delivered them to A. B. to deliver to him again, when, &c. and A. B. gave them to the plaintiff, and the plaintiff, by the property to be in A. B. at the time of the gift, took them, and the defendant took them again from the plaintiff, whereupon the plaintiff brings his action.—This is a good colour, and even a good plea. Dott, and Stud.

Colour of office, is when some unjust action is done under countenance of office or authority. See Bribery and Extortion.
To Colour stranger goods, is when a free man allows a foreigner to enter goods at the custom house in his name.

Colours, camp, are a sort of small colours painted on the right and left of the parade of a regiment when in the field. They are about 18 inches square, and of the colour of the facing of the regiment, with the number of the regiment marked on them. The poles, to which they are fixed, should be about 7 feet 6 inches long; except those of the quarter and rear guards, which ought to be about 9 feet long.

Colours, field. See Field.

Colours, guard. See Guard.

Colours used in the drawings of fortifications and military works, are chiefly Indian ink, carmine, verdigris, sap green, gum bich, Prussian blue, Indigo, indan, ultramarine, umber, sum color, which articles see separately, as well as the article Fortification.

Colours, Colours, in the Ancient Muses, was used to signify the musical species belonging to a genus.

In this sense the chromatic genus was laid to have three colours; and the diatonic two. The enharmonic, having no subordinate species, had but one colour. Hence the ancients reckoned three genera, and five colours, in music; namely, for every different divisions of the diatonic or fourth.

Colours, diatonic or musical scale of—In the course of Sir W. Newton's experiments on the properties of light, (Optics, book i. part ii. prop. 3.) he discovered the remarkable fact, that the spectrum of the sun's image, formed by a refracted light, let into a darkened room, is longitudinally divided by the points separating the different colours, viz., violet, indigo, blue, green, yellow, orange, and red into spaces which are respectively equal to $\frac{1}{5}$, $\frac{2}{5}$, $\frac{3}{5}$, $\frac{4}{5}$, and $\frac{5}{5}$ parts of the double length of the spectrum, as is supposed. The spectrum to be 360 parts in length, then $\frac{1}{5}$, $\frac{2}{5}$, $\frac{3}{5}$, $\frac{4}{5}$, and $\frac{5}{5}$ will represent the length of each colour respectively, and adding these successively in the reverse order, to $\frac{1}{5}$, we have $\frac{1}{5} + \frac{2}{5} + \frac{3}{5} + \frac{4}{5} + \frac{5}{5} = 2$, which, in their lowest terms, are $\frac{1}{5}$, $\frac{2}{5}$, $\frac{3}{5}$, $\frac{4}{5}$, and $1$, and appear to be the diatonic ratios answering to the octave, minor seventh, major sixth, fifth, minor fourth, minor third, major second, and key note; or, to VIII, 7th, VI, V, 4th, 3d, II, and key, represented in the gamut by, c, b, a, g, f, e, d, and c.

From the experiences of Dr. Brougham, jun. efq. Philosophical Transactions, 1795, it appears, that not only by refraction, but by inclination, deflection, and reflection, the rays of light may be separated on a chart or screen; and he mentions numerous experiments, wherein the limits of the several colours on the spectrum were carefully marked with the point of a needle, after which the papers thus marked were put away, and a fresh paper subtillicated for other experiments: the measurement or comparison of the lengths of the intervals occupied by each colour on the different papers, being purposely deferred, until the whole course of experiments was completed, in order to prevent any preconceived opinions from operating in making the experiments: the results are represented as agreeing, in the spaces $\frac{1}{5}$, $\frac{2}{5}$, $\frac{3}{5}$, $\frac{4}{5}$, and $\frac{5}{5}$ occupied by the violet, indigo, blue, green, yellow, orange, and red colours, being the very same, as to arrangement, as those by refraction above-mentioned.

It is observable, that the notes composing the octave thus produced, do not answer to the major-key of bB as it might seem to do, although some writers on musical intervals have alleged, that nature produces only the major-key or division of the octave, and that the minor third bE or $\frac{5}{4}$ is nowhere to be found in nature. If we were to consider the chromatic ratios $\frac{3}{4}$, $\frac{5}{4}$, $\frac{7}{4}$, $\frac{9}{4}$, $\frac{11}{4}$, and $\frac{13}{4}$, we should have a different series of intervals, and a different division of the octave. It is not the intention of this article to enter into a discussion of the merits of the different systems of temperament, but merely to give an account of the effects produced by each, and to point out the advantages and disadvantages of each. It is evident, that the system of equal temperament, which is the most generally adopted, is the most convenient for musical purposes, and the most satisfactory for practical music, as it is the most equal, and the most commodious for the production of the desired sounds. It is also the most convenient for the production of the desired sounds, as it is the most equal, and the most commodious for the production of the desired sounds. It is also the most convenient for the production of the desired sounds, as it is the most equal, and the most commodious for the production of the desired sounds. It is also the most convenient for the production of the desired sounds, as it is the most equal, and the most commodious for the production of the desired sounds.

The principal colours used by painters, are red and white lead or ceruf; yellow and red ocre; several kinds of cartes, as amber, &c. besides ophirmin; black lead, casiar, gamboge, lake, bice, verditer, indigo, vermilion, ver- degris, ivory black, biliur, lamp black, smalt, ultramarine, and carmine; each of which, with the manner of preparing them, their uses, &c. see under their respective heads.

Of these colours, some are used in and in oil, others in fresco, others in water, and others only for miniature.

Colours, in an Ecclesiastical Sense, are used both in the Latin and Greek churches, to distinguish several mysteries and feasts celebrated therein.

In the Latin church are only regularly admitted five colours, viz., white, red, green, violet, and black: the white is for the mysteries of our Saviour, the feasts of the Virgin, those of the angels, saints, and confessors; the red for the mysteries and solemnities of the holy sacrifice, the feasts of the apostles and martyrs; the green for the time between Pentecost and Advent; and from Epiphany to Septuagesima; violet in Advent, Christmas, in vigils, vigils, and in votive masses in time of war; indigo, black for the dead, and the sacraments thence belonging. Cloths of gold and silver, and embroidery, are indiscriminately for all solemnities.

In the Greek church the use of colours is almost obliterated, as well as among us: red, among them, was the colour for Christmas, and the dead, as black is still for the laity among us.

COLOURABLE title. See Title.

COLOURING, in Painting, one of the great component and essential parts of painting, is the art of giving to every object in a picture its true and proper hue, as it appears under all the various circumstances or combinations of light, middle-tint, and shadow; and of so blending and contrasting the colours, as to make each appear with the greatest advantage and beauty, at the same time that it contributes to the richness, the brilliancy, and the harmony of the whole.
It likewise possesses powers which, when judiciously applied, render it highly conducive to the character and expression of the subject represented.

A noble author, lord Lanfdowne, says, that verification is in poetry, what colouring is in painting, beautiful ornament, but the comparison is ill-founded. Verification is, indeed, an ornament; and so is colouring; but the former is necessarily the latter in the latter sense, necessary to the painter to enable him to make his imitation or representation complete. Should the most able painter in the world, says Mr. Webbe, attempt by that alone, a roe or grape, we should have but a faint and imperfect image; let him add to each its proper colours, we no longer doubt; we smell the rose, we touch the grape.

Colouring, like chiaro-scuro, may therefore be divided into kinds; that which is necessary for rendering the imitation just and intelligible, and that which is expedient or ornamental, as contributing to make the work at once more impressive to the imagination, and more harmonious and delightful to the eye. Truth in the local tints is alone required in the first kind; the second demands choice in their selection and distribution. For illustration, let us suppose the principal figure in a piece to be drest in sky-blue, and another figure near it, of lkea conflagrance in the story, to be represented in scarlet, with an under veilment of bright yellow, and let the light be made to strike equally on both: in such a case, it would be utterly impossible to give an effect agreeable or harmonious to the picture; although each of these objects should be painted with the utmost exactness and truth; nay, the combination, though found in nature itself, would excite feelings of difficulty and aversion: whereas, if the principal figure were drest in scarlet and white draperies, and the figure next it in blue of not too light or bold a tint, the effect would be harmonious and pleasing; and another point of great importance would be gained, as the eye would then be attracted by the principal figure, which could not have been the case in the former instance, where the gaudy combination of yellow and red must industriously, as is natural with all warm colours, have glorified the scene itself into notice. However, as the eye has the same intuitive abhorrence of harmonious combinations of colours, that the ear has of discordant sounds; it is, therefore, not surprising if we so seldom meet with enormities like the one above supposed, even in the works of the first artists who least of all can lay claim to the scientific arrangement of colours: to produce effects not harmonious, or disagreeable requires no great exertion of talent; but to perform all that can be done by the most skillful application of the various powers of the art is the lot of few.

In treating of chiaro-scuro, we have observed, that the part of it to which we have given the appellation of necessary or natural chiaro-scuro, was, in a greater or less degree understood and practised from the earliest period of the restoration of painting; the same was the case with respect to what we have termed necessary colouring, or truth in the local tints.

The oldest painters of Florence, Giotto, Buffalmace, and others; and still more, Simone Mammoli, Ambrogio Lorenzetti, and the rest of Siena-school of the same period, made frequently successful attempts at truth and even beauty in the tint of the flesh and other parts of their pictures; and figures produced a distribution of colours in no sense harmonious in the whole, though the prodigal style of gold grounds and gold ornaments bid defiance to an effect truly harmonious. Milpiero da Panicale, Mafaccio, Dominico Ghirlandajo, and Pietro Perugino, want much further, and we rarely find a want of delicacy of colouring in the parts of their pictures, or of harmony in the general effect. But this was not the result of a happy natural feeling for what was beautiful rather than of an approved and well-founded theory. It was not till the period when Leonardo da Vinci laid the foundation of an improved system of chiaroscuro, that the art of Venice began to revivify the beautiful effects resulting from the judicious combination or opposition of colours, at the same time that they attained a richness and truth in their local tints, far exceeding any thing hitherto practised. In both these qualities, however, they were soon far surpassed by their scholars, Georgione da Castel Franco, and Titian Vecelli, who, superadding to the most admirable richness of colour, the powerful light and shade of da Vinci, produced works in which, in their way, they have baffled all future attempts at improvement. The tone of colour of their pictures is not that of nature in her every day garb; it is ideal, like the chiaro-scuro of Coreggio or Rubens; that which may be supposed, but which, perhaps, is seldom or ever found in nature: the depth and mellowness of their tints can scarcely be accounted for but by the supposition of a tranquil but vigorous light shining through the heated atmosphere of a summer's evening. The world was astonished at this new style, and it is no wise suprising that Tintoretto, Paolo Veronese, and others who followed, being unable to do better, should attempt something different; the manly, the sober, temperamental dignity of Giorgione and Titian, was changed for magnificence, for show, for glitter, and for ornament; invention, composition, design, and expression, were all made subservient to the inordinate desire of effect of colour; the subject of the work could in many instances with difficulty be discovered, and their pictures may, in most cases, be compared to bewitching nonentities uttered by the silver tongue of the woman we love; to the sweet but fatal song of the Siren. There seems to be nothing in the colouring of Giorgione and Titian, incompatible with the greatest purity of design, sublimity of composition, or propriety of expression; but the splendid extravagances, the cased tints, the gaudy trappings of the more modern Venetians, are wholly inconsistent with true grandeur, and too frequently seem to remind the wretched effort of poverty to paragon opulence, or the disfuctions of the lacquey or courtier to cut the tinsel apparel the dignity of the nobleman, or the simple elegance of the woman of distinction.

While the two great founders of the Venetian school enraptured the eye by their transcendent and novel effects of colour, the Roman and Florentine painters, though principally applying their talents to the attainment of still higher objects, were not wholly unmindful of this part of the art. Many of the frescoes of Raphael in the Vatican, and in particular the dispute of the terracina, the St. Peter delivered out of prison, the mas of Bolsena, and the Hildoros, are fervently covered with the rich reds of Venetian tint, or with the pearly hue of Parme. However, from the latter works of this great master, it should appear that he did not at all times consider this branch of painting as worthy of his attentive regard. Fra Bartolomeo da San Marco, in his mandorla and apostle figure, aimed grandeur of design and breadth of chiaroscuro to a tone of colour at once dignified, tranquil, and harmonious; and Andrea del Sarto, except in some of his last works, where he in some degree adopted the gay and frivolous style then beginning to be in vogue, painted with a strength and sobriety of tint every way adopted to give increased interest and expression to the devotional or sacred subjects which he generally treated.
COLOURING.

At this period, as if nature then made holiday, and was prodigally lavish of her gifts, the great Coreggio appeared, and by his astonishing tricks in the cupolas, and other works at Parma, leamed to cast a new radiance on the world of art. In him the very soul of harmony reposed, and the magic of his pictures to infinitely intranced the eye, as to his renderings almost inescapable of discriminating, whether the astonishing effect is most the result of the breadth and softness of his chiaro-fucro, or the beautiful combinations and transitions of his colours. However, delicacy of tint seems to have been the aim of Coreggio; richness and luxuriance of colour that of the Venetians. And it has been observed of the great artist of Parma, that the flush in his pictures seems generally of too firm a texture, and to want that humid appearance, the result of inflexible transpiration, which forms one of the particular characteristics of human bodies, and which Titian and Giorgione succeeded so admirably in representing.

These are the great masters of colouring amongst the Italians. After this period a corrupt and frivolous style for some time predominated, and more particularly in the Roman and Florentine schools of painting. With them it was not uncommon to see yellow drapery shaded with purple, red ones with blue, or green with some other tint; as if it had been the intention to represent changeable flushes, and the eye seemed gradually to have become accustomed to the most unharmonious, the most gaudy and absurd combinations. Baroccio indeed made an effort to stem the torrent of this daltard taste. After having assiduously studied the works of Coreggio, he attempted to adopt his principle, and so far succeeded, that he deservedly has his admirers. But in the works of Baroccio, the red, the blue, and the yellow are too ostentatiously displayed, and want blending, which seems to justify the same critique on them that was made upon the works of Parrhasius, that his figures looked as if they had fed on roses.

The Venetian painters it is true, never entirely lost sight of the genuine principles of colouring; but even in this respect they fell far short of the great founders of their school above-mentioned, and the general frivolity of their taste, too frequently occasions even their merits to be passing by unregarded.

Coreggio had few followers; his divine spirit found not, like that of Donatello, a kindred place of abode amongst his successors; nevertheless, the Lombards preferred a certain richness and harmony of tint, which fluit in this particular, entitled them to a higher rank than their contemporaries of lower Italy. The Carracci, towards the latter part of the 16th century, rescued the art from the degeneracy into which it had fallen; and by uniting, as far as they were able, the different beauties of the Roman, Florentine, Lombard, and Venetian schools, produced a new style, and gave them to an academy eminent for the various talents which it called forth. Their colouring, however, is not so rich as the Venetian, nor so harmonious as that of Coreggio; but it is exempt from glaring defect, simple and tranquil, and well suited to the nobility and dignity of history painting.

Of Coreggio, their rival at Rome, it was hyperbolically said, that he dip't his pencil in flesh itself; but we have to regret that the black and opaque shadows which pervade his pictures, probably occasioned in some degree by the preferably nature of some colours which he used, destroy much of that truth of effect, which, from the Prefaces belloved on him in his life-time, we have grounds for supposing they originally possessed.

The pencil of Guercino is broad, and his tints fresh and vigorous, but his effect is generally more the result of chiaro-fucro than of any remarkably skillful arrangement of his colours.

The pictures of Guercino, in his first manner, possess considerable force of tint, but he afterwards abandoned this style of colouring, which he made of colouring weak and infipid; nevertheless, his grace, his knowledge of expression, and his unparalleled freedom of pencilling, gained him innumerable followers till at length, that which ought to have been considered one of his greatest faults, was numbered amongst his beauties. It is true, that shortly after this period, landscape was carried to the highest pitch of perfection by the Poullins, Salvator Rofa, and Claude Lorraine; the former giving to their pictures a style of colouring at once solemn and impressive, the latter a truth of aerial tint, never before or since attained. Nevertheless, a light and lively manner of colouring became one of the characteristics of the Italian schools, and the deferred daughter of Iris fought an asylum in the classic enemics of Flanders and Holland.

Amongst the Flemish painters, Rubens undoubtedly holds the first place; and his works, as Sir Joshua Reynolds observes, "have that peculiar property always attendant on genius, to attract attention, and enforce admiration, in spite of all their faults." This, however, is not the place for a general inquiry into his merits. With respect to his colouring, we have to observe, that it evinces that exuberance and boldness of genius, which in every other part of the art peculiarly characterises him. It possibles neither the sober richnes of Titian, nor the delicate harmony of Coreggio, but seems frequently, by the gorgous ammellation of tints, to vie with the gaiety of the charlet or ogrely. It is, however, a matter worthy of investigation, whether the great variety of colours, introduced by Rubens in the draperies and other parts of his pictures, has not, by the too great equality of their distribution, upon some occasions proved detrimental, rather than advantageous, to the richnes and splendour of effect, which at all times seems to have been his principal object; and whether that object would not have been more effectually attained, had he followed the preceedence of the early Venetians, in giving to two or three colours a more decided pre-eminence.

The style of Vandyke is more pure and chaste. The modest tendernes of his tints gently but irresistibly persuade; and his numerous portraits, by their deficyency and truth of expression, full captivate and interest the beholder, even where the perfomances they represent have been long buried in oblivion.

Rembrandt is, as Mr. Fuseli observes, a genius of the first clas in every thing which relates not to form; but though as a colourist he certainly holds a pre-eminent rank, the effect of his pictures is, perhaps, as we have said of Guercino, more the consequence of his altonishing chiaro-fucro, than of the frelhes of thehion and vigour of his tints. His works present not the gorgeous combinations of colour found in those of Rubens, or that liquid mellowness of tint in the flesh, so much admired in the pictures of Titian and Giorgione; nevertheless, they evince a most powerful conception of harmony, a beautiful gradation of tints, and great felociuity of tone. His lights have a brilliancy peculiarly his own; scarcely more owing to the powerful enpotation of his chiaro-fucro, than to the extraordinary method which he used of painting the luminous parts of his pictures with a very great body of colour in almost a dry mix; whilst his broad mades of shadow posses a magic transparency, making as it were darkneses visible.

It would be endless to enumerate the many admirable colourists of Flanders and Holland, who successively trod the
COLOURING.

footsteps of the great artists above-mentioned: indeed, there are few painters of those schools whose works may not be studied with advantage to this part of the art; the richness and harmony of their tints, the beauty and strength of their chiaroscuro, and the delicacy of their pencilling, comprise their chief excellence. Sir Joshua Reynolds, the great colourist of the last century, fully appreciated their merits; and by combining somewhat of their principle with the different styles of Titian and Coreggio, has succeeded in producing, in not a few instances, a richness and brilliancy of colour, inferior, perhaps, to neither, and, at the same time, different from all. Happy for his reputation, if from an inextinguishable desire of surpassing, he had not, in so many of his pictures, indulged himself in the use of colours and varnishes, which, like the more delicate blossoms of nature, are the earliest subject to decay.

We have been the more diffuse in our attempt to characterize the principal matters eminent for colouring, as we are aware that so little can be laid upon the preceptive part of this branch of art, which, more peculiarly than any other, seems to depend upon the delicacy and perfection of the organs of vision, and the nice discriminations of feeling and judgment. The great artist last-mentioned was perhaps the only colourist who ever wrote upon colouring, and we shall therefore have recourse to the effusion of his admirable discourse, in our attempt to give some idea of the leading principles of this part of the art.

It has already been observed, that chiaroscuro may exist in the greatest perfection, independently of colours; but colouring, without the aid of lights and shadows, would present us nothing more than the geographical chart or the harlequin's coat; and the study of it must therefore necessarily imply some previous knowledge of chiaroscuro.

In the commencement of the article we have, for the sake of distinction, divided colouring into two kinds: the necessary, and the expedient or ornamental: the necessary that which denotes truth in the local tints of the objects represented; the expedient or ornamental, that which is concerned in the distribution of the parts, and the harmony of the whole, depends. Although it might, upon first consideration, appear difficult to say, which of these two kinds or divisions of colouring requires the greatest exertion of talent; yet there seems little doubt but that examples of a very high degree of truth in the local tints in pictures, are more rarely met with than an equal measure of beauty in the general arrangement of the colours. To this truth of local tint, therefore, the utmost effort of the art should be directed; nature will be his best guide, and next to her the works of Giorgione, Titian, and Giacomo Daffano in figures, and those of Claude and some of the Dutch school in landscapes, and the other inferior departments of painting.

That species or division of colouring, which we have termed the expedient or ornamental, is of a very extended range, and may be compared to rhetoric, which gives additional lustre to truth, and enables the orator, even where proof is wanting, to support his argument upon fictitious Though falacious grounds. By a judicious opposition of one colour to another, the skilful painter is enabled to give to each an increased delicacy or an additional splendour; and by the same means a colour may be made to appear different from that which it really is; and thus a semblance of truth in the local tint may be frequently attained, even where that truth is in reality very far from existing. If the tint of the flesh be of too warm a hue, a yellow drapery placed next it, reiterates it to harmony; if too red, a crimson or a scarlet mantle takes away or diminishes the imperfection; if it appear cold, blue or purple opposed to it gives it a proportionable degree of warmth: and thus by contrasting one colour with another, the painter is enabled to give to each the degree of value he desires, according to his subject and the general effect of his work requires.

It was the custom of Rubens, when he wished to give brilliancy to the principal figures in his picture, to oppose to the flesh, a map of scarlet drapery, and another of pure white; by these means the tints of the solid parts acquired wonderful air of truth, at the same time that a splendid and harmonious effect was produced.

The balance of cold and warm colours in a picture seems to bear a strong affinity to the gradation or contrast of the chiaroscuro, and demands equal attention. "A certain quantity of cold colours," says Sir Joshua Reynolds, "is necessary to give value and lustre to the warm colours." He adds, "that the matter of light in a picture be always of a warm mellow colour, yellow, red, or a yellowish-white; and that the blue, the grey, or the green colours he kept almost entirely out of these masses, and be used only to support and set off these warm colours; and for this purpose a small proportion of cold colours will be sufficient." Let this conduct be reixed! continues this excellent writer, "let the light be cold, and the surrounding colours warm, as we often see in the works of the Roman and Florentine painters, and it will be out of the power of art, even in the hands of Rubens or Titian to make a picture splendid and harmonious. The illuminated parts of objects are in nature of a warmer tint than those that are in the shade: what I have recommended therefore is no more than that the same conduct be observed in the whole, which is acknowledged to be necessary in every individual part. It is presented to the eye the same effect as that which it has been accustomed to feel, which in this case, as in every other, will always produce beauty; no principle therefore in our art can be more certain, or is derived from a higher source."

We have treated of the doctrine of reflections in our observations on chiaroscuro; (see Clair, Obscur) it is proper, however, in this place to observe, that the body which receives a reflected light, receives, together with that light, somewhat of the colour of the object which gives the reflection, and this, in proportion to the strength of light on the body reflecting, and the vicinity of such body to that receiving the reflection. The skilful management of reflections is so inextinguishable a part of colouring, that it cannot employ too great a share of the student's attention; an excellent insight into the principles of it will be afforded him by the works of Rubens and Jordaens; and perhaps the least of the subjects having marked the reflections in their pictures with precision and distinctness, perhaps even beyond what is warranted by the appearances of nature herself.

With respect to the application of colouring, it should always be remembered, that like the other parts of the art, it is of a nature powerfully to contribute to the sentiment and expression of a picture; when the style adopted is in strict conformity with the character of the subject represented. This conformity is therefore the first thing to be considered. If the subject is awful or melancholy, a grave sombre tone of colour will be appropriate; if gay or magnificent, the most brilliant and gorgeous tints may be freely used. The dark hue given by Michelagnolo Buonarroti to his celebrated group in the boat, in the last judgment, with the cold light behind it, renders it perhaps not less a masterpiece of colour, than the Venus and Adonis of Titian, or the sleeping Nymphs of Rubens.
The following remarks of the author before cited seem highly applicable to the present purpose. "To give a general air of grandeur at first view, all trifling or artful play of little lights, or an attention to a variety of tints is to be avoided; a quietness and simplicity must reign over the whole work; to which a breadth of uniform and simple colour will very much contribute. Grandeur of effect is produced by two different ways, which seem entirely opposed to each other. One is, by reducing the colours to little more than chiaro-furo, which was often the practice of the Bolognian school; and the other, by making the colours very distinct and forcible, such as we see in those of Rome and Florence, but still the prevailing principle of both those manners is simplicity. Certainly nothing can be more simple than monotony; and the distinct blue, red, and yellow colours which are seen in the draperies of the Roman and Florentine schools, though they have not that kind of harmony which is produced by a variety of broken and transparent colours, have that effect of grandeur which was intended. Perhaps these distinct colours strike the mind more forcibly, from their not being any great union between them; as mortal music, which is intended to rouse the nobler passions, has its effect from the sudden and strongly marked transitions from one note to another, which that style of music requires; whilst in that which is intended to move the softer passions, the notes imperceptibly melt into one another."

It is not our intention here to detail the various modes adopted by artists in mixing their colours and varnishes, or the modes of preparing the different kinds of grounds used for painting on. Every school, and, more or less, every individual differs in his practice from another; and works of so high a class have been produced by each of these different methods, that we must conclude them all to be right, when rightly applied. However, in one point, the best colourists seem to agree, that the light parts of a picture should be painted with a strong body of colour, and the shadows with as much transparency as possible; and this is the more natural as well as the safest mode of procedure, as all the light colours, and particularly white, are opaque; whereas all the dark colours are in a greater or less degree transparent.

**Colouring of Glass.** See Glass.

**Colouring of Earthenware.** See Glazing.

**Colouring Matter.** For general account of the nature of colouring matter, see Dyeing, the art of; for the principal colouring materials, such as cochineal, indigo, madder, &c. see these articles respectively.

**Colouring of Porcelain.** See Porcelain.

**Colouring of Spirits.** See Spirits.

**COLPE.** In Ancient Geography, a town of Alia Minor, built, according to Pliny, in the place of Archopolis.

**COLPEDI, or COLPETI,** a people of Thrace, who inhabited the environs of Ænum. Steph. Byz.

**COLPISCH.** A name given by some to the fals Venetorum, or sickle-fish, commonly called the marmot fish by the people of Venice. See Falx.

**COLPODA.** In Zoology, a genus of animals (vermes infusoria) distinguished by being of a simple form, pellicid, flat, and finuate.

These worms are invisible to the naked eye. They have been discovered and examined, chiefly by Müller, Adams, Joblot, and other curious writers, whose attention has been particularly devoted to microscopical investigations. Of the genus colpoda, seven species only appear to be described.

**LAMELLA.** Elagated, membranaceous, and bent on the anterior part.

This resembles a long, narrow, pellicid membrane, which is narrower and obtuse behind, curved towards the upper part, and has a ridge or fold pelling through the middle. It is found in water, and when it moves is observed to proceed on the edge instead of flat surface. Found in common water.

**ROSTRUM.** O'long, and hooked on the anterior part. Discovered in water more pure than the former. The posterior part of this species is obtuse, and one of the edges from the top to the middle is dilated, thick, and apparently triangular.

**MELEAGRIS.** Changeable, with the anterior part hooked, and the posterior folded up.

Lives in water impregnated with vegetables, and is of a variable form, the anterior part clear, the posterior full of molecules, with the margin luminous.

**CUCULUS.** Oval, ventricose, with an incision beneath the tip.

Generally oval, and containing from eight to twenty-four bright molecules, the margin irregular. Common in a variety of vegetable infusions.

**REN.** Thick, and minutie in the middle.

Described by Jolot, who discovered it in the infusions of hay. The form is slightly kidney-shaped, of a yellow colour, opaque, and filled with molecules.

**PYRAM.** Convex, oval, the tip produced into a beak. The body is transparent, of a pale colour, and filled with molecules.

**HIPPOCREPS.** Thick, narrow in the middle, feblunus, and greenish. Found in flagmant meadow water.

**COPUSA.** In Ancient Geography, one of the ancient names of Chalcedon, according to Pliny.

**COSLA.** A town of Asia, placed by Ptolemy in Armenia.

**COSLIR.** In Geography, a town of Asia, in the country of Thibet; 50 miles N.E. of Harachar-Hiun.

**COLT.** In Zoology. See FOAL and HORSE.

**COLT'S foot.** In Botany. See Tussilago Farfara.

**Colt's foot.** Alpine. See Cacalia Potosif.

**CATHENA.** In Ancient Geography, placed by Ptolemy near the Araxes, and N. of Sidonians.

**COLTIE, among the Timber Merchants, a word used to express a tree which has a defect in some one of its annual circles, which renders it unfit for many of the uses it might have been otherwise fit for. In this case some one of the annual circles near the centre is perceived by the eye to be thicker than the rest, and its sap vessels larger. It has an appearance much different from that of the others, and is so loosely connected both to its involucrum, and invested circles, that, on faying a transverse piece of the trunk off, it will split off from the others, and to leave the heart loose, and the rest hollow, seeming to have been only fitt'd, not connected, to the others. In splitting the wood for other uses, it yet more readily drops out, and the timber of such a tree is therefore much less fit for general use than that of others. It is not easy to say to what accident, in the growth of the tree, this is owing, but it seems probable that it exposes the tree to other accidents; in particular Bobart seems to think, that among the trees which were split by the hard froiz, in the year 1687, while other trees of the like sizes and kinds escaped, this coltins might be the occasion of the mistaken, as well as of their being wind-shaken, or lagged. Philos. Trans. No 165.

**COLUMBIA.** In Ancient Geography, a people of India, placed by Ptolemy on the other side of the Ganges, and near to it.

**COLUMBA, in Zoology, a genus of serpents distingui

...shed
guised by having plates on the belly, and scales on the under parts of the tail.

The species of this genus are numerous. Linnaeus describes, upon the testimony of various writers, above ninety; and that number even has been considerably augmented by naturalists since his time. The species differ greatly in size and habit; some, as the vipers having the head large, flat-tish, and ferr-concorded, with the body and tail of a moderate length, or rather short; while others, as the greater part of the harmless serpents, have small heads, with the body and tail much longer in proportion. In some, exclusive of the usual scales under the tail, are a few feeta or unbrided lamelle, either at the beginning or towards the tip of the tail. The best works on this tribe of reptiles are "Synopsis methodica animalium Quadrupedum et Serpentium generis," of Ray; "Synopsis Reptilium," &c. of Laurenti; and those of Seba and Catesby. The observations of Boddaert, "Specimen novæ methodi distinguishendi Serpantia," Nov. Acc. Acad. Nat. Cur.; and "Betriebsfrendere Schlangen," &c. of Wiegel. The papers of Mr. Ellis, and another by Dr. Gray in the Philosophical Transactions, relative to venomous serpents, are also interesting. Several of those described by Count La Cepede deserve particular attention. Professor Pallis mentions some new kinds observed in Ruflia and Siberia; others are mentioned by Linnæus, and a number of the viper tribe occur in the "Historia of the Indian Serpents," published by the late Dr. Russell.

Linnaeus considered the number of abdominal plates and scales under the tail as a characteristic distinction of the different species of this genus; such, however, is the incongruity of this criterion that, in describing the same species, fearlessly two writers agree. Characters taken from the number of those plates and scales in the serpentine tribe, like those from the number of rays in the fins of fishes, are not to be relied upon. The colours are liable to some variation; but the peculiar form and disposition of the spots, lines, and other markings, afford, in general, a character by which the different species may be distinguished.

Species.

**Vipera.** Somewhat ferruginous; spotted with brown; beneath whitish; tail short and mucronated.

This is the common viper of Egypt. Haf- feh, who appears to have first described the species with accuracy, informs us, that it is imported in considerable quantities every year to Venice for the use of the apothecaries. Its size is somewhat smaller than that of the common viper; the head not so flat on the top, but very protrubent on each side; front very obtuse. The body is thick towards the middle, and somewhat quadrangular; but thin, and cylin- dric towards the head and tail, which is short, slender, conical, and terminated by a slightly incurved horn point or tip. The scales on the upper parts are oval and carinated. Haf- feh succinctly describes this species as being about two spans in length, exclusive of the tail, which measures only an inch. It is supposed by some to be the aip, by the bite of which the celebrated Chopratra determined rather to die than submit to be carried captive to Rome, to grace the triumph of Augustus. Mr. Bruce, on the contrary, considers the Crotalus to be the species employed on that momentous occasion. Schneider is of opinion, that the Egyptian viper (C. vipers) must be the true *Aphis* of the ancients, a reptile which was popularly reported to kill by occasioning the most excruciating thirst.

**Variegatus.** Above chestnut, variegated with grey and white; beneath, and on the sides, pale yellow. *Aphis variegatus, Laur. Amph. Seba, &c.*

Considered as a native of America, and resembles the last.

A native of America, and is probably only a variety of C. vipers.

**Intestinalis.** Body equal, slender, with a lateral and longitudinal dorsal line, the last furred near the eyes. Laur. Amph. Seba.

Inhabits Africa, and like the former is perhaps merely a variety of C. vipers.

This is the common English viper, and which is not only frequent in this country, but appears to be generally distributed over the rest of Europe, and some parts of Asia. If the varieties, described by Gmelin, are of the same species, it extends also as far as India. The variety of this author has the spots on the top of the head roundish, and somewhat confluent or running into a stripe; those near the tail transverse. This inhabits India. 3. Reddish with the head variegated; neck slender. A native of St. Eliface. 6. The arch of the hind head intercepting a white spot. Inhabits India. 1. Spot on the head multipartite. Inhabits the Celebes. The whole of these varieties are described and figured in the works of Seba.

Though the viper varies considerably in colour from a pale cinereous or yellowish ferruginous to deep or dull brown, the varieties agree in being marked with a continued series of confluent rhomboid blackish spots, extending from the head to the tail. The head is broad, and somewhat flattened, and more or less protuberant on each side at the back part; the front of the head is blackish, and on the upper part is a large divided and somewhat heart-shaped spot, the obverse divisions of which are directed backwards; the lips are somewhat barred or variegated with black and light grey, and along each side of the body runs a row of roundish subtriagonal dusky spots, continuing to the end of the tail. The scales on the upper part of the body are carinated, the under parts of a blackish colour, with a bluish gloss somewhat resembling that of polished steel. The general length of the viper is from eighteen inches to two feet, and it is ascertained by some writers to grow even to the length of three feet. The fangs of the viper, like those of other poisonous serpents, are situated on each side the fore part of the upper jaw, and are generally two in number, with a few smaller ones situated behind. The poison, as usual, lies in a receptacle at the base of the fangs, and being perforated, when the animal bites, the compression of those receptacles forces out a drop of the poisonous fluid, which prising through the aperture of the fangs is immediately inhaled into the wound. The tongue is forked, and being soft and flexible is susceptible of great extension; it may be perhaps superfluous to add that this tongue is altogether incapable of inflicting any wound, or injecting poison, as some ancient writers credulously affirm; it may affix the animal in the capture of its infect prey. The French naturalists are inclined to believe it is intended by nature to supply some detect of transpiration in the skin. Hitherto the viper has been considered the most poisonous of
of the European serpents, and many instances are recorded of the fatal effects resulting from its bite. That the bite of this serpent is always protracted of pain and temporary inflammation in the parts bitten is very evident; sometimes also the symptoms may become alarming, or, in a few instances, through neglect or injudicious treatment of the wound, may even prove fatal; but upon the whole the bite of this creature does not appear pregnant with all those dangers which the terrene and prejudices of the vulgar lead them to suppose. In England the bite of the viper is rarely attended with fatal consequences. Fontana seems to doubt whether any well attested instance can be adduced of the viper having killed any person by its bite, even in the warm climate of Italy. The testimonies of authors, both as to the nature of the poison itself, and its effects on the animal frame are, however, confessedly at variance. According to Dr. Mead, and his associates in the experiment, the poison of the viper, diluted with a little warm water, proved sharp and fiery when taken with the tip of the tongue, as if the tongue had been struck through with something scalding or burning. This sensation went off in two or three hours; but one gentleman, who would not be satisfied without trying a large drop undiluted, the animal and drink, found his face swelled with a slight inflammation; and the forenoon lasted two days. On the contrary, abbe Fontana and some others describe it as of no particular acrimony of taste, but rather resembling oil or gum, and Dr. Ruffell, in his work on Indian serpents, affirms the same even of the poison of the cobra de capello. Barthaeva is of opinion that the poison of the viper may be taken into the stomach without danger, and quotes the case of Jacob Sozzi, who, at the court of the duke of Tuscany, is said to have swallowed three drams of this poison without experiencing any ill effects. This poison, says Barthaeva, is rendered inactive by digestion in the stomach and bowels, so that it will not afterwards exert its fatal effects upon the blood; for a whole ounce of the venom taken by the mouth will not kill an animal, when, at the same time, a small needle only, dipped in the same fluid, taking up perhaps no more than a hundredth part of a drop, and then thrust into the blood of the living animal, almost infallibly kills. Fontana, on the contrary, affirms, that though the poison of the viper administered internally may not produce the same violent symptoms as the bite, that it cannot be taken with impunity. The opinion, pretty generally entertained among the ancients, seems to be in favour of the assertions of Barthaeva.

The symptoms which follow the bite of the viper (according to Dr. Mead) when it falls on one or both of the greater teeth or fangs in any part of the body, is an acute pain in the part wounded, with a swelling at first red, but afterwards livid, which, by degrees, spreads further to the neighbouring parts, and occasions great pain, and a quick, though low and sometimes interrupted pulse; great sickness at the stomach, with bilious, convulsive vomitings, cold sweats, and sometimes pain about the navels; and if the cure be not speedy, death itself, unless the strength of nature prove sufficient to overcome those disorders: and though it does, the swelling still continues inflamed for some time; nay, in some cases, more considerably upon the abating of the other symptoms than at the beginning; and often from the small wound runs a fangious liquor, and little pustules are raised about it; the colour of the whole skin, in less than an hour, is changed yellow, as if the patient had the jaundice. These mischiefs (although different climates, feaons of the year more or less hot, the greater or less rage of the viper, the animal itself being of a larger or smaller size, and consequently able to communicate more or less venom, the wound made deeper, in a part more nervous or tendinous, and therefore receiving more of the poiforous liquor, and the like circumstances may vary the heighten or abate them) yet usually dexter themselves much after the same manner in all; yule's the bite happen not to be accompanied with the effluvium of that liquor, which is the main instrument and cause of this violent and shocking disturbance." Dr. Mead caus'd several animals, as dogs, cats, and pigeons to be bitten by an enraged viper, which animals generally died, some in a longer and others in a shorter space of time; but it was observed that, immediately after the bite, they all exhibited signs of acute pain as if affected with rickards, painterings, and convolutions. The venomous properties of the poiforous fluid of the viper is not destroyed even by the death of the animal, as was proved by Dr. Mead; he took the head of a large viper that lay three hours after it was cut off, and was perfectly plac'd and without motion, and wound a pigeon on the thigh by the fangs of the head; the bird presently became convulsed, and died seven hours after. The Scythians, as Pliny relates, must have been aware that the poison of the viper would retain its venomous properties after being taken from the animal and dried; for they were accustomed to dip their arrows into its poison; this they previously prepared by mixing it with human blood.

From the following experiment it would seem that no very material difference takes place in the appearance of an animal killed by the bite of the viper, than if its death were occasioned by any other cause. To ascertain this fact, a viper, being enraged by the members of the Tufcane academy, and then suffered to bite the nose of a strong bull, the animal expired in a short time, and being opened by the most expert anatomists, no uncommon alteration could be perceived either in the solid or fluid parts of the beast.

The viper, though so much dreaded on account of its bite has been very highly esteemed both by the ancients and moderns as a retorizare and strengthening diet. The ancients used the flesh of this snake in lapis and other cales. The Greek physician Ctesorus, cured, as Porphyrius relates, a miserable slave, whose skin, in a strange manner, fell off from his bones, by advising him to feed on viper's flesh in the manner of lin. Galen says, that those afflicted with elephantiasis are wonderfully relieved by eating viper's flesh dried like eels, and relishes very remarkable cures of this disease performed by means of viper wine. In France and Italy, the broth, jelly, and flesh of vipers is in much esteem as a restorative medicine. In England we have to induce the well known circumstance of Sir Kenelm Digby, who caused his wife Lady Veneta to feed on eels, and vipers to recover her from a consumption. According to Dr. Lewis, the dried flesh of the vipers piffles none of the nutritious properties of the recent animal, and is totally insignificant. A volatile salt was formerly drawn from vipers and sold at a great price as a sovereign remedy against the bites of vipers, and other venomous animals, but it is now found not to be materially different from the volatile alkaline salts procured by chilling other animal substances.

The viper abounds most in dry, rocky, and chalky countries, or in the low herbage or underwood in thickets. It eats its skin twice in the year, namely, in spring and autumn, and is laid to attain its full size at the age of six or seven years, but are capable of engendering when two or three years old. They copulate in May, and go about three months with young. "The viper (I. v. Mr. White) is viviparous, producing its young towards the close of summer. On the 4th of Aug. 1752, we furnished a large
a large female viper, which seemed very heavy and bloated as it lay on the grass, basking in the sun. When we came to cut it up, we found that the abdomen was crowded with young, fifteen in number; the shortest of which measured full seven inches, and were about the size of full grown earth worms. This little fry shone into the world with the true viper spirit about them, flowing great streams as soon as disencaged from the belly of the dam; they tore and wriggled about, and let themselves up, and were very wide, when touched with a bick, flowing numerous jets of menaces and disdain, though as yet they had no manner of fangs that we could find, even with the help of our glasses. 1 The man in Mr. White's female viper was oviparous, which had in it a chain of eleven eggs, about the size of those of a black bird, but not so far advanced as to show the rudiments of the young. Several intelligent folks (adds Mr. White) assure me that they have seen the viper open her mouth, and admit her hebebs young down her throat on sudden surprizes, just as the opilion does her brood into the pouch under her belly upon the like emergencies; and yet the London viper catchers inful on it to Mr. Barringer that no such thing ever happens. Sir Thomas Brown feels inclined to believe this circumstance: the young, he observes, (supposed to break through the belly of the dam, will, upon any fright, for protection, run into it; for then the old one receives them into her mouth, which way, the fright being past, they will return again, which is a peculiar way of refuge, and although it seems strange is avoided by frequent experience and undeniable testimony. The fame is opposed by some other writers of no mean repectability.

The enemies of the viper are numerous, the herons in particular destroy vast numbers. Their prey consists of frogs, toads, lizards, mice, and various small quadrupeds. The viper is capable of supporting a very long abstinence; it being known that some have been kept in a box without food for six months, and yet did not abate of their vigour. They feed only for a short period annually, and as a viper has been known to be a whole month devouring and digesting a frog or toad, two such meals would be sufficient to support it for a twelve month. It is remarked, that they never eat during confinement, for if mice, their favourite food be thrown into their box, though they will kill they never eat them. The violence of their poison decreases in proportion to the length of their confinement. Vipers, when at liberty, remain torpid throughout the winter, but when confined have never been known to take their annual repose. The best method of catching them is by putting a cleft stick on or near the head, then laying them by the tail, and instantly dropping them into a bag. The viper catchers are frequently bit, but it is seldom the wound proves fatal: oil of olive, or cod liver oil, is said to be the most effectual remedy. M. Sonnini seems fully satisfied of the efficacy of eau de luce as an antidote to the poison of vipers as well as other venomous serpents, the good effects of which he tells us he has experienced on several occasions, and particularly at Guiama, where snakes are equal in number and formidable. In his travels through Greece and Turkey, M. Sonnini mentions an instance of a child he saw at Sisifour, three or four hours after it had been bitten by a viper or venomous snake, in the small of the leg. Both the leg and foot were much swollen, very hard, and of a blueish colour: the child suffered great pain, the wound no longer appeared, and the place was not distinguished but by a larger swelling, and by pains more acute, which were occasioned by touching it. He made the child swallow a few drops of eau de luce in half a glass of wine, and after some scarifications on the part bitten applied to it, a compress, steeped in this same water, which is known to be composed of volatile alkali and oil of amber. The result of this treatment was, that four hours after, the swelling was considerably diminished; the child no longer felt any pain; it became tranquil; the compress of eau de luce was removed, and the child left in a fair state for recovery. The true application is recommended by Sonnini in all his places; he observes, that the swelling of the wounded part is rapidly diminished, and the pain entirely removed in two hours: but the eau de luce must be taken internally, according to this writer, as well as applied to the wound externally, in order to proct the desired effect. The remedy which the Greeks commonly employ for curing the bite of snakes, as 3 smaller olives, boiled in cataplasms of excellent plants, calculated to promote suppuration. Now there is reckoned among them to poisons, particularly, a species virtue against this sort of venon. But this treatment, he adds, is very long; it frequently lasts two months, and never leaves the person; whether it is always successful, and do not nearly carry off the patient from the torments which this mode of treatment causes him to feel.

This is the black viper of English authors, and which so completely resembles the common viper in every particular, except the colour, that we are strongly inclined to admit it as a mere variety of that species. The black viper of Austria appears from a series of experiments made by Laurenti to be innocuous, since pigeons and chickens exposed to its bite were not otherwise injured than by mere puncture without suffering any symptoms of poison, but it is not entirely certain that the kind determined by Laurenti is of the same species as the black viper generally found in Europe, and which is almost universally allowed to be as poisonous as the common viper.

This is the common vipera, but of a much thicker skin, and entirely of a milky black colour; it is venomous in its nature, and, when irritated, exudes the venom which is naturally kept in a large black sac, and threatening at the same time with a horrid hiss: the fangs are large, and the animal is said to be as dangerous as the rattle snake.

It is a native of Carolina, inhabiting chiefly the higher grounds.

CRESSEA. Daily-bay, with black flexures dorsal hard, and the head oval, and whitish beneath. Coluber durfa, abdominal tests 150, subcaudal scale 34. Linna.

Habits the woody parts of Sweden, and is said to be most frequent in the province of Smaland, where it is greatly dreaded by the inhabitants, who consider its bite as mortal, unless the part bitten be immediately cut out. In the "Memoirs of the Swedish Academy" is an account of a young man, a labourer, hit by this animal on the toe of the left foot. In the space of six hours, the whole leg and thigh were red and swelled; the pulse intermittent, and the patient was oppressed with pains in the head and bowels. The first day the patient drank a glass of the juice expressed from ash leaves mixed with wine every half hour, and had besides a caraplain of the bruised leaves applied
to the wound; in the evening also, he took a glass of warm olive oil. By these means the patient was greatly relieved, slept well during the night, and found the swelling much reduced by the next morning; but neglecting to repeat the remedies the third symptoms returned, and were again diffused by the same applications, and in two or three days the patient recovered. Linneus attempted to cure a woman wounded by the bite of a viper of the kind by means of olive oil, but his endeavours were uneffectual, and his patient died.

The cobra eberiæa resembles the common viper, but still more to the common adder, though inferior in size, not often exceeding a foot in length. The colour is a dusky rufous brown, with a flaxen dextral band of a deeper colour; the head vernal, of a pale colour, and marked with a heart-shaped dusky spot, the divisions of which are directed backwards, and the body is round.

Scytha. Deep black above, beneath milk white, and polished. Coluber fyslb, abdominal fecca 153, subcu baud. Ams. 31. Palus L. Inhabits woods in the mountainous parts of Siberia, where it was observed by Dr. Pallus. This species is not esteemed very poisonous, and is of a small size, seldom exceeding nine inches in length, or the thickness of a finger; the head is somewhat heart-shaped.

Red. Head imbricated with very minute scales; body ferruginous, with a quadruple transverse dorsal series of short brown streaks. Coluber redi, abdominal fecca 153, subcu baud. Ams. 31. Palus L. fell; till one of the people who brought them to us, came near him, and though in a very disadvantageous posture, flicking, as it were, perpendicular to the side of the box, he leaped near the distance of three feet, and fastened between the man's forefinger and thumb, so as to bring the blood. The man showed no sign of either pain or fear, and Mr. Bruce and his party kept him with them full four hours without his applying any sort of remedy, or seeming inclined to do so. To make himself assured that the animal was in its perfect state, Mr. Bruce made the man hold the cerastes by the neck, so as to force him to open his mouth, and lacerate the thigh of a pelican, a bird he had tamed as large as a fawn. The bird died in about thirteen minutes, though it was apparently affected in about fifteen seconds, and this even can scarce be considered as a fair trial, because a few minutes before it had bit the man, and so discharged part of its venom, and it was made to scratch the pelican by force, without any irritation or action of its own.

It appears not only on the testimony of the above circumstances, but on the relations of travellers in general of the greatest respectability, that the natives of the countries inflected by the cerastes, have a method of charming, or rather stupefying these and other serpents to prevent their biting, or to render their bite innocuous, however irritated the animal may be. Some pretend to posses preternatural powers over these reptiles, while others say, they have certain preparations with which they anoint themselves to obviate the fatal consequences of their bite, and which is never ineffectually employed. Mr. Bruce speaks at some length on this interesting topic "a long dissertation (lays this writer,) would remain on the incantation of serpents. There is no doubt of its reality, the scriptures are full of it, all that have been in Egypt have seen as many different instances as they chose. Some have doubted that it was a trick, and that the animals so handled, had been first trained and then disarmed of their power of hurting; and, fond of their discovery, they have ruffled themselves upon it without experiment, in the face of all antiquity. But I will not hesitate to aver that I have seen at Cairo, (and this may be seen daily without trouble or expense) a man who came from above the catacombs, where the pits of the mummy birds are kept, who has taken a cerastes with his naked hand, from a number of others lying at the bottom of the tub, has put it upon his bare head, covered it with the common red cap he wears, then taken it out, put it in his breast and tied it about his neck like a necklace; after which it has been applied to a hen and bit it, which has died in a few minutes; and, to complete the experiment, the man has taken it by the neck, and beginning at the tail has ate it as one would do a carrot, or flock of celery, without any seeming repugnance."

"We know from history, that where any country has been remarkably inflected with serpents, there the people have been circumcised by this secret. The Phylli and Marma-rides of old, undoubtedly were defended in this manner."

"Ad quorum cantus mitis jacuer e caralcte."

SIL. ITAL. LIB. III.

"To leave ancient history, I can myself avouch, that all the black people in the kingdom of Senaara, whether Fungee, or Nuba, are perfectly armed against the bite of either scorpion or viper. They take the cerastes in their hands at all times, put them in their bosoms, and throw them at one another, as children do apples or balls, without having irritated them by this usage so much as to bite. The Arabs have this secret naturally, but from their infancy they acquire an exemption from the mortal consequences attending the bite of these animals, by chewing a certain root and washing themselves, (it is not naming) with an infusion of certain plants, in water. One day when I was sitting with the brother of Sheik Adelsin, prime-minister of Senaara, a slave of his brought in a cerastes, which he had just taken out of a hole, and was using with every sort of familiarity; I told him my suspicion that the teeth had been drawn, but he assured me they were not, as did his master, Kition, who took it from him, wound it round his arm, and, at my desire, ordered the servant to carry it home with me. I took a chicken by the neck and made it flutter before him, his feeming indifference left him, and he bit it with signs of anger, the chicken died almost immediately;—I find his seeming indifference, for I constantly observed that however lively the viper was before, yet, upon being feized by any of these barbarians, he seemed as if taken with fickness and feebleness, frequently flutt his eyes, and never turned his mouth towards the arm of the person who held him. I asked Kition how they came to be exempted from this mischiefs? He said they were born so, and so paid the grave and respectable men among them. Many of the lighter and lower sort talked of enchantments by words and by writing, but they all knew how to prepare any poison by medicines, which were decoctions of herbs and roots. I have seen many thus armed for a reason, do pretty much the same feats as those who possefs the exemption naturally; the drugs were given me, and I several times armed myself, as I thought, resolute to try the experiment; but my heart always failed me when I came to the trial; because, among those wretched people, it was a pretence that they might very probably have sheltered themselves under that I was a Christian, and that it had no effect upon me. I have still remaining by me a small quantity of this root, but never had an opportunity of trying the experiment."

Among the writers of antiquity we find abundant mention of the Pithili, or serpent-east; men who pretended to possess the inherent power of charming serpents, and de-ouering them without danger. Lucan speaks of the practice of the Pithili, or African tribes, and informs us they were employed by Cato to attend his expedition through the Lybian deserts, for the recovery of his soldiers bitten by serpents. Strabo tells us the Pithili, or men of Crene, possefs a secret antidote against the poison of those reptiles. It appears equally certain that there are tribes of men in the East, who, to this day practice the same arts. Savary relates that when at Rofetta, he was present at the festival of Sidi Ibrahim, in which the rear of a procession composed of the different tribes, and chiefs, or priests of the country, bearing the standard of Mahomet, was brought up by a troop of these modern Pithili. These men, says Savary appeared frantic, with naked arms, their eyes wild, and enormous serpents in their hands, which twined round their bodies and endeavoured to escape. They feized the serpents forcibly by the neck, avoided their bite, and, regardless of their bites, tore them with their teeth and eat them alive, while the blood flowed from their defiled mouths; other Pithili struggled with them to free away their prey, for the contention was who should devour a living serpent!—The astonished populace followed, and cried—a miracle!

The remarks of Sonnini, one of the last writers on this subject, may not prove uninteresting in conclusion. "The East," says he, was at all times the country of magicians, men boasting to have the power of charming serpents, of braving their bite, and their venom, of rendering them docile to their voice; they formerly existed there under the name of Pithili, and there are still to be found, people who pretend
pretend to have inherited their secrets. I knew one of those
vered in this kind of fascination; he was certainly the most
ignorant, and most foolish of the Greeks; his secret con-
filled chiefly in thirteen words, which it was necessary to
pronounce in fight of the serpents. He told me also, that, in
order to guard against the bite of these reptiles, it was
necessary to try to take one alive with the precaution of
feizing it strongly by the neck so as to prevent it from biting,
and not to concern myself about the body and tail,
the twirlings of which lightly squeeze the arm. You
must then flip round its neck a running knot made with
coarse thread, and draw it tight by degrees till the
animal is strangled. When it is on the point of dying,
you open it and take out its fat, with which you rub
your hands; then put my modern Pyllius to me, you
have nothing more to fear from the bite of every species
of serpent."

The figure of ceraflas, occurs frequently among the
hieroglyphic characters inferred upon remains of Egyptian
antiquity.

Nasicornis. Somewhat oblivious yellowish, va-
rigated with black; flexuous, lateral band pale, and two
horns on the front. Coluber nasicornis, horn-noc

This remarkable snake was first described by Dr. Shaw in
the Naturalist's Miscellany. The most striking peculiarity of
his species are the two large sharp pointed horns, situated
on the top of the nose, or anterior part of the upper jaw.
These horns stand nearly upright, but incline slightly back-
wards, and a little outwards on each side, and are of a fab-
flane somewhat flexible; their shape is rather triangular.
The length of those horns is about half an inch, and at the
base of each stands an upright strong scale, of nearly the
same shape with the horn itself, and thus giving the ap-
pearance of a much smaller pair of horns. The mouth is fur-
nished with extremely large and long fangs, or poisonous
teeth, two of which appear on each side of the mouth; the
hinder pair being smaller. The length of this animal is about
thirty-five inches. Its colour is yellowish, olive-brown,
very thickly sprinkled all over with minute blackish specks.
Along the whole length of the back, extends a series of yellowish-brown oblong spots, or marks, each of which is
imbedded in a patch of black; and on each side of the body
from head to tail runs an acutely flexuous, or zig-zag line,
or narrow band of an ochre colour, which is bounded be-
neath by a much deeper or blacker shade, than on the re-
mainder of the body. The belly is a dull ochre colour or cinctures
yellow, flecked with blackish spots and markings, and
besides these a number of black spots of various sizes are
sparsely dispersed over the whole animal; the tail is some-
what thin and short in proportion to the body. The scales
are hard, stiff and strongly carinated, the head is covered
with small scales, and is marked on the upper-part by a
longitudinal patch of brown, running out into pointed pro-
ceffes at the sides, and bounded by a space of dull lead
colour or cinctures. The shape of the head is broad and
flattened, the checks varied with black and yellow marks.
The horned snake is supposed to be a native of the interior
parts of Africa. The specimens above described, was ob-
tained from the matter of a Guinea vessel by the Rev.
Edward Charles Jenkins of Charleston in South Caro-
olina.

Aspis. Nofe terminated by an erect wart; body rufous,
with alternate, roundish, dulky, distinct, and confluent spots;
beneath fleec blue dotted with yellow. Coluber apsis,
abdominal scuta 146, subcaudal scales 46. Gmel. 146—34,
p. 106. n. 219.

Considered by some as a variety of coluber berus; it is a
native of Dauphiny, Lyons, and Poitiers. Cepede de-
scribes a snake that inhabits the northern parts of France
under the name of L'Afpe, but which, according to La-
treille, is not the true coluber alpis of Linneus, as its
name may imply. This kind, Cepede informs us, is about three
feet in length, of which the tail measures three inches
and eight lines. The head is rather large, and covered
with small carinated scales, the body larger, of similar
structure, the colour, pale rufous grey, and along the upper parts
are three longitudinal ranges, of roundish dark rufous spots,
bordered with black, and which unite or become confluent
near the tail, and thus exhibits the appearance of a zig-zag
band, similar to that of the common viper. The under-
parts of this snake, are of a dulky colour, marbled with dull
yellow; its fangs resembfe those of the common viper, and
it is reputed equally poisonous with that species. We in-
troduce this snake under the species alpis, conceiving it may
be hereafter ascertained to be of the same individual species,
although writers are not agreed on this point at pre-
sent.

Ammodotes. Brown or pale blueish, with a dentated
black dorsal band; nofe terminated by an erect wart.
Coluber ammodotes, abdominal scuta 142 21, subcaudal scales

Inhabits the Ealf, and mountainous parts of Illyria.
This species is greatly allied to the vipers, from which it is
distinguished principally by the erect process at the tip of
the nout. The colour is usually blueish grey or brown,
with a continued black dorsal band, refembling that of the
viper. This is considered as an extremely poisonous species,
and according to Matthioli, proves fatal in the space of
three hours. The flesh is used medically for the fame
purposes, as that of the common viper.

Lachesis. Yellowish-grey, variegated with brown; a
black transverse band above the eyes.—Cobra lachesis,

Described and figured by Seba, from whom it appears
this species is a native of Ceylon, and is known by the name of
bith. Its colour is a rich and somewhat irregular varia-
tion of deep and light brown, disposed in streaks and
patches, on a yellowish grey ground. The scales, which in
many parts are tipped with white, are large, strongly
carinated, and fixed only at the base, while the remainder
is loose or free. This singular disposition of the scales,
affords the animal an opportunity of elevating or depre-
ing them at pleasure, and in moving, is said to occasion a kind
of ruffling noise.

This is a poisonous species, being armed with large fangs,
and from its general form, appears to be an animal of consider-
able strength. The head is indistinct, or not distinguished from
the rest, by any contraction, or appearance at the neck.
The male is deeper coloured than the female, and seems to
have the body larger, and the tail more fender. The general
length of this snake, seems to be about four or five feet, and
the tail short in proportion to the body.

Clotho. Greyish-orange; variegated with numerous
waved black bands; keel of the fcares on the chin with a
white spot; tail very fender.—Cobra clotho, Laur. Amph.
Vipera, Bith. Cernhina eleganteviffina.

Inhabits Ceylon and Cuba, and is supposed to be a poi-
Noon species. This appears to be from the work of Seba
to be a large snake, measuring more than six feet in length,
C O L U B E R.

and being thick in proportion; the head large, covered with minute scales, and as in the coluber laheles, scarce distinguehed from the body, by any perceptible contraction at the neck. The colour of the upper parts, is greyish orange flecked with black specks, and marked with transverse undulate, or somewhat zigzag bars of black. The under parts are ciferous, variegated with a few black bars, and transverse stripes.

The length of this species is about sixteen inches; the head large, marked with four or five definite spots, and covered with small scales; the body rather bulky; the tail is short, measuring about a ninth part of the whole length. It is a native of America, and is considered as an extremely poisonous animal.

This, according to Cathey, is the size of the black American viper, measuring about two feet in length, and being large in proportion; he tells us it is a flagellis reptile, advancing deliberately even to escape danger, but will yet defend itself when attacked with much fierce ness, and its bite is said to be very venomous. It is found in Virginia, and Carolina, in the half of which it is called the trueman snake. This species preys on lizards, and other animals.

M E G A C R A. Brown, varied with yellow: head flat and heart-shaped, and a large orifice between the eyes and nostrils on each side. La Vipere Fer de Lance, Cepede.

This is a large species measuring five or six feet in length. It inhabits the island of Martinico, and some of the neighboring islands, and is considered one of the most formidable of the serpent tribe. A specimen of this snake, preserved in the British Museum, is a rich deep brown, with yellow variegations, the back being marked throughout the whole length, by pretty numerous equidistant, broken, and slightly alternating bars of dull yellow, which, defending and joining at intervals with the neighbouring ones, form either numerous and somewhat irregular markings of similar colours along the sides, with still more obscure crofflings on the part nearest the scutes, intermixed with smaller patches and spots: the abdomen is dull yellow, clouded and flecked on the sides with pale brown. The head is large, flat, heart-shaped, and covered with very small carinated scales; but the terminal scale of the nose, and those at the sides of the mouth, are very large, and above each eye is also a very large scale. The nostrils are small, and between them and the eyes on each side is a large orifice, which has been regarded as a passage to the organ of hearing; the scales on the whole upper parts of the body are moderately large, ovate, and carinated, the back slightly elevated, the sides rather flapping, and the abdomen flattish.

The fangs of this serpent are of a large size, about three quarters of an inch in length, and curved. The poison is said to resemble that of most serpents, being a clear yellowish fluid, like olive oil. The symptoms are alike as follows: from that of the viper, but it is a much stronger degree. When preparing to bite, it is said to throw itself into a spiral form, and to spring with great rapidity on its prey, but at other times to be rather slow in its motions, and of a torpid nature, concealing itself beneath the herbage, or within the hollows of trees. It frequents forest plantations, for the sake of the rats, which abound in such situations, and also preys on birds. The female goes for six months with young, and produces the new brood perfectly formed, and amounting to forty, fifty, or even sixty; they are observed to vary in colour when young, some being yellow, others grey, and others intermixed, yellow, grey, and brown.

C O R E L L A. Brown, mixed with white: head broad with a head coloured stripe behind each eye. Coluber colberti, abdominal scuta 150, subcaudal lquamae 22. Linnaeus.

Grows to the length of two feet nine inches, and varies much in the disposition of its colours, and the number of its abdominal scuta, and subcaudal scales. Gmelin enumerates no less than fourteen variations of this kind. It is a very common snake in America.

Refembles C. coronatus, and like that species, inhabits New Spain.

Inhabits most parts of Europe, where it frequents woods, moitl hedges, and shady places. Many varieties of this snake are described by writers, but the colour is in general either a bluish grey, or pale olive above, the sides variegated with black, and the under parts a mixture of black and white. The head is rather small comparatively, and is covered with large yellowish plates; the tail is of moderate length, and gradually tapers to the extremity.

This snake preys on frogs, mice, and small birds, insects, and worms; and occasionally frequents the water in search of the fish; it is capable of swimming, but not well. It deposits its eggs in any warm and moist situation in the form of a continued chain or necklace of ova, to the number of twelve, fourteen, sixteen, or even twenty, of the size of those of a blackbird, and of a white or yellow colour, and it appears hatched in the spring following. During the winter the snake conceals itself and becomes nearly torpid, and reappears in the spring, at which season it is said to cast its skin; we suspect that it calls its skin twice every year. This is not a poisonous species.

A T R O V I R E S. Black green speckled with yellow; abdomen yellow, with a row of black specks down each side. Anguis capulpho niger, Aldr. Serp. La Coluber vertu et jaune, La Cepede.

A species sometimes confounded with the preceding; it is described with accuracy by La Cepede, who informs us it is frequent in some provinces in France. Its haunts are woods, and moist shady places; in size and general appearance it resembles the ringed snake, coluber nitris, but differs in colour, being of an extremely dark or blackish green, appearing at the first view entirely black; the sides are marked with numerous rays of yellow specks, of different forms, some oblong, and some square; the eyes and edges of the mouth are bordered with yellow scales; the abdomen is also yellow, every plate being marked on each side with a black
but the snake, which he supposes to have been of this species, and which had been so completely tamed by a lady as to come to her whenever she called it; follow her in her walks, wave itself round her arms, and sleep in her bosom. One day, when this lady went in a boat to some distance up a large river, she threw the snake into the water; imagining that it would readily recover the boat by swimming; but the current proved unusually strong at that juncture owing to the advance of the tide; the poor animal in spite of all his efforts to reach the vessel was unfortunately drowned.

Gronovianus. Bleugh-ah, beneath blackish; a white arched spot each side the hind head, and one black: back-waved with black. Gmel. Laur. Amph. Bears a near affinity to the preceding, and is perhaps a variety only of the former, coluber matrix. Number of plates and scales not ascertained.

HUMANUS. Black spotted with white; tail alternately striped with black and white. Coluber humanus. Gmel. Nutrix humanum. Laur. Amph. A snake very commonly domesticated in New Spain; and also said to inhabit Amboyna.

Tyrolinea. Abdominal scuta 178, subcaudal scales 60. Gmel. Described after Scopoli, who informs us it inhabits the Tyrolean country, and deposits its eggs among flowers; these are white and leathery, with a lateral yok and turbid watery white, and are found sticking together in clusters of about fourteen in number.

Bipes. Abdominal scuta 116, subcaudal scales 58. Gmel. Scop. ann. hist. Mentioned by Scopoli as an inhabitant of the Tyrolean waters. This kind preys on fish and frogs; and is said to be furnished with two short procured or feet; the eyes are red or rny, lower jaw whites, dorsal scales elliptic and marginal; sides spotted with white; plates of the belly thick, with a brown spot in the middle.

Austriacus. Bluish-grey, with a double dorsal row of rufous spots, and reddish sides and abdomen. Coronella austriaca. Laurenti. La Lisse, Cepede. This bears a general resemblance to the common snake, coluber matrix, and seems to have been first described by Laurenti, who speaks of its being common round Vienna: it occurs also in France, and several other parts of Europe. The principal distinction between this species and the coluber matrix consists in the perfect smoothness of its scales, those of the matrix being somewhat carinated. This animal inhabits moist meadows, hedges, and swampy places, and bites with much eagerness, but is incapable of doing any injury, as nature has not provided it with poisonous fangs. It is said to be easily tamed, in which state it shows a considerable degree of attachment.

Length from eighteen inches to two feet; the colour pale whitish, with a more obscure cast on the back, and is marked throughout with nearly equidistant black bands, each surrounding the body, and divided half way up from the abdomen by a line or narrow stripe of the ground colour; thus giving a banded appearance to the lower part of each band. The head is covered with large scales, and marked on the fore part by a transverse black bar running across the eyes. This is a native of South America, and is said also to inhabit some parts of Asia.

The coluber naja is a native of India and the Ternate islands, where it appears to be one of the most common, as well as most noxious, of the serpent tribe; very frequently proving fatal in the space of a few minutes to those who unfortunately experience its bite. The form of this species is very remarkable: its general length seems to be three or four feet, and the diameter of the body about an inch or a quarter. The head is comparatively rather small, and is covered on the fore part with large smooth scales, as in the greater number of innoxious serpents; the scales on the back part and sides of the head, and also on the neck are smaller and ovate: those on the remainder of the animal, on the upper part oblong oval, not ill resembling the general form of a grain of rice. At a small distance beyond the head is a lateral swelling or dilation of the skin, which is continued to the dilation of about four inches downwards, where the outline gradually sinks into the cylindrical form of the rest of the body. This part is extensible at the pleasure of the animal; and when viewed from above, while in its most extended state, is of a somewhat cordate form, or wider at the upper than the lower part, and is marked with a fingular spectacle-formed spot of black and white, the mark itself being white, and the edges black, and the middle of each of the rounded parts black. This mark is more or less distinct in different individuals, and also varies occasionally in size and form, or in some individuals is altogether wanting.

The usual colour of the animal is a pale ferruginous brown above; the under parts bluish-white, sometimes slightly tinged with pale brown, or yellow; the tail, which is of a moderate length, tapers gradually and terminates in a slender, sharp pointed extremity. The title of cobra de capella, or hooded snake, has been given to this formidable reptile by the Portuguese, from the appearance which it presents when viewed in front in an irritated state, or when preparing to bite, at which time it bends the head rather downwards, and seems hooded, as it were, in some degree by the expanded skin of the neck.

Laurenti enumerates four varieties of this hooded snake, Naja tarenten, the common kind; f' Naja saucinata saucinatis per tonum corsus ex furo bruis, having tucatrous red bands over the whole body; j' Naja samoens, ex cinerea grisea, fumo dono rufa. Cinerous, with the back rufous; and j' Naja macula bia, ex furo rufa, spumis fuscis alba macula notatis; of a tawny yellow colour, and having every scale marked with a single white spot. But it appears from the work of Dr. Ruffell "On the Serpents of India," that there are many other varieties of this extraordinary snake. He describes no less than ten different kinds that are found in India alone, and seems to intimate that those are not the whole of the Nagoo tribe which infet that part of the world. It is possible, on further investigation, some of these described by Dr. Ruffell may prove to be intricately different: according to the character laid down by him, the number of the abdominal plates and scales on the belly, they are closely fo; but it is not on this criterion, the tally of which is too apparent, that we hazard an opinion; we adhere to the different conformation of the spectacle-like mark.
mark on the back of the neck, and still more to the di-

mearliness observable in the figure of the scuta and lamina; the variations in colour are but secondary particulars in con-

sideration. Dr. Raffell enumerates the varieties above-men-

tioned in the following order.

1. Aregua nago. With a pale central spot in the middle of each of the black spots of the spectacle-shaped mark. 
Abdominal scuta 180, subcoidal scales 60.

2. Coddum nago. This variety is darker than the other; and the skin is of a yellowish cast; but the principal limi-
tation is in the spectacle-mark, which consists of an oblong curved frame without the usual black eyes or centre-spots of the others. Abdominal scuta 187, subcoidal scales 57.

3. Sunko nago. The chief distinction of this is a plain hood, without any mark. This variety is supped by Seba to be the female of the species; but Dr. Raffell in-
forms us that one which he brought home from India, and pre-
cented to Mr. John Hunter was a male, and that the usual spectacle-mark is found indifferently both on the males and females. This variety is more rare than the reft. 
Abdominal scuta 185, subcoidal scales 56.

4. Mulla nago. The cervical scuta in this variety are spotted here and there with faint greyish spots, and four of the middle ones are entirely of a blueish-grey. 
Abdominal scuta 182, subcoidal scales 63.

5. Malle nago. The colour of this variety is of a lighter brown than the rest, and the scuta whiter; and, without spots, but seven of the pectoral ones are completely dark. 
Abdominal scuta 191, subcoidal scales 62.

6. Cunto nago. In this some deviations were observ-
able in the laminae; all the cervical scuta were dusky, and the trunk had a strong blueish cast. 
Abdominal scuta 186, subcoidal squamae 60.

7. Jenna nago. The skin of the hood in this is tinged with orange colour; the scuta of the neck spotted with 
grey, and fix of the lower ones wholly of a blue grey. 
Abdominal scuta 189, subcoidal squamae 57.

8. Nella tow pam. With the black on the hood uninfus-
dy deep, and all the jugular scuta remarkably dusky. 
Abdominal scuta 180, subcoidal squamae 62.

9. Kifna nago. The middle lamina of the three between 
the eyes remarkably broad, and the posterior part subovate 
instead of semi-cordate; five of the jugular scuta dusky, and fix of the pectoral almost black. 
Abdominal scuta 180, sub-
coidal squamae 63.

10. Korie nago. The three laminae between the eyes 
remarkably narrow; the large posterior part oval; colour of 
the trunk, and still more of the scuta unifundus blue. 
Abdominal scuta 184, subcoidal squamae 57.

The cobra de capello, it is observed, is everywhere exhibited 
publicly as a show in India; and is of course more universally 
known in that country than almost any other race of reptiles. 
It is carried about in a covered basket, and so managed by its 
proprietors as to assume, when exhibited, a kind of danc-
ing motion; raising itself upon its lower part, and alter-
nately moving its head and body from side to side for some 
minutes, to the sound of some musical instrument which is 
played during the time. The Indian jugglers, who thus exhibit 
the animal, first deprive it of its fangs, which renders it in-
capable of inflicting a poisonous wound by means of its bite.

Dr. Raffell, in his account of various experiments made in 
India with this serpent, affirms us that as a general standard 
for a comparison of the effects of its bite with that of other 
poisonous serpents, he never knew it prove mortal to a dog in 
less than twenty minutes, and to a chicken in less than half a minute. 
Thus fatal as it is, its poison seems not so speedy in opera-
tion as that of the rattle-snake, which has been known to 
kill a dog in the space of two minutes. The following in-
teresting experiments are related by Dr. Raffell to confirm 
the accuracy of this observation.

In the month of June 1787, a dog bitten by a Cobra de 
capello on the inside of the thigh, howled at first, as if in 
severe pain; after two or three minutes he lay down, con-
tinuing to howl and moan; after twenty minutes he re-fused, 
but with much difficulty, being unable to walk, and his 
whole frame appeared greatly distressed. He soon lay 
down again, and in a few minutes was seized with convul-
sions, in which he expired twenty-seven minutes after. 
This is the only instance mentioned in which the poisonous bite of the Cobra de capello proved fatal to dogs in much less 
than the space of an hour. — A large and very stout dog was 
bitten by another Cobra de capello on the inside of the thigh, which in a minute or two was drawn up, the first symptom in general of the poison having taken effect. He continued, 
however, nearly half an hour longer walking on the three re-
main ing legs, seeming not otherwise disordered; but after 
this time, he laid himself along in great inquietude, his head 
and throat being convulsed in an uncommon degree; he 
made several vain efforts to rise, his legs became both para-
lytic, and after continuing in this state for an hour, he ex-
pired. — A large dog was bitten by a Cobra de capello which 
had been captive only two days. He complained a 
good deal at the instant of the bite, and the leg was soon drawn up. In twenty-five minutes he was feebly convulsed, 
succeeded by fever, in which state he lay for ten minutes; 
the convulsions, however, returned, and he expired in a 
quarter of an hour, being fifty-six minutes after the bite. 
This experiment was tried on the 11th of November.

August 9th, a Cobra de capello, which had lost two of 
his longest fangs, but retained two of the second order, was 
made to bite a very large stout dog. At first the dog com-
plained loudly, though without drawing up the thigh, or 
swelling any other symptom of poison; but happening at 
this time to break loose, he was pursued, and brought back, 
after a chase of an hour and a half, much fatigued and 
heated. After reeling a quarter of an hour, water was 
ofered to him, which he refused, though he eat some mor-
sefs of bread thrown into it. About a quarter of an hour 
afterwards he became much dilated, grew entirely out-
rageous, howling violently, snapping at and gnawing the 
flake to which he was tied with incredible ferocity. This 
continued about three hours, when growing faint, his how-
lings grew weaker, his convulsions increased, and he expired 
about four hours after the bite. — A pig bitten by a snake 
of this kind, which had been fed only once in seven 
days with milk, became greatly disordered in twenty minutes, and expired in less than an hour. — A chicken has been some-
times known to survive two hours after being bitten by a 
Cobra de capello. Chickens and pigeons bitten by a Cobra 
de capello, whose fangs had been eradicated, suffered no 
symptoms of poison; but when poison taken from the same 
snake was infused into their bodies, either by incision or pun-
chure, they suffered the usual symptoms, and very often 
died.

It was endeavoured also to ascertain the effects of the bite 
of the Cobra de capello upon reptiles of the same freecies, 
the result of which appears doubtful. In some instances, 
the bitten animal experienced no kind of injury, while to 
others the bite proved fatal. An attempt was made, on the 
17th of August 1788, to make a Cobra de capello bite an-
other (of the variety called Naja paragallo) in the tail, but 
that part being found too small, the body was bitten, a little 
above the vent. The bitten snake soon left its former 
activity,
C O L U B E R.

difficulty and when put under a glass coiled itself up. In this state it was left, and after an hour and a quarter was found dead. On opening the belly, the parts immediately beneath the bite appeared much inflamed, though it could not be discovered whether any fangs had penetrated into the cavity.

A Cobra de capello, received by Dr. Ruffell from Ganjam, under the name of Saltana, was made to bite another remarkably large Cobra brought from the same place, under the name of Coultish. The poison was tied on the place, but no marks of fangs could be perceived, and the Coultish remained as well as before: this experiment was repeated with the same result, though a little blood as well as poison was found on the part bitten. Some days after this, a Cobra de capello (of the variety called Coudalum naga) was made to bite the Coultish on the belly; both fangs visibly acted; blood appeared on the wound, but no other consequence followed. A Tar tuta snake, bitten immediately after, in the same manner, died within two hours.

Rufus. Rufus, with dilatant reddish-fuscous bands; spectacle-spot somewhat heart-shaped, and marked with four black spots. Seba. Naja brasilienensis, Laurenti. La Cepede, &c.

Described by Seba and others also by him as a native of Brafil. This is perhaps a variety of the preceding.

According to Seba, this species is a native of Ceylon; he considers it as a kind of Cobra de capello, or hooded snake, in which respect it is mistaken. The length of this snake is between four and five feet; the head is extremely large, depressed, cordated behind, somewhat compressed at the sides of the mouth, and covered above by very large fleshy pates. At some distance from the eyes are two remarkable, oblong, brown spots. The neck is thin, and, together with the whole body, extremely compressed on the sides; tail long, round, and tapering to a fine point. From the head, along the back, runs a row of large, broad, hexagonal scales, those on the other parts are ovate; the abdominal plates are very narrow. The general colour of the animal is rufous-brown, with moderately distant, broadish, transverse, pale bands, each of which, at its juncture with the scuta, is marked with a white spot.

The abdominal plates, according to Dr. Ruffell, amount, in this species, to 168, and the scales under the tail to 59. The length of this snake is about four feet. Its colour an elegant pale yellowish-brown, marked throughout the whole length of the back with a continued series of large ovate spots of a deep brown colour, pailet in the centre, and surrounded by a narrow line of white. In some parts those spots are nearly confluent; on each side of the body is a row of brown oval spots, smaller than those on the back; and besides these, a few still smaller transverse marks are sparingly scattered on the sides; the under part of the body is white, with a few dully spots; the head is rather large, the front obtuse, the mouth wide, the fangs large, and, in several other poisonous serpents, double, a smaller fang being situated close to the larger one on each side.

Dr. Ruffell informs us, this species is scarce less common in India than the Cobra de capello; but from its not being carried about, like that and some other snakes, as a public show, is not at universally known either among the natives or Europeans.

Several experiments were made by Dr. Ruffell to determine the effects of its bite, from which it appears to be one of the most poisonous of its tribe. A chicken bitten in the pinion by one of these snakes, which had been caught two or three days before, and seemed in high spirits, was infantly infected, feigned with convulsions, and expired in thirty-eight seconds. Immediately after the chicken, a fowl dog was bitten in the thigh; within less than five minutes he appeared stupified; the thigh was drawn up, and he frequently moved as if in pain. He remained, however, standing, and ate some bread that was offered to him. In about ten minutes the thigh became paralytic; in fifteen minutes he entirely lost the use of the wounded thigh, and lay down, howling in a dismal manner, frequently licking the wound, and making, at intervals, ineffectual attempts to rise. In nineteen minutes, after a short convulsion, he again began to howl, mounted often, his breathing became laborious, and the jaws were completely shut. The few succeeding minutes were passed alternately in agony and flupor, and in twenty-five minutes after the bite he expired. A second dog, of much smaller size, was next bitten, and expired in the space of six hours. After this, a rabbit was exposed to the bite of the snake, and died in less than an hour; and, lastly, a chicken bitten in the pinion expired in less than six minutes. The whole of the above experiments were made with the same snake in the course of the same morning.

The length of this kind is about thirty inches. The head is rather large in proportion, and obliquely tapering, but not pointed, and is covered entirely with very small scales; the colour is as above described. This is a native of India, and was first described by Dr. Ruffell; it is of the poisonous kinds, and has the fangs remarkably long and slender. From the experiments of the last-mentioned writer it appears, that a chicken died, after having suffered strong convulsions, and afterwards flupor, in about eight minutes from the bite; pigs and dogs were feigned with a flupor, convulsions, &c., but in a few hours recovered from the effect of the poison.

Crotaulus. Cinereous, marked above with large alternate blackish spots; beneath yellow, flecked with brown. Coluber crotalus, abdominal scuta 154, subcaudal scales 43: Linn.

A large species, with the habit of the rattle-snake; the head is heart-shaped, the eyes lids protuberant, fakes carinated. Native country unknown.

Severus. Cinereous, with oblique linear whitish bands, edged with brown. Coluber severus, abdominal scuta 170, subcaudal scales 42. Linn.

Length about seventeen inches; thicknes moderate; head broad, obtuse, livid, with cinereous band between the eyes, and behind the nose; eyes large; neck thick; the colour of the upper parts as before described; the abdomen dull; sides speckled with white; tail short. The figure in Seba, quoted by Linnzeus, is of a pale rufous colour, with whitish bands, somewhat resembling Hebrew characters in form, and edged with brown; the abdomen pale yellow, with a row of blackish spots on each side.

Porphyraeus. Violet-black, with the abdomen and sides crinom, the scuta margined with black. Zool. New Holl. p. 27. pl. 10. Abdominal scuta 188, anal scuta 73, subcaudal scales 45.

First described by Dr. Shaw, who speaks of it as a moderately large and beautiful species; the general proportions nearly
COLOBER.

neatly the same with those of Coluber natrix, the common English snake. The head is rather small, and covered in front with large scales: the colour of the head and whole under parts very fine deep violet; sides and abdomen crimson, deep blue on the fore-part, the large scales near the vent being carmine-coloured, with black tips; the abdomen rose-coloured, with a tinge of yellow, each scutum deeply edged with black, thus forming a beautiful series of transverse black bars down the abdomen. The tail measures about a sixth part of the whole length, and is furnished beneath, exclusive of the divided subcaudal scales, with about seven scuta, or undivided laminae, commencing immediately beyond the vent, which is edged with familiar smaller squamae; the colour of the under parts of the tail is a blueish-ath. the rose-colour of the abdomen ceasing at the commencement of the tail. In the Zoology of New Holland, Dr. Shaw describes this species as distinct of fangs, and consequently innocuous; an error arising from the mistaken state of the fragment he examined. The snake has been since observed to be furnished with thistle organs; and, as Dr. Shaw remarks, in his General Zoology, to be highly dreaded by the natives of Arrabriba, as a poisonous species.

Seba describes this snake as a native of the East Indies, having received it from Persia and Japan. Its general length is about two feet or more; its colour red, varying to deeper or paler in different individuals, and sometimes inclining to brown; the variegations white or whitish. The head is moderately large, and covered in front with large scales; tail extremely short and tapering to a point. La Cepede considers it a poisonous snake.

Aquatius. Brown, with the abdomen banded with black and yellow. Water viper, Cathey.

We are acquainted with this species only from the account given of it by Cathey. "This serpent (says that writer) is called in Carolina the water rattle-snake; not that it hath a rattle, but is a large snake, and coloured not much unlike the rattle-snake, and the bite said to be as mortal. This snake frequents the water, and is never seen at any great distance from it. The back and head are brown, the belly transversely marked with black and yellow alternately, as are the sides of the neck; the neck is small; the head large, and armed with the like destructive weapons as the rattlesnake; it is very nimble, and particularly dexterous in catching fish. In summer great numbers are seen lying on the branches of trees hanging over rivers, from which, at the approach of a boat, they drop down into the water, and often into the boat on the men's heads. They lie in this manner to surprice either birds or fish, after which they plunge, and pursue them with great swiftness, and catch some of a large size, which they carry on shore and swallow whole. One of these I surprized swimming averse with a large catfish in his mouth. The tail is small towards the end, and terminates in a blunt horny point, about half an inch in length, and which, though harmless, is considered as of dreadful efficacy, by the credulous vulgar, who believe that the animal is able with this weapon, not only to kill men and other animals, but even to destroy a tree by wounding it with it; the tree withering, turning black, and dying."

Lacteus. Milky-white, the back marked by double black spots; head black, with a longitudinal white line. Coluber lacteus, abdominal scuta 203; subcaudal scales 32. Linna.

Length eighteen inches. A native of India and South America, and is reputed poisonous.

Melanis. Deep black; sides clouded with bluish, the eye brown, with the edge of the pupil silver. Coluber melanis, abdominal scuta 148, subcaudal scales 27. Gmel. Pallas.

Observed by Dr. Pallas on the borders of the Volga and Samara rivers in Siberia. It has the general appearance of the viper, but differs in colour, being of a deep black on the back, and of a yellowish beneath, marked with patches of a deeper call, while the sides are clouded, and spotted at intervals with bluish. The eyes are of a bright white, with perpendicular pupils, and ferruginous irides; tail short, and gradually tapering to the tip.

Buccatus. Whitish, with large double brown dorsal spots; head somewhat depreved, checks timid. Coluber buccatus, abdominal scuta 167, subcaudal scales 72. Linna. A poisonous species; it inhabits South America and India. Length twelve inches.

Atrox. Grey brown, with transverse linear whitish figures; abdomen dulky with white transverse variegations. Coluber atrox, abdominal scuta 150, subcaudal scales 67. Linna. Length about eighteen inches: it is a poisonous snake, and is a native of the island of Ceylon.

Coralinus. Glaucous, with scales somewhat heart-shaped, and three brown lines down the back. Coluber coralinus, abdominal scuta 159, subcaudal scales 82. Linna. Linnaeus describes this as a poisonous species; it is a native of the eastern regions; it preys on birds.

Liberis. Pale; head white; body marked above with linear black bands. Coluber Libera, abdominal scuta 110, subcaudal scales 50. Linna. Described by Kalm, who informs us that it is a native of Canada, and that the upper parts are traversed by linear black bands; the head white with two rusious spots on the top, and a triangular spot over the nose. Linnaeus mentions it as a poisonous species, a particular considered doubtful by Dr. Gray.

Aulicus. Grey brown, with transverse white bands bifurcating over the sides. Coluber aulicus, abdominal scuta 184, subcaudal scales 60. Linna. The length of this species is six inches; it inhabits America, and is one of the poisonous kind of snakes.

This is a beautiful species, measuring in length about two feet; the colour is white, marked down the upper part with a quintuple series of black spots with red centres; the middle row is composed of very small spots, the next on each side with larger ocellated ones, and the lowest on each side, next the scuta, resembling that on the middle of the back, and consisting of small pocks; the head is marked by a crooked-furred spot on the top, and by a few blackish ones across the frown; the tail is short, measuring two inches and a half in length, and tapering to a point.

Rhombeatus. Glaucous, with blackish lozenge-shaped spots, blue in the middle. Coluber rhombeatus, abdominal scuta 157, subcaudal scales 70. Linna. Length from two to three feet; colour, in general, grey, sometimes brownish, with three alternating rows of ovoid dulky spots, with large blue centres; the abdomen is pale or whitish, and often clouded with blueish grey. This is a native of India and South America.

Javanicus.
CO L U B E R.

MELANURUS. Yellowish brown, with black head, and two black spots on the tail. Ruffell. Ind. Serp.

A small species about ten or eleven inches in length, scarcely of the thickness of a goose quill, and nearly of equal diameter from the head to the tip of the tail. The colour is a light yellowish brown, with a dotted black line running from head to tail along the middle of the back, and a few fainter fillets on the sides; the head is small, ovate, black, and covered with large scales; the tail short, scarcely measuring more than an inch in length, and is marked at its origin on the upper part, by a large rhomboidal black spot edged with white; and having a white speck in the middle; the tip of the tail is also marked by a similar black spot; the abdomen is of a pale orange colour, and the under part of the tail white, speckled, and variegated with black. The bite of this species is said to be painful but not poisonous. It is a native of India, and is described among the serpents of that country by Dr. Ruffell.

JARA. Black, with double linear white specks, and yellowish collar and abdomen. Jara potoo, Ruffell, Ind. Serp.

This is one of the new species of serpents described by Dr. Ruffell. It inhabits India. The length is fifteen inches; tail very short and tapering suddenly to a point. The abdominal feuta are 175 in number, and the subcaudal scales 56.

ARNENSI S. Yellowish-brown with narrow blackish transverse bands edged with white, and pale abdomen. Arne feata, Ruff. Ind. Serp.

Inhabits the country of Arnee in the East Indies. The length is about eighteen inches; the colour above yellowish, with moderately distant blackish, or very deep brown, transverse bands which are whitish at the margins; the head is small; tail rather short and tapering to a sharp-pointed tip. Abdominal feuta 169, subcaudal feules 50.

SAGITTATUS. Brown, with whitish fagittated dorso spots edged with black. Tar tutta, Ruff. Ind. Serp.

The length of this snake is two feet; the head is rather large in proportion, round, obtuse, and covered with large scales; neck and body flender, the colour on the upper parts yellowish brown variegated, with a chain of series of somewhat triangular, or fagittated spots; the abdomen is yellowish white, and the feuta is marked by a dusky spot on each side. This is a native of India.

STRIATUS. Greenish black, with spotted white bands, and blueish-white abdomen. Gajso tutta, Ruff. Ind. Serp.

This is much smaller than the last, measuring only fourteen inches: the colour above is greenish black, marked with about twenty transverse bands, each composed of a number of longitudinal abrupt white or yellowish white stripes, and along the sides of the body are interrupted rows of similar stripes; the head is obtuse, and covered with large scales, the abdomen blueish-white. Abdominal feuta 174, subcaudal scales 40.

FASCIOLATUS. Cinerous, with whitish transverse bands and glaucous abdomen. Nooni paragoodos, Ruffell. Ind. Serp.

AGILIS. Banded alternately with white and fuscous, and varied with black dots: head small; tail short. — Coluber agilis, abdominal feuta 184, subcaudal scales 50. Linn. Corallus Agilis, Laur.

A native of Ceylon. The head is small, covered with large scales; body flender and smooth, about a span in length, and covered with small scales; tail short, taper, and terminating rather obtusely.

SIMUS. Blackish, with white transverse bands; nose turned up. Coluber. K. SIMUS.

JAVA NICUS. Grey; head striped with blue; body marked with transverse blue stripes edged with golden. Described by Mr. Warmb in the "Memoirs of the Batavian Society," for the year 1787: This is a large and most beautiful species, and is seen principally in the rice fields; whence it obtains the name of Oular-Sawra, or Rice-field Snake. Those which are found in the higher and more wooded situations arrive at a far superior size. The head of this snake is large and flat, and is covered, as in the major part of the coluber genus, with large leathery plates; the mouth is furnished with double rows of sharp teeth, but is deficient of fangs, the animal not being of a poisonous nature; the iris is yellow; upper part of the head grey, mixed with blue; from behind the eyes pass two blue stripes to the upper part of the neck, where they unite into an arch about an inch beyond the head; a third stripe of the same colour proceeds from the snout to the occiput, where it divides into two, and surrounds a yellow spot marked with a few blue specks; the upper part of the body is divided into a kind of lattice-work, formed by stripes of bright blue with gold-coloured edges; the middle parts of the square being of a grey colour, with changeable reflections of yellow, blue, and green; towards the sides the grey colour is of a lighter or paler cast, as well as on the tail, where the squares are smaller than on the back; each side of the body is also marked by a row of white spots, situated at the crotchings of the blue stripes. This snake preys on birds, rats, and various other small animals.

A new species described by Dr. Ruffell. The length of the specimen, examined by that writer, was about two feet and a half; but it is supposed to attain to a much larger size. It was short and thick with moderately large oblong-ovate head, covered with large scales; and the tail short and sharp pointed. The colour of the upper parts very pale or whitish brown, variegated on the back and sides, with large and small irregularly formed, deep-brown patches, and spots, those on the sides being mottly ocellated. The body is covered with very small scales, the three rows next the abdomen being much larger than the rest; abdomen white, the feuta being remarkably narrow or short, and reddish at the margins. The under part of the tail is variegated with black and white.

This is a native of India, and is represented as an animal of great strength, wreathing round the arm, if held for a short time, so closely as to numb the hand; it is not poisonous, its bite producing no other effect than that of temporary pain.

The serpent mentioned by Dr. Ruffell, under the name of Dera, is considered as a variety of coluber boformis, and so also is the Poddla poda, t. 23, 24. The fire is much larger than the serpent above described; the disposition of the scales and colours are the same, but the ground colour is white, and the tail is furnished beneath with several undivided lamellae towards the tip, or after those immediately succeeding the vent, while the tip itself is again terminated by a few divided scales. This snake is found at Calcutta, where it is pretended the bite is very soon followed by eruptions on different parts of the body, though it does not prove fatal in less than ten or twelve days, but the whole of this is regarded as a mere popular error. The other supposed variety, the pedda poda, grows to a very large size, having been seen nine or ten feet in length. In its general appearance it resembles that first described, but the scales are larger in proportion.

Vol. IX.

Length eighteen inches; head rather large, and roundish, with the nape flat in front, and turned up into a slightly pointed tip: between the eyes is a black curved band, and on the top of the head a white cruciform mark, with a black central spot; abdomen dusky. A native of Carolina, and other parts of North America.

Pelias. Brownish, with double transverse black bands, beneath green with a yellow lateral band—Coluber pelias, abdominal scuta 187, subcaudal scales 139. Linn.

A native of South America and India. Described by Linnaeus from the Museum of Diggel.

Mucosus. Blueth, beneath pale, with angular head: lips striped transversely with black. Coluber mucosus, abdominal scuta 200, subcaudal scales 140. Linn. 

A native of South America and India. Described by Linnaeus from a specimen in the Muf. Ad. Tr. It is a small species, measuring about eighteen inches in length; the native country is South America.

Cinerexs. Cinerexs; abdomen white; tail reticulated above with brown, and lined transversely beneath. Coluber cinerea, abdominal scuta 200, subcaudal scales 137.

Indies, according to Linnaeus South America and India; it resembles the common snake, and is about two feet in length.

Dipsas. Green with two white stripes. Abdominal scuta 152, subcaudal scales 155. Linn. Serpens furinamentis carules, Seba. inhabits Surinam and other parts of South America.

First described by Lepechin as an inhabitant of the shores of the Caspian sea, where it haunts the low grounds and bully places. It is reported of this species, that when disturbed it first endeavors to escape, but if pursued or irritated, springs forwards on its affblant with great fury, though incapable of doing any injury by its bite. The usual length is about five feet.

A native of Peru; described by Seba, who informs us it is rare in European collections. This is an innoxious species. Linnaeus does not notice this snake, as the number of its abdominal scuta, and subcaudal plates could not be ascertained.

Hygeia. White, with somewhat undulated black zones, and head faciatus longitudinally with black. Ser- pens fumurensis teneoillis, &c. Seba.

A small species of a white colour, barred with numerous irregular black bands, nearly surrounding the body; head small, covered with large scales, and marked by two broad longitudinal stripes uniting at the top of the snout; tail rather short and sharp pointed. Inhabits Siam.

This snake inhabits Africa. In the middle of the head, between the eyes is a large shining shield, composed of many plates; the sides of the head and hind-head is covered with imbricated scales each side; and the snout is sharp.

No less than nine varieties of this snake are described by Gmelin after Laurenti. These we shall enumerate in the Gmelinian order, observing only that on further investigation it is not unlikely some at least of those supposed varieties may prove to be specifically distinct. Those are not noticed by Dr. Shaw, but that writer thinks the C. Petularius of the Muscum Adolphici Friderici, can hardly be considered as a species distinct from Pethola.

E. Coronella Africana, &c. White, with spots on the back; those on the anterior part rounded, and gradually becoming rhomboidal, with the edges reddish. Laur. Amph.

f. Coronella ocellata, &c. Blueth, with a quadruple series of black ocellated spots, which are blue in the middle, and are disposed longitudinally. Laur. Amph.

g. Coronella fuscata, &c. Blueth white with black brown bands, and two longitudinal divided lines. Laur. Amph.

i. Coronella ocellofa, fuscata, &c. With yellowish confluent bands near the belly. Laur. Amph.

j. Coronella ephippium, &c. Brownish white, with very pale brown spots; occipital spots two, and longitudinal; dorsal ones elliptic, and disposed in a single stripe. Laur. Amph.

k. Coronella teniens, &c. Middle of the back marked with a brown stripe; belly and sides whitish brown. Laur. Amph.

l. Coronella anguiformis, &c. With entire circular brown bands, beneath obliquely concurrent.

A native of Africa. The length of this snake is about three feet, of a slender form, and yellowish white with marked throughout the whole length; at equal distances, with triple zones of black or deep brown, which entirely surround the body. The head is rather small, covered with large scales, and marked across the snout by a double zone, of which the smallest division pales across the nostrils, and the largest across the eyes. The whole animal is of a smooth and shining surface.

Lubricus. Flagelliform; white with equidistant black bands; body glossy. Coluber lubricus, Gmel.

Allied to the last species; the body is white, marked with fine black bands; the head is marked across the snout by a black band, and at the top by two oblique stripes nearly meeting at an angle in front; the skin is remarkably smooth and glossy. The length of this snake is eighteen inches. According to Gmelin it is a native of Surinam; the snake described by Seba, as Natrix lubricus, fuscus rubris, and which is considered as a variety of the same species, is a native of Surinam.

Doliatus, milk-white, marked above by large, approximated, suboval black rings. Coluber doliatus, abdominal scuta 154, subcaudal scales 43. Linn.

A small species measuring from eighteen inches to two feet in length; general color milk white, marked throughout by large oval jet-black rings, the ends of which approaching each other on the top of the back, give the appearance of double bars, corresponding with the description given of this snake by Boddaert, Coluber doliatus, annulus nigres per paria digiis. Inhabitats Carolina.

Germanus. Blue, with a black middle-stripe spotted with white, and two lateral white stripes. Le Chapela, 6.
La Cepede. Abdominal scuta 166, subcaudal scales 103.

The length of this beautiful snake is about fifteen or sixteen inches; the colour on the upper parts blue, with three narrow equidistant stripes from head to tail; the two lateral stripes being white, the middle one black, marked by a row of small white specks alternately oblong and round; resembling a small fringe on heads and bodies: the head is covered with large scales, and marked on each side with three or four spots, forming a band across the eyes, the top spotted with pale blue marks bordered with black; the abdomen white. The scuta are each marked at the edge with a small black speck, forming two rows down the abdomen. The native country of this kind is unknown, the species was described by La Cepede from a specimen in the royal cabinet.

This snake measures twenty-five inches in length, of which the tail exceeds six inches. The general colour is rufous; every scale is bordered with yellow, and down the back from the head to the tail run two bright yellow stripes of a golden hue. The scales on the head are large, those on the body smooth. The native country is unknown.

Trilineatus. Rufous, with three black lines. *La trois raie*, La Cepede.

The length is about eighteen inches; the head is covered with large scales; tail about two inches and three quarters long. This is a native of Africa.

Tripectiatus. Body marked with three broad black stripes, the middle one divided by a white line, and three spotted lines down the abdomen. Shaw Gen. Zool.

A small species, measuring a foot in length, and being rather thick in proportion; head rather large, blackish, with the future pale. Described from a specimen in the collection of Dr. William Hunter.

Dione. Pale blue, spotted with brown, and three whitish lines. Pallas It.

This species is a native of the salt deserts towards the Caspian sea, and of the hilly regions near the river Irin; and was first described by Dr. Pallas. It is of a flender form, about two feet in length; the head small, tetragonal and commonly reticulated with blackish futures. The two intermediate spaces between the three lines on the back are marked with a row of dusky alternate spots; and the tail is about one sixth of the whole length.

This snake is in general of a grass-green colour, and is distinguished in particular by the yellow line which extends the whole length of the body on each side of the abdomen. It is of a flender form, measuring about three feet and a half in length, and about half an inch in diameter. The head is moderately large, long, and sharp snouted, the upper jaw extending far beyond the lower. Linnaeus was erroneously led to consider this as a poisonous species, from the fang-like appearance of the large and long teeth in the upper jaw. It is a native of many parts of North America, where it is principally seen on trees, moving with great velocity in pursuit of insects, on which it feeds.

Gmelin describes the natrix flagellii forms of Laurenti, and also the anguis viridis of Catesby, as two varieties of the coluber mycteriian. *Butea Pflugrii* of Dr. Ruifell may be perhaps admitted likewise as a variety. This differs in the colour of the under parts, instead of green being of a cinerous pink colour, elegantly speckled with very numerous minute black and yellowish dots; the margin of the scuta being edged with dull yellow; the skin of the neck also, when the animal is irritated, exhibits by the dilatation of the skin on that part, a beautiful variegation of black and white reticulated marks, which do not appear at other times.

This creature is represented as of a ferocious nature, hissing violently, and snapping at anything opposed to it, but producing no other effect by its bite than that of temporary pain in consequence of mere puncture.

Coluber Nasutus. Serpens viridis, ore acuminato ex Java, officina species, Seba.

Whether this be distinct from the former is uncertain; the head is somewhat larger in proportion, and the body less flender: in other respects it very nearly corresponds. The length is about three feet. This snake according to Seba is a native of Java.

Lineatus. Blue-green, with three or five brown linear stripes, the middle one broadest. *Coluber lineatus*, Linn. *Serpens celedonica lineis subfusis*, Seba.

This snake is a native of India, and is commonly about three feet in length. The general colour is pale blueish green above, with a golden gloss, and is marked throughout the whole length by five longitudinal narrow bands, or stripes of dusky brown or greenish. In young specimens there are rarely more than three stripes. The form of this snake is long and flender, with the head small, the abdomen flatish, and the tail long and thin.

Resembles lineatus, but is smaller; the general colour white tinged with blue, and marked by three longitudinal stripes of black or deep brown, of which that in the middle is broadest. This appears to vary in colour, that described by Seba being whitish instead of white. The abdominal scuta are 163 in number, the subcaudal scales 77. This kind inhabits Surinam, and is considered as a harmless animal.

This, like the last, resembles coluber lineatus, being marked, as in that species, with five dusky stripes, the middle one of which is the broadest, and is nearly black, with a whitish speck on each of the scales. The head is ovate, covered with large scales, and marked with several oblong blue, subangulated spots, with black edges; and the tail is very long and flender. This animal is of considerable size, sometimes measuring four feet in length; it is a native of Asia, and is esteemed harmless.

Situla. Grey, with a longitudinal dusky band, bordered on each side by a black line. *Coluber situla*, abdominal scuta 256, subcaudal scales 45. Described by Haffelquist as a native of Egypt.

This is the ribbon snake of Catesby, a species about three feet in length, and very beautiful. The general colour is brown above, with three moderately-broad longitudinal blue-green stripes; the head is rather small and somewhat pointed, the body flender, and the tail thin. Catesby represents it as an animal extremely swifit in its motions; it inhabits Carolina and many other parts of North America, frequents trees, and is perfectly innoxious.

Vittatus. Whithif, with three black stripes, the middle one very narrow; abdomen white, with the edges of the scuta...
COLUBER.

The length of this kind seldom exceeds thirty inches; the colour is whitish, tinged with blue, and marked along the whole length of the back by three black or dark brown stripes, the middle one of which is the narrowest; between this and the principal longitudinal stripe on each side is a pair of extremely narrow or linear stripes, which are gradually lost after passing some distance down the back. The head is rather small; of an elongated form, covered with large scales, and marked with black variegations; the tail is of moderate length, slender, and gradually tapering to a point. This snake is a native of South America, and is not of the poisonous tribe of serpents.

*Monilis*. Whitish, with broad brown bands, and three spots on the neck. *Coluber monilitis*, abdominal scuta 164, subcaudal scales 82. Linn.

A native of South America. This is a small species measuring about a foot and half in length; the colour whitish, banded throughout the whole length with very broad transverse brown bars; the head is of moderate size, whitish, and bordered with brown.

Length about eighteen inches. The form rather slender; head small, and marked at the back of the neck with a few transverse streaks; the spots on the back are somewhat rhomboidal, of a brown colour, lightest in the centre, and disposed in a triple fies. This snake is a native of India.

Described as a native of Egypt; the abdominal scuta are 195, and the subcaudal scales 102.

*Coccineus*. Black, with the back yellow, spotted with red, and the abdomen pale. *Coluber coccineus*, abdominal scuta 175, subcaudal scales 35. Gmel.

Length about two or three feet, form rather slender, with the head small, the ground colour black, with about twenty-three foveate spots of bright red, with the spaces between yellow. This is a native of South America.

General colour milk white, marked throughout with a row of deep brown ovate patches; the head is brown, and covered with large scales; tail of moderate length, gradually tapering to the extremity. This is a native of South America.

A native of America. This is of a moderate size, measuring about two feet in length; the head is rather large in proportion, and covered with scales of considerable size; body rather slender, and the tail tapering rather gradually from the body. The colour is yellowish brown, clouded with irregular deep brown, or black fuscous variegations disposed somewhat in the form of bands, and nearly surrounding the body.

*Padera*. White, with black dorsal spots, connected by a line and lateral spots. *Coluber padera*, abdominal scuta 198, subcaudal scales 56. Linn. A native of India.

This is a large snake, measuring nine or ten feet in length, and being rather slender in proportion; the colour above deep or blackish brown, variegated with numerous yellow specks, arising from the circumference of the middle of every scale being marked with an ovate yellow spot. On the sides of the body many of the scales are yellow on one half and black on the other, and by degrees appear more tinged with yellow as they approach the abdomen, which is clouded with a mixture of brown and yellow; the head is small, and covered in front with moderately large scales; the teeth rather large, and unaccompanied, so far as can be ascertained from the dried specimens hitherto examined, by any poisonous fangs.

*Schoeckei*. Cinerous brown, with a double white longitudinal band each side; abdomen whitish; throat yellowish, and speckled with brown. *Coluber schoeckei*, abdominal scuta 180, subcaudal scales 114.

Described by Linnaeus after Forskal, as being about a cubit and a half in length, and the thickness of a finger; the colours as above described, except that, as the snake advances in age, a narrow stripe, composed of small whitish spots, is observable down the middle of the back. The head is ovate, oblong, and covered with large scales, and the tail about a third of the whole length. A native of the woody parts of Arabia.

*Hoelliei*. Entirely red. *Forsk*. Forskal describes this as a native of Arabia. It is about a foot in length; the bite of this snake is said to cause an inflamed tumour, and its breath to excite an itching in the skin.

Length twelve inches; the tail is of a moderate length, and rather slender, and the scales beneath are plain. A native of America, and confederated, by some writers, as an inhabitant likewise of America.

This is a small species; the head is of a moderate size, rather long, and covered with scales of a larger size; tail long, and tapering gradually to a point. Inhabits South America.

Inhabits South America and India. The length is three feet; the scale on the body are obsolete, and ranged in eleven rows; the head oblong and flattened; tail slender, a foot in length, and pale beneath.

*Daara*. Coppery-grey, with the edges of the scales whitish; beneath white. *Coluber diera*, abdominal scuta 234, subcaudal scales 45.

The length of the snake exceeds a cubit; the thickness less than a finger. The head is ovate, oblong, and covered with large scales, of which those in the middle between the eyes are larger than the rest. A native of Arabia. *Forsk*.

*Fulvis*. Fulvous, spotted with brown, the body annulated with black bands, and the tail very short. *Coluber fulvis*, abdominal scuta 218, subcaudal scales 31.

Length
COLUBER.

Length about eighteen inches; the head brown above, and covered with large scales; a native of North America.

CONSTRCTOR. Shining black, with the body very long and slender. Coluber constrictor, abdominal feata 186, subcaudal scales 92. Linn. Black snake, Cateby. Carol.

According to Cateby, this is a large and very long snake, some attaining to the length of six feet; they are entirely of a shining black colour, and are very nimble and beneficial in killing rats, which they purify with wonderful agility to the roofs and all parts of houses and barns, where rats are able to run, and for this service are preferred by most of the inhabitants; they are bold and furious, leaping at and biting those that attack them, though no harm ensues, their bite not being venomous; it is commonly said, in Carolina, they will attack the rattle snakes, and swallow them. "It is certain," says Cateby, "that all will attack one another, not only of their own but of all other kinds, which I have often seen; one, after a long struggle, swallowing another, but little less than itself."

SIRTALIS. Brown, with three blueish-green bands. Coluber fortis, abdominal feata 175, subcaudal scales 114. Linn. Described by Kalm as a Canadian species.

DECORUS. Blue-green, with a double lateral band of black, and black spots on each side the neck. A species described by Dr. Shaw, from a specimen in the British Museum. Its habit is slender and flagelliform; length about two feet and a half; the colour pale, blueish, gilded green, with iridescent variegations; beneath paler, or more inclining to white; on each side the body, near the abdomen, a double black stripe; head longish, covered with large scales, incommutated, and marked each side, through the eyes, by a broad dark black stripe broken into spots, and which, passing to form little distance along the neck, becomes divided, and forms the double lateral stripe before mentioned. The eyes are large; tail very long and slender.

DOMICELLA. White, with numerous deep black transverse bands meeting beneath, and a blackish abdominal line. Coluber Domicella, abdominal feata 118, subcaudal scales 6. Linn. Argus biolor elegans minus obscurus, Siba. Length about two feet and a half, diameter half an inch; the head is small, covered with large scales; tail rather short and tapering to a point. This is a native of India; it is said the ladies in India sometimes carry this snake in their bonnets, and hence Linnaeus named it domicella.

VIRIDISSIMUS. Bright green; abdomen whitish, with the feata dilated towards the middle. Coluber viridissimus, abdominal feata 157, subcaudal scales 122.

This beautiful snake is a native of Surinam. The length is about three feet; head slightly obtuse, of moderate size, covered with very large scales; the remainder of the upper parts with ovate scales; the tail is of moderate length and slender. The green on the back inclines more or less to blue or purple; in different individuals, and the abdomen in some than in others. It is esteemed a harmless species.

CURSOR. Greenish, with two dorsal stripes of linear white spots, and whitish scales and abdomen.—La Courtez, Cepede. Abdominal feata 185, subcaudal scales 105.

A species described by La Cepede, from a specimen in the Royal Cabinet at Paris. The length is about three feet; the head is covered with large scales, the tail of moderate length and gradually tapering to the tip. It is said to be a timid animal, and remarkable for the frowsifs of its motions. It inhabits the island of Martinico.

HISPANELLA. White, speckled above with blue, and variegated with blue on the abdomen. Serpens Hispanella Americana, Siba.

A native of South America, where it frequents houses, and is very useful in destroying rats, mice, and other vermin. It is about two feet and a half in length, the thickneds moderate, head oblong, and covered with large scales, tail rather short, and gradually tapering.

PERLATUS. Pearl-coloured; head and tail sea-green; the former marked by a red spot. Serpens ex novo Hispania, a Fabro Lynco. This snake is about two feet and a half in length, and rather thick, except towards the tail, where it gradually tapers to a slender point; the top of the head is covered with small scales except about the nape and between the eyes. It is a native of New Spain.

PLATONUS. White, spotted with brown, and annulated with broad brown zones. Shaw Gen. Zool. Described from a specimen in the museum of Dr. William Hunter. It resembles the common snake C. matrix, but the tail is rather more slender in proportion; the head is rather large, and covered with large scales of a black brown colour, elegantly marked with intervening spaces of white; the whole animal is about three feet and a half in length.

ARUS. Chestnut-brown, banded with transverse rows of ocellated red spots; beneath yellow. Coluber argus, Linn. Serpens arabicus brasilifusus boboboca, and Boiguacu dilia; alias argus, Siba.

The argus snake is a large and elegant species, measuring, according to Seba, above five feet in length, and being of a moderate thickness in proportion. The head is large, flatish, covered in front with small scales, and so very protrudent on each side at the hind part, so as to appear heart-shaped. The ground colour is brown, very beautifully marked from head to tail by numerous transverse rows of round ocellated red spots, surrounded by a white iris, and an exterior red one; the abdomen beneath is pale yellow; tail moderately slender and tapering to a point. It is a native of Arabia, and seems to be considered as a poisonous species.

OCELLATUS. Chestnut-brown, with ocellated brown spots, and yellow abdomen. Serpens guineensis rarissima argus dilia, Siba.

In size resembles the viper; the head is covered with small scales; tail tapers to a moderately slender tip. This, according to Seba, is a native of Guinea, and is a rare species.

CHIAMELLA. Blue, the scales marked with a white spot, body beneath yellow. Serpens americana chiamella dilia, Siba.

A beautiful species about four feet and a half in length, found in the West Indian islands.

CATUS. White; the scales disposed in fours, black, and thickly crowded into patches. Coluber catus, Gmel. Coronella catus, Laur. Amph.

A native of America; it is observed of this snake that it lies in wait, and springs upon mice like the cat, whence its name.

TESSELLATUS. Above alternately tessellated with black and brown; beneath black with white unequal spots each side; head long and shielded. Gmel. Coronella tessellata, Laur. Amph.
**C O L U B E R.**

**R u b e x.** Bright red with the spots alternately unting; beneath white. Gmel. A doubtful species.

**M o l e r u s.** Abdominal plate 248, subcaudal scales 59. Gmel.

This kind inhabits South America, and resembles the Boa tribe, but is distinguished by the plates, and large scales on the head, as in the coluber genus.

**M i n e r u s.** Glauces, with a brown dorsal stripe, and three on the head; abdominal scuta 238, subcaudal scales 90. Linn.

Length about eighteen inches; thickness exceeding that of a fawn quill; the colour glaucous, with a broad, longitudinal, brown band down the back, and three longitudinal bands on the head, two of which pass through the eyes. The head is oblong, ovate, convex, and smooth; the eyes large; tail slender, and measuring about a third of the whole length. Described by Linnaeus from a specimen in the museum Adolphi Friderici brought from the East Indies.

**S c u t a t u s.** Black; scuta extremely broad; tail sub-triangular. *Coluber scutatus*, abdominal scuta 190, subcaudal scales 90. Pallas.

Refines the common snake, *coluber natrix*; the length is about four feet; colour entirely black, except that the abdomen is marked alternately on each side with a row of smallish square yellowish-white spots. The principal character consists in the scuta being remarkably wide, extending on each side in such a manner as to embrace two-thirds of the body. This species was observed by Dr. Pallas about the borders of the river Ural; it is found occasionally both in the water and on land.

**H i p p o c r e p i s.** Livid, spotted with brown, with a reversed humeral or horde-shoe mark on the back part of the head. *Coluber hippocrepis*, abdominal scuta 232, subcaudal scales 94. Linn. Muf. Ad. Fr. *Natrix hippocrepis*, Laur.

Length about twelve inches; head of moderate size, marked by a transverse arched brown band between the eyes, and a larger horde-shoe-shaped mark on the back of the head; abdomen pale; tail tapering gradually from the tip. A native of America.

**D o m e s t i c u s.** Grey, spotted with brown; a bipartite black spot between the eyes. *Coluber domesticus*, abdominal scuta 245, subcaudal scales 94. Linn.

This is a native of Barbary, where it appears to be in some degree domesticated, being very common in the houses of the inhabitants, where it is kept to destroy the smaller kind of noxious animals. In its general appearance this snake is allied to the lat-mentioned species, and like that is perfectly harmless.

**E x a l b i d u s.** Whiteish with transverse broad spots mixed with black and white.

*Coluber exalbidus*, abdominal scuta 135, subcaudal scales 42. Gmel. *Coluber exalbidus maculis transversis latifinis et albo mixtis*.

**C a r h i n u s.** Grey, with large oval brown spots on the back, and small quadrangular notched spots on the sides; beneath silky white. *Coluber cabarinus*, abdominal scuta 239, subcaudal scales 82. Forik. Fn. Arab.

Inhabits Cahir. Length four feet and a half, and the thickness that of a finger; the head is flattish, sub-cardinated, with two pale oblong scales on the crown.

**C a l a m a r i u s.** Livid, with transverse brown bands and linear points; beneath teltellated with brown and white.

*Coluber calaminus*, abdominal scuta 140, subcaudal scales 22. Linn.

This is a small snake, measuring about a span in length, the thickness that of a goose-quill; colour above livid, sprinkled with linear dusky spots, and marked by several dark narrow transverse bars; the head is very small, convex, and ovate; the tail short and terminating obtusely. This species inhabits America.

**C a r i n a t u s.** Lizard-coloured, with large ovate, porous scales; back carinated; abdomen whitish. *Coluber carinatus*, abdominal scuta 157, subcaudal scales 115. Linn. Muf. Ad. Fr.

A large species, growing to the length of five or six feet, and of a moderate thickness; tail tapering gradually to a point; tail much carinated, rising into a ridge on the top; colour deep blueish brown, or cincereous, inclining to lead-colour, paler or whitish underneath; scales very large and marked with numerous impressed points as if pierced with pin-holes. This is represented as a harmless species; it inhabits North America, and varies in colour.

**G e t u l u s.** Blueish-black, with linear yellow lines on the sides and bifid bands on the belly. *Coluber getulus*, abdominal scuta 215, subcaudal scales 44. Linn. D. Garden.

Inhabits Carolina, where it frequents moit woods and shady places, and preys on lizards. Length about three feet. An elegant species.

Length from two to three feet; the colour brownish-yellow or livid, with a dusky and lateral stripe of confluent spots immediately above the centre, the anterior ones of which have a white dot in the centre. The abdomen is pale, and marked with three or sometimes four rows of small dusky spots. The head is covered in front with large scales, smooth obtuse; tail thick and rather blunt. The specimen described by Linnaeus measured, as above-mentioned, less than three feet, that described by La Cepede, a specimen in the Museum of the king of France, was more than six feet long, from which it appears this snake is of a large size when full grown.

**B a t a e n.** Spotted with black and white. *Fork. Fn. Arab.*

Described by Forskal as a native of Arabia; it is a foot in length and two inches in thickness, and is highly poisonous; the body swelling to a great size after being bitten by this snake.

**H a n n a c h i.** Entirely black. Gmel. Inhabits Arabia, a cubit in length, and as thick as a finger.

**P u r p u r a c e n s.** Abdominal scuta 189, subcaudal scales 122. Gmel.

**P i c t u s.** Abdominal scuta 172, subcaudal scales 142. Gmel. Boddaert.

**H a j e.** Black, with oblique bands, and scales half white. *Coluber haje*, abdominal scuta 207, subcaudal scales 109. Linn.

First described by Forskal. This snake inhabits Lower Egypt, is of a very large size, when irritated lifts up, and stretches out its head to bite.

**P u l l a t u s.** Bands of the body black with white dots; temples hoary with black spots; beneath white with black spots. *Coluber pullatus*, abdominal scuta 217, subcaudal scales 108. Gmel. A native of Asia.

**C a r a c a r a s.** Blue, with the scales on the fore-part of the
the body elongated; those behind rhomboidal, and the neck transversely frilled with black. Coluber caraceras, abdominal scuta 120. subcaudal scales 125. Linn. Serpens caraceras brasiliensiis singularis, Seba.

A species of moderate size, length two feet and a half; the head rather large and oblong; snout obtuse; from behind each eye a black streak; colour pale blue, the posterior part of the body tinged with rote colour; the scales on the fore parts of the animal are of a narrow lengthened form; and on the hind parts rhomboid; neck and anterior parts elegantly marked by numerous transverse black lines; tail rather long, and gradually tapering to the tip. This species inhabits Brazil.

Stolatus. Glauces, with two whitish stripes, and quadrangular transverse brown spots between. Coluber floslatus, abdominal scuta 143, subcaudal scales 76. Linn. Laurentii. Seba.

Described from a specimen in the Museum Adolphi Friderici as a poisonous snake, but it appears erroneously so. This species inhabits India. It is of the middle size, measuring from a foot and a half to two feet or more in length. The colour is blue above, with two rather remote white lines down the back, and a continued series of brown, transverse, equidistant zones. The abdomen is pale or white, each feutrum being marked on each side by two small specks; the head is covered with large scales, pale or blue above, and of moderate size; tail rather short and tapering to a point.

Length two feet and a half, and of moderate thickens in proportion; general color dull orange, with a broad dorso line of pale yellow; head rather large and covered with very large scales; tail rather short and tapering to an obtuse point. Inhabits South America.

Pallidus. Grey, speckled with brown, and marked with a double, interrupted black line on each side. Coluber pallidus, abdominal scuta 156, subcaudal scales 95. Linn. Amoen. Acad.

Linnaeus describes this as being a foot and a half in length, and the thickens of a fawn-quill, with the back slightly angulated each side. The head is roundish, much thicker than the neck and covered with large scales; the ground color pale variegated with scattered grey spots and points. Inhabits India.

Olivarius. Abdominal scuta 203, subcaudal scales 73. Gmel. Guingouya, Pf. Brasili. We only know of this species that the plates and scales are as above described, and that the species inhabits America.

Cenchria. Head globoso; body whitish, with transverse rhomboidal brown bands. Coluber cenchria, abdominal scuta 210, subcaudal scales 144. Linn. Anguis de cenchria americana, Seba.

A long and very slender species, growing sometimes to the length of three or four feet, and yet scarcely exceeding the thickens of a fawn-quill. The head is very large and nearly globular, the neck extremely thin; and the tail remarkably long, measuring nearly a third part of the whole animal, and gradually tapering to the extremity. The colour is white or yellowish, marked throughout the whole upper part from the head to the end of the tail, with numerous transverse rhomboidal bars, or patches of brown, the points of which descend on each side.

Flagellum. Extremely long; slender, and brown; abdomen pale. Coach-whip snake, Catefly.

This species measures from four to five feet; or even six feet in length, and is remarkably slender. Catefly, who describes this snake, speaks of it as an active nimble creature, running very swiftly and being perfectly harmless. "Yet, says he, the Indians report, not without gaining many profylets to their silly belief, that it will by a jerk of its tail, separate a man in two parts." This snake is a native of Carolina and Virginia.

The general colour is a bright blue green with a golden glint, and highly iridescent. The length is from three to four feet, and the diameter about three-fourths of an inch; the head is covered above with large scales, and the snout is slightly elongated, though not pointed; the tail is somewhat angular, and of considerable length. It is an innocuous species, is found in several parts of India, and is esteemed one of the most beautiful of the serpent race.

Long and slender, the general length about three feet; the head is obtuse; colour of the upper parts blue green, slightly tinged with purple; tail very long and slender. This kind inhabits many parts of North America, where it frequents trees and preys on flies and other insects. Catefly, to whom we are indebted for the above particulars, adds, that it is easily reclaimed from its natural wildness, becoming tame and familiar, and affirms that some people carry it in their bosoms.

Length about twelve inches, and thickens of a goose-quill; the colour above black, appearing like a broad dorso stripe, beneath white; the head is ovate, twice the diameter of the body, above black and beneath white; tail about one-third the whole length, very slender, and sharp-pointed. A native of India.

A small species, less than an earth-worm; head and upper parts jet black, and glossy; the head rather large, and covered with large scales; eyes flame-colored. This is a native of Pennsylvania where it inhabits crevices of rocks, old walls, &c. and feeds on insects.

Sipedon. Entirely black or deep brown. Coluber sipedon, abdominal scuta 144, subcaudal scales 73. Linn. A native of North America; described by Kalm.

Daboya Snake, Le dabota, La Capece. Described by La Cape who considers it as the species which in the kingdom of Juda, and some other parts of Africa, is regarded as a deity, and kept in temples consecrated to its worship. This superstition is said by the traveller, De Marchais, to have arisen from the following circumstance; the army of Juda being on the point of yielding to that of Arda, it happened that a large serpent of this species made its appearance, which the chief priest probably.
probably knowing it to be innocuous lifted it up in his arms and displayed as a kind of miracle, or at least as a proposi-
tions omen, persuaded the army again to rally, by which means a signal victory was obtained, and the animal was in
consequence exal ted to a divinity. It is said to arrive at a
very considerable size, and is of a whitish colour, orient-
mented on the upper part throughout the whole length by a
triple row of large oval ru fous patches bordered with
black, the head is rather large, and is covered with oval ca-
rinated scales similar to those on the rest of the animal.
The individual described by La Cepede was preserved in
the Royal Cabinet, and measured three feet five inches in
length.

Brazilian Snake, La brophane. La Cepede.
Length three feet; head and body covered with oval ca-
rinated scales, snout terminated by a large and almost perpen-
cular scale rounded at the top, but emarginate at the bot-
tom for the passage of the tongue; upper parts of the ani-
mal marked with large oval frous patches bordered with
black, and in the intervals between the large patches are se-
veral much smaller ones of a dusky colour; fangs very large.
This is a native of Brazil, and La Cepede believes may be
about six feet in length when it has obtained its full size.

Triangular-headed Snake, La tricéphalte, La Cepede.
Reminiscence of the common viper in general appearance.
The colour is greenish, with spots of different shapes on the
head and body, uniting so as to form a regular band down the
back; abdomen dusky, edged with white. The head is of a
more triangular shape than usual, and covered with smooth
scales, as are likewise the body. Its total length is
two feet. This kind inhabits the island of Eufatia.

Panther Snake, La tigrée, La Cepede.
Alied to the last; length about eighteen inches; head
as in the common viper. Colour of the upper parts whitish,
rufous, with dusky spots bordered with black like those on
the skin of the panther or leopard. The native country
unknown.

The coluber hydus, and coluber latiaudatus of Linnean,
are excluded from the above, and will be deferred under
the article Hydus, the new genus to which they are re-
ferred by Mr. Schneider, and which we think it right to
adopt. They are generally distinguished from the col-
ubrine tribe by having the body flender in front, becom-
ing gradually thicker, scaled, and the tail compressed.
See Hydus.

COLUMBRAIA Infusa, in Ancient Geography, an island of
the Mediterranean sea, near the Baleares. Pliny says
that the soil engendered serpents. It is thought to be the
present isle of Formentera, and the name with that which
the Greeks called Opduna, from εφι, obit, a serpent. It
lies S. of Yerca, and was inhabited.

COLVILLE, Cape, in Geography, a cape on the east
coast of New Zealand; lying in S. lat. 30°26’. E. long.
194° 27’. This cape rises directly from the sea, to a
considerable height, and is remarkable for a lofty rock,
which may be distinguished at a very great distance.
From the S. point of this cape the river Thames runs in a direct line S. by E., and is no where less than
tree leagues broad for the distance of fourteen leagues
above the cape, and there it is contracted into a nar-
row stream, but continues the same course through
a flat country, or broad valley, which lies parallel with the
sea-coast. On the east side of the broad part of this
town the land is tolerably high and hilly; on the west
side it is rather low, but the whole is covered with verdure
and wood, and has the appearance of great fertility, though
there were in Cook’s voyage, Nov. 1779, but a few small
spots which had been cultivated. Six leagues within cape
Colville, under the eastern shore, are several small islands,
which, together with the main, seem to form good harbours;
and opposite to these, under the western shore, the other
islands of which, probably, good harbours may be found.
The river affords good anchorage, and is defended from the
town by a chain of islands, lying across the mouth of it, and
on this account called by Cook “Barrier Islands”; these
of Baffin, and La Cepede believes may be
about six feet in length when it has obtained its full size.

Triangular-headed Snake, La tricéphalte, La Cepede.
Reminiscence of the common viper in general appearance.
The colour is greenish, with spots of different shapes on the
head and body, uniting so as to form a regular band down the

COLUMBA.

LIVIA. Stock dove. Wings with a double blackish band, called by Buffon \textit{bifet}, and by Albin the \textit{flock dove}.

CRISŢATA. Crested pigeon. Head ered; legs hislute and cinerous. \textit{Pigeon huppis}, Buff.

NORVEGICA. Norwegian pigeon. Head ered; legs hislute and irony. Frisch.

JUBATA. Turner pigeon. Cere hanging down from the crown like a mane. \textit{Turner pigeon}, Will.

This bird, is eight inches and a half in length. The bill is red, with a black tip; the irides red, and surrounded with a warty skin of the same colour; the upper parts of the body are rufous, with a purplish hue; the under part of the neck, with the bright flesh colour; belly, fider, and vent, somewhat rufous; under wing-coverts, quills, and tail rufous; legs red, with the claws black. Those birds inhabit Cayenne; they build in trees which have the boughs hanging low, and line their nests with hair and cotton. They feed on the berries of the myrtle. Dr. Latham suspeets, that this species is found in St. Helena, as a bird Vol. IX.

is mentioned in Mr. Anderson's catalogue, under the name of \textit{columba peninis}, and which is said to be very common in that island. A kind of pigeon, conceived to be a variety of the above, is described by Edwards; the forehead is of a clay colour; the head and neck, reddish purple; back, wings, and tail, red brown, with a gloss of copper-colour; the fore part of the neck is reddish clay colour; breast, belly, thighs, and under-tail-coverts, light clay colour; a white mark on each side under the eye, and another at the side of the throat, and all at the joint of each wing.

TETRAOIDE. Head, and neck black, with white margin. \textit{Scop. Tetraonir pigeons}, Lath.

The only account we have of this bird, is from the work of Strickland, Ann. t. p. 155. He informs us it equals the red-legged partridge, with a fire, and that the head and neck are black, and encompas'd with a white margin, as in that bird. The description was taken from a bird living in a menagerie.

Breed in vall numbers among the rocks on the coasts of Jamaica, St. Domingo, and the Bahama islands; and fubits on the berries of the sweet wood. The length is ten inches and a half; the bill red with a white tip; the eyes surrounded with a white skin, the irides yellow; crown of the head white, beneath changable; neck green and blue, varied with a gloss of copper; the quills, feathers, and tail are brown; the legs red, with grey claws.

This bird is the same size as the common turlte, and measures in length eight or nine inches. The bill is dally black. A fine blue skin surrounds the eyes, and according to the figure in the plates of Edwards, goes on to the blade of the upper mandible. The irides are crimson; the forehead, checks, and front of the neck and breast, pale rufous brown; hind part of the head and neck dull brown. The upper part of the body is dark brown, with a mixture of blue; greater wing-coverts the same, but the outer margins, and tips are white. The two middle tail feathers, are the same colour as the back, the red dull ash, with white tips; red legs, with black claws. The white winged dove, inhabits the East Indies, and is observed to flite up its tail at intervals, like the common wagtale.

FUSCA. Fuscous; eyes black; neck and breast white, undulated with black. Jacc. Betyr.

This is the size of the turlte, and inhabits Carthagenia, in America. Latham considers it as a variety of the last.

About the size of a turlte; the length nine inches and a quarter; the bill is red, and the eyes are surrounded with crifion tubercles; the head, neck, and upper parts of the body, are chestnut glossed with violet; the under parts of the body, more or less rufous; the quills the same as the upper, but on the outer edges only, the inner rufous; the tail feathers, the fame on both margins; legs reddish with brownifh claws. Inhabits Martinico. \textit{Le pigeons de la Martineque} of Briffon, and which Buffon calls \textit{Le pigeons roux de Ceylene}, is considered as a variety or rather the fe-
COLUMBA.

Male of the above mentioned bird; it is of a reddish brown colour, with a collar of golden violet; the wings are spotted with black; lateral tail feather black at the end, with the tip white. Inhabits also Martinico.

The length of this species is nine inches. The nostrils are much elevated, and form two tubercles at the base; the top of the head, with the under parts of the neck and body are in this bird half part of the neck varied with blue and purple; back, rump, and upper tail-coverts, purplish brown, with a light reddish tinge. This bird is found in the islands of Jamaica, in the month of January. It feeds on berries, frequents trees, and has a mournful note, which is sometimes very loud and disagreeable.

The crowned pigeon is nearly the size of a turkey, in which particular, it far exceeds any other species of the same tribe. Brisson has placed it with the pheasants, and his example is followed in the planche enfumées, but the bird possesses in every respect, the manners of the pigeon tribe; its note is cooing and plaintive like those birds, only louder in proportion. We are told, the mournful notes of these birds, alarmed the crew of Bougainville very much, when they touched in their voyage at one of the islands they inhabit, as they multiholk it at first for the cries of the human species.

The crowned pigeon, we are assured by Scopoli, has been known to build its nest and lay eggs in Europe, though the young were not hatched; they made a nest on trees in the monasteries, where they were kept, composed of hay and flax. The female it is observed never fat, but flock upon the eggs, and it is supposed by Scopoli, that it must be from this cause alone, these eggs proved abortive. In the East Indies, they are occasionally kept in court yards like other domestic poultry.

CRISTATA. Reddish brown, crested; under side, head, and neck, black; back and tail green; front with five very long, erect feathers. Columbia cristata, Gmel. Le coucou de Malacca, Sonnerat. Uncommon bird from Malacca, Phil. Trans. Lesser crowned pigeon, Lath.

The bill of this species is conical and rather bent; the colour black, except the under mandible, which is yellow at the base. On the fore part of the head, are fix very long black finely hairs, which stand upright, and may be depressed or elevated by the bird at pleasure; on the back part of the head, is a crest of a gilded red colour, composed of hard and stiff feathers. The space between the two crests is white, forming a band across the head. The eyes are encircled with thin white feathers. The legs are yellow; the toes are separated at their origin, and the hind claw isdlittle of a claw. Size of the common pigeon. A variety of this bird, formerly in the Leverian Museum, measured ten inches in length; the bill was yellowish, with the tip black; the back part of the head, crested as in the former; the forehead white, paling backwards on each side beyond the crest; the eyes were surrounded with feathers of a reddish colour, which palled backwards in a point; the head and neck were deep reddish brown; breast, belly, and vent, yellow black; the legs fine reddish brown; back, rump, and tail, dull brownish green; tail covert long and falling over the tail; legs reddish yellow, with black claws. The history of this bird is unknown, but it is considered as a variety, or possibly a sexual difference.

The pompadorus pigeon is a native of India, and appears to be most common in the island of Ceylon. It is constantly seen on trees, and for the most part on those known by the name of Warlingia grahamii, on the berries of which it delights to feed. They are shot by Europeans, who esteem them excellent eating: the natives take them with birds nets. The fize is less than that of the common turtle; the back, breast, and belly, are pale green; the wing-coverts of a fine purplish brown; tail green; and legs red. The female is paler, and has the wing-coverts the colour of the body. These birds are common in the country about Bengal, where they are called covania; it is said to have a whistling note, resembling that of the thrush.

ERYTHROPELA. Black; eye-brown, and front white; neck above, shoulders and wing-coverts garnet colour; tail from the base to the middle cincinnius; legs brown.

Length nine inches and a half; tail two inches and a half long and even at the tip; legs brown.

This inhabits the island of Eimeo. Another bird much resembling this, and supposed to be the female, was met with at Oahu: the forehead, throat, front of the neck and breast, were white, the hind part of the neck dusky; over the eye a ferruginous streak, passing a little downwards on each side of the neck; the back dusky black; belly dusky; quills and tail blackish. Another analogous kind, found in the South Sea islands, is of a reddish brown colour, with the breast, and eye-brow white, and the legs red.

A native of the island of Panay. It's size is equal to that of the common pigeon; the bill dull red with the irides yellow; the lesser quill feathers are green, with a metallic fulvous, and on the arm-pits is a semi-circular spot, half grey, and half green; the legs are dull red.

Size of the turtle; the bill scarlet and ten inches in length; nostrils blueish; forehead white, with a streak of the same through the eye. The sides of the head, neck, and breast is reddish, the hind part deep; upper part of the tail and wing-coverts green gold, glossed with coppery; ridge of the wing spotted with white; lower part of the tail, rump, and upper tail-coverts reddish brown; quills brownish, and russet next the base; tail three inches long; two middle tail feathers black; the rest cinereous, with the tips black; legs red, with black claws. A native of Ambon. Jacquin describes a variety of this bird, having the quills and tail feathers green; wing-coverts violet; and the rump and vent blue.

PURPURATA. Green; cap scarlet; vent fulvous; head, neck, and collar white. Columbia purpurata, Gmel. Purpurata pigeon, Lath.

A general inhabitant of the islands in the Pacific ocean, and subject to considerable variations in the colour of its plumage. The natives of Tongo Taboo call it horalor, those of Omate Oopa, and Oopara. It lives on the banana, and is easily tamed.

JANUSI.
COLUMBA.

Rather smaller than the common dove; the bill is yellow, the fore part of the head of a deep pink, resembling the colour of the blossoms of the jambos, whence its name of jambos pigeon; the back, wings, and tail are green, with the breast and crop white; the eyes are yellow, and from the orbits to the breast extends a white streak, edged on one side with green, and on the other with pink. This is a native of Java, and feeds chiefly on berries.

RUDEOPIZA. Violet-black; cap and orbits of the eye naked and red; neck, upper part of the back, and breast greyish. Columba atricapilla, Gmel. Le pigeon violet à tête rouge d'Antique, Soum. Red crowned pigeon, Lath.

Found in the isle of Panay by M. Sonnerat. This bird is the size of the jacobin pigeon. The bill is grey. At the base of the upper mandible is a thin membrane of a bright red colour entirely encircling the eye; legs grey.

PURPELA. Green; head and neck purplish; breast fulvous; vent scarlet. Columba purpeala, Gmel. Purple pigeon, Brown, Lath.

Size of the common wood-pigeon. The front is pale green; breast orange; back, leaupipers, and belly light grey; quills dirty. A native of Java where it is called sipon.

EMBREUS. Greenish brown; front, collar, and beneath vinaceous; crown and neck above brown; double band on the breast purple and white. Columba gencerus, Gmel. Purple pigeon, Lath. Inhabits the island of Eimeo. Length fourteen inches.

Inhabits the islands of Manilla and Panay. The female is of a greenish-grey, and greenish yellow beneath. The species is rather larger than the turtle.

Size of the common turtle; length ten inches and a half. The bill is greenish; crown grey; tail beneath black at the base, and at the tip whitish; legs grey or red. A native of Ambina.

The size of the common pigeon; the eyes are black, surrounded by blue orbits, with the wings and tail of the tip brown. Inhabits the island of St. Thomas.

CURVOOSTRA. Green; beneath yellowish; vent white; back and shoulders bay; wings with two yellow bars; middle tail feathers green; lateral ones cinereous with a black band. Columba curvostra, Gmel. Hook billed pigeon, Lath.

Inhabits the isle of Tanna in the South Seas; the bird, supposed to be the female of this species, differs from the male in having the back and shoulders green, and the under tail coverts, together with the vent white.

TANNENSIS. Green; wing-coverts spotted with white; secondary quill feathers edged with yellow at the tip. Lath.

Described from a drawing in the possession of Sir Joseph Banks. The bird is eleven inches in length, and inhabits the isle of Tanna. This is, perhaps, only a variety of the last.

A native of the island of Jamaica, Cuba, and other warm parts of America. Size of the common pigeon.

PACIFICA. Back greemish brown; head, neck, breast, and abdomen cinereous white; tail blackish. Columba pacifica, Gmel. Ferruginous veiled pigeon, Lath.

The length of this species is thirteen inches and a half; the nostrils are gibbous, the throat whitish; breast vinaceous, and the legs either red or brown. It is a native of the Friendly Islands. A variety of this species has the head, neck, breast, and belly whitish; back, wing-coverts, and tail greenish, and the bill gibbous at the base. This inhabits Otaheite and Tongataboo.

A native of Mexico; the irides are black; the legs red. Nativé. Above fulvous, spotted with black; beneath pale fulvous, under tail-coverts, and beneath the wings, cinereous. Columba mexicana, Gmel. Genus mexicana, Buff. Hoilolat, Ray. Black spotted pigeon, Lath.

Inhabits the farna country as the last, and frequents woods; size of the common pigeon.

PALUMBUS. Cinerous; tail feathers black on the posterior part; primary quill feathers white on the outer edge; neck on each side white. Columba palumbus, Linn. Le pigeon ramier, Buff. Columba fassinnola, Cetti. Ringel taal, Gueth. Ring pigeon, Lath.

Inhabits the woods of Europe and Siberia, and builds its nest on trees.

Inhabits the Molucca islands, and feeds on the nutmeg: its size is equal to that of the ring-pigeon. A variety of this species is described by Sonnerat, under the title of Pigeon oviree manqueur de myracle, and which appears to have been found in New Zealand; another variety has been met with at Amsterdam Island, where it is called Oruola ya.

This bird inhabits New Guinea, and is described by Sonnerat, who mentions its feeding on nutmegs, observing, that it is probably only the outer skin which serves them for nourishment, as the nut itself is voided whole, and so little altered, that, after passing through the organs of digestion, it is not rendered leis fit for vegetation; and hence it happens, that these birds flying from one island to another, different;
COLUMBA.

perfe, and sow the seeds of those valuable plants in every part they frequent. A variety of this species having the tail white instead of black.

Inhabits the rocky parts of Africa, and is in particular common about the Cape of Good Hope. The size is that of the wood pigeon; its bill is brown, irides yellow; head and neck cinereous, upper parts glossed with violet and purple; rump and belly white.

CARIBEA. Blueish; abdomen white; head, lower part of the neck, and breast purplish; tail feathers transversely with black. Columba caribea, Gmel. Columba cauda festiva notata, Ray. Ring-tail pigeon, Lath.

A bird the size of the ring-pigeon, and which is found in all the woods of the Caribbee islands. It is in great esteem for food, each bird selling for the table at the price of a dollar. In Jamaica it is frequently called the montain pigeon. A fantastic variety of this bird is described by Jucquin, which has the tail conical; the orbits bare of feathers, and yellowish, and the body bluish; the tail of the tail-mentioned bird is as long as the body, and is destitute of the black band fo conspicuous in the ring-tail pigeon. We conceive this ought fearlessly to be considered as a mere variety.

ZEALANDICA. Red; abdomen white; rump blue; tail black. Columba nova iselandica, Gmel. New Zealand pigeon, Lath.

A native of New Zealand, observed by the English circumnavigators, in Dusky bay, where the inhabitants call it Hugarréron. The length of this bird is eighteen inches. The bill and irides are red; quill-feathers dusky; vent blueish.

BRUNNEA. Cap, neck above, back, and wing-coverts brown; breast, neck beneath, and the rump shining green. Lath. Inhabits New Zealand; the bill and legs are fanguineous.

This beautiful bird is a species recently discovered, and was first described by governor Phillips, in his account of Botany bay. It is the size of the common wild pigeon, and appears to be found chiefly in Norfolk island. The most remarkable character of the bird is the rich band of coppery-gold across the wings; a few spots of the same colour occurs also on the lesser wing coverts. Its bill and legs are red; quill-feathers brown, beneath rufous; the two middle tail-feathers brown, the rest pale lead colour.

The length of this species is ten inches and a half; its size that of the common pigeon. The bill and legs are red; the eyes placed in a bare reddish skin; the feathers on the neck are narrower than the others, and have a mixture of ash.

A native of Madagascar. Length twelve inches; bill lead colour; eyes and legs fanguineous; posterior part of the abdomen and thighs spotted with black. Perhaps a variety of the last.

Francisc. Blue; orbits naked; rump and tail red; feathers of the neck long, narrow, and pointed at the end. Columba francisc, Gmel. Le pigeon hollandais, Sonner. Hackled pigeon, Lath.

This bird considerably exceeds the ring-pigeon in point of size. The bill and irides are crimson; the feathers of the head, neck, and breast are long, narrow, pointed, of compact texture, and with a deeply polished surface. It inhabits the Isle of France, and is never eaten, the flesh being reputed poisonous.

Maculata. Deep green; body above spotted with white; belly blackish; tail black, with the tip ferruginous. Columba maculata, Gmel. Spotted green pigeon, Lath.

Described by Dr. Latham from two specimens, one in the collection of general Dawes, the other in that of sir Joseph Banks. The length is twelve inches. The bill black, with the tip yellow; the general colour is dark green, with a glossy surface; the head and neck darker than the rest. The feathers of the neck are long and narrow; every feather of the wings and scapulars are marked with a pale cinereous-white, and sub-triangular spot; the quill-feathers are black, with the tip cinereous; the legs are brown, and are covered half way down with downy feathers. The native place of this species is unknown.

This is one of the most splendid of the pigeon tribe. Its size is that of the common pigeon; the bill is dusky; the irides hazel; head, neck, breast, belly, and thighs, and under tail-coverts dark blue-purple; the feathers on the neck are long and pointed, and with the upper parts of the wings are of the finest green colour, glossed with the most vivid hues of red, blue, copper, or golden. The tail and upper coverts are white; legs reddish. The female is distinguished by the plumage being less brilliant and glossy, and in having the pointed feathers of the neck shorter than in the male. These birds inhabit the isle of Nicobar.

Rather larger than the common turtle. The bill is red, covered with a white cere; the head ferruginous; neck and breast varied with rufous white and purple, each feather being rufous, with a white mark, and the margin blue, gives the whole plumage in this part a beautiful undulated appearance; the back and wings are ferruginous; quills darker than the rest; tail dusky black, and rounded; the legs red. The female is marked in the same manner as the male, but is much diller in colour. A native of Cayenne.

The turtle is a general inhabitant of Europe, China, and India, and appears to be most frequent in Turkey and the southern parts of Russia, and in the rocky country beyond the lake Balkal. In England those birds are not uncommon during the summer, but it is only in this season that
COLUMBA.

they are offered with us, for they arrive late in the spring, and depart in autumn. They build on the highest trees in thick and deep forests, and lay two eggs like the other kinds of pigeons.

It is related by baron de Tott, that this bird is highly favourable in the Turkish dominions, where it is extremely plentiful, government allowing a certain rate per cent. on the duty imposed on ears that those birds may be allowed to feed un molested. A crowd of them constantly alight on the eves which crows the port of Constantrine, and carry the corn uncovered either to the mills or magazine, and the boat-men never oppose them. This permission to feed on the grain brings them in great numbers, and familiarizes them to such a degree, that they are seen standing on the shoulders of the rowers watching for a vacant place where they might fill their crows in turn. The same custom is mentioned by Sonnini.

"In the Leverian Museum (says Dr. Latham) is a bird shot in Buckinghamshire, which differs from the common turtie in having almost the whole side of the neck black, instead of a patch only, and instead of each feather being tipped with white, there is a round spot of white on each very near the end, giving the sides of the neck a most beautiful appearance." There were three of those elegant birds in the Leverian Museum, including the male, female, and young, all which are now preserved in the London Museum. Those we are perfuaded ought rather to be considered as a distinct species than a variety of the turtle. Two others, considered as varieties of this bird, are the Portland dove of Albin, and La tourterelle grifé de l'ile de Bourbon of Sonnerat, the first inhabits Portugal, as its name implies, and is of a brown colour, with the spot on the side of the neck varied with black and white, and the lateral tail feather on the outer side tipped with white; the other is distinguished principally by having the two middle tail-feathers black, and the lateral ones white. This inhabits Manila. Bidas the above Dr. Latham describes La tourterelle brune de la Chine of Sonnerat as a further variety of this bird in his "Synopsis," but in the "Index Ornithologicus," it is enumerated as a species under the name of orientalis.

Orientalis. Griseous brown; feathers on the sides of the neck black, with pale cinereous tips; band on the wings yellow. Chinige turtle, Lath.

A native of China, and of the size of the common turtle; the bill and irides are red; head, neck, breast, and back dirty brownish grey, palest on the breast; wings brown; rump and tail deep cinereous grey; belly and thighs vinous grey; legs red.

Egyptiaca. Tertaceous flesh colour; chin spotted; the feathers black, and two lobed, truncated and furfusons at the tip. Forik. Fn. Arab.

This bird is described by Forkal, who informs us it frequently frequents houes in Egypt; the bill is black; head violet and flesh-colour; oribits naked and bluish; back cinereous; breast violaceous flesh-colour; belly and thighs whitish; wings brown; the two outermost tail feathers cinereous at the base, black in the middle, and the remainder white; the two next on each side cinereous at the base, black in the middle, cinereous beneath, and whitish at the tips, the fifth on each side brown, in the middle pale black, the two middle ones wholly brown; legs flesh-colour.

Surinamenesis. Cinereous, beneath white; chin varied with black and green; bill blue. Columba furanamensis, Gmel. La tourterelle, Sonnerat. Surinam turtle, Lath.

Length ten inches; the bill long and slender, of a fine deep blue without, and red within; and the legs red. The species is thus described by Fermin, who informs us it is a common bird in Surinam. It lays eggs twice in a year, making its nest in woods on the highest trees; the flesh is juicy and delicious.

Exceeds ten inches in length; the female differs from the male in having the colours less vivid, and inclining to grey. Inhabits India, and the southern parts of Europe. La tourterelle grise de la Chine of Sonnerat is considered as a variety of this bird; it is of a brown colour, beneath vinaceous grey; crown grey; black crescent on the neck, above spotted with white; lateral tail feathers black, spotted with white. This kind inhabits China and Madras.

La tourterelle mulet, turuter hybridus of Briff. is also of this species; or, at least, a mixed breed between the common and collared turtles. The head, neck, and breast are vinaceous; the back dull reddish ash-colour; belly, beneath the wings, and tip of the tail as in the last mentioned bird; the quills are brown; legs languidus.

This is a native of China, and is the size of the last. The bill is blueish ash-colour; the irides white; crown of the head ash-colour; tail pale brown; legs red, and claws white.

Length nine inches and a half; the bill three quarters of an inch long, and of a pale horn colour; the nostrils pale blue; irides blue grey. The eyes are placed in a bare white skin, which passes to the nostrils; forehead, cheeks, and throat pale blue; top of the head and hind head incline to rufous; upper part of the neck, the back, and wing-coverts are brownish ash marked with transfuse arnated black bands; fides of the neck and body bluish, crossfed with blue, black, transfuse transverse lines; fore part of the neck, breast, belly, and thighs tinged with rose-colour; under tail-coverts white; legs pale red; claws brown.

This bird is frequent at Malacca and the island of St. Helena; and is also found, according to Jacquin, in South America.

Suratensis. Griseous; neck above black; hind head white; nape banded with rufous; quill-leathers black; back, rump, and tail obscur grey. Columba suratensis, Gmel. La tourterelle de Surate, Sonner.

About ten inches in length. The bill is black; the irides and legs red. It is a native of Surat in the East Indies.

Cambayensis. Grey, beneath white; head somewhat vinaceous; collor beneath black, varied with rufous; lateral tail-feathers half black and half grey. Columba cambayensis, Gmel. La tourterelle grise de Surate, Sonner. Cambayan turtle, Lath.

Described after Sonnerat as a native of Surat, and other provinces of Cambay. Its size is that of the collared turtle.

The length of this bird is seven inches and three quarters. The bill is red; fore part of the head and throat ash-colour; the hind head and back part of the neck, back, rump, upper tail and wing-coverts, breast, belly, fides, and thighs green gold, gloffed with copper; the greater wing-coverts have the outer edges of the feathers at the tip fulphor-coloured; under wing-coverts ash, quills blackish; tail blue-green, gloffed with copper; the legs are red, and covered half their length with feathers; the claws grey-brown. This bird inhabits Ambouna.

A species the size of the last, and also described by Sonnerat. It inhabits the coast of Malabar. The bill and nides are red; the head, back, and wings are of a pale cinereous-grey; the neck and breast grey, tinged with vinaceous; the two middle tail-feathers grey; the belly white; and legs red.

Melanoccephala. Green; head somewhat cinereous; head blueish-ash; hind head black; chin and throat yellow; vent orange; six middle-tail-feathers green; the outer ones on each side fine crimson. *Columba melanoccephala*, Zool. Ind. *Turve, Buff. La tourterelle de Bataua, Pl. Enl. Black-capped pigeon*, Ind. Zool.

Found in the island of Java. The length is nine inches and a half; the bill black, short, and yellow at the tip; the tail is of a somewhat cuneated form; and the legs are black.

Length nine inches; the bill pale red; covered with a white cere; tail dusky beneath; legs red. Inhabits Java.

Size of the last; it is an inhabitant of China, where it is called by the natives *Taiyuan*. Common also in the island of Cuba, where it is caught in traps, and brought to the markets in great numbers as an article of provision.

The length of this bird is eight inches. The bill is reddish; top of the head ash-coloured; hind part of the neck, back, wing-coverts, and rump grey-brown; throat whitish; fore part of the neck and breast pale vinaceous; the belly, fides, thighs, and under tail-coverts dirty white; the upper tail-coverts are grey-brown, with the tips blackish; quills brown, with the inner webs rufous; on the wings are some spots of green gold-colour, gloffed with violet; the tail is two inches and three quarters in length; the two middle tail-feathers blackish brown, the rest grey-brown, with the ends blackish; the legs are red, with brown claws. This is a native of Senegal, and is the *Columba senegalensis* of Drifon, but not of Linneus; the latter writer describes the next species under that name.

The length of this species is nearly ten inches; the bill is blackish, the head, neck, and breast vinaceous; upper part of the back brown, lower cinereous; the fix middle feathers cinereous brown; the three others on each side dark-ash from the base to the middle, and from thence to the ends white; beneath the colours are all ash, and half black in the fix middle feathers, and white in the three outer ones; the legs are red, the claws brown. This bird is found chiefly near the river Senegal.

Size of the last, and inhabits the same country. The bill is blackish; head, neck, and breast sharct-colour; upper part of the back brown, lower cinereous; belly white; fix middle tail-feathers ash-coloured-brown; beneath from the base to the middle black, the rest cinereous.

First described by Sonnerat; it inhabits Manilla. The length of this bird is eight inches; the bill is black; the irides fuscous; collar on the neck violet, gloffed with green; the blood-coloured spot on the breast darkish in the middle; wings with three grey and two black transverse bands; quill feathers black; tail grey at the base, and black at the end; legs blackish; and somewhat violet.

This bird inhabits Manilla, and was first described by Sonnerat. It is a species of great singularity, the whole of the plumage being white, except the spot on the breast, which is of a deep tanguineous colour; the bill and legs are red, the irides purplish.

The ground dove is a native of the warmer parts of America, and the contiguous islands; and is observed as far north as Carolina, but more rarely. Wilughby says it is very common in Mexico, where it inhabits mountainous places. Dancroft observes, that it is the only kind of dove met with at Guiana. In the Caribbean islands it is very abundant, and is commonly eaten, being in much esteem for food; its haunts are lony places under bushes. It is also common in Jamaica, where, as Sloane mentions, "they feed on the ground like partridges, and spring as they do, rising and flying for a short flight, and then light again on the ground." They subsist chiefly on grain and seeds of vegetables; and are taken in traps baited with the seeds of the *Ricinus*, or castor oil.

This is a small and elegant species, the length about six inches. The bill is pale red, with the tip blackish; the irides orange; upper part of the head and neck ash-colour; back, rump, and upper tail-coverts the same, but deeper; front vinaceous; throat and breast spotted with brown; two middle tail-feathers are deep ash-colour; the others blackish; legs
legs red, the claws blackish. The female differs in the general colour of the plumage being paler.

There are several varieties of this species, one of which, found at Carthagena in South America, is distinguished by having fewer brown spots than usual; another has the body more inclining to reddish, and the eyes chestnut; and a third with the feathers of the neck and breast of many colours.

**MINUTA.** Brown ; wings with from five to seven rivel-blue spots; outermost tail-feathers white at the tip. Columba minut, Linn. Turto pavus fusius americanus, Briss. Cecidin alid genus, lapaleoecil, Will. Paffiere turtle, Lath.

It admits of some doubt whether this pigeon is distinct from the last, C. paffiera. This kind inhabits America, and is five inches and a half in length. The upper parts of the body are brown, the under more or less rufous-white; wing-coverts rufous; two middle tail-feathers brown, the others ash-coloured at the base, black in the middle, and brown at the tip; the bill and legs are black.

**MALACCENSIS.** Undulated with black lines; above cinereous-grey; beneath cinereous; sides of the neck white; tail-feathers fuscous, fides near the tips white. Columba malaccenis, Gmel. La petite tourterelle de queuda, Sonner. Malacca turtle, Lath.

This is a beautiful species, scarcely exceeding the size of the common hoopoe-sparrow; the bill is yellow, and in the middle black; the forehead and throat are light cinereous-grey; breast and belly vinaceous-grey; middle tail-feathers brown for two-thirds of their length, and from thence to the end white; thighs and under tail-coverts white; legs yellow. This species inhabits Malaca, and is esteemed a delicacy for the table.

**VERNANS.** Green; beneath yellowish; outer edges of the wings pale yellow. Columba viridavisphilippines, Briss. Pigeon vert des philippines, Buff. Columba vernanas, Gmel. A native of the Philippine islands; the bill and legs are red, the breast azure.

Those birds inhabit North America, passing the summer in the higher latitudes, and retiring to the more southern provinces at the approach of winter. They build in trees, and lay two eggs. It is said those pigeons are so abundant in America, that at the period of their migration they are seen passing from one place to another in flocks of two or three miles in length, and a quarter of a mile in breadth, and which literally darken the air as they proceed. Frequently at such times we are told they alight on trees, and sometimes in such immense numbers as to break down pretty strong branches. They are said to eat excellent eating, and, during the time of migration, furnish the common people of America with abundance of food. About Philadelphia they flock to these birds from the tops of their houses, or knock them down in the evening from their roosting places. In Louisiana they adopt another mode of capture; a party of five or six go in the evening into the woods, and taking with them several ditches, or other flat vessels, they let a brace on fire in these under such trees as the birds commonly prefer to roost upon, the smoke and vapour of which ascend to fluster the birds that they drop down from their roosting places, and are picked up and secured in flocks previously provided for that purpose. It is said fences parties are often accompanied in those nocturnal rambles by the ladies; this mode of taking pigeons being esteemed a delightful evening's amusement. The chief food of these birds are acorns, rice, corn, and other grain.

The passenger, or migratory pigeon of America, is about the size of the common domestic pigeon of this country. The bill is black, the space round the eyes crimson; irides orange; head, throat, and hind part of the neck, back, rump, and upper tail-coverts cinereous; wing-coverts the same, marked with dusky or black spots; the sides of the neck are glazy, variable purple; fore part of the neck vinaceous; belly, sides, and thighs, with the under tail-coverts, the same colour; paier, quills black brown, edged with white; the tail rather long, with the two middle feathers blackish brown, the ruf hoary; legs red, with black claws.

A variety of this species is described by Gmelin. The colour is brownish above, beneath whitish-rufous; neck on the forepart somewhat vinaceous; lateral tail-feathers with a round black spot in the middle on the upper surface.

Rather larger than the common turtle. The bill is blackish; irides black; front, throat, and breast rufous, with a green-gold and violet gloss. The hind part of the head and neck are brownish ash; the back, rump, upper tail, and wing-coverts ash-brown; on the wings, near the tip of the greater coverts, are a few black spots; quills blackish ash with whitish edges; tail-feathers unequal, the two middle ones four inches and an half in length; the outer ones very short; the two middle ones entirely ash-coloured; the next two on each side ash-coloured, marked with black in the middle, the others light ash-colour, whitish at the end, with a black spot between the two colours; the legs are red, the claws black. The female is destitute of the glossy violet colour on the breast. Those birds inhabit Carolina, Brasil, and St. Domingo.

Length thirteen inches; the bill blackish; upper part of the head, neck, back, and wings grey-brown; the lower part of the back, rump, and upper tail-coverts ash-coloured; throat and fore part of the neck grey-brown tinged with yellowish; wing-coverts marked with blackish brown spots; tail ash-coloured, the feathers tipped with white, except the two middle ones; legs red; claws black. In the female most of the feathers are tipped with dirty white, which gives the plumage a struck appearance. The native place is Canada.

**MARGINATA.** Body above fulvous; beneath brownish-grey; breast red; tail feathers black at the tip, the edges white. Columba marginata, Linn. Turtur Americanus, Briss. Tourterelle d'Amérique, Buff. Long taillé, Duf. Margined pigeon, Isth.

Inhabits America. Length ten inches; the bill is hoary; irides rufous; lores white; front and chin reddish brown; bird head blueish ash; under the ears a black spot; upper part of the body brown; shoulders spotted with black; throat rufous; two middle tail feathers blackish, the rest cinereous.

**AMBIGNENSIS.** Body rufous; neck waved with black. Columba ambignensis, Linn. La tourterelle d'Ambot, Buff. Ambina turtle, Lath.

Length fourteen inches; bill black; feathers of the crown,
crown, neck, and breast with a blackish transverse bar near the tip; feathers of the upper part of the back, and wing-coverts brown tipped with rufous; wings brown; tail reddish-brown. A native of Ambona.

*Capeensis.* Body grey-brown, beneath white; primary quill feathers rufous on the inside. *Columba capensis,* Linn. La tourterelle, Buff. Cape pigeon, Lath.

Inhabits the southern parts of Africa. The length of this bird is nine inches and a half; the bill is red; body grey-brown; belly whitish; spot on the wing fleshy; secondary quill feathers brown, with the exterior edge grey; tail black beneath; lateral feathers at the base grey-brown, with the tips blackish; legs red, with the claws black. The female differs in having the throat and forepart of the neck of the same colour as the ruf of the head, and the greater wing-coverts not tipped with black. There are several varieties of the Cape pigeon.

The length of this bird is twelve inches, the bill red, with a white cere; tail as long as the body; legs red. A native of Senegal.

*Bantamensis.* Orbits naked and fleshy coloured; neck, breast, and flanks waved with black and white. *Columba bantamensis,* Mül. Curt. f. 3. t. 67.

Common in the island of Java. The species is small, bearing about the size of the wry neck; the bill is black; body above hoary ash; beneath whitish; back, wings, and breast with lunate black spots; tail fame length as the body, and confining of fourteen feathers, the fix middle of which are black, the rest white towards the tip; legs red.

*Dominicensis.* Body grey; sides of the head and collar beneath the nap white; spot on the crown; band under the eyes, and collar on the neck black. *Tourterelle de St. Domingo,* Pl. Enl. Columba dominicensis, Lath. Ind. Orn.

A native of St. Domingo; the length of this bird is eleven inches; the bill black; wings with a few blackish spots; breast vinaceous; front, chin, and vent white; tail grey; the outermost feathers white; legs red.

*Columba raisoniaca,* a name given by authors, as Ray, Willughby, and Albin, to the black guilemot. See Cololumbus girile.

Columba is also the name of a military order instituted by John I. of Calilé, about the year 1739.

*Columba Novatie,* a small constillation in the southern hemisphere, consisting of ten stars. The longitudes, latitudes, &c. of which are given in Sharp's Catalogue.

Columbace denotes that part of the agallochum, which is between the heart, and that part next to the bark.

*Columbaria,* in Ancient Geography, an island of the Mediterranean on the coast of Etruria, according to Pliny.—Also, another island of the Mediterranean, near Drapanum in Sicily, called by the Greeks "Pelias."

Columbarium, a promontory of the Isle of Sardinia, N. of Portu Olbians, on. the E. coast: the same with Colymbium.

*Columbate of iron.* See Columbium.

Columbia, a county of America, in New York, bounded N. by Rensselaer, S. by Dutchess, E. by the State of Massachusetts, and W. by Hudson river, which divides it from the county of Albany. It is 32 miles long and 21 broad, and is divided into 6 towns, viz. of which Hudson, Claverack, and Kinderhook are the chief. It contained, in 1793, 27,732 inhabitants, and in 1796, 35,560 electors.

*Columbia,* a county of America, in the upper district of Georgia. bounded by the Savannah river on the E. and N., which separates it from the State of Carolina, and N.W. of Richmond county.

*Columbia,* a township of Washington county, in the district of Maine, on Penobscot river, adjoining Machias on the N.E., was incorporated in 1796.

*Columbia,* a poll-town of America, the capital of Kansas county, and the seat of government of S. Carolina. It is situated in Camden district, on the S. side of the Congaree river, just below the confluence of Saluda and Broad rivers. The streets are regular, and the town contains upwards of 70 houses. It lies 115 miles N.N.W. of Charleston, 35 S.W. of Camden, and 678 S.W. of Philadelphia. N. lat. 34° 15'. W. long 81° 57'.

*Columbia,* a flourishing town of Georgia county in the State of Virginia, on the side of James river, near its junction with the Rivanna, 45 miles from Richmond, and 35 miles from Charlotteville.

*Columbiana,* a town of America, in the county of Lancaster and state of Pennsylvania, seated on the N.E. bank of the Susquehanna river, 10 miles from Lancaster, and 76 W. by N. from Philadelphia.

*Columbia,* a town of America, in the county of Hamilton and State of Ohio, seated at the confluence of the Little Miami with the Ohio, 6 miles above Cincinnati. The settlement began in 1789. N. lat. 39° 20'.

*Columbiana College.* See College.

*Columbiana county.* See Washington.

*Columbiana,* a county of America, in the state of Ohio, bounded N. on the county of Trumbull, S. on Jefferson and Muskingum counties, E. on the state of Pennsylvania, and W. on the Muskingum river, and county.

*Columbic Acid.* in Chemistry. See Columbium.

*Columbiars,* in Geography, a town of France, in the department of the Aisne, and district of Rhodes; 10 miles W. of it.

*Columbina,* a name given by Aetius, and some other medical writers, to the verbena, or common vervain.

*Columbina Marga.* See Marle.

*Columbine,* in Botany. See Aquilegia.

*Columbine feathered.* See Thalictrum aquilegifo- lium.

*Columbine,* a kind of violet-colour, called also dove-colour. See Dyeing.

*Columbium,* in Chemistry, a new metal discovered by Mr. Hatchett, in the year 1802, in a mineral which he had from the British Museum. The mineral, it appears, had been fet with some specimens of iron ores from Massachusetts in America, to Sir Hans Sloane, in whose catalogue it is described as "a very heavy black stone, with golden streaks." By Mr. Hatchett it is described as of a dark brownish grey externally, and more inclining to an iron grey internally; it found the longitudinal fracture lamellated; and the transverse fracture had a fine grain. Its luster is vitreous, slightly inclining in some parts to metallic, moderately hard, and very brittle. The colour of the powder was dark chocolate brown; but the streaks were yellow mica. The particles were not attracted by the magnet. Its specific gravity, at the temperature of 65°,
COLUMBO, in Geography, the capital of the island of Ceylon, and the seat of government. It is situated on the S. W. part of the island, in about 7° N. lat., and 85° E. long., from London. It was captured from the Dutch by the British troops under General Sir Harry in 1756. A tough Trincomali, on account of its situation and history, is of greater consequence to the British nation to retain, yet Colombo is in every respect greatly superior. The number of its inhabitants is much greater; its fort and black town are much larger; the country in which it is situated much more fertile; and the rich district depending upon it much wider, being not less than 50 leagues in length and 10 in breadth. Colombo is commonly supposed to have been first fortified by the Portuguese; but Captain Percival questions the truth of this statement, as Laurence de Almeida, after his first treaty with the king of the island, found that the Moors and Malabars had a fortress here, on which some guns were planted, which had been procured from ships wrecked on this coast. That part of the fort, where these ancient works stood, is now strongly fortified, and shown as the first works of the Portuguese. It is in a manner detached from the main body of the fort, being separated from it by an entrenchment and wall, with a fosse or ditch, now almost choked up. The fortress was built on a precipitous loft, projecting into the sea, and it is thus exposed on all sides to the sea breezes, by which the air is rendered temperate and healthy, though it lies so very near the equator. This fort is upwards of a mile in circumference; and is indebted for its strength both to nature and art. On the south side the fort runs to high, and the shore is so rocky, that it would be dangerous to approach it. On the west side of the bay, where the sea is smoother, and near the wharf or landing place, which at all seasons of the year is safe for boats, the only attempt could be made; but these quarters are so well defended by the batteries which command the harbour, that there is hardly any probability of its succeeding. On the west side of the fort, and facing the sea, are two very fine batteries, **en barbet**, intended for the security of the harbour. These stand on a part that projects a considerable way from the main body of the fort, from which they are separated by a high wall and ditch flank'd with bastions, and have gates that communicate with the interior of the fort. Here the wharf or landing place is found; it consists of large piles of timber, extending several yards into the sea, and affords a very commodious station for loading and unloading ships and large boats, which may be brought close alongside. At this end several store-houses, and barracks for half a regiment are erected. The ramparts of the fort are very strong, having eight principal bastions; and they have also a number of lesser ones, with curtains, bastions, and parapets, communicating with each other all round the fort, and fitted for troops to march and defend with musketry and field-pieces. The whole fort is surrounded by a road and deep oval ditch, over which draw-bridges are thrown at each of the gates. On the outside are some small magazines, with a powder-mill and a saw-mill attached to the fort. Adjoining to the covert-way, and at the foot of the plain, is a lake extending three or four miles into the country, in a N. E. direction. For near a mile on the outside of the fort, the neck of land which connects it with the country, is not above five or six hundred yards wide; and in the middle of this space lies the lake, leaving room on each side only for a narrow cauleway. Near the plain an approach might be entirely cut off, by opening the sluices and cutting the road across, where the lake would be connected with the sea, and the garrison completely isolated.

In the centre of the lake is an island, communicating with it...
a fully-port on the east face, by a narrow causeway and draw-bridges. This is a pleasant spot, abounding with cocoa-nut trees, and was called by the Dutch "Slave Island," as it was the place whither they sent their sick slaves. A battalion of Malays is stationed here. This island is very convenient, as it lies contiguous to the fort, and opens the nearest way to the cinnamon gardens, which are close by it. The fort has three gates; the principal one, where the main-guard is stationed, which is called the Delphgate, and leads into the "pettah," or black town. It has two draw-bridges to pass over the ditch, which here forms an angle. At each of the gates are guard-houses, with a subaltern's guard placed over them.

The plan of Columbo is regular. It is nearly divided into four equal quarters, by two principal streets, which cross each other, and extend the whole length of the town. To these smaller ones run parallel, with connecting lanes between them. At the foot of the ramps, in the inside, is a broad fleet or way, which goes round the whole fort, and communicates with the battions and soldiers' barracks; and also affords, at the different angles, open spaces for their private parading. The grand parade is by no means sufficient for the garrison, as it can hardly contain one complete regiment. On one side of it are ranges of public offices for the civil and military departments, with the town or flad-houfe in the centre of them, where the Dutch held their high court of justice. On the arrival of the British troops they found a rack, wheel, and many other implements of torture, which had been used for inflicting punishment on criminals, particularly slaves, but these savage modes of punishment were immediately abolished by the British government. On the other side of the grand parade stand the cinnamon store-houses, or "go-downs," as they are here called. At the upper end of the parade the Dutch had begun to erect a church, which has never been finished. The Dutch usually attended divine service at a spacious and handsome church in the black town, about a mile distant from the fort; and worship is still performed there for the English, either before or after that of the Dutch inhabitants. The government house, which faces the harbour, is a very long and capacious building, but more convenient than elegant: several offices are attached to it, where the buxoms of government is transfixed. Behind it is an excellent garden, intended for a "tank" or reservoir, in case of a siege; for though every house has a well plentifully supplied with water through the year, yet it is of a brackish quality, and not fit to drink. The Europeans, therefore, both of the civil and military establishment, are supplied with water from a spring, about a mile from the fort, which is brought by means of barrels, in leather bags, called here "puckally bags," a certain number of which is attached to every regiment and garrison in India.

Columbo is built more in the European style than any other garrison in India. The interior of the fort has also more the appearance of a regular town; the Dutch houses are all regularly built, though few are above one storey high; and the windows have all glase-panes, after the European manner. Before each house, and connected with it, is a large open space, roofed in and supported on pillars of wood, called a "viranda," affording a shade from the sun, and exposure to the refreshing breeze of the sea. The houses are also agreeably shaded by a double row of thick foregoing trees, planted on each side of the several streets. The walls of the houses are plastered over and white-washed with a very bright lime, made of burnt shells. This beautifully white colour may contribute to the coolness of the houses, but it throws an unsupportable glare on the eyes of the passengers along the streets. The houses are for the most part uniformly constructed, consisting of the hall in the front, with a chamber at each side, and another room in the back part, equal in length to the other three, and called the "back viranda." Behind this are one or two ranges of small buildings, proportioned to the size of the house and designed for the accommodation of servants, for cells, and sometimes for sleeping rooms. The houses are covered with indented tiles, which afford no security against rain. In the centre of the principal street is a very handsome and lofty house, which belonged to the Dutch governor, and has since been occupied by the commander of the British forces on the Island. It serves as a convenient house for the commandant of the garrisons, with suitable offices and gardens. The hospital, detached or isolated and small, is a roomy and convenient building. Three or four battalions are usually stationed as a garrison in the fort of Columbo.

The harbour of Columbo, which lies on the west side, is an open road. Borrowing good and safe anchorage to ships for only four months of the year, from December to April, when the N.W. winds do not prevail, to any great degree; but about May, when the monsoon sets in on the Malabar coast, and extends its ravages to the west coast of Ceylon, the roads of Columbo no longer afford any protection. Hence it is, that Columbo is cut off from any intercourse by fra, with the other parts of the island, for two thirds of the year. For six months of the stormy season, this side of the island is subject to very heavy falls of rain, accompanied with dreadful thunder and lightning, and violent winds blowing in there. During this season the variations of the climate are very great. The heavy rains, predominating most by night, render the air damp and cold; and the excessive heat of the sun by day is almost intolerable. These transitions make the climate more unhealthy at this season than during the hot weather. During the rainy season, the Indians from the continent are very few to fluxes, dysenteries, and fevers. They are also subject to another very extraordinary disease, called the "Berry berry," occasioned by low diet and hard water, which swells the body and legs of the patient to an enormous size, and generally carries him off in twenty-four hours. The cure is effected by rubbing the disfigured person all over with cow-dung, oil, cinamon, lime juice, and other preparations from herbs, and then burying him up to the chin in hot sand. The British soldiers counteract the bad effects of the air and water, by drinking plentifully of arrack and smoking tobacco. The "Pettah," or black town, of Columbo deserves particular notice, on account of its extent and superior structure, compared with other fine towns attached to the forts of India. It is divided into two parts: that nearest the fort consists of one very large street, beginning at the esplanade near the walls, and running on till stopped by an old mud wall, and a gate called the "Kenman's port." In this division of the Pettah are most excellent houses, where many Dutch gentlemen and merchants reside. Through Kenman's port there is a narrow passage leading into the other division, which consists of a long straggling town, skirted on one side by the lake above described. Besides a principal street, there are several smaller ones running parallel to it, in one of which is a large well-constructed building, called the "Orphan Seminary, or School," where the Dutch used to educate the children of their soldiers and the poorer Europeans, as well as those they had by the native women. Here the boys were educated at the public expense, till they were fit for trades, and afterwards settled in some comfortable situation, or married to persons of their own rank. This laudable institution is still maintained by the
the British government. Close by the esplanade, and adjoining the black town, is the burial ground of the garrison. The shops, bazaars, and stalls, placed all along the streets, are replenished with various articles of merchandise, peculiarly in use among the natives of India; and the town, during the whole day, swarms with people of all descriptions. The boats or canoes used in the fisheries of Colombo are of a curious shape and construction. They are about fifteen feet long, and not more than two in breadth. They move with great speed, especially with the addition of a very large square sail; and, to prevent their over-flogging, a log of wood is extended five or six feet from the end of the boat, by way of out-rigger; this log is fastened to the boat by two long and bent poles, and seems to serve at once for helm and ballast. A paddle, somewhat in the form of a shovel, is used to guide the boat's head. The body of the canoe is a large hollowed out fire, or looped over by the carpenters. Along its sides boards are nailed to the height of about two feet, and in the form of a gun-wale, to prevent the water from getting in. When large burdens are to be carried inland by the canals or rivers, two or three of these canoes are lashed together without the out-riggers. Split-out, banana, bocce, or hotel trees, are then laid across them, in so as to form a kind of raft; which, though ever so much loaded, will draw but very little water. Other flat-bottomed boats of a much greater breadth are also used by the natives. These are thatched with coco넛-tree leaves, like a house, and are large enough to hold couches. Near Colombo may be seen two or three hundred of these boats in regular rows, moored along the banks of the rivers, with entire families on board, who make them their habitations.

Colombo, for its size, is one of the most populous places in India; and its population consists of a great variety of nations. Besides Europeans and Cingalese, the proper natives of the island, you meet, scattered over the town, almost every race of Asiatics; Moors of every clafs, Malabars, Travancorians, Malays, Hindoo's, Goons, Chinese, Parsees, Arabians, Turks, Maldivians, Javans, and natives of all the Asiatic isles; Perfoes, or woodhoppers of fire, who would rather have their houses burnt, and themselves perish in the flames, than employ any means to extinguish it. Here are also a number of Africans, Cafirnens, Bugneges, or a mixed race of Africans and Asiatics; both the half-casts, people of colour, and other races which proceed from a mixture of the original ones. Each of these different classes of people has its own manners, customs, and language. The language is not generally spoken by both the Europeans and Asiatics, who refer to Colombo is the Portuguese of India, a base, corrupt dialect, altogether different from that spoken in Portugal.

Colombo, though difficult of access, is situated in a rich district, and furnishes a great variety of articles to commerce; and, therefore, it is much frequented both by Europeans and the natives of the different coasts of India. From this district large quantities of cinnamon and pepper, the staple spices of the island, are yearly transported to Europe in vessels that touch here on their voyage from Madras and Bengal. A great quantity of arrack is made in the neighbourhood of Colombo and the other districts along the west coast. A large quantity of Cova rope, or cordage is also manufactured here, for the supply of our ships on the various stations in these seas. The inferior articles, exported by the Moors and Malabars, who refine here for that purpose, are betel-leaf and arca-nut, jaggery, or a sort of coarse blackish sugar, cocoa-nut, and oil, honey, bees-wax, cardamoms, coral, ivory, fruit, and a variety of other smaller articles. In return they import coarse woolen cloths, and calicoes, pieces of printed or painted cloths for women's apparel, coarse muffins, handkerchiefs, palampores, flodkings, china-ware, tin, copper, and a variety of toys; also bonellies, a species of fish peculiar to Bombay, and onions, from the same place, where they are remarkably good. Every year, generally towards February, a Portuguese or Cingalese ship arrives from Macao with tea, sugar, candied sweetmeats, hams, silks, velvets, nankeens, umbrellas, straw-hats, all kinds of china-ware and toys; all which articles find a very ready sale, and are paid for in hard cash. The current coin at Colombo, as well as in the other European dominions on the island, is the peice, of rix-dollars, a nominal coin, like one pound Sterling, valued at a certain quantity of copper money. There were besides several small copper coins, called pice or rivers, half-piece, and duides. Four pice or two duides made a fanny, and feven fanams were equal to a rix-dollar. New regulations have been adopted with regard to the coin since the island has belonged to the English. This rix-dollar is worth eight shillings sterling; and the fluctuation of the value of money in Ceylon is very great, and depends upon the plenty and scarcity of gold and silver there. The expence of coming at Colombo is more considerable than on the continent of India. Horses and servants are particularly expensive, vegetables are extremely scarce, and they form a great article of food in those warm climates. Such articles, however, as are the native produce of the island, are found in great abundance, and at a moderate price. Beef, fish, and fowl, in particular, are both cheap and plentiful. Mutton is excessively dear, as no sheep can be reared in the neighbourhood of Colombo, which some attribute to the noxious fumes of the climate or produce of the island, but which may be principally owing to their failing an easy prey to jackals, snakes, and other destructive animals, and also to certain poisonous herbs that occur in many places. Pigs and ducks are plentiful and cheap. Geese are rare, and turkeys are not to be had, except occasionally by importation from other parts of India.

The country round Colombo for several miles is flat and very rich. It is diversified with fields of rice and paddy, as well as a variety of gardens, in which the cocoa-tree is conspicuous. The scene is embellished by a number of small rivers, lakes, and canals. The sandy roads, which everywhere intersect the country, afford to the traveller an agreeable shelter; while the numerous country feasts and gardens which skirt them present his eye with a continual change of gratification. The river Mutawai extends itself here into a very broad channel, and by its numerous windings affords a most enchanting prospect from the road, which runs along its banks for many miles. Several temples of the natives are situated along the banks of this river and among the adjoining groves. One of the chieft-beauties in the vicinity of Colombo is the immense number of cinnamon trees, which produce the niceties of the island. In the woods they grow wild in abundance, and in the gardens they are now regularly cultivated with the greatest success. Painvil's Account of the Island of Ceylon, 1805.

Colombo, in the Materia Medica. This root was first brought from the town of Colombo, in the island of Ceylon.
in which country it had long been used as a valuable rem
dy in bilious fevers, and other disorders of the stomach and
bowels. Our practitioners in the East Indies adopted the
use of this root from China, and it is now deservedly in high
reputation in most parts of Europe. The plant that yields it
is not commonly known.

Columbo root comes to us in circular pieces about two
inches in diameter, covered with a thick wrinkled bark of
a dark brown externally, but a light yellow within. On
paring off this bark the root is seen to consist of three distinct
families. The whole is used indiscriminately in medicine.

Columbo root has an aromatic smell; the taste is better
and more nauseous. It gives no essential oil when distilled
with water, and contains fiercely any volatile aromatic parts.
When boiling water is poured on the powdered root a
strong infusion is produced, which possesses all the feebile qua-
lities and virtues of the plant, but it grows mouldy in a
day or two. Spirit of wine also extracts the active qualities
of this root very readily.

Columbo is employed with nearly equal advantage in sub-
flance in spirituous tincture or in watery infusion, and gen-
erally with the addition of cinnamon or some grateful aro-
matic. The latter is of singular efficacy in strengthening the
fibres of the stomach and bowels, either in chronic cases, or
more particularly in cholera morbus, dysentery, and other
violent disorders of the alimentary canal, where, after due
evacuations, it may be employed with great success in check-
ing the incessant vomiting action of the bowels that bring
down the powers of life with such rapidity.

An extract and a tincture of Columbo are kept in the
shops, the latter of which is by itself a very useful stomachic
taken daily in very small doses.

COLUMBUS, CHRISTOPHER, in Biography, a subject
of the republic of Genoa, celebrated in history as the disco-
verer of America. Neither the exact time nor place of his
birth can be ascertained with any degree of certainty, but
it is generally supposed that he was born in some part of
the Genoese dominions about the year 1447. He is said
to have been descended from an honourable family, reduced
by various misfortunes to a state of indigence. In whatever
rank of society his parents moved, it is certain that they
gave their son an education adapted to the bent of his ge-
nius; at school he acquired the elements of the Latin lan-
guage, and made some proficiency in geometry and the other
sciences which he was enabled in the future part of his life,
to apply to the practical parts of navigation. At the age of
fourteen he went to sea, and though his first voyages were
confined to the Mediterranean, yet he very soon ventured out on
the northern seas, and visited the coasts of Iceland, to which
the English and other nations referred on account of its
fishery. About the year 1467 he entered into the service of
a sea captain of his own name and family, and spent some
years in a predatory warfare against the Mahometans and
Venetians the rivals of his country in trade. In this situa-
tion he continued acquiring both wealth and reputation, till
at length in an obstinate engagement with some Venetian
vessels, off the coast of Portugal, the ship in which he served
took fire, and his, with difficulty, preserved him by throwing
himself into the sea, and swimming a distance of two
leagues to the shore. As soon as he had recovered strength
for the journey he repaired to Lisbon, where his brother
Bartolomew had settled, and where he found many of his
countrymen, who, like himself, had embarked in the sea ser-
vice. Here his merit and talents were soon appreciated;
and here he married the daughter of Pereiré, one of the
captains employed by prince Henry in his early navigations,
and who, under his protection, had discovered and planted
the islets of Porto Santo, and Madeira. Columbus got
possession of the journals and charts of this experienced na-
vigator, and from them he learned the course which the
Portuguese had held in making their discoveries, as well as
the various circumstances which guided and encouraged
them in their attempts. While he contemplated the labours
of his father-in-law, and read the description of the countries
which he had seen, his own impatience to visit them became
irresistible. To indulge it he made a voyage to Madeira,
and for several years traded with that island, with the Can-
aries, the Azores, the settlements in Guinea, and all other
places which the Portuguese had discovered on the conti-
nent of Africa. He now began to think of extending the
boundaries of nautical knowledge. He was satisfied, not
only that there must be lands still further to the west, than
those already explored, but that a shorter passage to the
East Indies, then the great object of the Portuguese naviga-
tors, might be found by steering in that direction, than
round the continent of Africa. When he had settled his
plan, he was anxious to secure the patronage and support of
some European power capable of undertaking so important
a project. With this view, he laid his scheme before the senate of Genoa, and, making his country,
for which he bore a filial and sincere affection, the brit
of tender of his service, offered to sail under the banners of
that republic, in quest of new regions, which he expected
would render illustrious his own name, and the nation which
should enable him to realize his vast projects. Genoa re-
jected his offer: and Portugal, to whom he next applied,
treated him with so much duplicity, that he went himself
spain, while at the same time he sent his brother Bar-
tholomew into England to make the like proposals to both
counts. By both, his schemes were at first slighted, till, by
the interposition of some zealous friends at the court of
Spain, a change was effected in his favour, and in the spring
of 1472 a treaty was signed with Columbus, by which Fer-
dinand and Isabella, the sovereigns of Spain, appointed him
their high admiral in all the seas he should discover, and
their viceroy in all the islands and continents. They
granted him and his heirs a tenth of all the profits that
should accrue from the enterprise, with some other important
advantages. As soon as the treaty was signed, Isabella,
by her activity and attention, in forwarding the preparations
for the voyage, endeavoured to make some preparation to Co-
lumbus for the time which he had lost in fruitless solicita-
tions.

On the third of August 1492, Columbus set sail with
three small ships and ninety men. The expense of which did
not amount to more than 4000l. He had already, in the most
public manner, implored the guidance and protection of heaven,
and on the morning of his departure the vessels were crowd-
ed with spectators, who sent up their supplications to the
Almighty for the prosperous issue of the voyage. Colum-
bus proceeded directly for the Canaries, where, on account
of the ill condition of the ships, he was obliged to ret
Having supplied himself with fresh provisions, he sailed from
Gomera, one of the most westerly of the Canary islands, on
the sixth day of September. Here the voyage of discovery
may be said to begin; for Columbus holding his course due
well, left immediately the usual track of navigation, over a
vast and unknown ocean, with no other guide, than well-
founded hopes and rational conjectures. Scarcely had he
lost sight of the Canaries, when several of his men ex-
hibited signs of consternation bordering on despair. He
comforted them with the vail wealth which was to be found
in those regions, whether he was conducting them, and in his
own person he flet such an example of patience and industry
COLUMBUS.

as could not fail of exciting the admiration of those about him. Scarcely did he allow himself time for necessary refreshments; he regulated every thing; he superintended the execution of every order, and kept the deck with the founding line or instrument for observation perpetually in his hand, and noting down every unusual appearance with the utmost accuracy and precision. Three weeks had they traversed the ocean, and had proceeded to a distance which Columbus thought it prudent to conceal, when his men became mutinous, and even threatened to throw their admiral overboard should he persist in an undertaking which they supposed must prove fatal to them all. He succeeded for the present in quieting their apprehensions, but in a few days they became more violent, declaring that nothing should induce them to proceed in so mad an enterprise; after trying every means of persuasion in vain, he at length promised to direct his course homewards within three days, should not land be discovered. This proposition did not appear unreasonable to the men, and to the commander it appeared sufficiently safe, for the prelages of discovering land by the flight of birds, &c. were now so numerous and promising that he deemed them infallible. From a variety of symptoms it was most certain that they were in a land near hand, that on the evening of the 17th of October, after the usual invocations to heaven for success, he ordered the sails to be furled, and the slings to be cast, keeping the 新boat watch, lest they should be driven on shore. During this interval of suspense and expectation, no man left his eyes, all kept upon deck, gazing intently towards that quarter where land was expected to be discovered. At ten o'clock Columbus, standing on the forecastle, observed a light at a distance: he pointed it out to another, and he again to a third person; all three saw it in motion, and at midnight there was heard from the forecastle vixel the joyful sound of land, land. Having, however, been frequently deceived by false appearances, every man was flow of belief; and waited in all the anguish of uncertainty and impatience for the return of day. When the morning dawned their doubts were dispelled, and an island was seen about two leagues to the north, white verdant fields, well flored with wood, and watered with many rivulets presented the aspect of a delightful country. Thanksgiving were instantly offered to heaven: never was gratitude more sincere, never were the expessions of joy more ardent, than those which proceeded from every tongue. Their duty to God was followed by an act of justice to their commander. They threw themselves at the feet of Columbus, with feelings of self-condemnation, mingled with reverence entreating pardon for their past conduct; and now they regarded as the favourite of heaven the man whom they lately reviled as a visionary and impostor. No sooner had the fun tinged with its rays the shores of the newly discovered island, than their boats were manned and armed. As they approached the coast with colours, music, and martial grandeur, they saw it covered with a multitude of people, whom the novelty of the spectacle had drawn together, whose attitudes and gestures expressed wonder and astonish ment at the strange objects which presented themselves to their view. The land proved to be one of the Bahama islands, named afterwards by Columbus, San Salvador: he was the first European who set foot in the New World which he had discovered, and he took solemn possession of it for the crown of Castile and Leon, with all the formalities which the Portuguese were accustomed to observe in acts of this kind, in their new discoveries. The Spaniards, while thus employed, were surrounded by many innocent and unsuspecting natives, who gazed in silent and awful admiration upon actions which they could not comprehend, and of which they could not foresee the direful consequences. Towards the evening Columbus returned to his ship accompanied with many of the islanders in their canoes. "Thus," says Dr. Robertson, "in the first interview between the inhabitants of the Old and New Worlds, everything was conducted amicably, and to their mutual satisfaction. The former, enlightened and ambitious, formed already well ideas with respect to the advantages which they might derive from the regions that began to open to their view. The latter firm; and undiscouraging had no forebore of the calamities and defolation which were approaching their country."

From San Salvador, Columbus proceeded on other discoveries; he saw several islands, and touched at three of the largest, on which he beffow the names of St. Mary of the Conception, Ferdinand, and Isabella. He visited also Cuba and Hispaniola; wherever he went he inquired for gold, and having obtained a certain quantity of the precious metal, and made other arrangements, he took his departure homewards. He encountered a violent tempest, in which he nearly lost his ships. While all on board were overwhelmed with a sense of personal danger, Columbus was only anxious for the means of preserving a record of his great discoveries. Retiring to his cabin, he wrote an account of what he had seen and done, which he covered with wax, enclosed in a tight cask, and committed to the sea with a proper direction, hoping that it might be fortunately landed on some European shore. The storm, however ceased, and in a few days he found himself approaching the Azores. Here he obtained provisions, and renewed his voyage. When he was almost within sight of the Spanish coast, another storm arose, that forced him to take shelter in the Tajus, from whence he proceeded to Lisbon; where, in the presence of the king of Portugal, he narrated every thing that he had done and seen. Columbus remained at Lisbon but five days, and on the sixteenth of March he arrived in the port of Palos, seven months and eleven days from the time when he set out thence. As soon as his ship was discovered, the inhabitants ran eagerly to the shore, to welcome their relations and fellow-citizens, and to learn the tidings of their voyage. Columbus repaired to the court, then at Barce lona, where he was received with all the respect and honour due to his great achievements. Every mark of attention that gratitude or admiration could suggest was conferred upon him. All his stipulated privileges were confirmed, his family was ennobled, and, which was most satisfactory to his active mind, was immediately fitted out for him. This consisted of 17 ships and about 1500 persons; of whom a large number were men of distinction, destined to settle in the newly discovered countries.

On the 25th day of September 1493, Columbus sailed from his second voyage from Cadiz. He first reached the Caribbe or Leeward islands, which he visited, and then proceeded to Hispaniola, where he had left a small garrison of his own men, but who had been destroyed, probably by misconduct on their own parts, by the natives. Instead of waiting his time in punishing past wrongs, Columbus took precautions for preventing any future injury. With this view he built a small town, which he named Isabella, in honour of his royal patrons. While some were employed in the necessary operations of building, he sent others to explore the interior of the country, in the hope of finding gold. The hardships to which the Spaniards were obliged to submit, rendered them impatient of control, and it was with the utmost difficulty that Columbus could maintain any subordination. Signs of mutiny were every where exhibited; and to the commander was imputed the most unworthy notions, by persons from
whole rank in society better and more rational conduct might have been expected. Having, however, by prudence and vigour allayed the ferment. He left his brother Diego as governor of the settlement, and proceeded with a squadron in quest of new discoveries. During a tedious voyage of five months, in which he endured every hardship, he discovered only the island of Jamaica. But on his return to Hispaniola, he had the satisfaction of finding there his brother Bartholomew, whom he had not seen for a long period, and who had brought with him a large supply of provisions and men. About this period the native Indians perceiving that the yoke imposed upon them by the invaders would prove intolerable, resolved, if possible, to free themselves from so dreadful an evil. Hostilities were commenced, and much blood was shed on both sides; but in the event the Indians were completely defeated. The conference with which the Indians were filled by the noise and havoc made by the firearms, by the impetuous force of the cavalry, and the fierce outlay of twenty large dogs trained for the purpose, was so great, that they threw down their weapons, and fled, without attempting further resistance. Many were slain, more were taken prisoners, and reduced to a state of the most humiliating servitude; a rigorous tax was imposed upon them of gold, which was the dearest object of European ambition, and which was now become necessary to plead the cause of Columbus in Spain, where numerous accusations had been laid against his conduct. Willing, however, to meet the charges in person, he invited his brother Bartholomew with full power of government during his absence, and then set sail. He arrived in Spain in 1496, and immediately appeared at court, with the modest but determined confidence of a man, conscious not only of his own integrity, but of having performed many very eminent services for the state, in whose employment he had embarked. The dignity of his conduct silenced his enemies; and, with the affluence of the gold and precious commodities which he had brought with him, he recovered the good opinion of his sovereigns. They resolved to make every exertion to render the new colony a permanent and complete establishment, by sending out fresh reinforcements as Columbus thought necessary for the purpose.

It was not, however, till late in the spring of 1498, that he was enabled to proceed on his third voyage; during which he discovered Trinidad, at the mouth of the Orinoco. The vast size of this river, though only ranking in the third or fourth magnitude of rivers in the New World, convinced him that it must have its rise in a great continent. He even touched upon various parts of the continent, without sufficient reasoning that they belonged to islands which he had not hitherto explored. Columbus arrived at Hispaniola in August, where he found that his brother had removed the colony to St. Domingo, on the opposite side of the island. During his absence, a mutiny had been excited, and some of his people had deserted from the main body. To calm the discontent, he gave them allotments of land, to which were annexed divisions of poor natives, that proved to them an intolerable source of oppression. New complaints were secretly transmitted to court against him and his brothers; and having no opportunity of vindicating his conduct, his powers were at first greatly abridged by a separate commission of discovering having been granted to Alphonso d'Ojeda; who was accompanied in his voyage by Amengo Velpice, after whom the whole New World has since been named. Columbus was then recalled, and Francis de Bovadilla appointed in his stead. By his unworthy and insolent successor, Columbus was thrown in chains, and treated with other indignities, which have for ever disgraced the court that granted to him so much power. The captain of the ship, to whose charge Columbus was given, offered, in the most respectful manner, to liberate him, but he indignantly refused to suffer his irons to be removed, but by the express command of his sovereigns. On his arrival in Spain, he was婴antly set at liberty, and treated with that civility and kindness from the king and queen which he had formerly experienced. Bovadilla was disgraced, but Columbus could not forget the injuries which he had suffered; he carried with him, wherever he went, the fetters he had worn, and ordered that they should be buried in the same grave with himself.

In 1502, he obtained permission to make a fourth voyage and on arriving off St. Domingo, he found eighteen ships richly laden ready to depart for Europe. His own experience led him to perceive an approaching storm; he accordingly requested permission to enter the harbour, and at the same time warned the fleet of the dangers to which it would infallibly be exposed by failing at that juncture. His request and his warning were equally disregarded. The hurricane came on, and though, by proper precautions, he saved his own vessels, he fell up in the fleet with so much violence, that only two or three vessels escaped; and Bovadilla, with several others of his most inconstant enemies, perished with all their ill-gotten wealth. Among the vessels that weathered the storm, was that on which the wreck of Columbus's property was embarked. This, which, by some, was referred to the superintendence of providence, was, by others, imputed to certain magical arts exercised by Columbus himself. In pursuing his voyage, he traced the coast of Darien, in hopes of discovering a strait, which he fondly imagined would open a new tract to the East Indies. Although he was disappointed in his expectations, he was, nevertheless, so much delighted with the fertility of the country, and conceived such an idea of its wealth, from the speciments of gold produced by the natives, that he resolved to leave a small colony upon the river Belem, in the province of Veragua, under the command of his brother, and to return to Spain, in order to procure the means requisite for rendering the establishment permanent. On his voyage, he was driven back by a violent tempest from the coast of Cuba, his ships fell foul of one another, and were so much shattered by the shock, that with the utmost difficulty they reached Jamaica. Here he endured the greatest calamities, as well from the mutinous dispositions of his own men, as from the suspicions of the natives, who refused to supply him with provisions, till, by his skill in astronomy, he predicted the event of an approaching eclipse, a circumstance that gave him an irrefutable authority over their minds. From this time the superfluous natives generated him as a god, and not only nurtured him profusely with provisions, but cautiously avoided every thing that could give him offence. Columbus was at length delivered by a fleet sent from Hispaniola; and, after various difficulties, he arrived at St. Lucar in Spain in December 1504. Here, in addition to his other fillings, he learned that his patroness, Isabella, was dead; from her alone he anticipated the redress of his wrongs, which he little expected from the king. To him, however, as the last resort, he applied, who comforted him with promises, but, who, instead of granting his claims, insulted him with the proposal of renouncing them all for a pension. Disgusted with the ingratitude of a monarch whom he had served with fidelity and succour; exhausted with the calamities which he had endured; and broken with the infirmities which he had brought upon him, Columbus breathed his last at Valladolid, on the 20th of May 1506, in the 59th year of his age. In the closing scene he exhibited a dignity and composure
of mind suitable to the greatness of his character, and to those sentiments of piety which he had ever cherished in all the trials to which his life had been exposed. Ferdinando, who had flighted his well-founded claims when living, bestowed upon him funeral honours, and confirmed to his children their hereditary rights. Columbus was buried in the cathedral at Seville, and on his tomb was engraved an epitaph, the memory of his renowned actions and discovery of a New World, which in justice ought to have been denominated Columbus, in order that the name might for ever excite the remembrance of the hero who, in spite of every obstacle, succeeded in realizing a project, esteemed by his contemporaries as the chimera of a disturbed imagination. Robertbt's Hist. of America.

Jullianus, in his curious edition of the P. thygleti Plater, 1516, of which a beautiful copy is preferred in the Cliche-rode collection in the British Museum, has introduced, by way of commentary on Pl. xix. 4, "their words are gone forth to the ends of the earth," a very curious sketch of the life of Columbus, an account of his discovery of America, and also a description of the inhabitants, particularly of the female native Americans.

COLUMBUS, Congregation of St., is the name of a congregation of regular canons, formerly of great extent; having under it an hundred abbeys or monastry-ries, in the Britith islands. See Congregation and Canon.

COLUMELLA, in Anatomy. See Uvula.

COLUMELLA, in Botany. See Pulv. Linn. In Bijography, was born at Cadiz, and flourished at Rome in the time of the emperor Clau-tus. He is chiefly celebrated for a work which has come down to our own times, entitled "De Re Rustica," and which contains, in twelve books, rules concerning the culture of various vegetables, and the management of domestic animals. A separate book "De Arboribus," is annexed to these. They have gone through many editions, but the best and most accurate is that in Gellner's collection of the Re Rusticae Scriptores. Mor.

COLUMELLA, Rufius teres, a name given by Morgagni, and some others, to the muscle called by Albinus azygos vena.

Sp. C. tenus. Root biennial. Stem cylindrical, pubescent, coruscous at the top. Leaves an inch and a half long, fiddle, linear, obtuse, hairy. Flowers both of the disc and ray yellow, fiddle, solitary at the divisions of the brancher. A native of the Cape of Good Hope.

COLUM, in Architecture, columna, Latin, derived from column, a support. In a strictly architectural sense a column may be defined as an object consisting of a nearly cylindrical shaft with a capital, and either with or without a base. The column, as forming the principal part of an order of architecture, will be considered under the articles Doric, Ionic, Corinthian, Tuscan, and Composite Orders, and in the present article we shall treat of columns according to their matter, construction, disposition, and use; under the first head may be placed

Column, moulded, is that made by impatation of gravel and flints of divers colours, which are bound together with a cement, which grows perfectly hard, and receives a polished like marble.

The secret of making these, it appears, the ancients were masters of, by the columns lately discovered near Algiers, which are, doubtless, the ruins of the ancient Julia Cefarea: on all these is found the very fame inscription in antique characters; the contours, accents, and even faults, being repeated in every shaft; an infallible proof of their being moulded.

Columns, fusible. Under this term are comprehended, not only columns of various metals, and other fusible matters, as glafs, &c. but also those of stone, fand to have been cast; the secret of which some will have us believe to have been known to the ancients.

Columns, transparent. Any column made of transparent matter, as were those of crystal in the theatre of Scaurus, mentioned by Pliny; and those of transparent ababaker, in the church of St. Mark, at Venice.

Columns, water, is a fort whole shaft is formed of a large jet d'eau; which spouting out water violently from the bafe drives it within the tambour of the capital, which is made hollow; whence, falling down again, it has the effect of a liquid crystalline column. See Fountain.

An instance of this we have at Quinto d'Avio, near Lisbon.

Columns, hydraulic, is that whole shaft appears to be of crystal; being formed by a number of little threads of water, falling from holes made in a gift of metal, at equal distances, by means of a pipe mounted through the middle thereof; as in the gardens at Versailles.

Columns, hydraulic, also denotes a column from whose top proceed a jet d'eau, to which the capital serves as a baloon; whence the water descends by a little pipe, which turns spirally around the shaft. Such are the Ionic columns of the cascade of the Belvedera at Firecati; and those of the vineyard Mathiei at Rome.

Columns, with regard to their Construction.

Columns of bands or tambours, a column whole shaft is formed of several courses of ilone or blocks of marble of less height than the diameter of the column, this is what Ulpius means by columna frustrata, or adpata, which is opposed to the columna solidi, or integra, i.e. of one piece. This method is only practised in very large columns, for instance as the Trojan column. Smaller columns are often composed of three or four pieces, and this method the French distinguished by a particular term, colomne par troncons, of which we have no proper translation.

Columns of False, is built of rough stones or compact bricks, and covered with stucco.

Columns, geminated, that whole shaft is formed by three similar and equal sides, or ribs of stone, fitted within one another; and fastened at bottom with iron pins, and at the top with cramp-irons. This is to be fluted, that the joints may be the less discernible.

Columns, retusated, is made of several ribs, or thin shells of fine marble, or some other rare stone, cemented upon a mould of flonses brick, or the like. This is done with design both to save the precious matter, as oriental jasper, lapis lazuli, agate, &c. or to represent pieces of such stones of an extraordinary size, by the neatness and clofeness of the inculcation, which renders the joints imperceptible.

Columns, banded; a column whose shaft has several bands or cinctures either plain or ornamented, which project somewhat beyond the general line of the shaft. Banded columns were first introduced by De Lorme at the Chapel de Villes-Cohores, and at the Thuilleries, who imagined
impressed this method of concealing the joints of the different blocks of stone forming the shaft.

**Columns, fluted.** Called also *channelled, and frieze columns*; that whose shaft is adorned with flutes or channeledings: either from top to bottom, or only two thirds of its height.

**Columns, cabled or rudimental.** Is a fluted column, whose channels are filled in with allargals which generally reach one third of the height of the shaft from the base.

**Columns, cylindrical.** Is that which has neither swelling nor diminution.

**Columns, diminuted.** Is that which has no swelling, but whose shaft is tapered in a slanting line from the base to the capital. This is the method observed in, we believe, all the Greek remains of architecture, and in many of the Roman, as in the portico of the Pantheon. The opposite practice of giving an entasis or swelling in the middle of the shaft is obscurely mentioned by Vitruvius, and has been generally followed by modern architects.

**Columns, oval.** There are a few instances of oval columns in the remains of antiquity. The Mausoleum at Rome, and the frontispiece of the church of the P. P. de la Merci at Paris offer some modern examples.

**Columns, polygonal.** That whose shaft is formed in imitation of the trunk of a tree, with bark and knots. This kind of column, in the Tuscan proportion, may be used in the gates of parks and gardens; and in the decorations of pastoral scenes, &c.

**Columns, polygonous;** a column of which the horizontal section forms a polygon. There are various examples of this form in Egyptian architecture, it is also observed in the lower part of the columns of a portico on the island of Delos and at the temple of Cora.

**Columns, twisted;** a column whose shaft is twisted round in the manner of a screw with six circumvolutions. Vignola first discovered a method of drawing it by rule. The barbarous and ridiculous practice of twisting columns has been much used by modern architects, especially in the foreen and altar-pieces of churches. The most celebrated instance is the Baldaquin of St. Peter’s. Columns spirally fluted are seen in the temple of Spolets, they are also not unfrequent on the sarcophagi’s and other ornamental works of the lower ages.

**Columns, Corinthian;** that adorned with foliages, or leaves and branches turned spirally around the shaft; or in form of crowns and feathers. These were used by the ancients for erecting statues on; which hence took the denomination of *corinthia.* They are very suitable in triumphal arches, and decorations of theatres.

**Columns, hermetic.** See *Herma.*

**Columns, denominated from their disposition.**

**Columns, inferted, or backed;** is that let into a well, a third or fourth part of its diameter.

**Columns, niched;** is that whose shaft enters, with half its diameter, into a wall, which is hollowed for its reception; with its plane parallel to the profile of the torus. Such is that in the portal of St. Peter at Rome.

**Columns, angular;** is an inferted column, placed in the coin, or corner of a portico; or inferted into the corner of a building; or even a column that flanks an angle, either acute or obtuse, of a figure of many sides.

**Columns, cantonned;** are those engaged in the four corners of a square pillar, to support four springs of an arch.

**Columns, coupled;** are those disposed, by two and two, as almost to touch each other at their bases, and capitals, as those in the peristyle of the Louvre and at St. Paul’s cathedral.

**Columns, doubled;** is an assemblage of two columns, joined in such a manner, as that the two shafts penetrate each other with a third of their diameter. Such are those of the four angles in the court of the Louvre.

**Columns, flanked, according to M. Blondel,** is a column engaged with one half, or at least one-third of its diameter, between two demi pilasters.

**Columns, grouped, are those placed on the same pedestal, or socle; either by three and three, or by four and four.**

**Columns, isolated, is that standing free, and detached on all sides, from any other body.**

**Columns, median.** Vitruvius gives the name *columna mediana* to the two columns in the middle of the porch, which have their intercolumnation larger than the rest; that if these last, for instance, be  pyrgoides, the medians are equilateral.

The term may also be applied to the middle row of columns, in a frontispiece adorned with three orders.

**Columns, denominated from their use.**

**Columns, aeronautical, is a kind of observatory, in form of a very high tower; built hollow, and with a spiral ascent to an armillary sphere placed at the top, for observing the motions of the heavenly bodies.** Such is that, of the Dei order, erected at the Hotel de Soffiens, at Paris, by Catherine De Medicis, for the observances of Orontus Finensis, a celebrated astronomer of that time.

**Columns, chronological, that bears some historical inscriptions, digested according to the order of time; as by lutes, Olympiads, falli, epochas, annals, &c.** At Athens there were columns of this kind, whereon were inscribed the whole history of Greece digested into Olympiads.

**Columns, funeral;** a column placed over a tomb, and bearing an urn, or some symbol or inscription relating to the deceased. See *Cippus.*

**Columns, gymnastic, is a cylinder, wherein the hour of the day is represented by the shadow of a style.** Of these there are two kinds; in the one, the style is fixed; and the hour-lines are no more than the projection of a vertical dial on a cylindrical surface.

In the other, the style is movable; and the hour-lines are drawn to the different heights of the sun, in the different feasons of the year. See *Dial.*

**Columns, indicatrix, that which serves to swew the tier, &c. along the sea-coasts.** Of this kind, is the milestone at Grand Cairo, whereon the overflownings of the Nile are expressed; by this they form a judgment of the succeeding feason; when the water, for instance, ascends to twenty-three feet, it is a sign of great fertility in Egypt.

**Columns, itinerary, a column with several faces, placed in the cross-ways in large roads; serving to swew the different routes, by the inscriptions thereupon.**

**Columns, titular, at Rome, according to Festus, was a column erected in the herb-market, which is now the place Montanara; which had a cavity in its pedestal, wherein young children, abandoned by their parents out of poverty or inhumanity, were exposed, to be brought up at the public expence.**

**Columns, legal.** Among the Lacedemonianas there were columns raised in public places, whereon were engraven the fundamental laws of the state.

**Columns, limitrophous, or boundary, is that which swews
the limits of a kingdom, or country conquered. Such was that, which Pliny says Alexander the Great erected at the extremities of the Indies.

As to those of Hercules, ordinarily called his columns, or pillars; they are two very steep mountains in the bleeding of Cadiz, now Gibraltar.

**COLUMN.** From the Latin *columna*, *spolia of the enemy*; a column adorned with trophies, built in imitation of trees, wherein the spoils of enemies were anciently hung.

**COLUMN, menian,** any column which supports a balcony, or menina. The origin of this kind of column, Suetonius and Aelianus refer to one Menias; who, having fold his house to Cato and Fleucus, confided, to be converted into a public edifice, referred to himself the right of raising a column without-fide, to bear a balcony; whence he might see the floods.

**COLUMN, military,** was a column of marble, raised by order of Augustus, in the middle of the Roman Forum; from whence, as a centre, the distances of the several cities, &c. of the empire were reckoned, by other military columns disposed at equal distances, on all the grand roads. This column was of white marble; the fame with that which is now seen on the ballustrade of the staircase of the capital at Rome. Its proportion is massive; being a short cylinder, supporting a symbol of the globe of the earth.

It was called *militarium aureum*, as having been gilt, at least the ball, by order of Augustus. It was restored by the emperors Vespasian and Adrian; as appears by the inscriptions.

**COLUMN, military,** among the Romans, a column wherein was engraved a list of the forces in the Roman army, ranged by legions, in their proper order; with design to preserve the memory of the number of soldiers, and of the order preferred in any military expedition.

The Romans had another kind of military column, which they called *columna bellica*, standing before the temple of Janus; at the foot whereof the consul declared war, by throwing a javelin towards the enemies countries.

**COLUMN, phosphorical,** a light house; or a hollow column, built on a rock or the tip of a mole, or other eminence, to serve as a lantern to a port.

**COLUMN, symbolical,** is a column representing some particular virtue, by the attributes proper thereto; as that of the French order, set with *fleur de lis*, in the frontispiece of the Jesuits church at Rouen: or some memorable action; as the *Corvinian column*, on which was a crown; erected to Valerius Maximus, surnamed Corvinus, in memory of his defeat of a giant in the army of the Gauls, by the assistance of a crow.

Under the title of *symbolic columns*, may also be comprehended those that serve for symbols. Such is that on a medal of Nero, which expresses the integrity of the Roman empire. See Symbol.

**Columns, hijlorical, memorial, honorary, triumphal.** Under this head may be placed various distinguished columns, which rank among the eminent works of art ancient and modern, and form the chief ornaments of the situation in which they are placed. The most celebrated of these is the triumphal column of Trajan at Rome. This monument was built by Apollodorus the most famous Roman architect in the Forum Romanum. The height of the column is 106 feet, with a diameter of nearly 13 feet; it is placed upon a pedestal of 19 feet high; upon the capital there is a crowning which formerly supported a statue of the emperor, but, at present, a bronze statue of St. Peter, about 14 feet in height. The base and capital are of the Tuscan order. The column, with the crowning, is composed of 34 tambours or blocks of white marble, and the shaft is adorned, mounting spirally from top to bottom, representing the victories of Trajan over the Dace. Four eagles at the corners of the pedestal support, in their beaks, feathers of laurel, and the sides of the pedestal are richly ornamented with a variety of military weapons. The inside of the column contains a staircase, which ascends to the capital, and as each block of stone forms the whole diameter of the shaft, the steps are wrought out of the solid.

The Antonine columns, though inferior in design, and the beauty of sculpture to the last mentioned, is one of the most considerable monuments of ancient Rome. It was erected by Marcus Aurelius, and consecrated by him to Antoninus Pius. The base was placed upon the summit, on the shaft however are represented the actions of Marcus in the Marcoman war. The column is 56½ feet in height, with a diameter of 11½, raised upon a pedestal of 26½ feet. The construction of this column is exactly similar to that of Trajan; its base and capital have Doric profile.

At Alexandria there is a remarkable column, which is commonly called Pompey's pillar. It is a column of the Corinthian order raised upon a short pedestal. The shaft is 67 feet long, and nearly nine feet in diameter, at the bottom of a single piece of granite. The whole height of the column and pedestal is about 300 feet. At Conflantinople there were two triumphal columns similar to those of Trajan and Antoninus; the column of Conflantine is entirely destroyed, and of the other erected by Arcadius by Theodosius, only the pedestal and the first course of the shaft remains.

Lastly, may be mentioned the monument of London, which is the largest column in existence, being fifteen feet in diameter, and 202 feet high, including the pedestal and crowning. This column was erected in memorial of the great fire of London; its architect was Sir C. Wren.

**COLUMN, rostral,** a triumphal column adorned with the beaks or prawns of gallies, in memorial of a naval victory. The first rostral column was erected in the capital, on occasion of the defeat of the Carthaginians by C. Dinnius. Augustus constructed four with the prawns of the ships taken from Cleopatra.

**COLUMN, scenography of.** See Scenography.

**COLUMN, in French.** Column has been very erroneously defined by many writers on military subjects to be a long deep box of崇高 or being. The definition, confining a column to a file of troops, is far from giving a true idea of it; it conveys one totally erroneous. For a column consists both of ranks and files. A column may, therefore, be defined to be a corps or body of men with ranks and files in the form either of a square or rectangle, who march in time, or with one and the same movement, keeping a sufficient interval between every two of the said ranks and files, in order to avoid confusion. A column may be in the form of a square, having its front equal to its depth; or it may be of a rectangular form, having either its front equal to one of the shorter sides of the rectangle, and its depth equal to one of the longest, or its front equal to one of the longest sides of the rectangle, and its depth equal to one of the shorter.

In marching troops in columns, particularly towards the enemy, great care should be taken, that they advance as nearly as possible alike, and not one before another, that they may, if attacked, be able to afford mutual aid and assistance to one another, and that as they approach the field of battle they prefer their distances with as much accuracy,
accuracy, that when they wheel and form there may be neither too much nor too little ground for each squadron and battalion. This is a nice point, and an operation that is seldom executed correctly.

The most disadvantageous order of march is that which compels an army to move in one column. The more columns it is divided into, and the smaller their depth, the more easily and expeditiously are the troops composing them formed in order of battle. And the most advantageous method of marching an army is that which makes it move in order of battle, without dividing it into columns at all. But open level, and uncultivated ground of sufficient extent for this purpose is rarely to be had near.

COLUMN Circa, a solid compact column, with very little space or interval between the divisions equal commonly to their respective fronts.

Column, Opera, a column with interval between the divisions equal commonly to their respective fronts.

Columns, among Præterit, is half a page, when the page is divided into two parts, from top to bottom. See Printing:

COLUMNAR, Famos, in Botany, a learned botanist, was born at Naples in 1768. His whole works, attached only to the study of natural history, particularly to acquire a knowledge of the properties of plants, in which he became eminent. He excelled also in the knowledge of languages, music, of mathematics, and in drawing, of which he is said to have made much use, the greater part of the engravings in his works being taken from his own designs. He was in the habit of studying the works of Dioscorides, Bournaveys, in order to find a remedy for certain ills, to which he was subject. That he was not successful in his search is probable, as he is said to have received the greatest benefit, having previously tried numerous medicines, by the application of a cautery to one of his thighs. The operation was performed by Severinus in the year 1650. He died in 1671, aged 83 years, and is said to have totally outlived his faculties.

Haller gives him great credit as a reformer and improver of the study of botany, for the light he threw on the many obscure pollices in Dioscorides, and for the number of plants he described not before known. The figures of the plants he has given, which are generally collected in executing, are among the earliest copper-plate engravings in the knowledge of natural history. His first work, which was published when he was only 25 years of age, "Plantarum Aliquot Historia, in qua decemvium plantarum rariorum, antiquarum delineationibus respondent." was notified in 1560, 4to, far exceeding what had been done before in that line. The engravings are all more accurate than had been before been seen. "In plu (the wild vatican) charter eximia exemplis." Haller says, it is the plant, the root of which Dioscorides recommended in his complaint. He took of it for a long time with advantage; he left it, but it did not effect a cure. The works were reprinted in 1544, 4to by James Plancus, with observations by the Lucre, a society of naturalists, to which Plancus had belonged. Annexed is a short history of his life. "Minus cognitam rarissima phantastica ejus oratio orientum illustrat, cepha frea non pacis ab antiquis descripsit dicendum, et declarat." Rome, 4to. This was prepared for the press in the year 1600. The dedication was in the year 1562, but did not appear until the year 1650. He now dedicated the flowers, fruits, and seeds of the plants, and began to arrange them from the first of their parts. A second part of this work soon followed.

In 1675, his "Adnotationes, et additiones ad opus Francisci Hernandes, et Naui Antonii Recchi" appeared. In this he makes further advances in the classification of plants, from the resemblance of the petals. "Stilum et Flamina novum." In his work appear the first drawings of the flowers, by which Linnaeus, more than a century afterwards, became immortalized. He was a member of the illustrious academy of the Lincei, established at Rome, which rendered great services to the republic of letters as long as it subsisted. Columna invented a natural instrument, which he called "Synhicus Lycus," from the name of his academy; it was composed of 500 rings of different lengths, and the tone of each was divided in four parts, according to the method of Antiochus, to include all the genera, diatomic, triatomic, and tetratomic. He published his invention in a work like wise entitled "Synhicus Lycus," printed at Naples in 1618. Some later editions were published under the title, "Delin instrumento perfetto." We make no reflections on the excellence of this instrument, having never seen if but conjecture, that from the belly being loaded with so great number of rings, the tone must be very feeble; it must likewise have been difficult to tune for the three to the unaided ear. The rings are difficult to keep in tune.

COLUMN Affe, is used by some writers of anatomy, for the fibrous end of the nodule, putting out over the upper lip.

COLUMN Arie, is sometimes used for the veins.

COLUMN regio, in Ancient Geography, a place of Italy, over against Sicily, on the bank of the Strait, and near Regium Julia. It is mentioned in the Itinerary of Antonine.

COLUMNAE, a name given by Ephorus, cited by Pliny, to the small island on the route from the Red Sea to the island of Crete. G. Hardouin thought they were the Macareus Iles.

COLUMN Alban, or white columns, called by Herodotus (I. iv. c. 138.) "Figuris harmonie," a place of Atia Minor, to the south of the river Menelas, and very near it.

COLUMNAE, in Anatomy, called also lacerati, and columnae cordis, are several small muscles in the ventricles of the heart; derived, and, as it were, detached from the parietes of those ventricles, and connected by tendinous cords to the two parts of the heart.

These little columns, or pillars, being fastened to the parietes of the heart on one side, and the tricuspid and mitral valves on the other, do, by the contraction in the fylodes of the heart, draw out the valves; and by that means not only shut the orifices of the veins, but more exactly close the ventricles in their fylode.

COLUMNAr Herculis, the columns of Hercules, in Ancient Geography, the name given to the first of Gibraltar, called also Fretum Cadizium and Fretum Herculeum. These columns of Hercules were proper to the two mountains of Calpe in Europe, and of Abyss in Africa. Some have supposed that Hercules called them by his name; but others consider Hercules as an imaginary hero, whose name is formed of the Phoenician "Harahkel," signifying a merchant or voyager. Hence, they say, it is not astonishing, that this should be called "the Strait of Voyagers," and that its name should be derived from the Phoenician language, since the Phoenician navigators had made it known, and continually sailed through it.

COLUMNAE Marble, See BASTARTE.

COLUMNAE Fretae, a mineralogical term for the prisms into which different floras of the earth are sometimes found fault or divided, generally in a direction perpendicular to the lamina of the floras or nearly; these most commonly occur in basalt or trap, those of Stope in Saxony, exceed 300 feet in length, without any articulation or division. Dolomse observed columnar basalt in the floras of mount Etna.
Etan. At Cleteton in Devonshire, Mr. Hawe observed an irregular column in the Toad flax or trap. (Mawe's Dib. c. 40 and 51.) Porphyry is often found in a columnar form, see 2 Brg. Journ. 1790. 325, and Harding, 48. Sand-flax in the east and north parts of Bohemia, are often split into columns, resembling billets, 2 Berg. Journ. 1790. 70. Lime-flax is sometimes found rent into polygonal pillars of 4, 5, &c. sides like halftas, as at Rioms and Rhodin in the Vivarais, and in Saxony. Charpentier 29. See Basalt Trap and PRismatic columnars.

COLUMNARIS, in Botany, a name given by Gome to the in the tail, nolky holl flower; the camparina halesfenca, Ger. Emac. 5. 2.

COLUMNARIUM, in Roman Antiquity, a heavy tribute, demanded for every pillar of a house. It was first hit on by Julius Caesar, in order to put a stop to the extravagant expenses laid out on sumptuous buildings.

Gen. Ch. Cal. One-leaved, deeply five-efled, generally somewhat swelling at the base, permanent; segments erect, equal, lanceolate. Cor. monogynous, much longer than the calyx, labiate; upper lip erect; lower lip two or three-cleft. Stam. Filaments four free; anthers joined together. Filj. Germ superior, egg-shaped; style filiform, the length of the upper lip; style bifid, obtuse. Peric. Capule globular, one or two-celled. Seeds numerous, small, attached to a large receptacle.

94. Flor. Ind. occ. 2. 1060. (Achimeles major; Brown. Jam. 270. tab. 39. fig. 3. Rupennis polyanthos; Millan. Jam. 278. tab. 170. fig. 1.) "Leaves egg-shaped; acuminate, serrated, rough, with hairs on the upper surface, segments of the calyx tooth serrated, bifid; corolla bifid; upper lip bifid." Rest perennial. Whole plant succulent. Stem thick, throwing its branches to the height of four or five feet when supported. Leaves opposite alternately larger. Flowers large, beautifully variegated; segments of the calyx almost punctated like those of the rose. A native of the cooler mountains of Jamaica; introduced in 1780, by the margin of Rockingham; flowering in November. 4. C. bifolia. Mart. 4. Wild. 4. Swartz. Prod. 94. Flor. Ind. occ. 2. 1063. "Leaves egg shaped, obtuse, slightly toothed, bisped bifid; segments of the calyx entire, hairy; stem hairy, scabrous." A native of Jamaica. 5. C. hirtus. Mart. 5. Wild. 3. Swartz. Prod. 94. Flor. Ind. occ. 2. 1063. "Leaves ovate-lanceolate, slightly toothed, rather scabrous, bifid and coloured under beneath, calyx villous; segments linear; corolla villous." A native of Jamaica, in shady woods, attached to the trunk of trees. 6. C. foliata. Wild. 6. Loud. Cochon. 384. "Leaves pinnate bilabiate; stem creeping." Stem herbaceous, perennial, cylindrical, slender, whitish. Branches somewhat erect, four inches long, very tender. Leaves egg-shaped, three lines long, ferrate in threes, pale green, obtusifrons, petiolate. Flowers white, fringed with red, axillary, bifid, peduncled; tube of the corolla slightly gibbous; upper lip arcuate, trifid; lower bifid; anthers egg-shaped, connected, separated with difficulty. Capsule oval, two-celled. The whole plant, except the capsule, hairy. A native of Cochinchina. It is an aquatic, of a very pleasant appearance and smell, and being emollient and cooling, is used as a wash by the women, for which purpose it is cultivated in pots or tubs filled with water, having earth at the bottom.

Columnea erubens; Lam. See Cyrrilla pahella.

Propagation and Culture. All the species require the heat of a stove. They are propagated by seeds, and should be treated like other tender exotics.

COLUMNELLA, little column, denotes the substance that passes through the capsule, and connects the several partitions and seeds.

COLUMNIA, Pompei, in Ancient Geography, a place of Thrace, at the entrance of the Thracian Bosphorus, on the coast of the Exine sea.

COLUMNIATED winding flax. See Stairs.

COLUMNIFER.E, in Botany, the thirty fourth natural order in the "Philosophia Botanica," of Linnaeus, and the thirty-seventh of "Prælectiones." In the "Philosophia Botanica," it contains the following genera: camelina, xylon, jossypium, uroca, bifibus, turmera, malope, lavatera, althaea, aleua, malva, melochia, fida, napec, waltheria, mentheza, hermennea, helicteres, and flavaria. In the Preflection, all these are continued, except mentheza, which is removed to the calycahnae; and oxylon, which was suppressed as a distinct genus by Linnaeus himself, and its species placed under oxylon. The following are added by Linnaeus, triumfetella, bixa, corchorus, theobroma, gewia, munginiga, tita, all of which apparently formed part of the above. 28. tab. 170. fig. 2. "Flowers for malchara; patapetes, bombax, adansonia, kieocarpus, antehorus, maherna, kleinoviis, ayenia, microro, then, higgleria. Stereophia is placed by Linnaeus under both the columunfere and the tricocere. In the "Philosophia Botanica," it had been placed among the latter, and when it was after-
wards removed to the former, it was most probably left in its original situation, merely through inadvertence. The following have since been added; but Gilbe acknowledges himself in doubt whether the arrangement would in all cases have been approved by Linnaeus. Symposco, Linn., and Clematoniæ, Linn., referred to this order by Swartz; palavaria, Cav.; anodo, Cav.; muscad., Cav.; affonia, Cav.; ombroa, Swart.; paronia, Cav.; aeliana, Syd. Swart.; (malavifus, Dill., Cav.) Lignarea, Cav.; cistus, Cist.; cypri, Schreb.; Cypri; (Quarzacca, Abbl. Cav.) abietii, Serb.; (Aesch., mays., Aed. Swart.) Maria, Swartz.; umbrosa, Schreb.; mulceolus, Mitchell. Cav. eretea, Swart.

Linnaeus confined that the essential character of the order is not to be understood from the name, which properly belongs only to some of the more remarkable genera. In all of them the root is fibrous; in some bulbous, or tuberous. The stem in most is herbaceous, but some are large trees; it is among the latter only, that thorns are to be found, and prickles only in some hibiti. Scarcely any plant in the whole order is smooth. All have stipules in pairs. The leaves are never opposite, most commonly petiolate; the foliation, as far as Linnaeus could recollect, always parted, and many have glabrous-pubescent under the rib. There are no tendrils in any plant of the order. The full reference is various. The calyx in many is single and five-cleft; in some double. The petals in most are five; but since the filaments are united, and in most genera adhere to them, the corolla falls off all together, as if it consisted only of one petal. Their claws, by converging often, constitute the nectar. The stamens, or at least the filaments, are equal in number to the parts of the fruit. The fruit is always superior, but various in other respects. None of the species are poisonous or fatal; they are generally more or less medicinal; and the flowers of most are beautiful.

COLUMPNATENSIS, in Ancient Geography, an episcopal see in Africa in Mauritanian Caesariensis, according to the conference of Carthage.

COLUMPA, in Botany, Rehed. See Illecebrum fissile.

CULURES, in Geography and Astronomy, are two great circles, imagined to intersect each other at right angles in the poles of the world.

The word is derived from colec, muttil, or truncate, and wta, tail; q. d. appearing with the tail cut off; because never seen entire above the horizon.

The culures pass one of them through the folilitia, and the other through the equinoctial point of the ecliptic; whence the first is denominated the fissile, and the second equinoctial.

The equinoctial curve determines the equinoxes; and the folilitia, the foliices.

By thus dividing the ecliptic into four equal parts, they also mark the four seasons of the year.

It is disputed over what part of the back of Aries the equinoctial curve passed in the time of Hipparchus. Sir Isaac Newton, in his Chronology, takes it to have been over the middle of the constellation. Father Soucius infits on its having passed over the dad-estimoration of Aries, or midway between the rump and frill of the tail. We have some observations in the Philosophical Transactions, N° 466, concerning the position of this curve in the ancient sphere, from a draught of the constellation Aries, in the Aratae published at Leyden and Amsterdam, 1652, which seem to confirm Sir Isaac's opinion; but the antiquity and authority of the original draught may still remain in question. See Chronology.

COLURI, in Geography, an island in the gulf of Egin, near the coast of Livadia, about seven miles long and two wide; 10 miles W. of Athens. N. lat. 38°. E. long. 25° 36'.

COLUSITANUS, in Ancient Geography, an episcopal see in the preconifer Africa, according to the conference of Carthage; supposed to be the same with Canthiuma.

COLUMUSA, a Creek town of Paphlogania.

Eff. Chi. Calyx five-cleft. Stigma bearded on one side. Legume peduncled, membranous, inflated or compressed, one-celled.

This species is nearly allied to algaragulus and phaera.

The total want of a partition in the legume is its only certain generic distinction. The algaragulus are completely two-celled. The phaera have a partial partition, which extends the whole length, but only half the breadth of the legume, making it semi-limbacular.

Sp. 1. C. arborifera. Common bladder-fenn. Linn. Sp. Pl. 1. Matt. 1. Linn. 1. Willd. 1. Gart. tab. 135. fig. 4. Linn. 11. 624. fig. 2. Prit. mag. tab. 81. (C. vicaria; Bauh. Fam. 305. Tourn. 649. C. hirsuta; Roth. Germ. 1. 305. H. 168.) "Leaflets inerably heart-shaped." Linn. "Leaflets oval-obovate; standard gibbos, abbreviated." Hort. Kew. A shrub. Stokes several, woody, twelve or fourteen feet high; branches numerous, woody. Leaves alternate, winged, terminated by an odd one; leaves nine or eleven, green and smooth above, glaucous beneath. Flowers yellow, with a reddish curved line at the base of the standard, in a short raceme, consisting of three or four flowers; wings only a little shorter than the keel. Legume closed at the tip. Seeds twenty or more. A native in the other parts of Europe; observed by Mr. Ray in the affluent to the crater of Mount Vesuvius, where there are fewest any other plants. It flowers with us in the early part of June, and sometimes again in the month of August, continuing till October. Both leaves and legumes are purgative, and may be substituted for the officinal fenn. (caffia fenn.) but must be taken in larger doses. They have a pungent, nauseous taste. In the quantity of a dram or two excited vomiting; but notwithstanding these qualities, the plant is said by Haller and Ray to afford a food grateful to cattle. 2. C. erucina. Oriental bladder fenn. Mart. 2. Willd. 2. L'Heritier Stup. nov. 2. tab. 41. Hort. Kew. 3. 55. Linn. 11. tab. 624. fig. 3. (C. orientalis, flore, fanguea coloris, lutecia macula notata). Tourn, Cor. 44. C. fanugiae. Pal. off. 1. 88. C. orientalis. Lam. 2. humilis. Scop. inembr. 2. 23; tab. 12. "Shrubby; leaflets wedge-shaped, inerably heart-shaped; standard gibbos, obtuse, very small." Stem woody; branches seven or eight feet high. Leaves pinnaled; leaflets eleven or thirteen, small, smooth, glaucous, more febly than those of the preceding specie. Flowers.
Flowers: deep red, with two yellow spots on the standard, small; wings considerably shorter than the keel; keel erect, appearing cut off at the end. **Legume** opening beneath the tip into a wide hole. Discovered by Turnfort in the Levant; cultivated by Miller in 1752. 3. *C. pocockii*. Pocock's bladder-fenna. Mart. 3. Wild. 3. Hort. Kew. 3. 55. (C. procumbens) L'Heritier Stirp. nov. 2. tab. 42. G. halepica; Lam. 3. 1) Shrubby; leaflets roundish-circular, very obtuse, mucronate; standard gibbous, elongated, acending. A lower shrub than the proceeding. **Branches slender, spreading.** Leaflets thirteen or fifteen, very small, entire, of a cinerous-green colour underneath. Flowers bright yellow, larger than those of *C. arboreform*, opening a month earlier, and continuing in succession till late in the autumn; peduncles shorter than the leaves, axillary, solitary, one or two flowered. The seeds were first brought to England from Cape by Dr. Pococke, and are said by Dr. Ray to be very common about Aleppo. 4. *C. fruticosum*. Scarlet bladder-fenna. Linn. Sp. Pl. 2. Mart. 4. Lam. 4. Wildl. 4. Bt. Mag. tab. 181. 1) Leaflets oblong, retuse, hoary underneath; branches silky-tomentose. A shrub, from two to four feet high; branches erect. Leaflets from twenty-one to twenty-five, green and smooth on their upper surface. Flowers bright scarlet large; peduncles axillary, from three to five flowered; keel considerably longer than the standard; wings very small. **Legumes** very large. A native of the Cape of Good Hope, and other parts of Africa. 5. *C. americana*. Mart. 8. Hoult. MSS. 2) Shrubby; leaflets egg-shaped, emarginate; legumes oblong, compressed, acuminate. Stem twelve or fourteen feet high, much branched; leaflets seven, light green. Flowers bright yellow, two or three upon each peduncle. **Legumes** near four inches long, compressed, winged, ending in long points. Sent to Miller in 1752, by Dr. Houton, from Vera Cruz in New Spain. 6. *C. galegosifolius*. Bot. Mag. tab. 792. 3) Shrubby; leaflets oval, emarginate, in about nine pairs, with a terminal one; legumes by longligid pedicels. Stem low, branches herbaceous, angular. Stipules two, egg-shaped, small, embracing the common pedicel, but distinct from it. **Flowers** dull red, inclining to orange, in a many-flowered raceme; common peduncles longer than the leaves, axillary; pedicels alternate, short, curved; bracteate under each flower, single, small, egg-shaped; calyx-teeth wide at the base, with white villous margins; standard roundish, somewhat reflexed, marked at the base with a greenish yellow spot; wings smaller than the keel; keel one-petaled, when folded nearly orbicular; style hairy on the upper surface of its whole length. **Legume** inflated, membranous, veined, oblong, oval, beaked, on a pedicel four times longer than the calyx. **Seeds** many, shining, kidney-shaped. A native of New South Wales. 7. *C. procumbens*. Mart. 9. 4) *Stems trailing; leaflets oblong, egg-shaped, tomentose; flowers axillary, on very long pedicels.* **Stems** several, woody, slender, much branched; branches not much more than a foot long; leaflets twenty-five or twenty-seven, small, narrow. **Flowers** purple, small; peduncles with three or four flowers. **Legumes** little more than half an inch long, but like a fiddle, compressed. **Seeds** kidney-shaped. A native of the Cape of Good Hope. Cultivated by Miller in 1753. 8. *C. rigida*. Wild. 5. Thumb. prod. 134. 5) Shrubby; leaflets lanceolate, smooth; *item* erect, smooth. A native of the Cape of Good Hope. 9. *C. obtusata*. Wildl. 6. Thumb. prod. 134. 6) Shrubby; leaflets linear; *item* erect; flowers in racemes, reflexed. **A native of the Cape of Good Hope.** 10. *C. lineiris*. Wildl. 7. Thumb. prod. 135. 7) *Herbaceous; leaflets linear, acute; item erect; racemes terminal, inflexed.* A native of the Cape of Good Hope. 11. *C. horrida*. Linn. Sp. Pl. 2. Mart. 6. Lawi. 8. Gaert. tab. 154. fig. 2. 8) *Leaflets linear, emarginate, smooth; item herbaceous; racemes peduncled.* Roots terminal or triennial. **Seeds** near a foot and half high, clothed with very short hairs, branched. **Leaflets** fifteen or seventeen, greenish. **Flowers** dark blood-red, small; *item* standard fimbriated, the length of the wings and keel. **Legumes** small, membranous, somewhat transparent, very thin, compressed, egg-shaped, obliquely mucronate, two-valved, peduncled. **Seeds** two or four, rather large, kidney-shaped, compressed, of a dull chestnut colour. A native of the Cape of Good Hope, cultivated by Miller in 1751. 12. *C. perforans*. Mart. 5. Wildl. 9. Hort. Kew. 3. 59 Jacq. Hort. 3. tab. 3. (C. fruticosum) Retz. Obs. 3. 42. Mart. 7.) **Herbaceous; leaflets oblong, pubescent; item erect; racemes terminal.** Root perennial. **Seeds** two or four, rather large, kidney-shaped, compressed, of a dull chestnut colour. **Flowers** white, shining, with white villous hairs, but bearded only at the tip. **Legume** oval-roundish, acuminate at both ends, compressed, flat, little inflated, smooth, membranous, somewhat pellucid, not opening of itself. **Seeds** few, compressed black. A native of the Cape of Good Hope; introduced by Dr. Jacquin in 1775. 13. *C. profusia*. Wildl. 10. Thumb. prod. 134. 9) *Leaflets lanceolate, villous; item herbaceous, diffuse; peduncles axillary, with about two flowers.* A native of the Cape of Good Hope. We should have supposed this to be *C. procumbens* taken up by professor Martin from Miller, if Miller had not expressly asserted that his plant was *C. fruticosum*. 14. *C. caudata*. Wildl. 11. Thumb. prod. 134. 10) *Leaflets egg-shaped, cut; item herbaceous, decumbent; racemes terminal.* A native of the Cape of Good Hope. 15. *C. vascularia*. Wildl. 12. Thumb. prod. 134. 11) *Leaflets egg-shaped; item herbaceous, decumbent villous; legumes orbicular, inflated.* A native of the Cape of Good Hope. 16. *C. lomento*. Wildl. 13. Thumb. prod. 135. 12) *Leaflets egg-shaped, hoary; item herbaceous, tomentose; flowers in racemes.* A native of the Cape of Good Hope. 17. *C. alpina*. Lam. 6. (Phaca alpina) Linn. P. leguminibus pedulis fernoviatis; Gmel. Sib. 4. 35. tab. 14. Altragalus; Hall. Helv. n. 401. Altragaloides eliator, ercta, vicis folis, foliis penatibus. Amon. Ruth. 148.) **Herbaceous, much branched; leaflets oblong, elliptical, hairy underneath; flowers pale yellow.** Root perennial. **Stems** near a foot and half long, weak, sometimes quite upright, sometimes half decumbent and diffuse. **Leaflets** nineteen or twenty-one, green and smooth above, diminishing in size towards the top. **Flowers** yellowish, in peduncled spikes, situated in the axils of the upper leaves; calyx bell with a few short blackish hairs. **Seeds** very small, perfectly one-celled, pedicelled in their calyx, semi-oval, or a little crescent-shaped, acute, pendulous on the common pedicle. **Seeds** from four to six, small, kidney-shaped. A native of the mountains of Dauphiné, Switzerland. Lapland, and Siberia. 18. *C. auritalis*. Lam. 7. (Phaca auritalis) Linn.; altragaloides alpina supina giaiura, Till. Hort. Pin. 19. tab. 14. fig. 1.) **Herbaceous, diffused; leaflets lanceolate, nearly smooth; peduncles longer than the leaf.** Root perennial. **Stems** from five to seven inches long, slender, weak, commonly procumbent, almost smooth, branched. **Leaflets** thirteen or fifteen, acute.
bene. Stultius two, embracing the flow, oval-obtuse. Flowers yellowish white, with a tint of violet at the extremity of the keel, sulline, in axillary spikes. *Leguminosae* demi-oval, peculiar in their calyx, terminated by a short bent thread, perfectly one-celled, smooth, not pendent. *Sesamum* five or six, small. A native of the mountains of Provence, Italy, and Switzerland. After some hesitation, we have placed the last two species under this genus, in concurrence with Le Marché, although that botanist has not, in this particular, been hitherto followed by any other author. Gérard has even figured the legume of this species alone, to illustrate the genus phase. As far, however, as the partition is concerned, he completely gives up the point, acknowledging the legume to be absolutely one-celled, without a veilage of a partition. He has accordingly introduced *宓polis,* into his generic character, and has found the essential difference between colutea and phasea on the form of the flowers. To us the entire want of a partition appears decisive. Jacquin, indeed, has attributed to his alpin a half two-celled legume; but he seems to refer to a different plant. There is much confusion in authors with respect to the synonyms of phaca-alpina, and that with the kindred species, stands in need of further investigation.

Coluthus, in Biography, a Greek poet. a native of Lycopolis, lived under the emperor Amphilus in the beginning of the sixteenth century. His only work that has come down to us is upon the "Rape of Helen," which, though of inferior merit, has been frequently edited, and was translated into French by M. du Molard in 1742. Molard.

Colvius, Andrew, was born at Dordt in Holland, in the year 1524, where he officiated during a considerable part of his life as pastor of the Walloon church. In 1629, he was chaplain to the embassy at Venice, and cultivated an intimate friendship with the celebrated father Paul, whose treatise on the inquisition he translated from the Italian into the Latin language. Colvius was intimately acquainted with many literary characters of his own age, and was himself a philosopher and poet of eminence, but he is chiefly known as a collector of rarities of every description, of which, in the year 1675, he published a catalogue intitled "Catalogus Rariorum And Colvii." He died at Dordt in 1675. Moreri.

Colymba, or Colymbus, a term in the Greek Liturgy, signifying an offering of corn and boiled puffs, made in honour of the saints, and for the sake of the dead.

Ballamon, P. Gour, Leo Allatins, and others, have written on the subject of *colymba* the substance of what they have said, as follows:

The Greeks boil a quantity of wheat, and lay it in little heaps on a plate; adding beaten peas, nuts, cut small, and grape-hones, which they divide into several compartments, separated from each other by leaves of parsley. A little heap of wheat, thus seasoned, they call *xolymb.*

They have a particular formula for the benediction of the *colymba,* wherein, praying that the children of Babylon may be fed with puffs, and that they may be in better condition than other people, they declare God to bless those fruits, and those who eat them, because offered to his glory, to the honour of such a faint, and in memory of the faithful deceased. Ballamon refers the institution of this ceremony to St. Athenasius; but the Greek Synaxary to the time of Julian the Apostate.

Many of the Latin divines having spoken injuriously of this ceremony, Gabriel archbishop of Philadelphia, has written a discourse in its vindication: wherein he endeavours to shew that the design of the *colymba* is only to represent the resurrection of the dead, and to confirm the faithful in the belief thereof. The *colymba,* he says, are symbols of a general resurrection; and the several ingredients added to the wheat, signify so many different virtues.

Colymbasinis, in Ancient Geography, an episcopal see of Africa, in Pamphylia, according to the acts of the council of Constantiople, held in the year 381.

Colymbus, in Ornithology. Bellonius describes the tufted duck *anas fuligata* of modern writers under the name of *colymbus.*

Colymbus, a genus of the *anseridae,* having the bill torted, fabulate, straight, and pointed; throat denticulated; noftrils linear, and situated at the base of the bill; legs fettered.

Linnaeus includes in the *colymbus* genus three families of birds: the guillemot, the divers, and the grebes, each of which, in the opinion of most ornithologists, ought to be considered generically distinct. The guillemots live chiefly cloe to the sea, and inhabit rocks; they have a slender tongue the fize of the bill, and the bill itself of a compred form, with the upper mandible a little bent, and the base covered with short feathers: they are principally distingvished by having the feet three-toed. The divers have a strong bill, les pointed. cylindrical, the edges of the mandible turned in, the upper one longe; noftrils divided in the middle by a membrane tongue long, sharp, serrated at the base each side; legs slender; tail-feathers twenty in number; the chief character of these comit in the feet being furnished with four toes, and palmites; they frequent fresh waters. The grebes are without a tail, have a strong bill; lores naked; tongue a little clefs at the tip; body depressed, and thickiy covered with soft thinning plumage; wings short, and the legs comprised; the principal characteritc of this family are the lobate feet; consisting of four toes each. Those last mentioned birds frequent meres, and other inland watery places.

* Feet three-toed, Guillemot.

Macroratus. Above streaked with chestnut and brown; beneath
COLUMBUS.

Inhabits the western parts of America and Kamtschatka. This bird is ten inches in length; the crown is dusky; some of the greater quill-feathers edged with white; chin dusky, with white fringes.

In America and Kamtschatka. This bird is ten inches in length; the crown is dusky; some of the greater quill-feathers edged with white; chin dusky, with white fringes.

This bird is nine inches long; the head and neck are brown; the back of the neck is red, and the rest of the body is white. It is found in the Arctic regions, and is called the "Arctic diver." It is a large bird, measuring about three feet, with a large white spot on the head, and is found in the Arctic regions.

A general inhabitant of Europe and America, frequenting the sea-coasts, and preying on fish; it builds its nest on the ground, the eggs are white, and spotted with black. This species is liable to some variation in the disposition of its spots, and appearance of plumage. One variety found at Amsterdam is of a footy black colour, with a double white band. Another is streaked above; beneath white, banded with cinereous; upper wing-coverts variegated with white and black; this is the white banded of Brunnich, and inhabits Greenland. A second variety mentioned by the same author has the back, wings, and tail black; head, neck, and body beneath, with the spot on the wings white. Dr. Latham describes a variety from Kamtschatka of a black colour, with the crown clouded; the greater wing-coverts, and under side of the body, varied with white and black; throat entirely white; and lastly, the unia grayibides of Brunnich is considered by some as a variety of this species; the upper part of the plumage of this bird is spotted white and black, the colour beneath white.

This bird inhabits Europe and America, and is found in maritime situations, as its principal food consists of sea-fish; its usual resort is the steep and molten inaccessible cliffs on the sea-shore, and in such places where the water is shallow on our own coasts during the summer, in which season they breed. The places most celebrated for the resort of these birds are the Isle of Portland, in Devonshire, between Caenarvonshire and the island of Anglesea; on a rock called Godrevy, not far from St. Ives, Cornwall; the Farn island, near the coast of Northumberland; and the cliffs about Scarborough, Yorkshire. They are rare birds, and so stupid, that having once attained access to their haunts, they may be knocked down in any numbers with a stick, for though they see their companions killed before them, they never attempt to quit the rocks. In many parts they are killed by the inhabitants both for the sake of their flesh and skin; the former is, however, not remarkable for its delicacy, and has a strong fishy taste. The natives of Greenland and Kamtschatka make garments of their skins. Like the auk, this bird lays but a single egg; the eggs are in two, white, of medium size, for the table the flesh. The length of this

bird is seventeen inches. There are several varieties of this species.

We have followed the example of Linnaeus and Gmelin in confounding the four above-mentioned birds as appertaining to the columbus genus, but it should be at the same time observed, that Brunnich constitutes a distinct genus of them under the title of uria, and that this genus is adopted by Dr. Latham, in his Index Ornithol. Junc., though he adheres to the Linnaean method in his "General Synopsis."

**9.** Feet four-toed, paleated, Diver.

This is a large bird, measuring about three feet in length; the upper part of the body with the bill, legs, and tail are black; the back and upper part of the wings is marked with a number of white spots disposed in rows. Inhabits the Northern seas, and is rare in England. The specimen in the London Museum.

In Iceland and Greenland, where those birds breed, they are very frequent. It is also abundant on the shores of Norway, and along the Arctic coasts as far as the river Obey, in the dominions of Russia. It is seldom seen on land, except in the breeding season, being, for the most part, in the open sea, where it is continually diving for fish, which it does with the greatest address. Among the northern marine nations, the skins of these birds are prepared by the natives, and manufactured with the feathers on them in caps and other articles of dress. Gauntlets, we are told, made of these skins are warm, and never imbibe the least moisture, and are also more durable in wet than might be imagined. The bird is likewise met with among the lakes of Hudson's bay, where the natives adorn their heads with circlets of their feathers.

The length of this bird is two feet; the feathers of the back, wings, and tail are edged with white; in the male bird the front and sides of the head and neck are spotted with brown. This species inhabits the Arctic ocean; it ranks as a British species, but is rarely taken in our country.

**Stellatus.** Cinereous-brown or dusky, spotted with white; throat pale ash, beneath white. Columbus stellaris, Brun. Gmel. Micros minor, Buff. Columbus marmoratus stellaris, Will. Le petit plongeur, Buff. Speckled diver, or loon, Lath. Observed in plenty about the shores of the Baltic, and white sea, and in America. They occasionally migrate in flocks, pursuing the same course as the shoals of herrings and sprats, the latter in particular, and it is for this reason known in many parts by the name of speck loon. These birds are more common in the temperate, or southern parts of Europe, than any other of the diver tribe. The length is twenty-seven inches, the bill horn colour; legs brown. It builds no nest, but lays its eggs, which are two in number, in the grass on the borders of lakes contiguous to the sea-coast; these eggs are dusky, spotted with black.

Arcticus.
**Columbus.**

**Arcticus.** Head hoary; neck beneath violaceous, black, with an interrupted white band. *Columbus arcticus*, Linn. *Mergus guttus nigro, Briff.* Black-throated diver, Lath. Length two feet; inhabits the north of Europe, Asia, and America.

Inhabits Europe, Asia, and America, frequenting lakes, and oftentimes the open sea in qucg of prey, which consists of fish, marine infecls, and crabs. The body is brown above, with minute white spots, beneath white; bill black, head and chin cinereous, spotted with brown; neck above with small white and brown lines; the legs dusky. Length about thirty inches. These birds lay their eggs in June, the young are hatched and ready to fly before the end of August, and undertake their annual migrations with the parent birds in September. They breed chiefly in America.

**Borealis.** Body above blackish, with numerous white flecked spots; beneath white; neck on the fore-part rufous. *Columbus borealis*, Brunn. This bird was shot near Copenhagen; it resembles in size and appearance *Columbus flectatus*, and is, perhaps, a variety of that bird. Brunnich considers it as a distinct species.

**Striatus.** Blackish, beneath white; head and neck grey, lined with black. *Columbus striatus*, Gmel. Striped diver, Lath.

Inhabits North America, where it frequents lakes; it is represented as a noisy clamorous bird, and one continually in motion or on the wing, flying backwards and forwards. The bill of this species is dusky, or black, and strong; the cheeks white.

**Sinensis.** Greenish-brown, with deeper spots; breast and belly reddish-white, spotted with rufous; wings and tail blackish. *Columbus seinae*, Gmel. Chinese diver, Lath.

This species inhabits China, and is supposed to be one of those kinds of aquatic birds which are trained up, and employed by the Chinese for catching fish. The bill is dusky; and the tridens and legs cinereous.

**Fuscus.** Fuscous, beneath white; head rufous; collar black; secondary quill-feathers white. *Columbus crissatus*, Linn. *Columbus cornutus*, Briff. Le grebe cornu, Buff. Crested grebe, Lath.

Length of this species twenty-three inches; bill flesh-colour, with the tip brown, beneath white; head tumid, varies in colour by age, and has been described in the first, second, and third years' plumage, as three distinct species.

Like the rest of the grebe tribe, these birds form a floating nest, composed of grass and flags, interwoven with the roots and stalks of other aquatic plants. The female lays four eggs, which are of a white colour, and fits in the nest half immersed in water till the eggs are hatched. It preys on eels and fish, which it procures with great facility, by diving into the water. The flesh is rank, but the skins, which are prepared with the beautiful silver and silver-white plumage on them are in high request for muffts and reticuts. Many of the grebes are taken on the lakes of Geneva for that purpose. In England, those birds frequent the meres of Shropshire and Cheshire, and the great lacs of Lincolnshire, in all which places they are known to breed. The tippec grebe is said to be the young of this species.

A native of Cayenne. This bird is nineteen inches and a half in length; the bill and legs are dusky; and the lower mandible yellow at the base.

Inhabitants many places in Europe and America. Length eleven inches. The bill is black, and red at the sides; irides and lores purple; upper edge of the wings white; legs flesh-colour, inclining to purpl.

**Cornutus.** Head glossy-green, and tumid; neck beneath, and breast fulvous; through the eyes a yellow tufted band. *Columbus cornutus*, Gmel. Horned grebe, Arch. Zool.

An inhabitant of Hudson's bay; length twelve inches. Dr. Latham describes the little horned grebe, *le petit grebe cornu* of Buffon as a variety of this species.

The length of this bird is eighteen inches; the bill is dusky, and at the sides at the base tawny; the legs dusky. This is a British species; the male is very rare, the female scarcely known; both sexes are preferred in the London Museum.

**Caspicus.** Head smooth; body above dark brown, beneath silverly; bill lead colour; chin and checks white; wing-coverts brown. S. G. Gmel. Inhabits near the Caspian sea.

**Thomensis.** Fuscous; beneath white, spotted with grey; quill-feathers pale rufous; breast with a black spot. *Columbus thomensis*, Gmel. Le grebe due laart, Buff. Black-breasted grebe, Lath.

Less than the common hen; the bill is black, with the tip pale; irides and spot between the bill and eyes white; legs dusky. Inhabits St. Thomas's island in America.

This bird inhabits Europe and America, is ten inches in length, and feeds on worms, small fish, and aquatic insects. Buffon describes a variety of it under the title of "Le Cailleux des Philippines;" it is larger than the former, the plumage above purple brown; and the cheeks and sides of the neck reddish. Found in the Philippine isles.

**Dominicus.** Head smooth; body beneath thickly spotted. *Columbus dominicus*, Linn. Le cailleux de St. Domingue, Buff. White-winged grebe, Lath.

Inhabits the Antilles and Surinam. Its length is eight inches; the bill is black; body dusky, beneath silver grey; quill-feathers cinereous white; legs brown.

**Henricus.** Head smooth; body blackish; chin black;
throat; throat fuscous; belly cinereous, mixed with "Columbus huebovicus, Gmel. Black-bellied grebe, Lat.
A small and rare species, found chiefly in Tiree, one of the islands of the Hebrides.
Podiceps. Body fuscous; bill olive, dusky at the base, with a transverse black band in the middle. *Columbus podiceps,* Linn. Le caglanaux à bec circé, Buff. *Podil bill grebe, Lat.
A native of North America; length fourteen inches; irides white; chin black, surrounded with white; body beneath silvery; breast waved with cinereous; secondary quill-feathers black at the tip. The female has no black mark on the bill.

LUDOVICIANUS. Fuscous; sides of the neck and body fuscous; beneath white, with transverse blackish spots. *Columbus ludovicanus, Gmel. Le grebe de la Louisiane, Buff. Louisiane grebe.
Inhabits Louisiana. The head is smooth; legs dusky; middle of the belly silvery white.

CULYTON, or CULLITUS, in Geography, is a small but ancient market town in Devonshire, England. It is called by Risdon, a "burgh of reputation:" the housekeepers of a small district, called the borough, annually chose a portreave at the lord's court. At the Norman conquest, Colyton was the king's demesne; and King John granted the inhabitants a fair, to continue eight days. The houses are in general built with flats and mostly thatched. The parish church is a spacious stone fabric, with a tower rising above the chancel, the upper part of which is octagonal. On the south side of the chancel is an inclosed burial-place, belonging to the De la Pole family, containing various effigies, and other monumental decorations: and in a small aisle adjoining, is the figure of a girl, apparently about five years of age, under a canopy of f Wrocław; she is said to have been the grand-daughter of Edward IV., and to have been choked by a fish-bone; over her are the royal and Courtenay arms. Colyton arms are situated 153 miles S.W. from London; the number of houses is 289; of inhabitants 1641.

CULYTIUS, or CULLITUS, in Ancient Geography, the name of a quarter of the city of Athens, belonging to the Egeide tribe, and adjoining to that called Melitone. *Culm., or Com., in Geography,* one of the oldest, and formerly of the largest town of Perita in the province of Irak Agami. It has suffered greatly by the civil wars with which the Persian empire has been so often distracted, but is still a very populous place; 50 miles S. of Calamis, and 150 N. of Ithaka. It is celebrated for its silk manufactures, chiefly velvet. N. lat. 34°. E. long. 50°.

COMA. See COMO.

COMA, in Medicine, a preternatural propensity to sleep, though the patient frequently does not sleep, or if he does, awakes without relief. If sleep continues, the disease is called *coma profundum;* in this case the patient continues in a profound sleep, and when awaked, immediately relapses, without being able to keep open his eyes. If he does not sleep, but is continually awakened with frightful dreams, it is called *coma vigilia;* in this case he appears to sleep, having his eyes continually shut. Coma is produced by debility, by the want of food, extreme, &c. See APPHLE.

COMA, in Botany, from *epin,* a head of hair, is applied to a leafy crown, whether of the proper leaves of the plant, or of branches, rising above the fructification. In the place where the crown is, it is of the tender kind; *Coma huminum*, or purple topped clary, of the latter, being more elegantly elegant with pink or purple. See Comine.

COMA, in Astronomy, a town of Venetia.

COMAGIENA. See COMAGINE.

COMAGINE, a place of Noves, dillant, according to Antonium's itinerary, 24 miles from mount Cetius.

COMANA, a town of Pontus, seated on the river Iris, towards the mountain of Paryade, on the north. It was famous for a temple of Bellona. The town and territory depended on a pointil, who, on solemn days, wore a diadem, and possessed a kind of sovereignty. Venus also was worshipped in this city: here was celebrated with great magnificence, and the had many courtizens.

COMANA, a town of Asia, in the greater Cappadocia, fented on the river Sarus, in Cappadocia. It was also called Chrysa, and be the appellation of Cappadocian.

COMANA, or BZOSA, a town of the island of Taprobana, according to Ptolemy.

COMANA, or COMNACIUS, a town of Asia, in Phrygia. - Also, another town in Phrygia. Ptolemy.

COMANA, in Geography, a town of South America, in the northern division of Terra Firma. It lies on the north-callerimost part of the sea-coast.

COMANCES, or HILTANUS, a tribe of Indians in Louisiana in America, who have no fixed place of residence, and who have neither towns nor villages. They are divided into many hordes, that they have scarcely any knowledge of one another. They never continue in the same place for more than a few days, but follow the buffalo, the deer of which is their principal food. Some of them purchase of the Pous or Touskies, another tribe, corn, beans, and pumpkins; but their number is so great, that these articles furnish a small quantity of their food. Their tents are made of...
of skins neatly dressed, and fashioned in the form of a coat, affording room for a family of 10 or 12 persons; those of the chiefs are capable of accommodating 50 or 65 persons. When they pitch their tents, they form regular streets and squares, exhibiting a fort of town suddenly raised, as it were by incantation, and at a signal for march, they are as suddenly struck: to every tent are allotted two horses or mules, one for carrying the tent, and another for removing the poles or stakes, which are mostly made of red cedar; they all travel on horseback. Their horses are tied for grazing with a long halter, and they are so numerous as to require frequent change of place. Their horses are so managed, as to be remarkably dexterous and gentle. It is their practice to hunt the buffalo on horseback; and they kill this animal with the bow, or a sharp stick like a spear, which they carry in their hands. They are generally at war with the Spaniards, committing frequent depredations upon the inhabitants of Santa Fé and St. Antoine; but they have been always friendly and civil to any French or Americans who have been amongst them. With regard to their persons, they are strong and athletic, and, in advanced life, corpulent. As savages, they are uncommonly clean; the dresses of their women is a long loose robe, reaching from the chin to the ground, tied round with a fancy fast or girdle, all neatly made of dressed leather, on which they paint figures of different colours and significations: the dresses of the men consists of close leather pantaloons, and a hunting shirt, or frock of the same. Their attire in the dance place does not admit of their making any plantation; but the small Cayenne pepper grows spontaneously in the country, and with this, together with some wild herbs and fruits, particularly a bean that grows plentifully on a small tree, resembling a willow, called Mapete, the women cook their buffalo beef in a manner that renders it grateful food. They alternately occupy the immense space of country from the Trinity and Braces, crossing the Red river, to the heads of Arkania and Misfouri, to river Grand, and beyond it, about Santa Fé, and over the dividing ridge on the waters of the Western Ocean, where, as they say, they have seen vessels, which they describe as ships, with sails and rigging. Their native language differs from that of any other nation; but they have a mode of making themselves understood to the Indians by signs. Amongst them are many Spanish men and women, who are slaves, and who were made prisoners by them in their youth.

COMANI, in Ancient Geography, a people of Asia, probably of Scythia, who inhabited the country Comania, mentioned by Piny. They were probably the same the fame with the Com of Ptolemy, and the Comari and Comami, placed by Pomponius Mela in the vicinity of the Paropamisians.

COMANIA, a country of Asia, according to Xenophon. See COMANIA.

COMANIA, also called Daghestan, a country in the northern part of Turkey in Asia, south from Little Tartary, and north from Georgia bounded on the east by the Caspian sea, W. by the Caucasus, N. by Circassia, and S. by Kirwan. Its inhabitants are known by the name of Comamses. See DAGHESTAN.

COMANNA, an inland country of Africa, on the Slave coast, bounded on the east by Infoko, on the south by Lobadde and Ningo, two provinces of Aquambo; its northern limit is unknown. Little is known of the country, except that its natives bring great quantities of gold to the markets of Akkaradi, a kingdom touching it on the west, who affords bread carry it to Aboni, and then to the negros of the sea-coast. Beyond Comanna, in regular succession from E. to W., but with unascertained boundaries to S. and N., are the kingdoms of Lathi, Equa, Bonu, situated far north; Tahi, Quaka, Aboni, Sankug, Agum, and Achem, all supposed to be rich in gold; but more especially Quaka.

COMARCHIOS, in Antiquity, the name of a particular air, or tune, designed to be sung at entertainments.

COMARGO, in Geography, a town of North America, in New Leon, Situate on the south side of Rio Bravo, which empties itself into the gulf of Mexico on the west side.

COMARIA PROMONTORIUM, in Ancient Geography, a maritime place of India, at the extremity of the peninsula, on this side of the Ganges. See Cape COMARIN.

COMARIS, in Lichology, a genus given by the Greek writers to the sejunctae, or asplenoce.

COMAROIDES, in Botany, alpina argenteum; Segal.

See Potentilla nigula.

COMARTCH, in Geography, a river of South Wales, in the county of Brecknock, which runs into the Yvon, eight miles W. of Buich.

Gen. Ch. Cad. Perianth one-leafed, ten-eleft, very large, spreading, coloured, permanent; alternate segments smaller, inferior. Cor. Petals five, oblong, acuminate, inserted on the calyx, much smaller. Stam. Filaments about twenty,awl-shaped, inserted into the calyx, length of the corollis, permanent; anthers crenate-shaped, deciduous. Ped. Germs numerous, roundish, very small, collected into a head; styles simple, short, from the middle of the germ; frigmas simple. Peric. none. Seeds naked, even-surfaced; attached to a large, egg-shaped, fpongy, villous, perforating receptacle.

COMARUS PORTUS, in Ancient Geography, a name given by Dion Cassius to a port of Epirus, which he places in the gulf of Ambrocia. Strabo calls it Comarus Sinus, and makes it a small gulf of Epirus.

COMAYUAGUA, or VALLADOLID, in Geography, a large town of the province of Honduras, in Old Mexico, or New Spain, in North America, on a river which falls into the gulf of Honduras. It is the see of a bishop, and has rich silver mines in its neighbourhood; 90 miles S.E. of Truxillo. E. long. 80° 4'. N. lat. 14° 30'.
COM

COM

COM

inch in diameter; this arbor is mounted between two circular brass plates. II, fig. 1, connected by three pillars, it carries as many circular filed cutters, or faws, K, fig. 4, as the comb to be cut is to have teeth. M, fig. 5, represents another arbor, which is fixed in the frame-plate, fig. 1, by its ends; it is triangular, and has a piece of filet, L, fig. 4 (called a guide), fixed on it between each faw, on the arbor, b. These parts are put together by first putting the end of the arbor, b, fig. 2, through the hole in the centre of the frame-plate, I, and screwing on the catch, a; the end of the arbor fig. 5, is put into a square hole made in the plate, I, and is fixed by a screw; a guide, L, fig. 4, is then put on the arbor, M, close against the shoulder, d; next a cutter, K, is put on the arbor, b, touching its shoulder, e; a piece of filet plate, N, called a guide-washer, is then put on the arbor, M, and another guide, L, close to it; the guide-washer is a little thicker than the cutter opposite it, so that the cutters each turn between two guides without touching them. These being in their places, a small washer, O, fig. 4, is put on the arbor, b, and a cutter, then a guide-washer and guide, on the arbor, M, and so on alternately, till the greater number of cutters are put on; the filet shoulder, f, is then taken, and with the octagonal nut, g, screwed fast up against the last cutter, put on the arbor, b, this will pinch all the cutters and washers between the shoulders, e and f, and hold them fast. The fame: is done to the arbor of the guides, and, lastly, the frame-plate, H, is put on the ends of the pillars, and screwed fast; the whole forming the frame-plate shown in fig. 1. The frame plates with the arbores, as in fig. 1, are now to be put in their place in the machine, fig. 3, the horns of the catch, a, going into two holes in the pulley, F, and the other end of the arbor, b, into a centre that goes up with a screw in the puppet, Q; the screws, b, are designed to steady the frame-plates (which hold the arbor of the guides) against the dove-tail, P, supported by brackets projecting from the front of the clock, sufficiently to let the block, i, which slides in the dove-tail, and holds the comb, be drawn forwards to give room for the hand to put in or take out the combs clear of the cutter. To the base of the dove-tail is screwed a plate, holding one of the centres for a worm wheel, k, whose axis is made of filet, and has its end cut with a deep thread-screw; the screw-end of this axis works in a centre, fixed to the base of the dove-tail, and the block, i, is cut away to pass clear over it and the threads of the screws, without touching them. The worm-wheel, k, is turned by an endless screw, on the arbor of the wheel, r, which receives its motion from the pulley, t, by an endless line. The block, i, which holds the comb, moves in the dove-tail, and is to carry the comb towards the cutters while cutting. As the screw on the axis of the wheel, K, is to carry the block up in its nut; a knife-edge, fastened to a small lever, l, movable on a centre in the face of the block, is applied to it, and kept down (so that the knife-edge may take into the threads of the screw) by a catch similar to the latch of a door, which is released by pulling in a thumb-fluid, and allows the spring, a, to throw up the lever, l, and disengage the screw, so that the block may be brought forwards in the dove-tail. The piece of ivory intended to be cut is put under a plate, p, and held down by two screws to the face of the block, which is in the same plane with the arbor of the cutters; the workman then puts down the knife-edge, and the catch keeps it to; he then turns the machine by his foot, and pushes the block towards the cutters (the comb sliding close on the guides) till the knife-edge take the slide thread of the screw, which it must round as before described, and pushes the block and comb up to the cutters, as far as the
the fore extends, and the cutters saw the teeth in the comb;
the thumb and is then pulled in, and the spring, o, throws
the knife-edge up, so that the block can be brought back by
hand, and the comb taken out. The distance which the
comb projects from the face of the block towards the cutters,
and consequently the length of the teeth, is regulated by a
straight edge of metal on the top of the block, i, under the
plate, p, against which the back of the comb rests; it can
be moved parallel to itself across the top of the block by
two screws, (which are seen at the upper corners of the face
of the blocks), for combs of longer or shorter teeth. The
handle of the comb has a wheel. R, on it, turning an arbor,
s, by a line, which carries a set of cutters for pointing the
comb. The arbor is shown separately in fig. 6, and a cutter
in fig. 7; it is made up in the same manner as the former
one, and followed by a screw, T; the ends of the teeth of
the comb are applied to this cutter by hand, first on one side,
and then on the other, till the points are made. This is
performed to one comb, while the teeth are cutting in
another.

Comb, or Coomb, in Hydraulics, a measure of corn, con-
forming to 2 long strakes = 4 Wincheller bushels = 16
pecks = 32 dry gallons = 128 dry quarts = 256 dry
pints = 860.16 cubic inches = 4.97 cubic feet =
1.843621 cubic yards = 17,321.42 cubic links; in some
places the bushel contains eight gallons and a quart.

Comb, or Coomb, in Carnook, of wheat, according to the
9th and 11th Henry III. 12th Henry VII., &c., was 2706.
troy = 210.9514 lb. windropic = 2 strakes = 16 pecks
= 32 gallons = 256 pints or pounds.

Comb, in Ornithology, the crest, or red flabby tuft growing
on the head of a cock.
Comb, in a floor, a little piece of timber, set under the
lower part of the back-level near the middle: it has two
holes in it, and supplies to the fore-tacks, what the chet-
trees do to the main-tacks; that is to bring the main-tacks
aboard.

Comb, in the Manufacture of Tapestry. See TAPESTRY.

COMBA-MARTIN, in Geography, a town of England, on the
north coast of Devonshire, in the Briduil channel, with a
small creek for boats; near it are silver-mines, which
formerly yielded a considerable quantity of ore; 39 miles
W. of Bridgewater, and 176 W. of London.

COMBA, in Ancient Geography, a town of Asia Minor,
in the interior of Lycaia, and in the vicinity of Mount
Cragus. Ptolemy.—Aio, a marlch of Greece, in Macedonia,
near mount Athos, mentioned by Athenaeus.

COMBAMIEE, in Geography, a considerable river of South
Carolina, which enters St. Helena Sound, between Cooba
and Aheepoo rivers. The ferry of the same name on this
river is distant 17 miles from Jackson's borough; 15 from
Pocotiah, and 52 from Charlton.

COMBAM, or COOM, a town of Hindostan, in the
country of Cuddapah; 85 miles N. of Cuddapah. Com-
ban is reckoned 25 colleges from Tanacordi, and 32 from
Ongole, or about 51 geographical miles from the latter.
Taverner calls it Raman.

COMBAMET, a town of Hindostan, in the country of
Golconda, 268 miles S. of Hydrabad.

COMBANA, or NORMANIA, in Ancient Geography, a
town of Africa, in Carthage, situated near the sea.

CAMBAROSES, in Antiquity, the fellow-barons or
commandy of the Cuque-Patt.

COMBAT, in a general sense, denotes an engagement;
or a difference decided by means of arms.

Authors sometimes distinguish in an army, between a
combat and a battle; the latter expressing the general en-
tation of the whole army; the former only a particular skir-
mish, or engagement of a single part; so that the combat
is properly a part of a battle.

COMBAT, in Law, or single combat, denotes a formal trial,
between two champions, of some doubtful cause or quarrel,
by the sword or halberds.

This form of proceeding was abundantly very frequent,
particularly among the barbarous nations in their original
settlements; and obtained, not only in criminal, but
also in civil causes; being built on a presumption
that God would never grant the victory but to him
who had the best right. It was originally permitted, in or-
to determine points respecting the reputation of individuals,
but afterwards became much more extensive. See Duel.
The form and ceremony of the combat are described in
the grand Coutumier of Normandy. The accouter, full, fiowerte
to the truth of his accusation in; the accouter gare him the
lie; upon which, each threw down a page, or pledge of
battle; and the parties were committed prisoners to the
day of combat. See CHAMPION.

If florians tell us, that Alphonso, king of Castile, in the
eleventh century, desiring to abolish the Molca bic liturgy,
and to introduce the Roman office; the people
opposing it, he was agreed to terminate the difference by
combat, and leave the cause to the decision of Heaven.
One of the earliest restrictions of this practice that occurs
in the history of Europe, is that of Henry I. of England;
which was afterwards followed by an edict of Louis VII.
of France to the same effect. Robertson's Hist. of Chalce.
Vol. v. p. 61, &c., and 350. &c. 8vo.

COMBAT is also used for the solemn games of the ancient
Greeks and Romans, performed in honour of their gods;
as the Olympic games, Pythian, Isthmian, and Nemean
games; the hith Atian, Circenid, &c. which fee in their
places, OLYMPIC, ISTMHUS, &c.

The combats here celebrated, were running, wrestling,
bowing, eoufus, &c. The combattants, who were called athletes,
prepared themselves for it from youth, by combat
exercise, and a very rigid regimen: they only eat certain
things, and at certain hours; drank no wine; had no com-
merce with women; and both their labour and their rest
were regulated.

COMBATANT, in Heraldry, termed by the French
heralds confronté, when two animals are borne in com-
bat, in a fighting posture, erect on their hind feet, and
facing each other.

COMBATANT, in Ornithology, the name given by
French writers to the Linmeau Tringa pagana, the bird
known in this country by the name of Kufft and Keever,
the male being called the Kuff, the female Keever. See
Tringa pagana.

COMBEAUFONTE, a small town of France, in
the department of Upper Saone, chief place of a canton,
in the district of Veroil. It contains 583 and the canton
7356 inhabitants. The territory includes 190 kilometres
and 17 communes.

COMBETIS, FRANCIS, in Biography, a learned French
monk, was born at Guimene, in the year 1665. He pursued
his studies first under the Jesuits at Bourdeaux, and after
wards at Paris. He devoted himself principally to the pur-
pose of Greek literature, and was employed in editing new
editions of the Greek fathers, for which he received a very
handsome remuneration. He likewise published a collection
of the lives of different fathers, prophet, and martyrs; some
additions to the " Bibliotheca Graecoum Patrum," in
Greek and Latin, in three volumes folio; "Historia Briz-
zantinum Scriptorium, post Theophanem," undertaken by
command
command of the celebrated Colbert. He died in 1679 of the stone, a disease to which fluminous and sedentary men are peculiarly liable. \textit{Nat. Diit. Brit.}

COMBANY, in Geography, a river of South Wales, in Carmarthenshire, which discharges itself into the Loughor, 5 miles N.E. of Llanelli.

COMBER, THOMAS, in Biography, was born at Wetheram in Kent, in the year 1645, where he received the rudiments of a learned education; from thence he was admitted to Eton College Cambridge. He was remarkable for diligence in his studies, and took his degrees of B. of arts in 1665, and of Master of Arts in 1666. Some years afterwards he was created doctor of divinity, probably by a diploma from Lambeth. After this, he attained to considerable rank in the church, and was preferred to the precentorship of York, the deanery of Durham, to be chaplain to their majesties, and other posts of emolument and honour. Dr. Comber maintained a correspondence with Tullotson, Burnet, and other most eminent divines of the age in which he flourished. The excellence of his character, and his zeal for the church of which he was a member, were the causes that led him to that distinction to which he attained, and which was a sure earnest and pledge of still greater preferment if he had lived, but he died in November 1699, in the 55th year of his age, and was buried at Stonegrave in Yorkshire, of which he was rector. He was author of many learned works relating principally to the Common Prayer, and to the offices of the Church of England.

There was also another Dr. Thomas Comber, born in Suffolk, Jan. 1575, who was educated in Trinity College Cambridge, and afterwards made dean of Carlisle. In 1642 he was imprisoned, plundered, and deprived of all his preferments, and died at Cambridge in 1653. He is known as the author of "An Historical Vindication of the Divine Right of Tythes," 4to, written in answer to "Selden's History of Tythes," Basingstoke, England.

COMBER, in Ichthyology, a species of wrasse or old of fith, found sometimes on the coast of Cornwall, and which is described under this name in Ray's Synopsis, No. 163. See Labrus Comber.

COMBER-MERE, in Geography, a lake in the county of Chester, on the borders of Shropshire; five miles S. of Nantwich.

COMBINATION, properly understood of an amalgamation of several things by two and two; but is more particularly used in \textit{Mathematics}, to denote the variation, or alternation of any number of quantities, letters, sounds, or the like, in all the different manners possible.

P. Merian gives us the combination of all the notes and sounds in music, as far as sixty-four; the sum whereof amounts to ninety figures, or places.

The number of possible combinations of the twenty-four letters of the alphabet, taken first two by two, then three by three, &c. according to Mr. Pritchard's calculation, amounts to 13971642888675259903241384965930300.

The words in the following verse may be combined a thousand and twenty-two different ways:

\textit{Tet tilli fonte dores, virga, quot sidera celo.}

F. Truchet, in the Memoirs of the French Academy, fells, that two square pieces, each divided diagonally into two colours, may be arranged and combined sixty-four different ways, so as to form so many different kinds of chequer work, which appears surprising enough, when one considers that two letters, or figures, can only be combined twice. This note may be of use to nations, paviours, &c. See \textit{Pavement}, and \textit{Changes}.

COMBINATION. \textit{doctrine of.}—Any number of quantities being given, together with the number in each combination; to find the number of combinations.

One quantity, we observe, admits of no combination; two, a and b, of one, viz. ab; of three, a, b, c, there are three combinations, viz. \(ab, ac, bc\); of four, \(x, a, b, c\); of five, ten, \(ab, ac, bd, cd\), &c. Hence if the number of things to be combined be \(q\), the side of the number of combinations will be \(q-1\) and therefore the number of combinations \(\frac{q-1}{1} \times q - 0\). See \textit{Triangular number}.

If three quantities are to be combined, and the number in each combination be three, there will be only one combination, \(abc\), if a fourth be added, the combinations will be found \(abc, abd, abd, acc, \) &c. if a fifth, \(ten, abc, ad, \) &c. &c. &c. &c.; if a sixth, twenty, &c. The numbers of combinations, therefore, proceed as 1, 4, 10, 20; i.e. they are the first pyramidal triangular numbers, whose sides differ by two units from the number of given quantities. See \textit{Pyramidal number}.

Hence, if the number of given quantities be \(q\), the side will be \(q-2\); and therefore, the number of combinations \(\frac{q-2}{2} \times q - 1\). See \textit{Triangular number}.

Hence it is easily deduced a general rule for determining the number of combinations in any case: for suppose the number of quantities to be combined, \(q\), the exponent of the combination \(n\), the number of combinations will be \((q-n+1) \times \frac{q-n+2}{2} \times \frac{q-n+3}{3} \times \frac{q-n+4}{4} \times \frac{q-n+5}{5}\) &c. till the number to be added be equal to \(n\).

Suppose, \(v, gr\), the number of quantities to be combined \(v = 6\); the exponent of the combination \(4\); the number of combinations will be \(\frac{6}{1} \times \frac{5}{2} \times \frac{4}{3} \times \frac{3}{2} \times \frac{2}{1} = 15\).

Coral. If it be defined to have all the possible combinations of the given quantities beginning with the combinations of the several two's, proceeding to three, &c. there must be added \(\frac{2}{1} \times q - 0\), \(\frac{2}{1} \times q - 1 \times q - 2\) \(\frac{3}{2} \cdot 3 \cdot 4\) &c. Hence the number of combinations possible will be \(\frac{q+1}{1} \times \frac{q-1}{2} \times \frac{q-2}{3} \times \frac{q-3}{4} \times \frac{q-4}{5}\) &c. which is the sum of the unex of the binomial, raised to the power \(q\) and abridged of the exponent of the power increased by unity, \(q+1\). Wherefore if \(q = 2\) represent the binomial to which these belong, \(2^q - 1 - 1\) is the number of all the possible combinations. \(v, gr\) If the number of quantities be \(q\), the number of possible combinations will be \(q^q = 2^q - 2^q = q = 26\).
2. Any number of quantities being given, to find the number of changes and alternations which these quantities, combined in all the manners possible, can undergo.

Suppose two quantities, \( a \) and \( b \), their variations will be 2; consequntly, as each of these may be combined, even with itself, to these there must be added two variations. The whole number, therefore, will be \( 2 + 2 = 4 \). If there were three quantities, and the exponent of the variations were 2, the combination will be 3, and the changes 3; to which if the three combinations of each quantity with itself \( a, b, c \), be added, we shall have the number of changes, \( 3 + 3 + 3 = 9 \).

In like manner it is evident, if the given quantities were 4, and the exponent 2, the number of changes would be \( 2^4 = 16 \); and, in general, if the number of quantities \( n \), and the exponent \( n \), the number of changes will be \( n^n \). By this proceeding, it will be found that if the number of quantities \( n \), and the exponent \( n \), the number of changes will be \( n^n \); wherefore, if all the antecedents be added, where the exponent is \( k \), the number of possible changes will be \( n^k + n^{k-1} + n^{k-2} + \ldots + n + 1 \), &c. Till at length, the number subtracted from \( n \) leaves 1; because the beginning is from single quantities taken once.

Since then the number of possible changes is in a geometrical progression, whose first or smallest term is \( n \), the greatest \( n^n \), and the ratio \( n \); it will be \( n^{n-1} \).

Suppose, \( n = 4 \), the number of possible changes \( n^{n-1} = 4^{4-1} = 40 \). Suppose, again, \( n = 24 \), the number of possible changes \( n^{n-1} = 24^{24-1} = 340 \).}

COMBING of wool. See Combs.}

COMBINE, to unite, to join together.
COMBS. In Geography, a town of France, in the department of Puy de Dôme, chief place of a canton, in the district of Riom, containing 1508 inhabitants. The territorial extent is of 125 kilometres, with a population of 7580 individuals distributed in 12 communes.

COMBS of Béa. See Honey-camb.

COMBURENDO HERETICO. See Heretic.

COMBUST, in Astronomy. When a planet is in conjunction with the sun, or not distant from it above half their disk; it is said to be combust, or in combustion.

According to Argol, a planet is combust or in combustion, when not above eight degrees and thirty minutes distance from the sun, either before or after him.

COMBUSTA, in Ancient Geography, a town of Gallia Narbonensis, marked in the Itinerary of Antonine, on the route that leads from Narbona to the passage of the Pyrenees.

COMBUSTION pecuniare, the ancient way of trying mixed and corrupt money, by melting it down, upon payments into the Exchequer. In the time of king Henry II., a constitution was made, called the trial by combustion; the practice of which differed little or nothing from the present method of assaying silver. But whether this examination of money by combustion was to reduce an equation of money only or of sterling, viz., a due proportion of alloy with copper, or to reduce it to pure fine silver, does not appear. On making the constitution of trial it was considered that though the money did answer numero et ponderis, it might be deficient in value; because mixed with copper or brass, &c., like Lowndes's Essay upon Coin, p. 5.

COMBUSTION, a fire, a burning, denotes the decomposition of certain substances, which are thereby called combustibles; accompanied with heat and light. The process of combustion, the various phenomena it exhibits, its abluminating effects, its infinite uses, and its devastations, have at all times, rendered it the principal object of human attention in all the various branches of life. The whole extent of civil economy, the preparation of food, as well as almost all the articles of necessity and of luxury, most of the arts of more essential use to mankind, such as the manufactures of metals, of guns, of pharmacy, &c., depend almost entirely upon combustion. The inconvenience of the weather, and the dismal darkness of night, are removed by means of combustion. The most active instruments of destruction depend upon combustion. The grandest scenes of wonder, admiration, and terror, like the confutation of towns, and the eruptions of volcanoes, are those in which combustion is the sole actor.

Whilst the wants and the economy of the multitude, have at all times called forth their industry in devising easy methods of lighting and warming their apartments, of cooking their victuals, &c., the calm contemplations of philosophers have endeavored to investigate the cause or causes, the commencement, the progress, the various intensity, and the products of combustion. It is natural to suppose that their first ideas must have been extremely fanciful and incoherent; since the present theory, which rests upon the foundation of innumerable experiments and strict reasoning, is vastly different from any fort of hypotheses, which even the wisest philosopher would have been led to form, without the light of those experiments.

The first plausible theory of combustion was formed by Stahl, an eminent chemist. The striking difference between bodies combustible and incombustible is, between bodies that are, and those that are not susceptible of combustion; induced him to suppospe that the combustibles were endowed with a peculiar principal of inflammability, which the incombustibles had not, and to this suppossession he gave the name of phlogiston. According to this supposition, when combustibles were heated to a certain degree, they began to part with this phlogiston, and continued to burn as long as they had phlogiston to lose; after which, they remained in a state of incombustibility; hence, in the former state, those bodies were said to be phlogisticated, and in the latter they were said to be dephlogisticated. With certain bodies the combustion was attended with a separation of other components, so that afterwards they could not be brought back to their former state by the mere addition of phlogiston; but with other bodies, as for instance, with the metals, the processes of dephlogistication and phlogistication might be repeated without end. Thus, a piece of zinc in the metallic state was fopposed to be loaded with phlogiston, therefore, when exposed to a sufficient degree of heat, it would burn, viz., it would part with its phlogiston, and would thereby be reduced into the state.
flame of a calx, distillate of phlogiston, and of the metallic appearance; but by placing this calx in contact with bodies which contained abundance of phlogiston, in a proper situation, the calx would thereby be enabled to recover its phlogiston, and with it its metallic state and combustibility. It might then be burnt again, and so forth. This phlogistic theory was no sooner made known, than it was eagerly adopted by philosophers and chemists; so that for a long period it remained the most prevailing theory of combustion. But though the theory was universally adopted, the existence of the principle upon which it was founded could not be proved. There was no exhibiting the phlogiston by itself; and it was merely a supposition that a body acquired or lost its inflammability, according as it was combined with, or deprived of, its phlogiston. A supposition, which, on a closer examination of facts, was found inadequate to the explanation of the concomitant phenomena. For instance, when a piece of zinc (and such was also the cafe with other combustibles as far as they might be subjected to experiments) of a determinate weight, was burnt and reduced to a calx, the weight of the calx was found to exceed the original weight of the zinc. It was, therefore, evident that it had acquired something ponderable, and this was utterly repugnant to the phlogistic theory, for by the loss of phlogiston it ought rather to have lost part of its original weight. In answer to this, a strange idea was suggested, namely, that the phlogiston was a principle of lightness; so that bodies became lighter by the addition of phlogiston and vice versa. But this supposition, so singular and so repugnant to the general laws of gravitation, was soon abandoned by philosophers when a variety of decisive experiments, the concurrence of recent discoveries in other branches of phlogistry, and a fresh mode of reasoning, introduced a new theory of combustion, which is both supported by accurate experiments, and sufficient to account for the phenomena. One of the principal labours in the experimental investigation, and the full establishment of this new and rational theory, was the unfruitful Lavoisier, to whose genius, and to whose persevering industry, the scientific world must ever think itself indebted.

In order to render this theory more easily understood by the reader, we shall prefix the following experiment. Take a glass vessel of a cylindrical shape, having a flappable lid, of excluding the entrance or exit of any air, and at the outside of this vessel be graduated, so as to divide its capacity into pretty small portions. Put into this vessel, full of common air, a piece of dry phosphorus of a determinate weight; close the vessel tight, and heat gradually that part of it in which the piece of phosphorus stands, by means of the flame of a candle. As soon as the phosphorus has been heated to a certain degree, it takes fire of itself, burning with a flame and thick white smoke; but it soon ceases to burn. Suffer the vessel to cool, and the smoke will fall in the form of flakes, if the vessel and the air contained in it were quite dry, otherwise these flakes will settle in the moisture. If, in this experiment, the vessel be weighed before and after the combustion, it will be found precisely of the same weight. When the vessel is cooled to the actual temperature of the atmosphere, plunge the aperture of it under water, and in that situation remove the fl MSS. You will find that the water rises in it, which shows that a portion of the air has been destroyed or absorbed; in short, it has disappeared. By measuring the height of the water risen within the vessel, which is indicated by the graduation on the outside of it; in general, it will be found that about one quarter of the original quantity of air has disappeared; and the remaining air will be found unfit for the combustion of phosphorus or of any other combustible; and likewise unfit for the respiration of animals, so that if a bird, a mouse, or any other animal be confined in it, death will soon ensue. If the water which has rushed into the vessel be examined, it will be found to have contained a four volume indicating that an acid has been generated. If the vessel, instead of being opened in water be inverted and opened in quick-firer, then the flakes which in the preceding experiment were dissolved by the water, will now remain on the surface of the quick-firer. This is the acid of phosphorus, and if it be carefully gathered and weighed, it will be found together with the remaining phosphorus (if part of it remains unburnt), equal to the weight of the original quantity of phosphorus together with the weight of the air that has disappeared. Therefore it is evident that the whole proceeds of combustion consists in a decomposition of the purest part of respirable or atmospheric air; the pure part of it, which is about a quarter of the whole, is decomposed, its base is absorbed by the combustible, and generally communicates to its acid properties, in consequence of which that portion of the atmospheric fluid has been called oxygen gas, from the Greek; meaning the acidifying principle. Therefore, in combustion, the decomposition of the oxygen gas is effected by the burning body, when this body has been heated to a certain degree, which degree varies with the nature of the body. The base of the oxygen gas is able both and fixed by the burning body, which has thereby its weight increased, and its water charged; whilst the calour being disengaged, puffs oil in the state of sulphuric heat, and sometimes with such a portion of sight as gives the appearance of red or white heat. Acids in general are not formed from the absorption of oxygen during combustion. See Oxygen Gas.

When the combustion is accompanied with red heat, but not with flame, it is called ignitition. But ignition may also be applied to incognizable substances, for these may be rendered red or white hot, without suffering any decomposition. When a vapour arising from the heated body burns over it, it is then called inflammation; and when the inflammation is rapid and attended with noise, it is called detonation. Having now comprehensively stated the new theory of combustion, it is now easy to add several necessary remarks respecting every part of it, which could not be intermixed with the theory without rendering it confused and less intelligible.

In the next place, since the process of combustion consists in a decomposition of oxygen gas, the universal spirit of modern phlogistry includes every process, in which oxygen gas is decomposed, under the general name of combustion; thus, animal respiration, in which this gas is decomposed, its base absorbed, and heat evolved; may be reckoned amongst the processes of low combustion. See Respiration. The gradual absorption of oxygen by metallic bodies may also be reckoned amongst these processes.

Since combustion consists in a decomposition of oxygen gas, it naturally follows that without oxygen no combustion can take place. The oxygen, however, may be contained in other substances, in consequence of which those substances become capable of supplying combustion. Now there are seven of their substances, which, from their containing oxygen, are called combustibles; and these are oxygen gas, atmospheric air, nitrous oxys, nitric oxyd, which is prepared by digesting copper and mercury in diluted nitrous acid, and collecting the gas which is extracted, nitric acid, oxygenized me
riatic acid, and hyperoxygenezed mariatic acid. See the
nature of those substances under the article Gas. It also
follows that with a given combustible, the quickness of the
decomposition is proportionate to the supply of oxygen,
which flows the reason why a fire is increased by blowing
common air, and much more by blowing oxygen gas upon
it. But consider paniers with different combustibles, the
fire is strongest when the combustible has the stronger
traction for oxygen. The flame of hydrogen gas agired by
oxygen gas is reckoned to produce the most intense heat.

A combustible body, though exposed to oxygen, generally
requires to be heated to a certain degree before the combustion
commences. That degree varies with the nature of the body,
and the purity of the oxygen; so much so that some of
them, though not many, take fire immediately on being
exposed to some of the above-mentioned supporters of com-
bustion in the common temperature of the atmosphere,
whilst others must be heated to a red and even to a white
heat, before the combustion takes place.

When the combustion has once commenced, the heat or
calorie, in the form of sensible heat, which is extricated
from the oxygen gas, raises the temperature of the adjacent
parts of the combustible to that degree which is necessary
for its combustion, and the heat evolved by the burning of this
part heats the next and so on. But this is not the case
with all sorts of combustibles; for some there are which
must be kept up at a given high temperature in order to
effet their combustion, and a diamond is of this sort.

However the nature of combustibles in this respect varies
according to the purity and quantity of oxygen. For instance, if
a slender piece of wire be exposed to the flame of a candle in common
air, that part of it only will burn, which is acted upon immedi-
ately by the flame: but if the flame be lighted by means of a bit of tinder, and then be plunged in a vessel
full of oxygen gas, it will burn successively to the very end,
lke a-hip of paper; exhibiting a remarkable bright light,
and very considerable heat.

Of the simple bodies of nature, the chemists reckon
three combustible ones, and two that are incombustible.
The former are sulphur, phosphorus, and hydrogen; and the
latter are azote and mariatic acid; but amongst the
compound bodies, the combustibles are much more numerous.
Such are oils, acids, and a va-It variety of others which being
of a fluctuating nature need not be particularly specified.

A variety of experiments, which may be found under the article Gas, prove that gasses owe their clastic nature to a
certain quantity of caloric, in which must necessarily combine
with their bafe, in order to assume the aerial form. Therefore,
when, in consequence of the superior affinity of the
combustible for oxygen, the oxygen gas is decomposed,
and its bafe condensed, the caloric, which was necessary to
its aerial form, being set at liberty, appears in the form of
sensible heat; hence the heat which accompanies combustion
is naturally supposed to proceed from the oxygen gas
and the quantity of it varies according to the rapidity of the
processes, so much so that in certain processes like the decom-
position of oxygen effected by metallic substan-
ces in common air, it is not attended with any sensible degree of
heat; for the heat evolved, being very light, is instantly dis-
fipated among the surrounding bodies.

With certain combustible bodies a peculiar process takes
place. It is a remarkable slow process of spontaneous
combustion. The body, by attracting oxygen from the
atmosphere, becomes thereby gently heated; in consequence
of which its affinity to oxygen is increased, a greater de-
composition of the latter takes place, more heat is evolved,
and thus the process is gradually accelerated until flame and
visible combustion take place. Such is sometimes the case
with hay, the sawdust of certain woods, and various other
substances. The well known mixture of iron filings and
fulphur moistened with a little water, is an instance of this
sort; for if this mixture be buried a little below the surface
of the ground, it will of itself, after the lapse of several
hours, burst forth in a late of ignition. This experiment
has been generally called the artificial volume.

Though heat in combustion is derived from the oxygen
gas, the derivation of light is not so evident. It has
been for a long time supposed that this element also
was one of the components of oxygen gas; but the
observations made respecting the light yielded by se-
veral bodies when they are lightly heated, or even spontaneous,
and that some of them yield much more light than others, seem to prove, that light forms a compo-
nent principle of most bodies, and that it is evolved from
the combustible. It is likely, however, that part of it may
be derived from the oxygen also.

The following list of bodies subject to spontaneous in-
flammation is given by professor Barthold: meaning the in-
flammation occasioned by different bodies acting upon each
other, without the aid of another body previously in a state
of combustion.

1. Friction. Thus pieces of wood rubbed against each
other are thereby inflamed. The bell for this purpose are
box-wood rubbed against mulberry, or Laurel against poplar,
or against ivy, &c. It is in consequence of friction that the
wheels and axletrees of carriages sometimes take fire, when
they are not sufficiently greased. In burning also, pieces of
wood sometimes take fire.

2. The action of the sun's rays concentrated by len-
ses, or concave reflectors, or even by plane reflectors, provided
their reflections be thrown upon the same spot. See Burn-
ing Glasses, and Reflectors.

3. The sudden flashing of quicktime has sometimes
been known to produce the combustion of adjacent bodies.

4. The fermentation of animal and vegetable sub-
stances. Thus great accumulations of hay, turf, or flax, and hemp,
heaps of linen rags in paper mills, &c. take fire, provided
they are not quite dry; for without moisture, fermenta-
tion and the consequent evolution of heat cannot take
place.

5. The accumulation of animal and vegetable sub-
stances covered with an oil, especially when the oil is of a drying
quality. Thus lamp-black mixed with linseed oil is apt to
take fire, and an earth of a brown colour, called the block
of Dunsford, sprinkled over with a little linseed oil,
takes fire and appears red-hot like burning small coal, in
about an hour's time.

6. There are several substances, which have the property
of inflaming spontaneously, increased by torrefaction.
Coffee, French beans, lentils, &c. are of this nature.

7. Sulphurated and sulphated hydrogen gas. The
causes of subterraneous fires and volcanoes in general, is attri-
buted to the decomposition of pyrites, or metallic sulphur-
cets, buried in the interior of the earth. These pyritic
masses are decomposed by the contact and concurrence of
water and air, and the decomposition is always accompanied
with a great extraction of caloric, and a disengagement of a
very inflammable gas, called sulphurated hydrogen gas.
This gas 1-flames at an elevated temperature, and com-
municates the inflamation to the sulphur of the pyrites, to
the coal and other bituminous matters, which generally ac-
company it.

8. Sulphur and phosphorus of lime and of potash,
formed in the combustion of several vegetables.

The last particulars which we need take notice of, concerning the theory of combustion, are its products. But there must not be mistaken for those bodies which existed in certain combustibles, and have been left by them, as when the other components of the combustible have been separated, such as everly particles, &c. The real products of combustion are those which did not exist before, and these upon a first examination, will be found to be either water, or an oxide, or an acid. Water consists of oxygen and hydrogen. See Water. An oxide is a compound of the combustible with oxygen, but not such as to possess dashed acid properties, (and this oxide is called oxidation); or an acid, which consists of the acidifiable part of the combustible, combined with oxygen. Closely to give it decided acid properties. Thus, the combination of carbon and oxygen forms the carbonic acid gas, and this is produced in almost every combustion, also in respiration, &c.

COMCHE, in Geography, a town of Persia, where the caravans rest in their way from Ithyra to Ormus.

COME, in Biography. See Caesar.

COME. The tail of or tails of mat, upon its first flessing forth, is thus called.

COME IN. Soldiers are said to come in as recruits, volunteers, &c. when they come to join any particular corps or battalion.

COME-OVER. When men differ from one army and join another opposed to it, they are said to come over to the one, which they join or go over to.

To come in to, to join, to bring aid or assistance.

To come up with, to overtake.

COME FRAPE, in the Iliad, has, literally signifies as above, and is used when any foregoing part is to be repeated.

COME IN, in Ancient Geography, a place of European Metropolis, which was an episcopal see, called by the council of Nice, Conceriz.

COMEDAE, a people of Scythia, confpired by Tis.cky, under the general name of Saec.

COMEDONES, a name given to a species of worm, with which the children of Minna, and some other countries, are terrably afflicted; and of which Hoffman, in his "Treatise of Endemic Diseases," gives this account; children in the country are frequently fized with a fort of tabs, which so destroys their flesh, that they appear merely like skeletons. The common people generally suppost these children to be under the influence of witches, but such as have inquired more narrowly into the subject, have found that it is owing to certain worms, resembling black hairs or cords, lodged under the skin. When the skin is rubbed with honey, in a bath, or any warm place, they will appear and come out; but when it is contractcd by cold, they keep concealed within. See Affection Ecima, and Dracunculi.

COMEDY, in its proper sense, signifies an allegorical representation of some characteristic passions in private life. The drama, under its various forms, has in all ages and countries been cultivated, not only as a rational and polite amusement, but as a serious art, affecting the moral conduct of men, and influencing the education of society. According to the field it occupies, whether the lighter traits of incidental character, or the important events of life, it assumes the form of tragedy or comedy. The first commands awe; the last excites more pleasureable and exhilarating sensations. The first exhibits the fall of a hero; the last conducts the fortunes of lovers to the goal of marriage, and sets down the eccentricities of every character it meets with on the way. If therefore tragedy is more exalted, comedy comes closer to the heart, and appeals more powerfully to the experience of man. The stronger passions, the virtues, the crimes, the sufferings of mankind are the theme of the one; our humours, our follies, the effervescence of youth, or the severity of years the topics of the other. Terror and pity are the instruments of pleasure in the first, but ridicule in the last.

It is therefore very easy to discriminate the general spirit and strain of comedy from that of tragedy. Neither is it more moral or less so than tragedy considered as a faithful exhibition of human life, with all its improprieties and absurdities. There is nothing in the nature of these compositions, in either kind, which militates against good morals; though a French author endeavoured to fix the imitation of a preface and antichristian spirit on the great Corneille. The improvement of manners, the regulation of fould int rueure, the subjection of vicious conceptions to the laws of religion, are among the benefits resulting from this species of poetry. R. dice often succeeds where argument fails. Yet it is a dangerous weapon, when unskillfully wielded. For it is by no means the test of truth. It may be applied to muld ad and deceiving, instead of reforming; and the blended colours of ideology are sometimes more difficult to detect, than the lurid lights and shades of truth and error. Cicero quotes some lines of a comedy, where love is represented as the greatest of the deities. Of the strength of this sentiment, he exclaims loudly against all comic poetry as a corrector of morals; contending at the same time, that the art could not exist, if it had not vanity or ridicule to feed upon. Besides this, it happens too frequently, that the ridicule aims where it is least deserved. This, however, is the fault of the writer, and not to be imputed to the nature of the subject. It depends on the conduct, whether the comic shall be drawn in a good cause, or is a bad one. The success of stage representations gave rise to the ancient comedy at Athens. In the latter, as well as in the former, t' unity of action and subject is absolutely requisite, and these of time and place should be as nearly as possible preserved. By this is meant, that the time of action should be reduced to moderate limits, and the pace never changed but with the termination of the act. The scenes of conversation must be united in a natural succession, and the stage should be perpetually occupied during the continuance of the act. The audience should likewise be made to perceive the necessity of the various personages appearing and disappearing just as they do. By these means, the imitation is allied to probability, and the places in proportion. Probability is indeed more indispensably necessary in comedy, which depends on ordinary life, than in tragedy. Nature, whether in the management of the incidents, or the delineation of character and sentiments, is in the only solid foundation for the art of writing. The scene and subject of comedy should be laid in the country and time, where and when it is to be represented. The little proprieties or idiosyncrasies of character and behaviour vary with the moment, and become unintelligible or non-existent, except where they are seen and known in real life.

The various personages in a well managed comedy ought to be distinctly marked, without the stiff station of controlling them by pairs. Ordinary writers may seem to require a strong light and shadow by quaint artifices like those; but a matter looks no better than real life, and represents it as it is. The action should be easy, natural, and polished, on a level with the conversation of gentlemen in the higher walks, but above the profanities of the vulgar in the lower. Perhaps there is nothing in the art so difficult, as to support a spirit and happy dialogue. The parade of misplaced wit has spoofed almost as many comedies as actual delusion.
COMEDY.

The feast of Bacchus, Safforion on his flag, and Theopis in his cart, are the humble origin usually ascribed to the drama. Safforion represented his first piece toward the year 550 B. C. Theopis made his first attempts tragically, and added his Aeschylis in 550 B. C. The former attacked the vices and absurdities of his time; and the latter treated more noble subjects, which he took from history. Sixty

Drama and Theatre. Comedy had three flags among the Greeks. The ancients indulged in the licence, not only of dramatizing actual and well-known occurrences, but of identifying them with living persons. The name even of Socrates was not withheld from theatrical ridicule; and, the philosopher was among the number of the audience. This licence in process of time was intruded by the authority of the magistrates. The players no longer sought liberty to sport with real names, contrived masks to resemble the features of those whom they meant to attack: this was the middle comedy. This latter abuse was severely felt by the former; and was at length prohibited. Depredation of names as well as of names, the new comedy confined itself within those modest and moral bounds, which Menander set to its irregularities in the time of Alexander the Great. On this mode, Plautus and Terence formed their style, without taking the trouble of tracing even the scene to their own country. Their pieces of entertainment were then fearfully naturalized among the Romans; and their performances were rather translations than original works. In the course of time, Rome distinguished its comedy, founded on native manners, by the name of Comedia Togata, and that which was borrowed from the Greeks, was distinguished as the Comedia Palliana.

Before the introduction of modern comedy, a species of dramatic representation was in vogue, taken from the stories in the Old and New Testament, the Martyrology of the Saints, and other religious subjects. They were called mysteries: as the mystery or the Play of the Passion, the mystery of the Acts of the Apostles, the mystery of the Apocalypse, &c. These entertainments were at first given in the churches, and made a part of the ecclesiastical ceremonies. Afterwards the mysteries were played on a public stage. On the entrance of Charles VII. into Paris in the year 1437, scaffolds were erected all along the great street, St. Denys's, on which were acted, with splendid and appropriate decorations, the Annunciation of the Blessed Virgin, the Nativity, our Lord's Passion, his Resurrection, the day of Pentecost, and the last Judgment. In the year 1487, the chapter of the cathedral at Lyons voted sixty livres to the performers in the mystery of Jesus Christ's passion. About 1542, the same city exhibited on Sundays and holidays, for the space of three or four years, the greater part of the historical facts in the Old and New Testament, succeeded by a farce, in the same manner as in our theatres. The popular name of the play-honour was Paradise. These farced comedies were much in fashion in France under Francis I. who patronized them, and attended their representation. One of these, which attracted his approbation, was entitled the mystery of the passion of our Lord and Saviour Jesus Christ. It is said in the title-page to have been performed "triumphantly at Angiers," and indeed so it must have been; for there were one hundred and forty-one characters in the dramatis persona. The date of it is 1541. But the abuses to which these religious performances gave rise occasioned at length a very severe law throughout the kingdom, against the exhibition of "Our Lord's Passion," and other similar subjects. Many of these pieces are still extant in print.

One of the first objects in modern comedy, is the Spanish theatre, fertile as it has been in dramatic productions. Lopez de Vega, Gyllius, and Calderon, are the principal comic writers of Spain. The "Don Juan," and the "illicit," are said to have written above a thousand plays. But our surprise at their number is heightened when we become acquainted with the nature of the plays. Neither the marquis, nor any other role of dramatic writing is in any degree observed. One piece often contains the plot of a man, the scene is limited to one quarter of the globe. They are for the most part tragic comedies, taken from Spanish history; where war and heroism are most happily mixed up with ridicule and buffoonery. Allegorical and mystical characters, the Pater and the sacred mystery, contribute their jest to the extravagant and unique performances. Yet they are not without strong traits of genius, and much space and of imagination. The characters are sometimes well drawn, and the situations happy. To this writer, more than any other, are the public indebted for that taste for the surprising, which so strongly pervades the modern dramas. It is plain from his own apologies, that Lopez de Vega complied with the whimsical fancies of his countrymen; and that he had been at liberty to have led the tale of his times, instead of following in, his Hecules would have been more natural, his intrigues more life-like, his entanglements and unravellings, and his characters more constantly preferred.

The French comic theatre is in general an excellent school of manners; correct, chaste, and decent. It may well boast of such writers as Regnard, Dufreyne, Dancourt, and Marivaux; but Moliere is the glory of their stage. No writer in any department rose to a higher reputation in the brilliant age of Louis XIV. It may indeed be questioned, whether any comic writer has ever appeared with so many excellencies and so few defects. Vice and folly are the only objects of his satire. Though his characters are often peculiar to his own country and times, the ridicule is applied so judiciously as to leave his theatre with foreign and with politeness. His merit is not concealed at the expense of good morals. The "Misanthropus," and "Tartuffe," are in verse; they therefore rise into greater dignity, and assume the style of elegant satire. In his profe comedies he is more ludicrous. His excellence consists more in the strength of his characters, than in the conduct of his plots. He is occasionally too farcical in his life, and too severe in his verse. "Tartuffe" in the grave comedy, and his "Avare," in the lighter, are usually considered as his masterpieces.

English comedy abounds more in original characters, than the comedy of any other modern nation. Humour is a leading feature in the character of the people. The freedom of our government and manners afford a wider scope to the comic muse, than she is allowed in the declamatory courts of the continent. This boldness has, however, too often degenerated into a licence almost bordering on the immorality of the ancient Greek comedy. But this error has, however, been corrected in later times, and the stage has conformed to the more decent manners of an age which is rapidly discarding the grossness of vice from public view.

It now only remains to give a character of some of our most eminent comic writers. Shakespeare decidedly takes the lead in each department of the drama; but his excellences are so universally felt and understood that it would be superfluous to enter into a criticism of his productions. Of Jonson it will only be necessary to notice a few leading pieces. "Every Man in his Humour" is a play which places this writer fearlessly lower than..."
than the highest, whether we advert to the variety of its characters or the energy of its composition. It is to the credit of the present tale, that it retained possession of the stage, in defiance of its oblique allusions, and antiquated garb. "Every Man out of his Humour" has much left to recommend it than the preceding comedy, though strongly marked in point of character. It has undergone the usual fate of personal satire, to die with the individuals at whom it glanced.

"Cynthia's Revels" and the "Poetaster" are chiefly to be remembered, as having been acted by the children of queen Elizabeth's chapel; a relic of theatrical entertainment after the mode of its ancient institution, when the sacred mysteries were represented by the choir of the church or monastery.

Volpone is perhaps the best of this author's comedies. The language and character are brought up to the highest finish, and the poet exhibits an originality of plot, conception, and execution, which proves that he could throw aside the trammels of the student, and lay claim to the honours of an unaided thinker, as well as those of a successful imitator. The pictures of Volpone and Mosca are finely imagined, and their circumstances most happily delivered. His "Epigrams," "Repetition," and "Alchemist," the merits of which are universally allowed, though the object of its satire has given place to other errors and other follies, we shall form such a constellation of comic genius, as will outshine all composition but that of his illustrious contemporaries. His later pieces, consisting of his "Bartholomew Fair," "Staple of News," "New Inn," "Magnetical Lady," and "Tale of a Tub," rather detract from his reputation than augment it; and prove, what many other dramatic writers would have done well to consider, that faculties devoted to the entertainment of the public will at length be exhausted, without some sources of replenishment from change of scene or circumstances.

The triumvirate, such as was never equalled, before or since, in the republic of letters, was completed by John Fletcher, whose merits are closely blended with those of his associate Beaumont. His genius rather affinities with Shakespeare than with Jonson, to whom he is confessedly inferior in propriety and precision, while he surpasses him in creative powers and poetical fecundity.

The next writer that obtained a large portion of the public favour and attention was Davenant, whose propensity to poetry is said to have appeared sufficiently early in life to attract the favourable notice of Shakespeare, though the great bard died when this young rhymster was only ten years old. What is commonly considered as Davenant's first play was produced in 1629, though he had attempted dramatic composition two or three years before. It is not worth while to enumerate the order or titles of his plays and masques; which were in general well received, and procured his promotion to the laurel, vacant by the death of Jonson, as a reward for the affability with which he directed the diversions of the court, as long as the troubles of the times permitted it to have any. It was to his address, that the people were indebted for the gradual reformation of the rules, after an interregnum of severity and gloom. At first he prevailed on men of taste and learning to countenance a hasty species of dramatic melange, which was allowed because it was bad, by the ignorant bigots who held the reins of empire, while rational and regular plays were absolutely prohibited. But he imperceptibly enlarged his sphere of composition, and after the restoration obtained the patent of the theatre in Lincoln's Inn Fields. The stage is not perhaps more deeply indebted to any man than to Davenant, for the convenience and utility of its arrangements in the manager's department. Besides many less material improvements, it owes to him the introduction of female performers, and painted scenery; and from his revival of "Macbeth" and the "Tempel," may be dated that devotion to embellishment, which has ever since inundated the English stage, and, in the judgment of severe critics, overwhelmed the sense and discernment of the audience. His irregular entertainments, resorted to in the first instance only as substitutes for better things, may indeed be considered as the root of all that theatrical evil, we so gravely condemn, but at the same time so freely encourage. Yet he had the power of bringing forward to the public eye scenery, women, and Betterton.

Maturin was also among the feeling supports of the English drama; of which he may justly be regarded as one of the fathers. His style was rough, manly, and vigorous; he prefixed upon his subject with a few but masterly hands; his wit was acute, and his serious dialogue, according to its subject, firm and impressive, or natural, easy, and interesting.

Dryden did not commence his career as a writer for the theatre, till the thirty-second year of his age; but from that period he kept possession of it, and produced eight and twenty dramas, not indeed without competition or censure, but with a large share of predominant reputation. His first production was the "Wild Gallant," a comedy, which met with no indifferent a reception, that had Dryden been a man of fortune, the stage had never again been benefited by his assistance. He was associated with Davenant, in the alteration of the "Tempest," but he acknowledges the invention and writing of the new characters chiefly to belong to his colleague. We cannot, however, help contemplating the perfections of Shakespeare with affection, when we find that two such powerful minds could produce little or no addition to the effect.

On the character of his comedies, it will not be difficult to decide. He has, himself, acknowledged his inaptitude to that species of composition; and certainly his plays in general have much less merit than his other writings. Yet, after all, he has established a reputation that will never fade, even in this branch of poetry; and his drama of the "Spanish Friar" may be looked upon as an instance of happy coincidence and real ingenuity, in the combination of serious and rible materials. Indeed the unfitness of his comic performances for modern representation arises more from their extreme licentiousness and immorality than from any defect of power.

The comedies of Otway are deservedly excluded from the reading desk as well as from the stage, on account of their undisguised obscenity.

Congreve, at the age of twenty-one, produced the "Old Bachelor," at the theatre in Drury Lane, to amuse himself in a slow recovery from a fit of fickness. It received some requisite touches from the mature judgment of his friends, and Dryden declared that he had never seen such a fine play. The "Double Dealer," and "Love for Love," succeeded it, at an interval of a year each. Five years afterwards his comedy, called the "Way of the World," closed his dramatic labours at a time of life, when writers in general are but beginning their career. The indifferent successes of his masterpiece excited his disgust at the caprices of the public. He never resumed his pen in the service of the theatre, except to write a masque, called the "Judgment of Paris," and
and an opera, called "Semee," which was never repre-
rented; but as his fame rests on his five regular pieces, we
may consider him as loft to the stage, after the unkind re-
ception of a play, which hassince vindicated its station
among the most brilliant ornaments of the drama.

It is on his comedies principally, that Congreve's
reputation subsists. Here, all is luminous, all genuine,
pointed, and original. His men of fashion are gentlemen, 
and even his tops are wits. Congreve is considered as having left
humour and lefts of real life, than his illustrious rivals of the
fock. But, surely "Firefights" abounds with the richest
humour, and that of a description, which, though now anti-
quated, was living and current at the time. Indeed it is an un-
doubted testimony to the happy drawing of this character,
that though it is only recognized by the modern spectator
as a picture of the days that are gone by, it never fails to
excite riviency on the stage in a very powerful degree.
The leading feature of Congreve's genius is wit. Dr.
Johnson says, that he formed a peculiar idea of comic ex-
cellence, which he supposed to consist in gay remarks and
unexpected answers. Now, certainly, in adopting such
a theory of composition, he too much narrowed his own
sphere. Still, however, no more is to be required of a
writer, than what he himself undertakes; and Congreve
performed what he undertook with a brilliancy of succees,
which, with the exception of Mr. Sheridan, has neither been
rivalled nor approached in the revolution of the century that
has elapsed. It has been objected, that "his personages
are a kind of intellectual gladiators; every sentence is to
ward or bite; the contest of smarthen is never inter-
mittent." This remark is undoubtedly true; yet, when we
find Congreve thus formidably enfored for the exuberance
of his wit, it is impossible not to feel as the king of Prussia
did, when he wihibited a certain mad commander to bite some
of his generals.

Could the licentiatunue of Congreve's topics be as easily
justified as the overflows of his gaiety, his fame would
continue to blaze without danger of eclipse. But in truth,
the offence his mule occasions to the purer ears of a more
moral age, has an unhappy tendency to shorten his theatri-
ical existence. The observation applies equally, if not in a
greater degree, to all his witty, but graceless contemporaries;
and it may be remarked on such freedoms in general, that
they create disgust and alienation, at least in some minds,
in a place and on an occasion, where it should be as much
an author's study never to offend any, as occasionally to
please all; consequently though they may increase the num-
ber of temporary plaudits, they infect the vitals of a reputa-
tion, that otherwise might have been immortal, with a
principle of early decay.

To particularize the merits either of Congreve's rivals,
Wycherly, Farquhar, Vanburgh, &c. or the numerous
clain of writers in the succeeding ages, who have culti-
vated the comedie larmoyante, would exceed the limits of this
article. The latter is indeed almost as obsolete as the coarse
but flaring wit of king Charles's days. It has given place to
the diversified portraits and philosophy-run mad of the
German school; a taste from which it is most devoutly to
be wished that the drama may be speedily rescued.

COMENII, in Ancient Geography, a people of Illyria,
according to Ptolemy, adjoining to the Daurntian and Var-
dzani.

COMENITZA, in Geography, a town of European
Turkey, in the province of Epire, 52 miles S.W. of Delfino.

COMENIUS, JOHN ASOS, in Biography, a celebrated
grammarian and divine, was born in the year 1522, in Mo-
navia. He studied at Heborn, and returned to his own
country in 1614, and was appointed rector of a college
there. In 1618 he became pastor of the church at Fulnic,
and was appointed master of the school which had been
lately erected. Here he conceived the idea of an improved
method of teaching the languages, but his writings on this
subject were destroyed in 1621, when the town was taken
and plundered by the Spaniards. In 1624 he retired from
the persecutions inflicted upon the Protestants in Germany,
and to Lefa, a city of Poland, where he devoted himself to the
instruction of young persons in the Latin language; here he
published in 1631 his "Jania Linguarum referata," a work
which obtained for him great reputation, and which was
speedily translated into 12 European languages, and also
into the Arabic, Persian and Mogul languages. He was now
invited into Sweden to take the charge of the public schools in that kingdom, which he declined; and
having published the "Panophilus Prodomus," or "Fore-
runner of Universal Science," he was solicited by the parlia-
ment of England to undertake the reformation of the schools
there. He arrived in London Sept. 1641, but owing to the
civil wars his proposals were neglected, and he went to Swe-
den, and from thence to Elbing in Prussia, where he em-
ployed six years in perfecting his new method of instruc-
tion, but did not meet with sufficient encouragement to induce
him to publish his thoughts on the subject. In 1648 Co-
menius was invited to the court of Sigismund Ragotiski,
prince of Transylvania, where he lived four years, and pro-
posed regulations for the college of Patak, upon the plan of his
Panophobia, from whence he returned to Lefa, and con-
tinued there till 1656, when the town was burnt in the war
between the Swedes and the Poles. On this occasion he lost
all his manuscripts excepting what he had composed on his
Panophobia, and the Apocalypse. He fled into Silesia,
thence to Brandenburg, afterwards to Hamburgh, and
lately to Amsterdam, where he continued till his death, which
happened in 1671. At Amsterdam he published his "New
Method of Teaching," which added nothing to his reputa-
tion, and which the learned Bayle has declared of no worth
whatever in the art of instruction. In this opinion he is
sanctioned by the concurrent voice of the learned in every
succeeding age to the present time.

Comenius was not only intent upon the reformation of
scholastic learning, but he embraced the notions of a speedily
approaching millennium, and pointed out as characters who
were to be eminently distinguished in fulfilling the prophe-
cies, Guiliamus Adolphus, Cromwell, and others, who had
little claim to the honours of a divine mission. Succeeding
events contributed to dissipate, in some measure, the enthu-
siastic notions which he had embraced and cherished. By
some of his contemporaries he was charged with having
possessed more knavery than credibility, but of this there
seems to be no satisfactory evidence. He published "Com-
mentaries on the Apocalypsc," some treatises on the Soci-
nian controversy, and "Historia Fratum Bohemorum," in

COMENOLITARI, in Geography, a country of mo-
dern Greece, which comprises the ancient kingdom of Ma-
cedonia and Thessalia.

COMENSES, in Ancient Geography, a people of Aia
Minor, towards Galatia, according to Pliny. Hardouin
calls them Chomenes, deriving their name from Choma, a
town situated in the interior of Lyca.

COMERCHIN, in Geography, a town of European
Turkey, in the province of Romania; 62 miles E. of Em-
boli.

COMES Nervi Phrenici, in Anatomy, is a small branch
of the internal mammary artery. See Arteries.

COMES,
This opinion, therefore, Aristotle easily overturned; substituting another in its stead. According to Aristotle, comets were only a kind of transient fires or meteors, consisting of exhalations rising to the upper region of the air, and there set on fire; far below the moon's course. But rather is this hypothesis more just than the other: for on this principle, the light of the comet, being independent of the sun, would be suffered every which way, without any appearance of a train; or tail, which is contrary to the phenomena. Moreover, they are observed at the same time in places on the earth very remote from each other. Both the modern astronomers who have measured the distance between the comets and the earth, find that the comets have no sensible diurnal parallax; which could not be, were they not much more remote than the moon, whose parallax is visible; and yet as they have a sensible annual parallax, they are not so remote as the fixed stars. Indeed, there were some, Ptolemy tells us, among the ancients, who, "had juster notions; who took these stars to be perpetual, and believed they moved in their proper orbits; but were never seen, unless when left by the sun." Aristophanes, in his first book of Meteors, mentions this doctrine of the ancient philosophers; and observes, that some of the Indians, called Hyperboreans, said, that a comet is one of the planets, but that they do not appear unless after a long time, and are seen but for a short time, which happens also to Mercury. Aquinas Myndius declared, that he took comets for regular stars; affirming also, that the comets were reckoned by the Chaldeans among the planets, and to have their periods like them. He also ventured to assert, that one day the periods and laws of their motion would be discovered. And more fully Seneque, Quod. Nat. lib. vi. He hid himself, feen at last two comets, one in the reign of Claudius, the other in that of Nero; and that which he saw in his youth, a little before the death of Augustus, which in one place he calls a comet, and in another a prodigy. He intimates that he thought them above the moon, and argues strongly against those who imagined that they were meteors elevated into the air by winds, or who held some other absurd opinions concerning them. "I am not of the common opinion," says he, "nor do I take a comet to be a sudden fire, but esteem it among the eternal works of nature." Quid autem miracum cometas, tam rarum mundi spectaculum, nonum tamur legibus certis, ne initia illorum hanc obsevisisse, quorum ex ingentibus us intervallum recurritur eff? Veniti tempus quo sita quae nunc latint; in lucem dies erubuit, & longiora evit diligentia. Veniet tempus quo posibi nifi veliam tam opera nusse sove mieruntur. Lati qui demofreti, si quando, in quaibus comites paribus erunt; cur tam defeunt calvis erunt. quanti quaevis fact.

This prediction we have so admirably accomplished in our days by the great sir Isaac Newton; whole doctrine concerning them will appear in the sequel of this article. Saccre recommended it to astronomers to keep a catalogue of the comets, in order to be able to determine whether they returned at certain periods. The authority of Aristotle, however, long prevailed; and comets were generally considered as meteors, existing in our atmosphere, till the time of Tycho Brahe. This excellent astronomer was the first among the moderns, who, after diligently observing the comet of 1577, and finding that it had no sensible diurnal parallax, ascribed to its true place in the planetary regions. (See his book De Cometa, anno 1577.)

Although few comets have approached to near the earth as to have a diurnal parallax, they afford sufficient indications of an annual parallax; that is, the revolution of the earth in her orbit causes their apparent motion to be very different from
from what it would be, if they were viewed from the sun, or any fixed place. See the first of the phenomena recited in the figure. This shows that they are not to distant as the fixed stars, which have no annual parallax; and, as Huygens observes, affords a proof of the earth's revolution round the sun; for, without supposing that, these motions of comets are inexplicable. Tychos was preceded by Kepler, who, in his book "De Cometis," concluded from observations of the comets which appeared in 1607 and 1618, that comets move freely through the plane of the equator, and that the most remote of such different comets were to be revolved in nearly an elliptical orbit; but of what kind he could not precisely determine. He was followed by Huygens, an accurate observer of the heavenly bodies, who, found, by his own observations of two comets that appeared in his time, that they were not subject to diurnal parallax; that calculations of their places, made upon a supposition that they moved in straight lines, did not agree with their true places; but that their orbits were concave towards the sun; and concluded, that they moved in parabolic trajectories.

Hevelius, from a great number of observations, proves it as his opinion, that the comets, like the solar prominences or spurs, are formed and condensed out of the greater exhalations of his body; or that they are generally in the atmosphere of a planet, and discharged from it, partly by the rotation of the planet, and then revolved about the sun in a parabola by the force of projection and its tendency towards the sun, in the same manner as a projectile upon the earth's surface describes a parabola. In which notion he agrees nearly with Kepler, who maintains, that comets are generated in the mother in vast numbers, like flocks in the ocean; though they do not all become visible; either because of their smallness, or because they lie a long time under the horizon.

But Sir Isaac Newton has shown the fallacy of this hypothesis, by proving that the comet of 1680, in its passage through the neighbourhood of the sun, would have been dissipated, had it consisted of exhalations of the sun and planets; for the heat of the sun, it is allowed, is as the density of his rays, i.e. reciprocally as the squares of the distances of places from the sun. Wherefore, since the distance of that comet in its perihelion, December the 5th, was observed to be to the distance of the earth from the sun, nearly as 6 to 1000; the sun's heat in the comet at that time, was to his heat with us at midsummer, as 10000:36, or 28000 to 1.

And again, finding by experiment, that the heat of boiling water is little more than three times the heat of one dry earth, when exposed to the midsummer's sun; and assuming the heat of red hot iron to be about three or four times as great as that of boiling water, he thence concludes, that the heat of the dried earth, or body of the comet in its perihelion, must be near 2000 times as great as that of red hot iron.

Such an immense heat once acquired in its perihelion, the comet must be a long time in cooling again. The same author computes, that a globe of red hot iron, of the dimensions of our earth, would scarce be cool in 50000 years. It then the comet be supposed to cool 100 times as fast as red hot iron; yet since its heat was 2000 times greater, supposing it of the bigness of the earth, it would not be cool in a million of years.

James Bernoulli, in his "Systema Cometarum," supposes some primary planet revolving round the sun in the space of four years and one hundred and fifty-seven days; and at the distance, from his body, of 258; semidiameters of the magnus orbis; this planet he concludes, either from its vast distance, or smallness, to be invisible to us: but, however, to have, at various distances from him, several satellites moving round him, and sometimes descending as low as the orbit of Saturn; and that these becoming visible to us, when in their perigee, are what we call comets.

Descartes advances another opinion: he conjectures that comets are only stars, formerly fixed like the rest, in the heavens; but which becoming by degrees covered with maculae, or spots, and at length wholly robbed of their light, cannot keep their place, but are carried off by the vortices of the circum-solar storms; and, in proportion to their magnitude and solidity, moved in such manner as to be brought nearer the orb of Saturn; and thus coming within reach of the sun's light, rendered visible.

But the vanity of all these hypotheses abundantly appears from the phenomena of comets; the chief of which we shall enumerate; as being the tell by which all theories are to be tried.

First, then, those comets which move according to the order of the signs, do all, a little before they disappear, either advance slower than usual, or else go retrograde, if the earth be between them and the sun; and more swiftly, if the earth be situated in a contrary part. On the other hand, those which proceed contrary to the order of the signs, proceed more swiftly than usual, if the earth be between them and the sun; and more slowly, or go retrograde, when the earth is in a contrary part.

2. So long as their velocity is increased, they move, nearly in great circles; but towards the end of their course, they deviate from these circles; and as often as the earth proceeds one way, they go the contrary way.

3. They move in ellipses, having one of their foci in the centre of the sun; and by radii drawn to the sun, describe areas proportional to the times.

4. The light of their bodies, or nuclei, increases in their receds from the earth towards the sun; and on the contrary, decreases in their receds from the sun.

5. Their tails appear the largest and brightest, immediately after their transit through the region of the sun, or after their perihelion.

6. The tails always decline from a full opposition to the sun towards those parts which the bodies, or nuclei, pass over, in their progress through their orbits.

7. This declination, ceteris paribus, is the smallest, when the heads, or nuclei, approach nearest the sun: and is least, if the nucleus of the comet, is towards the extremity of the tail.

8. The tails are somewhat brighter, and more distinctly defined in their course than in their recede part.

9. The tails always appear broader at their upper extreme than near the centre of the comet.

10. The tails are always transparent, and the smallest flares appear through them.

These are the chief phenomena of comets; which it is evident, cannot safely be reconciled with the wild notions of the ancients, and the weak conjectures of many of the moderns.

"The comets," says Sir Isaac Newton, "are composed, solid, fixed, and durable bodies: in one word, a kind of planets; which move in very oblique orbits, every way with the greatest freedom; perpetuating in their motions, even against the course and direction of the planets; and their tail is a very thin slender vapour, emitted by the head or nucleus of the comet, ignited or heated by the sun."
This at once solves all the foregoing phenomena: for, 1. It is evident, that those which proceed according to the order of the Signs, a little before they disappear, must move more slowly, or appear retrograde, if the earth be betwixt them and the sun; and swifter if the earth be in a contrary part. On the contrary, those proceeding against the order of the Signs, &c. For since this course is not among the fixed stars, but among the planets; as the motion of the earth either conspires with them, or goes against them; their appearance, with regard to the earth, must be changed; and, like the planets, they must sometimes appear swifter, sometimes slower, and sometimes retrograde.

2. "When the comets move the swiftest, they must proceed in straight lines; but in the end of their course, decline," &c. Because, in the end of their course, when they recede almost directly from the sun, that part of the apparent motion which arises from the parallax, must bear a greater proportion to the whole apparent motion.

3. "The comets must move in ellipses, having one of their foci in the centre of the sun." For otherwise they would not wander precariously from one fictitious vortex to another; but, making a part of a polar systeim, return perpetually, and run a constant round.

Hence, their elliptic orbits being very long and eccentric, they become invisible, when in that part most remote from the sun.

From considering the curvity of the paths of comets, Sir Isaac concludes, that when they disappear, they are much beyond the orb of Jupiter; and that in their perihelion they frequently descend below the orbit of Mars, and the inferior planets.

4. "The light of their nuclei must increase in their recedes from the sun, and vice ver.§." Because as they are in the regions of the planets, their accretes toward the sun bears a considerable proportion to their whole distance.

From observations of the comet of 1680, Sir Isaac Newton found, that the vapour in the extremity of the tail. January 23d, began to ascend from the head before December 1st, and therefore upon more than 20 days in its ascent; but the tail, which appeared December 10th, ascended in the space of those two days, then pulsated five times its period. The vapour, therefore, at the beginning, when the comet was near the sun, ascended with a prodigious swiftness; and afterwards continued to ascend with a motion retarded by the gravity of its particles; and by that ascent increased the length of the tail; but the tail, notwithstanding its length, continued almost wholly of vapours, which had ascended from the time of its period; and the vapour which ascended first, and composed the extreme of the tail, did not vanish till it was too far from the sun to be illuminated by it, and from us to be visible. Hence also, the tails of comets that are shorter, do not ascend with a quick and continual motion from the head, and then presently disappear; but are permanent columns of vapours and exhalations, gathered from the head, by a very gentle motion, and a great space of time; which yet, by participating of that motion of their heads they had at the beginning, continue easily to move along with their heads through the celestial regions; whence also the vacancy of those regions is argued. — See Vacuum.

5. "Their tails must appear the largest and brightest immediately after their transit through the region of the sun." Because, then, their heads being most heated, will emit the most vapours.

From the light of the nucleus, or apparent star, we infer their vicinity to the earth, and that they are by no means in the region of the fixed stars, as some have imagined; since, in that case, their heads would be no more illuminated by the sun, than the planets are by the fixed stars.

6. "The tails must still decline from a distinct opposition to the sun, towards the parts which the heads pass over, in their progress through their orbits." Because all smoke, or vapour, emitted from a body in motion, tends upwards obliquely, still receding from that part, towards which the smoking body proceeds.

7. "That declination will be still the nearest to the nucleus of the comet; and when the comet is nearest the sun." Because the vapour ascends more swiftly near the head of the comet, than in the higher extremity of its tail; and when the comet is at a less distance from the sun than when at a greater.

8. "The tail is brighter, and better defined in its convex part than in its concave." Because the vapour in the convex part, which goes first, being somewhat nearer and less swifter, will be more rarefied, and therefore made of the light more copiously.

9. "The tail will appear broader towards the higher extremity of the comet than towards the head." Because the vapour in a free space is perpetually rarefied and diluted.

10. "The tails must be transparent." Because consisting of infinitely thin vapour, &c.

Thus accurately does the hypothesis tally to the phenomena.

Comets, phaenomena. — The nuclei, which we also occasionally call the heads and bodies of comets, viewed through a telescope, shew a very different face from those of the fixed stars, or planets. They are liable to apparent changes, which Sir Isaac Newton ascribes to changes in the atmosphere of comets; and this opinion was confirmed by observations of the comet in 1744. Hilt. Acad. Scien. 1744. Sturmius tells us, that, observing the comet of 1680, with a telescope, it appeared like a coal dimly glowing, or a rude mass of matter illuminated with a dusky yellow light, its visible at the extremes than in the middle, rather thin than a flat, which appears with a round disk, and a vivid light.

Hevelius observed of the comet of 1661, that its body was of a yellowish colour, very bright, and conspicuous, but without any glittering light; in this middle was a dense ruddy nucleus, almost equal to Jupiter, encompassed with a much fatter, thinner matter. February 5th, its head was somewhat bigger and brighter, of a gold colour; but its light more dusky than the tail of the stars: here, the nucleus appeared divided into several parts. February 6th, the disk was lessened; the nucleus still existed, though less than before; one of them, on the lower part of the disk, on the left, much denser and brighter than the rest, its body round, and representing a very lucid little star: the nucleus still encompassed with another kind of matter. February 10th, the head somewhat more obscure, and the nucleus more confused, but brighter at top than bottom. February 13th, the head diminished much, both in magnitude and brightness. March 2d, its roundness a little impaired, its edges lacertated, &c. March 28th, very pale and exceeding thin: its matter much diffused; and no distinct nucleus at all appearing.

Weigelius, who saw the comet of 1664, the moon and a little cloud illuminated by the sun at the same time, observed, that the moon, through a telescope, appeared of a continued luminous surface; but the comet very different; being perfectly like a little cloud in the horizon illuminated by the sun.
fun. From these observations it was, that Hevelius concluded comets to be like macules, or spots formed out of the solar exhalations.

Comets, magnitude of. The estimates that have been given by Tycho, Hevelius, and some others, of the magnitude of comets, are not sufficiently accurate to be depended upon; for it does not appear, that they distinguished between the nucleus and the surrounding atmosphere. Thus Tycho computes that the true diameter of the comet in 1577, was in proportion to the diameter of the earth as 3 is to 14. Hevelius made the diameter of the nucleus of the comet of 1661 and also that of 1665 at the commencement of their appearances to be less than a 10th part of the diameter of the earth, and from the parallax and apparent magnitude of the head of the comet of 1652 on the 10th of December, he computed its distance to be that of the earth, as 52 to 100. By the same method he found the true diameter of the head of the comet of 1664 to be at one time 12 semi-diameters of the earth, at another time not much above 5 semi-diameters. The diameter of the atmosphere is often ten or fifteen times as great as that of the nucleus; the former, in the comet of 1682, was measured by Flamsteed, and found to be 2', but the diameter of the nucleus only 11 or 12'. Some comets, from the apparent magnitude and distance compared, have been judged to be much larger than the moon, and even equal to some of the primary planets. The diameter of that of 1744, when at the distance of the fun from us, measured about 1', and therefore its diameter must be about three times the diameter of the earth; at another time the diameter of its nucleus was nearly equal to that of Jupiter.

Hence it has been conjectured that some of the solar eclipses, recorded in history, that cannot be explained by calculation from tables of the fun and moon, have been occasioned by the interposition of comets between the fun and the earth. The eclipses of the fun mentioned by Herodotus (4. vii. c. 37, and 4. ix. c. 10.) have been thus accounted for, and also the eclipse that happened a few days before the death of Augustus, mentioned by Dion: and it is observable, that Seneca saw a comet the same year. History records some comets that have appeared as large as the fun, (vid. Seneca, N. Q. 1. 7. c. 15.) and, therefore, if such a comet near its perigee were to come between the fun and our earth, it would eclipse him for a time. Some have thought that the darkness which occurred at our Lord's crucifixion might have been occasioned by a comet then passing between the fun and the earth. (Hevel. Cometogr. p. 542. Forroi, relations sur un ancien phenomenon celeste au temps d'Olympe, Mem. de l'Acad. de Literature, vol. xix. p. 357.)

Dr. Herchel observed several comets which seemed to him to have no nucleus. The six comets discovered by his father were of this kind, and appeared to be mere collections of vapours condensed about a centre. Five more were observed by him, which were nearly of the same nature. This circumstance, he says, is "throws a mystery over their definition, which seems to place them in the allegorical view of tools, probably designed for some salutary purposes to be wrought by them; and, whether the restoration of what is lost to the fun by the emission of light may not be one of these purposes, I shall not presume to determine. The motion of the comet d'evolized by M. Meffier, June, 1770, plainly indicated how much its orbit was liable to be changed by the perturbation of the planets, which, and the little agreement that can be found between the elements of the orbits of all the comets that have been observed, it appears clearly that they may be directed to carry their salutary influence to any part of the heavens." Vol. IX.

Comets, Formation of the tails of. Sir Isaac Newton shews, that the atmosphere of comets will furnish vapour sufficient to form their tails: this he argues from that wonderful rarefaction observed in our air, at a distance from the earth; a cubic inch of common air, at the distance of half the earth's diameter, or four thousand miles, would necessarily expand itself so far as to fill a space larger than the whole region of the planets. Since then the comar or atmosphere of a comet, is ten times higher than the surface of the nucleus, counting from the centre thereof; the tail, ascending, much higher, must necessarily be immensely rare: to that it is no wonder the flares should be visible through it.

Now, the ascent of vapours into the tail of the comet, be supposed occasioned by the rarefaction of the matter of the atmosphere at the time of the perihelion. Smoke, it is observed, ascends the chimney by the impulse of the air wherein it floats; and air, rarefied by heat, ascends by diminution of its specific gravity, taking up the smoke along with it: why then should not the tail of a comet be supposed to be raised after the same manner by the fun? for the fun beams do not act on the mediums they pass through any other wise than by reflection and rarefaction.

The reflecting particles, then, being warmed by the action, will again warm the ether wherewith they are compounded; and this, rarefied by the heat, will have its specific gravity, whereby it before tended to descend, diminished by the rarefaction, so as to ascend, and carry along with it those reflecting particles, whereof the tail of the comet is composed.

This ascent of the vapours will be promoted by their circular motion round the fun; by means whereof, they will endeavour to recede from the fun, while the fun's atmosphere, and the other matters in the celestial spaces, are either at rest, or nearly so; having no motion but what they receive from the fun's circumrotation.

Thus are the vapours raised into the tails of comets in the neighbouring of the fun, where the orbits are molten curve; and where the comets, being within the denser atmosphere of the fun, have their tails of the greatest length.

The tails thus produced, by preferring that motion, and at the same time gravitating towards the fun, will move round his body in ciphers, in like manner as their heads; and, by this means, will ever accompany, and freely adhere to their heads. In effect, the gravitation of the vapours towards the fun will no more occasion the tails of the comets to forsake their heads, and fall down towards the fun, than the gravitation of their heads will occasion them to fall off from their tails: but by their common gravitation, they will either fall down together to the fun, or be together suspended, or retarded. This gravitation, therefore, does not at all hinder, but that the heads and tails of comets may receive and retain any portion towards each other, which either the above mentioned curve, or any other, may occasion. The tails, therefore, thus produced in the perihelion of comets, will go off along with their heads into remote regions; and either return thence, together with the comets, after a long series of years; or rather, be there load, and wait by little and little, and the comets be left bare; till at their return, descending towards the fun, some little short tails are gradually and slowly produced from the heads; which, afterwards, in the perihelion, descending down into the fun's atmosphere, will be immensely increased.

The vapours, when they are thus diluted, rarefied and diffused
C O M E T.

diffused through all the celestial regions, the same author observes, may probably, be little and little, by means of their own gravity, be attracted down to the planets, and become intermingled with their atmospheres.

He adds, that for the conservation of the water, and moisture of the planets, comets seem absolutely requisite; for in whole condensed vapoours and exhalations, all that moisture which is spent in evaporation and putrefactions, and turned into dry earth, &c. may be refublimed and recreated. For all vegetable grow and increase wholly from fluids; and, again, as to their greatest part, turn, by putrefaction, into earth again; and earthly fire being perpetually precipitated to the bottom of putrifying liquors. Hence, the quantity of dry earth must continually increase, and the moisture of the globe decrease, and at last quite evaporated, if it has not a continual supply from some part or other of the universe. And I suspect, adds our great author, that the spirit, which makes the finest, sublimate, and the best part of our air, and which is absolutely requisite for the life and being of all things, comes principally from the comets. So far are they from pertaining any hurt or mischief to us which the natural fars of men are apt to conjecture from the appearance of any thing that is uncommon and astonishing.

On this principle, there seems to be some foundation for the popular opinion of prelages from comets; since the tail of a comet thus intermingled with our atmosphere, may produce changes very sensible in animal and vegetable bodies.

But the transmutation of water into earth is now justly exploded. Woodward, Borelave, and others, having observed that water is only an agent in conveying the nutritions matter to vegetable bodies, and not that matter itself.

Another use which Sir Isaac Newton conjectures comets may be designed to serve, is that of recruiting the fun with fresh fuel, and repairing the consumption of his light by the comets continually sent forth in every direction from that luminary. In support of this conjecture he observes, that comets in their perihelion may suffer a diminution of their projectile force, by the resistance of the far atmosphere; so that by degrees their gravitation towards the sun may be so far increas’d, as to precipitate their fall into his body. Thus alfo, fixed stars which have been gradually wasted, may be replenish’d with fresh fuel, acquire new splendour, and be taken for new stars; of this kind are those fixed stars, which appear as a body, or flame with a surprising brightness at night, and afterwards vanish by degrees.

There have been various conjectures of the generation of the tails of comets. Apian, Cardan, Tycho Brahe, and some others, apprehended that they were produced by the sun’s rays transmitted through the nucleus of the comet, which they supposed to be transparent, and there refracted as in a lens of glass, so as to form a beam of light behind the comet. But this cannot be the case, because the figure of a comet’s tail does not correspond to such a refraction, and also because such refracted light would not be seen by an eye placed sideways to it, unless it fell upon some reflecting substance denser than the surrounding ether. Kepler supposed, that the rays of the sun carry away some of the gross parts of the comet which reflect the sun’s rays, and give the appearance of a tail. Hebus thought, that the thinnest parts of the atmosphere of a comet are raked by the force of the heat, and driven from the fore-part and each side of the comet towards the parts turned from the sun. des Cartes accounted for the phenomenon of the tail by the refraction of light from the head of the comet to the eye of the spectator. If this were the case, the planets and principal fixed stars must have tails also; for their rays pass through the same medium before they reach our eyes, as light from the comets does. Maarian supposes that the tails are formed out of the luminous matter that composes the sun’s atmosphere, which is supposed to extend as far as the orbit of the earth, and to furnish matter for those northern lights called the Aurora borealis, which see. M. de la Lande combines this hypothesis with that of Newton above recited. He thinks, that part of the vapour which forms itself is out of the atmosphere raked by heat, and is pushed forward by the force of the light streaming from the sun, and also that a comet passing through the sun’s atmosphere is devolved therein, and carries away some of it. Mr. Rowning, who is not satisfied with Sir Isaac’s opinion, accounts for the tails of comets in the following manner. It is well known, says he, that when the light of the sun passes through the atmosphere of any body, as the earth, that which passes on one side, is by the refraction thereof made to converge toward that which passes on the opposite side; and the convergence is not wholly effected either at the entrance of the light into the atmosphere, or at its going out; but beginning at its entrance, it increases in every point of its progress. It is also agreed that the atmospheres of the comets are very large and dense. He therefore supposes that by such time as the light of the fun has passed through a considerable part of the atmosphere of a comet, the rays thereof are so far refracted toward each other, that they would begin sensibly to illuminate it, or rather that the vapours floating therein, and so render that part they have yet to pass through visible to us; and that this portion of the atmosphere of a comet, thus illuminated, appears to us in form of a beam of the sun’s light, and passes under the denomination of a comet’s tail. Rowning’s Natural Philosophy, part iv. chap. 11.

We have an inquiry into the cause of the tails of comets, by Mr. Euler, in the Mem. de l’Acad. de Berlin, tom. ii. p. 177, seq. He thinks there is a great affinity between these tails, the zodiacal light, and the Aurora borealis; and that the common cause of them all, is the action of the fun’s light on the atmosphere of the comets, of the sun, and of the earth. He supposes that the impulse of the rays of light on the atmosphere of comets, may drive some of the finer particles of that atmosphere far beyond its limits; and that this force of impulse combined with that of gravity towards the comet, would produce a tail, which would always be in opposition to the sun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, must vary the position and figure of the tail, giving it a curvature, and deviation from a line drawn from the centre of the fun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and that the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be so great, that the force of the sun’s rays may produce a new tail, before the old one can follow; in which case the comet might have two or more tails. The possibility of this is confirmed by the comet of 1744, which was observed to have several tails while it was in its perihelion. See Aurora borealis, and Zodiacal light.

Dr. Hamilton urges several objections against the Newtonian hypothesis; obferving, that we have no proof of the existence of a solar atmosphere; that if we had, that when the comet is moving in its perihelion, in a direction at right angles to the direction of its tail, the vapours which then arise, partaking of the great velocity of the comet, and being also specifically lighter than the medium in which they move,
mufl suffcr a much greater refinement than the dense body of the comet does, and therefore ought to be left behind, and would not appear opposite to the fun; and afterwards they ought to appear towards the fun. Besides, if the fpecular of the tails be owing to the reflection and refraction of the fun's rays, it ought to diminifh the latitude of the fars seen through it; which would have their light reflected and refracted in like manner; and consequently their brightness would be diminished. He concludes that the tail of a comet is formed of matter which has not the power of reflecting or reflecting the rays of light; but that it is a lucid or self-luminous substance; and from its similarity to the Aurora borealis, produced by the fame caufe, and a proper electrical phenomenon. Dr. Hamilton supports his opinion by the following arguments. A spectator, at a distance from the earth, would fee the Aurora borealis in the form of a tail opposite to the fun, as the tail of a comet lies. The Aurora borealis has no effe on the fars seen through it, nor has the tail of a comet. The atmosphere is known to abound with electric matter, and the appearance of the electric matter in vacuum resembles exactly that of the Aurora borealis, which, from its great altitude, may be confidered to be in as perfect a vacuum as we can make. The electric matter in vacuum fuffers the rays of light to pass through, without being affected by them. The tail of a comet does not expand itself sideways, nor does the electric matter. Hence, he fuppofes the tails of comets, the Aurora borealis, and the electric fluid to be the fame kind of matter. As a further confirmation of this opinion it may be added, that the comet in 1607 appeared to shoot out the end of its tail. Le P. Cyfat remarked the undulations of the tail of the comet in 1618. Hevelius obferved the fame in the tails of the comets in 1652 and 1661. M. Pingré obferved the fame appearance in the comet in 1716; and there are circumftances similar to the Aurora borealis. Dr. Hamilton conjectures, that the ufe of the comets may be to bring the electric matter, which continually escapes from the planets, back into the planetary regions. Threfe arguments very much corroborate this hypothesis; and if it be true, we may further add, that the tails are hollow; for if the electric fluid only proceed in its frift direction, and do not diverge sideways, the parts directly behind the comet will not be filled with it; and this thinness of the tails will account for the appearance of the fars through them. Dr. Halley fowed inclined to this hypothesis, when he faid, that the dreams of light in an Aurora borealis fo much recombined the long tails of comets, that at frift they might well be taken for fuch; and that this light seems to have a great affinity to that which the effufion of electric bodies emit in the dark. Phil. Tran. No. 347. Hamilton's Philosophical Effays, p. 91, &c.

Hevelius particularly informs us, that he obferved the comet of 1665 to call a shadow upon the tail, for in the middle of its length there appeared a dark line. Callini also obferved in the tail of the comet of 1680 a darknes in the middle of the tail; and the fame appearance was taken notice of by a curious obferver in the tail of the comet of 1744. The lengths of the tails of comets are various, and depend on a variety of circumftances. Longomontanus mentions a comet that in 1618, December the 10th, had a tail which appeared under an angle of 104°; that of 1680 appeared under an angle of 70°, according to Sir I. Newton, and very brilliant; the comet of 1744 had a tail, which at one time appeared to extend 16° from its body; and which, allowing the fun's parallax to be 10°, mufl have been above 23 millions of miles in length. The diameter of its nucleus was nearly equal to that of Jupiter. The tail of the comet of 1759 appeared, according to M. Pingré, under an angle of 50°; but the light was very faint. The length of a comet's tail may be thus found. Let S (Plate IV. Astronomy, fig. 23.) be the fun. E the earth, C the comet, C.L. the tail when directed from the fun; then, knowing the place of the comet, we know the angle C.L., E.C, and the angle C.E.L., the angle under which the tail appears; hence we find C.L., the length of the tail. If the tail deviate by any angle LCM, found from obervation, we shall then know the angle ECM, with C.E, and the angle C.E.M., to find CM.

M. Fatio has obferved that fome of the comets have their nodes fo very near the annual orbit of the earth; that if the earth fhould happen to be found in that part next the node, at the time of a comet's paffing by; as the apparent motion of the comet will be incredibly swift, fo its parallax will become very ftrifte; and the proportion thereof to that of the fun will be given: whence fuch tranfits of comets will afford the belft means of determining the diftance of the earth and fun.

The comet of 1472, v. 97, had a parallax above twenty times greater than the fun's; and if that of 1618 had change. In the beginning of March to its defending ufed, it would have been more near the earth, and its aparallax much more notable. But hitherto, none has threatened the earth with a nearer appulfion than that of 1680: for, by calculation, Dr. Halley finds that November 11th, 1 h. 6 min. P.M. that comet was not above one femidiameter of the earth, to the northward of the way of the earth; at which time had the earth been in that part of its orbit, the comet would have had a parallax equal to that of the moon: what might have been the confequence of fo near an appulfion, a contact, or, laftly, a fchock of the cedal bodies?

If the earth had been at this time in that part of her orbit nearest to that node of the comet, through which it paffed, their mutual gravitation must have caufed a change in the plane of the orbit of the earth, and in the length of our year. Dr. Halley adds, that if fo large a body, with fo rapid a motion as that of this comet near its perihelion, were to flike against our earth, a thing by no means imprifible, the shock might reduce this beautiful frame to its original form, and from Flamit's measure of the apparent diameter of this comet, concluded its nucleus to be about ten times as big as the moon, or equal to a fourth part of our earth, attributes the univerfal deluge, in the time of Noah, to its near approach. His opinion was, that the earth paffing through the atmosphere of the comet, attracted from it a confiderable part of the waters of the flood; that the proximity of the comet raised a great tide in the subterraneous waters, fo that the outward cufm of the earth was not changed from spherical to ovall; that this could not be done without making fifures and cracks in it; that through these fifures the subterraneous waters were forced, in confequence of the change of the folve of the earth into a flat, capacious form; that, along with the water thus fqueezed up upon the surface of the earth, much flame or mud would rile; which, together with the grofler parts of the comet's atmosphere, would, after the subfiding of the water partly into the fifures and partly into the lower parts of the earth to form the fea, cover all over to a confiderable depth the antediluvian earth—and thus he accounts for trees and bones of animals being found at very great depths in the earth. He alfo fuppoled, that before the fall of the earth revolved round the fun in the plane of the eclipse, keeping always the fame points of its surface towards the fame fixed fars; by this means, as every meridian would come to the fun but once in a whole revolution, a day and a year were then the fame: but that a comet striking obliquely upon the
COMET.

earth gave it the diurnal rotation. Moreover, he apprehended, that the antediluvian year consisted of 360 days; but that the additional matter deposited upon the earth from the atmosphere of the comet at the time of the deluge, so retarded its revolution round the sun, that it is not now performed in less than 365 days and about a quarter.

The same comet, he imagined, would probably, by coming near the earth after being heated to an immense degree in its perihelion, be the instrumen tal cause of that great catastrophe, the general confusion, foretold in the Sacred Writings, and from ancient tradition, mentioned by heathen writers. See CONFLAGRATION, DELUGE, and Theory of the Earth.

COMETS, Method of. The analogy between the periodic time of the planets, and their distances from the sun, discovered by Kepler, takes place also to the comets. Hence, the mean distance of a comet from the sun may be found by comparing its period with the time of the earth's revolution round the sun: thus, the period of the comet that appeared in 1531, 1607, 1681, and 1750, being about 76 years, its mean distance is found by this proportion; as 1 to the square of one year, the earth's periodical time; so is 5770 to the square of 76, the comet's periodical time, so is 1000000 to the cube of 100, the earth's mean distance from the sun, to 5776000000 the cube of the comet's mean distance; the cube root of which is 1794, the mean distance itself, in such parts as the mean distance of the earth contains 100. If the perihelion distance of this comet 58 be taken from 3558 double the mean distance, we shall have the aphelion distance 3530 of such parts as the distance of the earth contains 100; and this is a little more than 35 times the distance of the earth from the sun. By a like method the aphelion distance of the comet of 1682 comes out 138 times the mean distance of the earth from the sun, supposing its period to be 577 years; so that this comet in its aphelion goes to more than 14 times the distance from the sun that Saturn does.

The limit of a comet's distance may be very easily ascertained from its tail, it being supposed to be directed from the sun. Let S (fig. 24.) be the sun, E the earth, E'T' the line in which the head of the comet appears, EW the line in which the extremity of the tail is observed, and draw ST parallel to EW; then the comet is within the distance ET; for if the comet were at T', the tail would be directed in a line parallel to EW, and therefore it could never appear in that line. T'EW is known by observation, and consequently its equal E'T'S, together with TES, the angular distance of the comet from the sun, and E'S, to find ST the limit. E.G. On December 21, 1680, the distance of the comet from the sun was 32° 24', and length of the tail 70°; hence ST : SE :: sin. 32° 24' : sin. 70° :: 4 : 7 nearly; consequently the comet's distance from the sun was less than 4 of the earth's distance from the sun. Hence Sir Isaac Newton deduced this comet to be more than all comets, whilst they are visible, are not farther distant from the sun than three times the earth's distance from the sun. This must, however, depend upon the goodness of the telescope, and magnitude of the comet. Vince's Altr. vol. i. p. 446.

Comets, motion of. If the paths of comets be supposed directly parabolic, as some have imagined, it would follow, that being impelled toward the sun by a centripetal force, they descend as from spaces infinitely distant; and by their falls acquire such a velocity, as that they may again run off into the remotest regions; and moving upwards, with such a perpetual tendency as never to return. But the frequency of their appearance, and their degree of velocity, which does not exceed what they might acquire by their gravity towards the sun, seem to put it past doubt that they move, planet-like, in elliptic orbits, though exceedingly eccentric; and so return again, though after very long periods.

The apparent velocity of the comet of 1772, as observed by Regiomontanus, was such as to carry it through 45° of a great circle in 24 hours; and that of 1770 was observed to move through more than 45° in the last 25 hours.

G. S. De révell, minifler at Pfizen in Upper Saxony, made observations upon the comet of 1650, and found that its motion might very well be represented by a parabola, which the sun in its focus; but not understanding the laws by which the motion of a body in a parabola is regulated, he erred considerably in his parabola, making the perihelion distance about 12 times greater than it was. This was published five years before the "Principia" of Newton, in which this illustrious author proved that Kepler's law, by which the planetary motions are regulated, was a necessary result of his theory of gravity; whence it immediately followed, that comets were governed by the same law, and the observations upon them agreed so accurately with his theory, as to leave no doubt of its truth.

Newton, Flamsteed, Halley, and the English astronomers, etc. seem satisfied of the return of the comets. Caffini, and others of the French, thought it highly probable; but de la Hire, and others, opposed it.

Those on the still more side suppose the comets to describe orbits prodigiously eccentric, incomprehensible that we can only see them in a very small part of their revolution; out of this, they are lost in the immense spaces; hid not only from our eyes, but from our telescopes. That little part of them, which reaches us, Newton has found to pass between the orbits of Venus and Mars.

For the reasons of the return of comets, M. Cassini gives these which follow. 1. In considering the course of the comets, with regard to the fixed stars, they are found to keep a considerable time in the arc of a great circle, i.e. a circle whose plane passes through the centre of the earth: indeed, they deviate a little from it, chiefly towards the end of their appearances; but this deviation is common to them with the planets.

2. Comets, as well as planets, appear to move so much the faster as they are nearer the earth; and when they are at equal distances from their perigee, their velocities are nearly the fame.

By subtracting from their motion the apparent inequality of velocity occasioned by their different distances from the earth, their equal motion might be found; but we should not be certain this motion were their true one, because they might have considerable inequalities, not discernible in that small part of their orbit visible to us. It is, in fact, quite the contrary; nournal motions, as well as those of the planets, is unequal in itself: and hence we have a reason why the observations made, during the appearance of a comet, cannot give the just period of their revolution.

3. There are no two different planets whose orbits cut the ecliptic in the same angle, whose nodes are in the same points of the ecliptic, and whose apparent velocity in their perigee is the same; consequently, two comets seen at different times, yet agreeing with all these three circumstances, can only be one and the same comet. And this were the comets of 1577 and 1680 observed to do; and those of 1652 and 1695; not that this exact agree-
agreement, in these circumstances, is absolutely necessary to determine them the same comet. M. Caffini finds the moon herself irregular in them all; accordingly, he is of opinion, there are several which disagree herein, and yet may be accounted the same.

The great objection against the return of comets, is, the rarity of their appearance, with regard to the number of revolutions affirmed to them. In 1701, there was a comet, or rather the tail of one, seen at Rome, which M. Caffini takes to be the same with that observed by Aristotle, and that since seen in 1668, which would imply its period to be thirty-four years. Now, it may seem strange, that a star which has so short a revolution, and of consequence such frequent returns, should be so seldom seen.—Again, in April, of the same year, 1702, a comet was observed by Maffi, Banchini, and Maraldi, supposed by the latter to be the same with that of 1693, both by reason of its motion, velocity, and direction. M. de la Hire took it to have some relation to another he had observed in 1678, which M. Caffini refers to that of 1652. On this supposition, its period appears to be forty-three months; and the number of revolutions between 1652 and 1703, fourteen: but it is hard to suppose, that in this age, wherein the heavens are so narrowly watched, a star should remain so long a time undiscovered; especially such a star as this, which might appear above a month together: and of consequence be frequently disengaged from the crenufula.

For this reason M. Caffini was very averse in maintaining the hypothesis of the return of comets, and only proposed those for planets, where the motions are easy and simple, and are resolved without standing, or allowing many irregularities.

M. de la Hire proposes one general difficulty against the whole system of the return of comets, which would seem to hinder any comet from being a planet: and it is this; that by the disposition necessarily given to their courses, they ought to appear as large at first as at last; and always increase, till they arrive at their greatest proximity to the earth: or, if they should chance not to be observed, as soon as they become visible, for want of attention thereto; at last it is impossible but they must frequently Flew themselves before they have arrived at their full magnitude and brightness. But he adds, that none were ever yet observed till they had arrived at it.

But the appearance of a comet in the month of October 1723, while at a great distance, so as to be too small and dim to be viewed without a telescope, may serve to remove this obstacle, and set the comets, still, on the same footing with the planets.

Sir Isaac Newton supposes, that as those planets which are nearest the sun, and revolve in the least orbits, are the smallest; so among the comets, such as in their perihelion come nearest the sun, are the smallest, and revolve in lesser orbits.

In order to prove that comets describe ellipses, and not parabolas or hyperbolas, Dr. Halley, in his "Synopsis of the Astronomy of Comets," advances the following reasons. "Hitherto I have considered the orbits of comets as exactly parabolic; upon which supposition it would follow, that comets being impelled towards the sun, by a centripetal force, would descend as from spaces infinitely distant; and, by their so falling acquire such a velocity, as that they may again fly off into the remotest parts of the universe, moving upwards with a perpetual tendency, so as never to return again to the sun. But since they appear frequently enough, and since none of them can be found to move with an hyperbolic motion, or a motion

†twice than what a comet might acquire by its gravity to the sun, it is highly probable they rather move in very eccentric elliptic orbits, and make their returns after long periods of time; for their number will be determinate, and perhaps not so very great. Besides, the space between the sun and the fixed stars is so immense, that there is room enough for a comet to revolve, though the period of its revolution be vastly long. Now the latus rectum of an ellipse is to the latus rectum of a parabola, which has the same distance in its perihelion, as the distance in the aphelion, in the ellipse, is to the whole axis of the ellipse. And the velocities are in a subduplicate ratio of the same; therefore, in very eccentric orbits, the ratio comes very near to a ratio of equality; and the very small difference which happens, on account of the greater velocity in the parabola, is easily compensated in determining the situation of the orbit. The principal use therefore of the table of the elements of their motions, and that indeed which induced me to construct it, is, that whenever a new comet shall appear, we may be able to know, by comparing together the elements, whether it be of any of those which has appeared before, and consequently to determine its period, and the axis of its orbit, and to foretell its return. And, indeed, there are many things which make it believe, that the comet which Apian observed in the year 1531, was the same with that which Kepler and Longomontanus more accurately described in the year 1607; and which I myself have seen return, and observed in the year 1682. All the elements agree, and nothing seems to contradict this my opinion, besides the inequality of the periodic revolutions; which inequality is not so great neither, as that it may not be owing to physical causes. For the motion of Saturn is so disturbed by the rest of the planets, especially Jupiter, that the periodic time of the planet is uncertain, for some whole days together. How much more therefore will a comet be subject to such like errors, which rises almost four times higher than Saturn, and whose velocity, though increased but a very little, would be sufficient to change its orbit, from an elliptic to a parabolical one. And I am the more confirmed in my opinion of its being the same; for, in the year 1356, in the summer-time, a comet was seen passing retrograde between the earth and the sun, much after the same manner, which, although nobody had observed such revolutions upon it, yet, from its period, and the manner of its transit, I cannot think different from those I have just now mentioned. And since looking over the histories of comets, I find, at an equal interval of time, a comet to have been seen about Easter, in the year 1356, which is another double period of 151 years before the former. Hence, I think, I may venture to foretell that it will return again in the year 1758." Dr. Halley computed, levi calano, as he himself informs us, the effect of Jupiter upon this comet in 1682, and found that it would increase its periodic time above a year, in consequence of which he predicted its return at the end of the year 1758, or the beginning of 1759. M. Clairaut computed the effects both of Saturn and Jupiter, and found that the former would retard its return in the last period 100 days, and the latter 511 days; and he determined the time when the comet would come to its perihelion to be in April 15, 1759, observing that he might err a month, from neglecting small quantities in the computation. It passed the perihelion on March 15, within 53 days of the time computed. Now if we suppose the time stated by Dr. Halley, to mean the time of its passing the perihelion, then if we add to that 100 days, arising from the action of Saturn which
COMET.

which he did not confide, it will bring it very near to the time in which it did pass the perihelion, and prove his computation of the effect of Jupiter to have been very accurate. If he meant the time when it would first appear, his prediction was very accurate, for it was first seen on December the 14th, 1758, and his computation of the effects of Jupiter will then be more accurate than could have been expected, considering that he made his calculations only by an indirect method, and in a manner professedly not very accurate. Dr. Halley, therefore, had the glory, first to forecast the return of a comet, and the event answered remarkably to his prediction. He further observed, that the action of Jupiter, in the deflection of the comet towards its perihelion in 1682, would tend to increase the inclination of its orbit; and accordingly the inclination in 1682 was found to be 22° greater than in 1677. From the observations of M. Meller upon a comet in 1770, M. Edric Proprina, member of the Royal Academies of Stockholm and Upsal, showed, that a parabolic orbit would not answer to its motions, and he recommended it to astronomers to seek for the elliptic orbit. This laborious task was undertaken by M. Lexell, who has shown that an ellipse, in which the periodic time is about 5 years and 7 months, agrees very well with the observations. (See Phil. Trans. for 1779.) As the ellipses which the comets describe are all very eccentric, astronomers, for the sake of calculation, suppose them to move in parabolic orbits for that part which lies within the reach of observation, by which they can very accurately find the place of the perihelion of a comet, its distance from the sun, the inclination of the plane of its orbit to the ecliptic, and the place of the node. But before we can determine the orbit of a comet, from observation, it will be necessary to premise such particulars respecting the motion of a body in a parabola, as may be requisite for such an investigation.

Accordingly let APM (fig. 25) be a parabola, S its focus, A the vertex, P the place of the body, draw PQ perpendicular to AS, and PD perpendicular to the tangent PT, also SM perpendicular to AD. Now, by the property of the parabola, QD is equal to the latus rectum; hence if AS = t, then QD = 2t; also the angle ASP = 2 PDA; therefore if QD be radius, PQ will be the tangent of PDA, or 2 PSA; hence to the radius AS, PQ will be twice the tangent of 2 PSA; therefore if 2t = PQ, t will be the tangent of (2t) half the true anomaly of PSA, to the radius AS = t. Also, by the property of the parabola, AQ = 4 ASQ; hence AQ = t; also the area AQP = 2t²; and as QS = t + t, the area QPS = t³; hence the area A SP = 2t² + t; also the area ASM = 4t. Now let a and b be the times in which the comet moves from A to M, and from A to P, then, as the areas described about S are proportional to the times, a : b :: 2 : 3 t² + t; therefore a t³ + 3 a t² = 4 b.

Hence if a and b, the true anomaly be given, we have the time b = 4 a t³ + 2 a t. Also, because a : b :: 4 : 3 t² + t, therefore if the true anomaly, and consequently b, be given in different parabolas, the times of describing those true anomalies from the perihelions will be in proportion to the times of describing 90° from the perihelions.

If the times a and b be given, the true anomaly may be found from resolving the cubic equation t³ + 3 t² = b, which may be done thus. In the right-angled triangle C A B, (fig. 26) let A B = b, A C = b, and compute BC; then and two mean proportionals between BC + A C and BC — A C, and their difference is the value of t.

Take the fluxion of t + 3 t² = b, and we have \( i = \frac{4}{3} \times \frac{b}{t³ + t} \), but \( i = t + t^2 \times t + 1; \) hence we get \( 2 \times \frac{b}{t³ + t} = \frac{4}{3} \).

\[ \frac{b}{t³ + t} = \frac{8}{3} \times \text{col. } t + t^2 \times t^3 \text{ the variation of the true anomaly corresponding to any small variation } \frac{b}{t³ + t} \text{ of time expressed in decimals of a day, } \frac{b}{t³ + t} \text{ being expressed in days.}

Let SA (fig. 25) be the mean distance of the earth from the sun; then the area of the circle, described with that radius, will be \( 3 \times 14159 \) also the area AM = 4. Now the velocity in the parabola: velocity in the circle: \( \sqrt{2} : \frac{1}{3} \), for let PP (fig. 27) be an indefinitely small arc described by the body, S the place of the fun, SN a line drawn from the focus, S, perpendicular to a tangent to the parabola A P D at the point P, then, \( \therefore \), The velocity u in any point P of the parabola, is as the square root of the parameter divided by SN: for, the velocity is as the arc PP or \( u = p \); now, \( p \) M be perpendicular to PS, in the similar right-angled triangles p P M, P S N, S N: \( S P \cdot p \cdot M = \frac{p \cdot M}{S N} \). But the parameter is as the square of the described sectors; therefore R (the parameter) = \( p \cdot M \cdot S P \), and \( \sqrt{R} = \frac{p \cdot M}{S N} \); and by substitution, \( p \) P or \( u = \sqrt{4 \cdot A S} \times S N \), or \( u = \sqrt{4 \cdot A S} \times S N \), from the nature of the parabola. 2dly, \( \therefore \), The velocity u in any point P of the parabola, is to the velocity V of a body running through the circumference of a circle with a central force tending to its centre, the radius being equal to SP, as \( \sqrt{\frac{1}{2}} : 1 \). For, since \( u = \sqrt{4 \cdot A S} \times S N \), \( u = \sqrt{4 \cdot A S} \times S N \); or, because \( S N^3 = S P \times S A \) (by the property of the Parabola), \( u = \sqrt{4 \cdot A S} \times S P \times S A = \frac{4 \cdot A S}{S P} \). But the circle whose radius is SP, being taken as an ellipse, its parameter is = \( 2 \cdot S P \); and the velocity V being uniform, it is everywhere as \( \frac{4 \cdot A S}{S P} \); therefore \( V = \frac{2 \cdot S P}{S P^3} = \frac{2 \cdot S P}{S P^3}; \therefore \) consequently \( u = \frac{4 \cdot A S}{S P} \); therefore \( V = \frac{2 \cdot S P}{S P^3}; \therefore \) for the time the time in the circle = \( 3 \times 14159 \) of \( 4 \cdot 365 \cdot 6 \). \( \therefore \), the time of describing A M = 1009d. 14h. 46m. 20s. Now as the time of describing AM is in a given ratio to the time in the circle, which varies as \( S A^3 \), therefore if \( r = \) the perihelion distance in any other parabola, we have \( r = \frac{15}{149} \); \( r = \frac{15}{149} \); \( \therefore \), the time of describing 90° in that parabola from the perihelion. Hence, knowing the time corresponding to any true anomaly in that parabola whose perihelion distance = 1, we know the time corresponding to the same true anomaly in any other parabola, because the times
times of describing 90° are as the times corresponding to the same true anomaly; therefore if \( n \) be the number of days corresponding to any given anomaly in that parabola whose perihelion distance is unity, then \( n r^{2} \) will be the time \( r \) corresponding to the true anomaly in that whose perihelion distance is \( r \). This may be readily found thus. Multiply the log. \( r \) by 3 and divide by 2, and to the quotient add the log. \( n \), and the sum will be the log of the time required.

Hence also \( n = \frac{r^{2}}{3} \); therefore if from the log. \( r \) we subtract \( \log \, r \), it gives the log. \( n \) of the number of days corresponding to the same anomaly in the parabola, whose perihelion distance is unity. This anomaly will be found from a table which exhibits the times corresponding to the true anomaly for 250000 days from the perihelion, in that parabola whose perihelion distance is unity. This table may be constructed by the preceding problem, by taking \( a = 109 \), 6154, and allowing \( b = 1, 2, 3, 4, \ldots \), and finding the corresponding values of \( t \).

Dr. Halley first constructed a table of this kind. M. de la Caille changed it into a more convenient form, by putting the areas for the times; Mr. Vincen has given that which was computed by M. de Lambre. (See Vincen's Alton. vol. i. p. 454, &c.)

Draw \( SY \) perpendicular to the tangent; then \( SP : SY = SA : \sqrt{SA} \), therefore \( \sqrt{SP} = \sqrt{SA} : \sqrt{SY} \); rad. \( : \) cos. \( PS \), or \( \frac{1}{2} \) PSA the true anomaly; or \( SP : SA = \cot. : \sqrt{SA} \), true anomaly. Hence, if \( SA = 1 \), and \( a + x = \frac{1}{2} \) PSA, \( a - x = \frac{1}{2} \) PS, then \( \sqrt{SP} = \cot. \cdot \sqrt{SA} : \sqrt{SP} = \cot. \cdot \cot. : \sqrt{SP} = \cot. : \tan. \cdot \cot. = \cot. \cdot \cot. = \cot. \).

Hence \( SP = \cot. \cdot \sqrt{SA} \), radius being unity; therefore from log. \( SA \) subtract twice the log. \( \cot. \), log. \( \frac{1}{2} \) true anomaly, and the remainder is the log. of the distance of the comet from the sun.

Erect \( BD \) (fig. 28) perpendicular to \( AB \), take \( BC = AB \), produce \( AC \) to \( E \), and draw \( DEF \) perpendicular to \( A E \), meeting \( AP \) parallel to \( BD \) in \( F \), join \( AD \), and draw \( DG \), \( CH \) parallel to \( AB \). Then, as \( EAF = 45° \), \( EA = EF \), and \( GFG = GD = AB \); hence \( AF = BD + BA \), and \( GH = BD - BA \); and for their similar triangles, \( AF \) or \( BD + BA \) : \( CD \) or \( GH \) = \( EF \) or \( BD - BA \) : \( ED \) or \( BA \). From \( \tan. \cdot \cot. \), and \( \cot. \cdot \cot. \) we have \( BD = \sqrt{SP}, \) and \( BA = \sqrt{SP} \), then \( \sqrt{SP} = \cot. \cdot \sqrt{SP} \).

The elements of the Orbit of a Comet, to compute the place at any time.

The elements of the orbit of a comet are: 1. The time when the comet passes the perihelion. — 2. The place of the perihelion. — 3. The distance of the perihelion from the sun. — 4. The place of the ascending node. — 5. The inclination of the orbit to the ecliptic. From these elements, the place at any time may be computed; and, for example, we shall take that given by M. de la Caille in his Astronomy. The place of the comet in 1739, which was retrograde, passed its perihelion on June 17th, at 1st. 9° 27' mean time; the place of the perihelion was in 3° 12° 38' 45"; the perihelion distance was 0.69738, the mean distance of the earth from the sun being unity; the ascending node was in 0° 27° 25° 14"; and the latitude of the orbit 55° 42' 44"; to compute the place from the earth on August 17th, at 14° 20' mean time.

Let \( W, AV \) (fig. 28) be the parabolic orbit of the comet, \( N \) the ascending node, \( P \) the place of the comet, \( T \) the corresponding place of the earth, and draw \( \mathfrak{p} \), \( \mathfrak{p}' \) perpendicular to the ecliptic; produce \( SN, S \mathfrak{w}, S \mathfrak{p}, S \mathfrak{p}' \) to \( n, n', \mathfrak{p}, \mathfrak{p}' \) the sphere of the fixed stars, and describe the great circles \( n \mathfrak{p}, n' \mathfrak{p}, \mathfrak{p} \mathfrak{p}' \). and \( \mathfrak{p} \).

I. The interval of time from the perihelion to the place of the comet in 616. 46. 10° 30', 61. 1741, whole log. is 1.86575; or, the log. of the 0.8785, is 4.826, of which log., from the nature of logarithms, is 9.74258, which subtracted from 1756567 leaves 4554985, the log. of 11685667 days, which, by the table, answers to 3° 21' 39" the true anomaly \( \mathfrak{p} \) of the comet at the given time.

II. Subtract 3° 21' 35" from 3° 12° 38' 45" the place of the perihelion, because the comet was retrograde, and had passed the perihelion, and it leaves 12° 17' 11" for the heliocentric place of the comet in its orbit.

III. The longitude of \( n \) is 27° 21° 14", also \( \mathfrak{p} = n = 27° 25° 14" = 12° 17' 11" = 15° 8' 13" \); hence radial: \( \cot. \cdot \mathfrak{p} = \cot. \cdot n = \frac{1}{2} \cdot 43' 44" \); tan. \( \mathfrak{p} = \cot. \cdot n = 15° 8' 13" \); tan. \( n = \frac{1}{2} \cdot 35° 53" \) the distance of the comet from the ascending node, measured upon the ecliptic.

IV. Subtract this value of \( \mathfrak{p} \) from the place of the node, and there remain 18° 45' 21" = \( \mathfrak{n} \) the true heliocentric place of the comet reduced to the ecliptic.

V. As rad.: \( \mathfrak{n} = 15° 8' 13" \); \( \mathfrak{n} = 55° 42' 44" \); \( \mathfrak{n} = 12° 25° 34' \) the latitude seen from the sun, which is north.

VI. The true place \( T \) of the earth at the same time is 10° 42° 34° 36°; hence \( T \mathfrak{S} = 33° - 5° 24" \); therefore \( T \mathfrak{S} = 14° 10' 45" \). Also \( T \mathfrak{S} = 10.0171 \).

VII. By
VII. By a preceding article, vol. 45° 10' 49". rad. 1: 9.6758: SP = 1:3557
VIII. Astr. vol. 1:227' 34". SP = 1:3557
S = 1: 12: 32: 37.
IX. In the triangle TS v, we know TS, S and the included angle TS v; hence, by plain trigonometry, we find the angle ST v = 77° 33' 38" 1, which subtracted from 4° 24° 34' 36", the place of the fun, leaves 2° 7' 9" 1 for the comet's true geocentric longitude.

X. Moreover, as fin. 54° 10' 47": sin. 77° 33' 38" 1: tan. P ST v = 1:227' 24": tan. P ST v = 1:227' 4": the comet's true geocentric latitude.

To determine the Orbit of a Comet from Observation.

Sir I. Newton first resolved this problem, which he called "Problema longe difficilissimum." The orbit of a comet may be computed from three observations: but although these data be sufficient, the direct solution of the problem is impracticable. Astronomers therefore have found it necessary to resort to indirect methods, first finding an orbit very near to the truth by mechanical and graphical operations, and then, by computation, correcting it, until such a parabola was found as would satisfy the observations. Mr. Vine therefore begins, by the method of which the orbit may be nearly determined; and then explains the manner in which it may be corrected by calculation.

M. de la Lande proposes the following mechanical method of finding the orbit nearly. Divide the distance of the earth from the sun into ten equal parts, and describe ten parabolas whose perihelion distances are, 1, 2, 3, &c., of these parts, and divide these parabolas into days from the perihelion, answering to the motion of a body in each. Let S (fig. 31.) be the fun. a, b, c, the places of the earth at the times of three observations of the comet. Then take three geocentric latitudes and longitudes of the comet, and set off the elongations S a, S b, S c, in longitude. From a, b, c, extend three fine threads a m, b n, c p, vertical to a s, b s, c s, making angles with them equal to the geocentric latitude of the comet. Then take any one of the parabolas, and placing its focus in S apply the edge to the threads, and observe whether you can make it touch them all, and whether the intervals of time cut off by the threads upon the parabola be equal to the respective intervals of the observations, or very nearly so; and if these circumstances take place, you have then got the true parabola, or very nearly the true one. But if the parabola do not agree, try others, till you find one which does agree, or very nearly so, and you will then have got very nearly the true parabola, whose inclination, place of the node, and perihelion, are to be determined as accurately as possible from mensuration; also the projection upon the ecliptic. If none of these parabolas should nearly answer, it shows, that the perihelion distance must be greater than the distance of the earth from the sun, in which case, other parabolas must be constructed; but this does not very often happen. This method will determine the elements very nearly; but it would be extremely troublesome to construct and divide for many parabolas, if we only wanted to compute the elements of one comet; for that purpose to make many computations of this kind, it must be worth while to have a set of parabolas thus divided. To avoid this trouble therefore, Mr. Vine proposes to do it in the following manner, by means of one parabola, without dividing it.

Take a firm board perfectly plane, and fix on paper for the projection; let a groove be cut near the edge, and five perpendiculars be movable in it, so that they may be fixed at any distances. Let S (fig. 32.) represent the sun, and describe any number of circles about it. Compute five geocentric latitudes and longitudes of the comet, from which you will have the five elongations of the comet at the times of the respective observations. Draw S a, S b, S c, S d, S e, making the angles A S B, B S C, C S D, D S E, equal to the sun's motion in the intervals of the observations; and on any one of the circles, make the angles S a S b, S b S c, S c S d, S d S e, equal to the respective elongations in longitude, and fix the five perpendiculars, so that the edge of each may coincide with a, b, c, d, e. From the points a, b, c, d, e, extend threads to the respective perpendiculars, making angles with the plane equal to the geocentric latitudes of the comet, then the focus of the parabola, in S, and apply the edge to the threads, and if it can be moved to touch them all, it will be the parabola required, corresponding to the mean distance S x of the earth, which we here suppose to revolve in a circle, as it will be sufficiently accurate for our purpose. If the parabola cannot be made to touch all the threads, change the points a, b, c, d, e, to such of the other circles as you may judge, from your present trial, will be most likely to succeed, and try again; and by a few repetitions you will get such a distance for the earth, that the parabola shall touch all the threads, in which position, and the inclination, observe the place of the node, and measure the perihelion distance, compared with the earth's distance, and you will get very nearly the elements of the orbit.

The next method of approximating to the orbit of a comet, which we shall explain, is that given by Boicovich. Let S (fig. 33.) be the sun, X the orbit of the earth, supposed to be a circle; T the place of the earth at the first observation, and t at the third; draw T C, t C to represent the observed longitudes of the comet, and let a, b, c, be the longitudes at the first, second, and third observations of the fun and n the geocentric latitudes of the comet at the first and third observations; and t, T, the intervals of time between the first and second, second and third observations. Assume C for the place of the comet, at the first observation, reduced to the ecliptic; then to determine the point at the third observation, say T x sin. a = T x sin. 7 = 1. = TC: tc, and e will be nearly the place required; (See B from "Opuscula," vol. iii. or for II. Engle- held's valuable work upon comets, p. 27.) Join C x, and it will represent the path of the comet on the ecliptic, upon this assumption. Perpendicular to the ecliptic draw C K, e, taking C K: T C = tan. m: radius, and e k: t c = tan. n: radius, join K k, and it will represent the orbit of the comet, if the first assumption be true. But C x e m, and draw x y parallel to C K, and y will befe k; join y S. Let S X = r; then if v be the mean velocity of the earth in its orbit, the velocity of the comet at y = \sqrt{x^2 + v^2} / \sqrt{y^2 + v^2}; taking therefore v = T t, compute \sqrt{x^2 + v^2} / \sqrt{y^2 + v^2}, and if this be equal to K k, measured by the scale, the assumed point C was the true point. But if these quantities be not equal, assume a new point for C, in doing which, the error of the first assumption will direct you which way, from the first assumed point, it must be taken, and about how far from it; if, for instance, the computed value of K k be greater than the true value, and the lines C K, e k, are diverging from each other, and receding from the sun, the point C must be taken further from T, and how much further we must conjecture from the value of the error, and also from hence, that the velocity of the comet diminishes as it recedes from the sun. These con-
Comet.

The solar system to vast distances beyond the orbits of the most distant planets return again to the neighborhood of the sun, the paths they describe must be nearly elliptical; and then, if observations have been made sufficiently exact to be a basis of the operations, the requisite of the problem may be determined in the following manner: Let \( A \) \( B \) \( D \) \( E \) be the trajectory of a comet, \( A \) its major axis, \( E \) the minor, \( S \), the two foci, the former of which being the place of the sun, \( C \) the place of the comet. \( S \) is its distance from the sun, \( C \) the space it passes over in a very small portion of time, \( D \) \( E \) a tangent to the curve in the point \( C \), \( S \) \( D \) \( F \) \( E \), perpendiculars demitted thereon from the focus: draw \( S G \) parallel to the tangent, and join \( F C \). Also, let \( A \) \( L \) \( B \) be a circle, described on the major axis \( A B \); \( A \) \( P \) \( T \) a rectangle about the ellipse \( A T \), and \( A \) \( Q \) \( R \) \( B \) a square about the circle \( A L B \). Lastly, let \( A \) \( N \) \( O \) be the elliptic orbit of any planet, \( S \), its focus; put \( S C = a \), \( S D = b \), \( C E = r \), the time in which it is described \( f \), the major axis of the cometary orbit \( A B = x \), of the planetary orbit \( A O = q \), the circumference of the circle \( A V O \) described on the same axis \( p \), the periodical time of the comet \( t \). and that of the planet \( = n \).

The space \( C c \) described, the distance \( S C \), and the angle \( S C D \), being all determinable by observation, are given quantities. The mean distance of the comet is \( A H = S K = \frac{x}{2} y \), and of the planet is \( A S = S N = \frac{n}{2} q \); and, because the squares of the periodical times are as the cubes of the mean distances, we have

\[
\left( \frac{1}{2} x^3 \right)^n = \left( \frac{1}{2} q^3 \right)^n \quad \text{or} \quad t = \frac{1}{2} \sqrt{\frac{x^3}{q^3}}.
\]

But it is necessary to find another expression for the periodical time \( t \), which may be done thus: because \( Cc \) is a very minute portion of the orbit, it may be esteemed a right line, and the factor \( C C \) \( S \) \( C \) as a rectilineal triangle, whole area

\[
\frac{1}{2} S D \times C c = \frac{1}{2} b e \text{ is given}; \text{then, as the area} \frac{1}{2} b e, \text{is to the whole area of the ellipse} A K D I = A, \text{ft is the time} \]

\[f \text{ to the whole periodical time} t; \text{wherefore} t = \frac{f}{b e} \times A.
\]

Now, in order to determine the area \( A \), we must find the semi-conjugate \( H K \); and here, because \( A B = S C + F C \), we have \( F C = x - a \); and by the similar triangles \( S D C \), \( F E C \), we have \( S C = \frac{S D \times F C}{F E} \); \( A \) \( S \) \( C \) \( D \) \( C \) \( F \) \( E \), which \( a \) \( b \) ::

\[
x - a = \frac{b x - 2 a b}{a} = F E; \text{consequently} \quad F G = F - G E = \frac{b x - 2 a b}{a}. \text{Again,} \quad S C = D C = F C = CE; \text{or} a :: \sqrt{a^2 - b^2} :: x - a \quad \text{hence} \quad D E \text{ or}
\]

\[
S G = CE + CD = \frac{x - a}{a} \sqrt{a^2 - b^2} + \sqrt{a^2 - b^2} - \frac{x}{a} \sqrt{a^2 - b^2}.
\]

But \( F G = b x - 2 a b \); therefore \( F S = \frac{\sqrt{a^2 - b^2} + x}{a} \sqrt{x} \sqrt{b x - 4 a b x + 4 a b^2 + a^2 x - b x^2} \)

\[
= \sqrt{\frac{b x^2 - 4 a b x + 4 a b^2 + a^2 x - b x^2}{a^2}}
\]

\[
= \sqrt{\frac{a^2 x^2 - 4 a b x + 4 a b^2 + a^2 x}{a^2}}; \text{and of course} \quad S H = a \sqrt{\frac{a^2 x^2 - 4 a b x + 4 a b^2 + a^2 x}{a^2}}.
\]

Moreover, since \( S K = A H = \frac{1}{2} x \), \( \Pi K \); \( \sqrt{S K^2 - S H^2} = \sqrt{\frac{4 a x - a^3 - 4 a b x + 4 a b^2 + a^2 x}{4 a^2}} \)

\[
= \frac{b}{a} \sqrt{a x - a^3}; \text{therefore} \quad K = 2 \frac{b}{a} R \sqrt{a x - a^3}.
\]
\[ \frac{\sqrt{a x} - \sqrt{a x}}{a} = \text{area of the rectangle} \]

A \text{ P T B}. \text{ Let } P \text{ be the periphery of the circle } A I B, \text{ whose diameter is } x, \text{ then its area will be } \frac{\pi}{4} \cdot x^2, \text{ and we shall have } x^2 = \frac{1}{\pi} \cdot x^2 P, \text{ and } A B = \frac{x}{\pi} P = A Q R B + A I B; \text{ that is } q^2 = \frac{1}{4} q^2 \]

\[ \frac{1}{a} \sqrt{\frac{a x - a^2}{a}} = A I B. \text{ But if} \]

\[ 2 A I B = A I K B = A = \frac{b}{q} \sqrt{a x - a^2}; \text{ therefore,}
\]

substituting this value of \( A \), in the preceding expression, we have \( t = \frac{b}{q} \sqrt{a x - a^2}. \) Equate this value of \( t \), with that already given, then \( \frac{n x}{q} \sqrt{\frac{x}{q}} = \frac{b x}{q} \sqrt{a x - a^2}; \) which equation reduced, gives \( x = \frac{a f^3 P^3 q}{f^2 P^2 q - \alpha e^2 n^2} = A B, \text{ the major axis of the comet's elliptical trajectory.}
\]

If we substitute this value of \( x \), in the above equation, for \( t \) we shall have \( t = \frac{f^3 P^3 a^3}{q^2 P^2 q - \alpha e a^3} = \frac{1}{2} \) the periodical time. Also, because the conjugate \( K = \frac{2 b}{q} \sqrt{a x - a^2} = t, \) we have \( x = \frac{a f^3 P^3 q}{f^2 P^2 q - \alpha e^2 n^2} \) whence by reduction, we find \( e = \frac{2 b \alpha n}{\sqrt{f^2 P^2 q - \alpha e^2 n^2}} \), the minor axis of the orbit.

From these equations, it obviously appears, that when the velocity of the comet is such that \( f^3 P^3 q = a \alpha e^2 n^2, \) the axis \( x \) will be infinite, and consequently the trajectory will be a parabola; if \( a e^2 n^2 \) be greater than \( f^3 P^3 q, \) the direction of the axis will be on the other side of the curve, which will be an hyperbola; in either of which cases, the comet can never return: but in every instance where \( f^3 P^3 q \) is greater than \( a e^2 n^2, \) the comet will describe an ellipse amongst these

we may comprize the circle, where \( x = 2 a \alpha = \frac{a f^3 P^3 q}{f^2 P^2 q - \alpha e^2 n^2} \) and \( f^3 P^3 q = 2 a e^2 n^2, \) whence \( e = \frac{f^3 P^3 q}{2 a} \sqrt{\frac{f^2 P^2 q - \alpha e^2 n^2}{f^2 P^2 q}} \), the arc of the circle described in one day, or one hour, according as the value of \( e \) is given in days, or hours.

Let the earth be the planet we supposed to describe the ellipsis A N O; then its mean distance was 10,000,000, or \( q = 200,000, \) and \( P = 365 \times 318 \) and the periodical time \( n = \frac{1}{2} \); then if \( C \) be the portion of the comet's orbit described in one day, we have \( f = \frac{1}{365 \times 318} = 0.000273 \).

The other expressions will become as follow: for the principal axis \( x = \frac{\frac{30^1}{318} 650,033 \times a}{\frac{30^1}{318} 63,9033 \times a} = \frac{a}{2.3} \), and for the periodical time
\[ t = \frac{\text{arc}}{\text{time}} \]

It is extremely difficult to determine, from computation, the elliptic orbit of a comet, to any degree of accuracy; for when the orbit is very eccentric, a very small error in the observation will change the computed orbit into a parabola or hyperbola. Now, from the thinness and inactivity of the atmosphere with which the comet is surrounded, it is impossible to determine, with any great precision, when either

the limb or centre of the comet passes the wire at the time of observation. And this uncertainty in the observations will subject the computed orbit to a great error. Hence it happened, that M. Brouwer determined the orbit of the comet in 1749 to be an hyperbola. M. Euler first determined the same for the comet in 1744; but having received more accurate observations, he found it to be an ellipse. The period of the comet in 1665 appears, from observation, to be 57.5 years, which M. Euler, by his computation, determined to be 1664 years. The only safe way to get the period of comets, is to compare the elements of all those which have been computed, and where you and they agree very well, you may conclude that they are elements of the same comet; it being so extremely improbable that the orbits of two different comets should have the same inclination, the same perihelion distance, and the places of the perihelion and node of the same. Thus, knowing the periodical time, we get the major axis of the ellipse; and the perihelion distance being known, the minor axis will be known. When the elements of the orbits agree, the comets may be the same, although the periodical times should vary a little; as that may arise from the attraction of the bodies in our system, and which may also alter all the other elements a little. We have already observed, that the comet which appeared in 1759, had its periodical time increased considerably by the attraction of Jupiter and Saturn. This comet was seen in 1661, 1687, and 1731, all the elements agreeing, except a little variation of the periodical time. Dr. Halley suspected the comet in 1650, to have been the same which appeared in 1606, 531, and 44 years before Christ, when Julius Cesar was murdered; and that its period was five hundred and seventy-five years. Mr. Dunton, however, in the Phil. Trans. vol. xlvii., has endeavoured to shew from a MS. in Pembroke Hall Library, that the comet of 1106 could not be the same with that of 1685. But M. de la Lande adopts the opinion of Dr. Halley. He also conjectured, in the first edition of his Synopsis, without repeating it in the second edition, that the comet observed by Apian in 1532, was the same as that observed by Hevelius in 1661; if so, it ought to have returned in 1798 or 1799, but it has never been observed. The interval between the passages of the comet by the perihelion in 1532 and 1661 is 128 years. 8 days, 1 hour, 29 minutes, (32 of the years being bissextile) which, added to the time of the perihelion in 1661, together with 11.7 days, to reduce it from the Julian to the Gregorian file, would now put it out of the time of the next perihelion, to be April 27th, 11270. In the year 1759, Mr. M. Mechain having collected all the observations in 1752, and calculated the orbit again, found it to be sensibly different from that determined by Dr. Halley, which renders it very doubtful whether this was the comet which appeared in 1661; and this doubt is increased, by its not appearing in 1790. The comet in 1770, whose periodical time M. Lexell computed to be five years and seven months, has not been observed since. There can be no doubt but that the path of this comet, for the time it was observed, belonged to an orbit whose periodical time was that found by M. Lexell. As the computations for such an orbit agreed to very well with the observations, but the revolution was probably longer before 1770: for as the comet passed very near to Jupiter in 1770, its periodical time might be sensibly increased by the action of that planet; and as it has not been observed since, we may conjecture, with M. Lexell, that having passed in 1772 again into the sphere of sensible attraction of Jupiter, a new disturbing force might probably take place and destroy the effect of the other. According to the above elements, the comet would be in conjunction with Jupiter on August.
COMET.

August 25, 1770, and its distance from Jupiter would be only \( \frac{2}{7} \) of its distance from the sun, consequently the sun's action would be only \( \frac{2}{7} \) times that of Jupiter. What a change must this make in the orbit! If the comet returned to its perihelion in March 1776, it would then not be visible. See M. Lexell's account in the Phil. Trans. 1779.

The elements of the orbits of the comets in 1645 and 1756 were so nearly the same, that it is very probable that it was the same comet; if so, it ought to appear again about the year 1848.

Mr. Cole, in his "Theory of Comets," advances an hypothesis, which, in some cases, may perhaps, be accurate. He supposes that the orbit of a comet is not an ellipse; but that, when it passes its perihelion, it has acquired so great a velocity, that its centripetal force is overcome by its centrifugal, and that consequently the comet continues to fly off in a parabola or hyperbola, till it come within the attraction of some fixed star; that this attraction may give it a new direction, and increase its velocity till it come to an aphelion below that star, when it may again fly off either in a parabola or hyperbola, and proceed till it fall into the attraction of another star, and thus visit many different systems.

Dr. Halley has given us a table of the astronomical elements of twenty-four comets, on the supposition that they moved in parabolas; though he thought it extremely probable that they really moved in very eccentric ellipses, and consequently returned after long periods of time. This table commences with the year 1337, and closes with 1678. By means of this table, and others similar to it, it may be determined whenever a new comet shall appear, by comparing it therewith, whether it be one of those which have already appeared, and consequently its period and the axis of its orbit be ascertained, and its return foretold. See his Synopsis of the Astronomy of Comets, annexed to Gregory's Astronomy. This was first published in the Philosophical Transactions in 1705, and republished with his Astronomical Tables in 1749. M. de la Caille changed this table into another of a more convenient form, by putting the areas for the times.

Another table has since been computed, from the observations contained in the Philosophical Transactions, De la Caille's Astronomy, and De la Lande's Histoire de la Comete de 1759, and Connaissance des Muevements Celestes 1762 & 1764. In this table are seen the elements of twenty-five other comets, from the year 1264 to 1762. The most extensive table for calculating the motions of comets, was computed by M. de Lambert; it is inserted, as we have already mentioned, in Mr. Vince's Astronomy, vol. i.

Another table on an extensive scale, computed by Mr. Lex, an ingenious friend of the editor, an excellent astronomer, and an attentive observer of the heavens, is annexed to this article.

The number of comets that are flated in the most accurate accounts to have appeared, since the commencement of our era, is about 500; and before that era, about 100 others are recorded to have been seen, though it is probable that not more than half of them were comets.

The elements of the comet of 1770, and the trajectory of its path, may be found in the Transactions of the American Philosophical Society, vol. i.

In Whiston's Solar System, the orbits of several comets are delineated, and the periods of as many of them as were then known, expressed.

COMET, To determine the place and course of a. For this purpose, it will be advisable to take the apparent diameter very frequently; and a judgment may thus be formed of its relative distance at different times; its degree of motion, its brightness, &c. must also be regarded; for when it moves with the greatest velocity, or appears most bright, we may infer that it is near its perihelion. If the place of the comet can be observed when it has no latitude, the place and time of its being in one of its nodes will then be exactly known; but as this can seldom be actually observed, these elements are generally obtained by approximation from other observations. In order to obtain the proper course of a comet, observe its distance from two fixed stars, whose longitudes and latitudes are known; or, find its altitude when in the same azimuth with any two known fixed stars; from the distance or altitude thus found, calculate the place of the comet by trigonometry, after the manner delivered under Planet, or in the preceding article. By repeating the observations and operations for several days successively, the course of the comet will be had.

COMET, To determine the course of a, mechanically, and without any apparatus of instruments. The following ingenious method, by a thread, we owe to Longomontanus: Observe four stars round the comet, such, as that the comet may be in the intersection of the right lines that join the two opposite stars; which is easily found by means of a thread placed before the eye, and extended over against the stars and comet.

Suppose, v, gr. the comet's place in the heavens A (Pl. IV. Astronomia, fig. 36.) between the four stars, B, C, D, E; where the line joining the stars B and D, passes through the body of the comet; and the like does the line passing through C and E.

On a globe, whereon these four stars are found, extend a thread through B and D, and another through C and E; the point of intersection will give the place of the comet. This practice being repeated for several days, the comet's course will be had on the globe; which course will be found to be a great circle; if this great circle, drawn through three distant places, and drawing its path among the stars, be continued till it intersects the ecliptic, it will shew nearly the place of the node, and the inclination of the orbit to the ecliptic. The plane of the node and inclination of the orbit being thus found from several triplets of places independent of each other, a medium of the results may be considered as tolerably accurate.

COMET, to determine the parallax of a. See Parallax.

COMET, trajectory of a. See Trajectory.
The Elements of Ninety Seven Comets.

**Notes:**
- Halley's comet was named after Edmond Halley, an 18th-century English astronomer who predicted its return in 1758 after its previous appearance in 1682.
- The comet's orbit is elliptical and it travels around the Sun, sometimes passing close to Earth.

COMETARIUM.

On the subject of Comets, see Newton's Principia, lib. iii. Halley's Synopsis of Comets; Sisson Ellai fur les Cometes, 1755; M. Pingre's Cometographie, 2 vols. 1781; Sir H. Englefield's work "On the determination of the Orbits of Comets," M. Bode's General Considerations on the situations of the Orbits of all the Planets and Comets which have hitherto been calculated, in the Memoirs of the Academy of Sciences of Berlin; Dr. Gregory's Astronomy; O. Gregory's Treatise on Astronomy, 1803; De la Lande's, l'Academie des Cometes, 1759, and Astronomie, vol. iii; An Account of the Discoveries concerning Comets, with the way to find their Orbits, &c. by Mr. Wm. Herschel. Viz., Astronomy, &c. 1757.

COMETARIUM, or Cometarian, in Mechanics, is the name of a machine, contrived by Dr. Desaguliers, for the purpose of exhibiting and explaining the eccentric motion of a comet, agreeably to that law of planetary motion, by which equal areas are described by the radius vector in equal times. Dr. Martin has given an account of this machine, in his "Young Gentleman and Lady's Philosophy," and Mr. Ferguson has described it still more particularly in his "Astronomy," but as those authors have not given a perspective view of the parts of the machine, we have thought it necessary to give a new drawing, such as we conceive will render the mechanism clearly intelligible to every reader. In Plate I. of Planetary Machines, fig. 1, represents the cover of the cometarium, taken from the box which contains the wheel-work, and fig. 2, shews the box and its contents, with the exception of the cover, and one side, the latter of which is hinged to be removed, in order to disclose more fully the disposition of all the contained parts. A bin, fig. 2, is the bottom of the box, which supports the lower pivots of the three vertical arbors; C is a longitudinal bar inserted into the ends of the box, and bearing the upper pivots of the said arbors, as may be clearly seen in the figure; E is the handle put on the end of the horizontal arbor F, which arbor is pivoted into the front and back sides of the box; on this horizontal arbor, under the letter C, is an endless screw actuating the wheel G, with teeth not rounded but cut a little obliquely; the number of which teeth may be ascertained, to correspond to an aliquot part of a circle, suppose 720, in which case one tooth, or revolution of the handle, will correspond to 5°; at the inferior end of the arbor of wheel G, is fixed another wheel H, of the same number of teeth, that actuates a similar wheel I, on the second vertical arbor; so that these two wheels, H and I, also revolve each in 4° part of a circle, or 5°, at each revolution of the handle. Mr. Ferguson has placed the endless screw as in fig. 2. of Plate II., between the wheels H and I in such a way, as to impel them both in contrary directions at the same time, which construction is still more simple, as it dispenses altogether with the wheel G, and requires no rounding of the teeth; to the arbor of wheel I a solid plate K, in the form of an ellipse, is fixed at a point out of the centre, and has a groove round its edge to admit a cord to pass round it; and a second elliptic plate L, every way similar to plate K, is attached, at a point equally distant from the centre, to the third vertical arbor, but in such a way, that, when an endless cord is made to embrace the grooves of both, after crossing between them, the long radius of one is always directed towards the short radius of the other reciprocally, so that as the radius of plate K continues to lengthen in revolving half round, the radius of L continues to shorten, and vice versa during the other half of the revolution; this alteration of gradual lengthening and shortening of the radii, of the equably moving elliptic plate K, produces an alternate acceleration and retardation of motion in the plate L, such as corresponds with the equated motion of a heavenly body, describing equal areas in equal times; and the quantity of eccentricity given to the elliptic plates determines the quantity of the greatest equation in the orbit to be represented. Above the cross-bar CD is fixed an elliptic plate M, by two screws, seen in both the figures, round which the comet O is confined to move in its motion round N, the sun, which is a ball attached to the superior end of the arbor of the plate L of unequal motion; to the ball N, the arm or radius vector NO is attached, which therefore also moves with alternation, or receives with plate L; and as the comet O has liberty to slide along the radius vector, while a fluid under it penetrates the black elliptic groove, made in the cover round the plate M, the variation of distances is thereby effected as the comet is carried round: the point of the greatest distance, where the motion is slowest, is called the aphelion, from αφελς, from, and οψω, the sun, and the point of nearest distance, where the motion is quickest, is called the perihelion, from περί, round, and οψω, the sun. The two circles of signs, and also the graduated ellipse, are marked on the cover of the machine, and the arm G, in fig. 1, is placed on the equably moving arbor of wheel G, in fig. 2, so that when the arm G moves through the signs in the small circle, by equal areas in equal times, the arm NO movable round the point N, passes through corresponding unequal areas in the larger circle of signs, while the difference between the places of the two said arms shows the quantity of proportional, or equation in any situation in the large graduated circle, which is assumed to be parallel to the comet's motion. In order that the nature of the comet's motion may be the more apparent to the eye of a spectator, when referred to its own orbit, the small elliptic, beyond the darkened aperture that regulates the distances, is also divided into signs, but in such a way, that the angles subtended by each sign, when referred to the point N, or centre of motion, are unequal among themselves throughout each six successive signs, and if lines were drawn from each point where the comet is found at the end of each day or week, to the point N, they would include equal areas, or plane surfaces taken geometrically; in some of the machines indeed, those lines are actually drawn, and the separate triangular areas corresponding to each equadial period are painted alternately black and white, to render the doctrine of the celebrated Kepler still more evident to the eye. The principal objections to the construction of the machine before us is, that the comet O is apt to move by jerks in certain parts of the orbit, particularly when the eccentricity is great; and also the cord is liable to slip in some situations, without producing the corresponding motion in the elliptic plates K and L; the latter of which objections has been attempted to be obviated, by attaching forked pieces of metal to the plate of one of the elliptic plates near its end, and pins to the other, as in fig. 2. Plate II. to form a kind of teeth; but a better plan, and which has been adopted sometimes in practice, where the eccentricity is not very great, is to cut the elliptic plates themselves into toothed wheels, and to substitute for them the wheels H and I, in which case the cord may be dispensed with altogether, and the arm NO, we presume, will thus be less liable to jerks.—After all, however, this machine does not profess to represent the period of a revolution of any of the comets or planary bodies, but is intended merely to explain the law of their motion, which it will do in a very satisfactory manner, when well made; and it is easy to see, that, as the plate M may be fixed more or less out of the centre, such a change of distance
distances may be produced, as shall correspond to the changes of angular velocity; which is the chief difficulty to be overcome in the mechanical representation of the orbit.

New Cometarium by Mr. Jones.

Subsequently to our writing the preceding account of the cometarium, Mr. W. Jones, optician in Holborn, has favoured us with a drawing and description of a new construction of the cometarium, which he says is free from the jereks that we have stated as an objection to the plan of Dr. DeFageliers, and which, therefore, we lay before the public as nearly in the author's own words as our arrangement and observations on it will admit.

Fig. 1. of Plate II. of Planetary Machines is a representation of the external part of the machine, which is not confined to any particular dimensions, but has generally been made as follows; viz. A B C D is a mahogany box, about 12 inches long, 9 wide, and 4 1/2 deep, containing the wheeless that gives motion to the comet \( x \); the dark elliptical space is a groove representing the orbit of the comet, which is carried round in the direction of the alphabetical order of the letters. The point \( a \) is the perihelion, and the point \( g \) the aphelion; and the triangular spaces or areas, \( a S b, B S e, \&c. \) are all respectively equal to each other: in one turn of the handle \( N \), the comet \( x \) is moved over one of these areas; consequently, in the same time that it moves from \( f \) to \( g \) or from \( g \) to \( b \), it moves from \( m \) to \( a \), or from \( a \) to \( b \), and in like manner through each succeeding area, the quickest motion being at \( a \), and the slowest at \( g \); thus showing that the velocity of a comet in its orbit continually and gradually decreases from the perihelion \( a \) to the aphelion \( g \), and increases in the same proportion from the aphelion to the perihelion. The elliptical orbit is divided into twelve signs with their respective degrees, and in a similar manner is the circle no p a t, which represents a great circle in the heavens, and to which the motion of the comet is referred by the extremity of the wire \( W \), movable at \( S \), and actuated by the stem of the comet, which slides against it, in and out alternately, in its progress in the orbit. During the comet's motion in its orbit from \( f \) to \( g \), its apparent motion is only about five degrees in this circle, as pointed out by the end of the wire \( b \); but in the same time as the comet moves from \( m \) to \( a \), or from \( a \) to \( b \), it appears to describe the large angular space \( t a, o \) or \( n \) in the heavens, each of which arcs contains about \( 30^\circ \), or four signs; and if the eccentricity of the orbit be more or less greater, the greater would be the difference between the two extreme velocities. The figures 1, 2, 3, 4, \&c. to 12, represent a small comparative circular orbit, for shewing the equable motion of a body, supposed to move concentrically round the sun \( S \), and to describe equal arcs, as well as equal areas, 1 S 2, 2 S 3, \&c. in equal times with those of the comet \( x \) in its elliptic orbit before mentioned. Suppose now the bodies \( n \) and \( o \) to commence their motions at the same instant from the points \( a \) and \( i \), and to arrive at the same respective points again, after a revolution of each, at the same instant, it will be observed, during their progress, that the body \( n \) will be more forward than the body \( o \) in the first six signs from \( a \) to \( g \), but more backward in the next six signs from \( g \) to \( a \), and the difference between the places of the two bodies, in any part of the small or equable orbit, will be the equation of the centre in that particular part. At the points \( a \), 1, and \( g \), 7, the bodies are together, and consequently the equation vanishes, and from thence begins to take an opposite character, changing from plus to minus, and vice versâ at the respective points; also, the distance from the aphelion point, in the small orbit, is called the mean anomaly, reckoned in signs and degrees; and the distance from \( a \) in the large circle, reckoned in a similar manner, is called the true or equal anomaly. Thus the reason appears evident, why, in astronomical calculations taken from the tables of Dr. Halley, or La Lande, the grand equation of a body moving in an elliptical orbit is additive in the first six signs, and additive to the second six, with respect to the place anterior to an approximation of mean motion; and the same application of the grand equation, after some modification of its varying quantity, is used from the apex to the perigee, and back again from the perigee to the apex of the lunar orbit.

The mechanism, by means of which these motions are produced in the original cometarium, has been already explained above, from which that of Mr. Jones is very different, and is thus explained by him.

From the circumstance of its being considered as impracticable to obtain an easy and uniformly ready motion of a comet, by Dr. DeFageliers's mechanism, Mr. Jones has adopted the plan of using only one great wheel revolving on an arbor placed out of the centre, agreeably to the drawing exhibited in fig. 3, of Plate II. near the point \( I \), and under the cock attached to the plane of the wheel, by three visible screws. The different parts and action of the mechanism are these; \( A B \) represents the inside bottom of the box, seen in fig. 1, of the same plate; \( C D \) is an oblong piece of mahogany, fitted to as to slide easily but flexibly into the grooves of two parallel side-pieces of the frame wood, made fast to the bottom, and denoted by the letters \( E \) and \( F \); \( G \) is the large brass wheel, about five inches diameter, which we have said revolves on an eccentric arbor, near the point \( I \); over this point is placed the cock, or bent arm, \( H \), with an oblong slit through it, to receive the sliding piece \( a \), which piece supports the lower end of the frame that carries the comet \( X \) in fig. 1. \( K \) and \( L \) are two wheels pivoted above into a bridge \( P \), shaped like a crook, and have equal numbers of teeth, the latter of which wheels is actuated by the contrarate wheel \( M \), inserted on the axis \( B \), of the handle \( N \); on the same arbor with \( K \), and close under the bridge \( P \), is a small wheel (seen in the figure) that impels the large wheel \( G \), round its eccentric arbor; it will not perhaps appear evident to an ordinary mechanic, how the action of the small and large eccentric wheel is rendered continual, and the pitching of the teeth made good all round the great wheel, notwithstanding the constant changes of the distances from the eccentric point, which is the centre of its motion, and the successive points of its circumference; to effect this apparently difficult purpose, considerable ingenuity was necessary; by examining the crooks and rim of the large wheel, it will be seen, that the thicknees of the crooks, and of the teeth, is less than of the rim, so that the rim may be laid to have a circular edge-bar on its plane projecting upwards; this edge-bar is embraced by two rollers, the larger one moving round on the arbor of wheel \( K \), above the small wheel, and the smaller one carried by a cock \( O \), fall to the crooked bridge \( P \); so that, as the great wheel is urged round by the small one, these two rollers give motion to the sliding piece of wood \( C D \), alternately in and out, and consequently bring the teeth of the wheel borne by this sliding piece, into a proper depth to act with its small impelling wheel, in every part of the revolution of the former, which therefore acts as well, when the teeth are directed towards the centre of motion, as if the arbor had been in the centre of the wheel, and placed on a stationary bar. The wheel, however, has many more teeth coming successively into action during one half of its revolution, round the eccentric point of its motion, than it has during the other; and on this circumstance depends the variable velocity of the comet attached
to its arm I, as it regards the said centre of motion. We shall have occasion to shew, in another place, that the equation, produced by this cause only, would be just one half of the proper equation of the centre, or very nearly so, provided the fun were placed exactly over the centre of motion, or eccentric point of the wheel: it is also not difficult to shew, that if the wheel had no eccentric motion, but had the fun placed at a similar distance out of its centre of motion, one half of the due equation would also, in that case, be effected, supposing the circle of funs, point ed to by the wire, to be eccentric with regard to the wheel, and supposing the fun to be in its centre; now, in the instrument before us, these two causes operate together to produce the total equation due to the orbit, where the eccentricity of the wheel is to its radius, and also the eccentricity of the fun's position, at the opposite side of the wheel's centre, to the same, as the eccentricity of the comet is to the radius of its orbit. It must, however, be acknowledged, that the joint agency of the two said causes of the equation, supposes the sliding bar CD to be stationary, in which case the action of the wheels would be impeded; consequently, that part of the equation which depends on the fun's eccentric position, as it regards the wheel's arbor, is variable, and in some measure must determine the scale or equation. As it would have been, if the wheel's arbor had been stationary; the remedy for this small deviation from perfect accuracy in the scale of equations thus produced by the joint agency of three causes, is best effected by making the straight lines, that form the triangular areas, to correspond, not to a geometrical measurement, but to the actual turns of the handle, one of which will correspond to each triangular area, when the centre wheel M, and also the small wheel over K, have each one twelfth part of the number of teeth that the great wheel has, which wheel, in that case, may have any optional number that is divisible by twelve. When the centre of the large wheel lies exactly in a line joining the centre of motion H, and the arbor of K, the sliding board C D is the most pulled out, and the comet is at the aphelion A, fig. 1., moving slowly; but when the centre of the wheel's motion lies between the central point of it and of wheel K, then the comet is at the perihelion a, moving quickly. The cock y, in fig. 1., holds the elliptic plate, with the triangular areas marked on it, and bearing on it the fun, in such a situation, that the groove round its edge, in which the stem of the comet moves, limits the distance at all times of this body, as it respects the fun, which is done by making the sliding piece in fig. 3, move in or out in the slit of the arm 1, already described. Thus the jerks of the old cometarium are avoided, and all its apparent properties are preserved, except that a portion of the large graduated celestial circle is unavoidably concealed by the superior elliptic plate of triangular areas.

COMETITES, in Natural History, a name given by some writers to a kind of allrostes, which has flars much larger than those of the common kind, and therefore called comets.

COMEUS, in Mythology, a surname of Apollo, under which title he was worshipped at Seleucia, whence his statue was carried to Rome, and placed in the temple of Apollo Palatine.

COMETS, STONY, in Natural History, drop-flores or confets. These are flascles, broken into short pieces, somewhat resembling comets, and certain kinds of suggar-plums, and which in Italy and other places are sometimes put up in boxes and labelled, so as to deceive strangers at first sight, in supposing them to be real comets.

COMFLOENTA, in Ancient Geography, a town of Spain, in the Tarraconian territory, placed by Ptolemy in the country of the Arcavi.

COMFORT. POINT, in Geography, is the south eastern point of Elizabeth county, in Virginia, formed by James river, at its mouth in Chichapay bay; 19 miles W. by N. of Cape Henry.

COMFREY, or COMPHRY, in Botany. See Symphytum.

COMHOLA, in Geography, a river of Ireland, which runs into Bantry bay; 3 miles N. of Bantry.

COMI, in Ancient Geography, a people of Asia, in Bactria, faid by Ptolemy to have dwelled in the vicinity of the Chomari.

COMIDAVA, a town of Dacia, according to Ptolemy.

COMILLAH, in Geography, a town of Hindooistan, in the province of Bengal; 160 miles E. N. E. of Calculor, and 176 E. S. E. of Moorhredabad. N. lat. 23° 25'. E. long. 91° 15'.

COMIN and COMNOT, two small islands in the Mediterranean, lying between Malta and Gozo; the former supposed to be the Hephestia, or isle of Vulcan of the ancients. They were formerly uninhabited; but by the care of Vircnacourt, a fort having been built upon each of them for their safety, they have been since partly inhabited, and that of Comin, which is about 4 or 5 miles in circuit, breeds a large quantity of cattle. See MALTA.

COMINES, a town of Flandres, situated on the Lis, which divides it into two parts; formerly a considerable place, but reduced by war and various accidents; 25 miles S. of Brussels, and 7 N. of Lille.

COMINGE, in Military Language, a shell of uncommon magnitude, which takes its name from the person who invented it.

COMING-TO, in Sea Language, denotes the approach of a ship's head to the direction of the wind.

COMINNIUM, in Ancient Geography, a town of Italy in Samnium, which did not subsist in the time of Pliny.

COMIOLA, in Botany, a name given by some of the old Roman authors, to the plant commonly called Lutellia, or dyers' weed.

COMITATU commissio, in Law, a writ or commission, by which a sheriff is authorized to take upon him the charge of the county.

COMITATU et astro commissio, a writ by which the charge of a county, together with the keeping of a castle, is committed to the sheriff.
COMITATUS, in Law, a county. Inculphus tells us, that England was first divided into counties by king Alfred; and the counties into hundreds. and these again into tvythings; and Forte-Cuce writes, that regnum Anglie per comitatus, ut regnum Francie per bellavitnos, diftinguitur. Sometimes it is taken for a territory or jurisdiction of a particular place; as in Mat. Paris, anno 1234. See County.

COMITATUS, pp. 73. See Posses.

COMITIA, an assembly of the Roman people, either in the Comitium, or Campus Martius, i.e. Field of Mars; meeting for the election of magistrates, or for consulting on the important affairs of the republic.

The word comes from the verb cceo, or cemo, to go together.

There were certain days fixed for these assemblies, called dies comitiales; marked with a C in the calendar of Julius Cæsar. Comitial assemblies, held for the election of consuls, were called comitular comitia, in like manner, the other comitia took names from the officer to be created; whether a tribune, a pontiff, addie, or the like.

There were three kinds of these comitia: viz. curia, centuria, and tributa, so distinguished from the manner wherein the people voted, and gave their suffrages, viz. by curia or parishes, tribes, or centuries.

The power of calling these assemblies was vested in each of the chief magistrates, and sometimes to the foreign pontiff.

The authors make the difference between comitia curia and comitia curiata, to consist in this: that in the former the whole people were called together, in the latter only a part.

Comitia curiata. Romanus instituted the comitia curiata, or the public assemblies of the people, called to vote in their several curiae; and it is agreed by all that the matters subjected to their decision, were the choice of all the magistrates, and the right of making laws, war, and peace: an ample jurisdiction, comprehending the most important articles of government, yet not wholly absolute, according to Dionysius, unless the Senate were conjoined with them. This method of transacting all the greater affairs by the people, assembled in their curiae, after it had continued through five successive reigns, was found to be inconvenient.

Servius Tullius, the sixth king of Rome, in order to correct the inconvenience of the comitia curiata, instituted a new division of the people into six classes, according to a cenus, or valuation of their estates; whence proceed the comitia centuriata: then he subdivided these classes into one hundred and ninety-three centuries, and contrived to throw a majority of these centuries, that is, ninety-eight of them, into the first class of the richest citizens. By which regulation, though every man voted now in his century, as before, in his curia; yet, as all matters were decided by a majority of the centuries, so the balance of power was wholly transferred into the hands of the rich; and the poorer were deprived of their former weight and influence in the affairs of state: which wise institution was ever after observed, through all succeeding ages, in the elections of the principal magistrates, and the determination of all the principal transactons of the republic.

COMITIAL days. Paulus Manutius is of opinion, that there were certain days on which the Roman senate might regularly be assembled; and others on which it could not: and that these last were called comitial days, and marked under that name in the calendars, as days wholly defined, and set apart by law, for the assemblies of the people. But Sigerinus contends, that the senate might meet on any of those days, unless when the people were actually assembled, and transacting business on them; and consequently that the title of comitial denoted such days only, on which the people might be legally assembled, not such on which they were of course to be assembled. Middlet. of Rom. Senat. p. 138, fct.

The truth of the matter seems to be this, that though the days called comitial were regularly defined to the assemblies of the people, yet the senate also might not only be convened on the same, but the comitial assemblies were dissolved; but had the power likewise, whenever they found it expedient, to supercede and postpone the assemblies of the people to another day; and, by a particular decree, to authorize their own meetings upon them, for the dispatch of some important affair therein specified.

COMITIALIS morbus, in Medicine, an ancient term for the epilepsy, or falling sickness; so called, because if any person was feized with it in the Roman comitia, the assembly was immediately dissolved; this being esteemed an unholy omen; or, rather, because those liable to it were chiefly feized in the comitia, or great assemblies. See Eeplepsy.

COMITIUM, the place where the comitia were ordi-

narily held, which was a large hall in the Roman Forum: it was a long time open at top; on which account the assemblies were often interrupted by bad weather: it was first cov-

ered over in the time of the second Punic war. See Forum.

Rofinus observes, that the consuls and tribunes were not created in the comitium, but in the Campus Martius.

It was in this place that the rostra were placed. See Comitia.

COMITLAN, in Geography, a town of North America, in Mexico, and province of Chiapa.

COMITOLO, Paul, in Biography, one of the ablest of the society of Jesuits, acquired great reputation by his instructions in morality and theology at the commencement of the seventh century. He died in 1626, at the age of eighty years. His publications are "Catena illustrium authorum in Librum Job," translated from the Greek into the Latin language; — "Concia fei. responsa moralia;" "Defrinita de contractu univerello." Nouv. Dict. Hift.

COMMA, in Grammar, a point, or character, formed thus [ ]; serving to mark a short stop, or pause; and to divide the members of a period.

The word is formed from κόμμα, seco, I cut.

It is very difficult to fix the precise use of the comma; different authors define and use it differently: the ordinary doctrine is, that the comma serves to distinguish nouns, verbs, adverbs, and the several parts of a period that are not necessarily joined together. But this conveys no clear, precise idea; for what is it to distinguish the parts of a period not necessarily joined together? F. Buffier has carried the doctrine of the comma farther: according to him, the comma serves to distinguish those members of a period, in each whereof is a verb, and the nominative case of the verb. Thus, "That so many people are pleased with trifles is owing to a weakness of mind, which makes them love things easy to be comprehended."

Besides this, the comma is used to distinguish, in the same member of a period, several nouns sublittantive, or nouns adjectives, or verbs, not united by a conjunction. Thus, "Virtue, wit, knowledge, are the chief advantages of a man:" or, "A man never becomes learned without studying constantly, methodically, with a just application, &c."

If those words be united in the same phrase by a conjunction, the comma is omitted: thus, "The imagination and the judgment do not always agree." The comma may also be omitted between the phrases that are very short; especially
if they depend upon the same regimen, and are united by a conjunction: thus, "Alexander conquered Asia and established the monarchy of the Greeks."

The legumineous author of the tract "De Ratione Integrap-

1724. lays down the use or a comma to be, to dilate the

time in a period, or sentence; i.e. such as only contain of one subject, and one definite verb. Thus Cicero, "Neque neque ad volupates agricorum, quibus ego

credibiliter delictor. qua sic ut ilia impedimentum lente, & nihil ad lapsus vitam proxime accedere videtur," See Sentences.

But this rule does not go throughout; the same author

denouncing many particular cases, not included herein, where yet the comma is allowable.

Sometimes, e. g., a proposition includes another, which

may be called parenthetical, as being only a part of the entire

phrase: in which case, the two are to be divided from each

other by commas. Thus, "He always says, as he tells us,

the finest things in the world."

The points, or pauses in discourse, it is observed, are in a

kind of musical proportion: the comma marks the reader's

voice while he may privately tell one; the semi-colon, two;

the colon, three; and the period, or full-stop, four. Others

make the stop at the colon four: and the period fix.

Professor Ward observes, that the pause of the voice

should be twice as long for a comma, as between words separated by no mark of distinction; thrice for the semi-

colon; and so in the fame proportion. Bishop Lowth

subdivides the period a pause in duration double to the cola-

to the colon, double of the semi-colon; and to the semi-

colon, double of the comma: so that they are in the fame proportion to one another as the semibreve, the minim, the

crotchet, and the quaver in music. But whatever be the

duration of the several pauses, the proportion between them would be ever invariable, if the doctrine of punctuation

were exact. Intro. to English Grammar, ed. 1772.

p. 157.

The ancients only made use of two kinds of points, or

pauses, in a period; the larger they call members, the Greeks

 latina, marked thus [, ]; the smaller interius, the Greeks com-

ma, thus [, ].

The moderns, resuming on their predecessors, have subdi-

vided the first into a colon, and semi-colon; some lay, with-

out any good foundation in nature; though others maintain

the usefulness of the division.

As the member, or colon, divides the period into two parts,

each containing a fonce, though that imperfect: thus, "An-

tequam de republica, patres conscripti, dicas ea que dicenda

hoc tempore arbitratus," where the fonce does not resist, nor

is the period or sentence perfect, without the addition of

"e exploited vobis breviter & profectio & reverberationes

meas:" the comma subdivides each interval into intermediate
divisions, which, of themselves, have no precise meaning at all: e. g., "Nihil e. mihi credo, virtute formosum, nihil

pulchrum, nihil amabile." From these considerations, and on other occasions they promote perspicuity and dihincnclas, and cafe the reader, both in the
teachful and comprehension of his author; so, in oratory, are of especial use and effect; particularly where an adver-

tory is to be closely and pointedly attacked, upbraided, re-

prehended, wounded, &c. Witness that of Cicero against

Verres: "Non enim nos color urbe fervis, non pilos optime,

non dentes putridi deceptemur: osculum superificia, frons,
vulps denique totus, qui fera quidam tacitus mentis est,
hic in fraudem, homines impulsit: hic, eos, quibus crat

ignotus, deceptor, feclitus, in fraudem induxit: pauci tua ita

inutentia vitia novimus; pauci tarditatem inerzium, fluporem,
debilitatque linguam," &c. On the use of commas, see

Murray's English Grammar, ed. 8. p. 224, &c.

Comma, in Music. By this term, theoretic writers on

music have denominated several different small intervals in

the musical scale, which makes it necessary that we should

here enter rather minutely into the subject. We shall begin

with that very essential interval in almost all musical calcula-

tions which is for the most part implied by the word comma

without further addition, otherwise the

Comma Major, Greater Syntonic or Elementary of va-

rious writers, being also the schisma or schifma of Des Cartes,

Holden, and others. This interval seems first to have been

noticed by the Greek writers, as the quantity by which the

major tone $\left(\frac{1}{14}\right)$ exceeds the minor tone $\left(\frac{1}{15}\right)$; its ratio is $\frac{14}{13}$ and its value in the common or Briggs's

logarithms is .5944096811, or when reckoned down-

wards $\log_{10} \frac{14}{13} = 0.0532$, and in the logarithms of Euler

.07904; this last being, in fact, its decimal value, com-

pared with the octave $= 1$. This comma is usually marked

C, and is equal to $11.0078631$ times the schifma $\left(\frac{2}{3}\right) = 1.0078631$ times the kifer fraction $\left(\frac{2}{3}\right)$ = to

$1.10078631$ the comma fraction $\left(\frac{2}{3}\right) = 1.10078631$ the minute (m), and is to $= \frac{1}{12}$ the octave nearly.

It is equal to the sum of $11$ schismas and a minute, ($1 \times 11 + m$), or of a minor comma and a schifma: it also

refutes as the difference or remainder, after subtracting

the following intervals from each other, viz. a schifma from a dia-

chifma, a minor comma from an enharmonic schifma, a

semitone minor from a femitone medius, a femitone medius from an apotome, (here observing that $\frac{4}{13}$ is the apotome and not

$\frac{4}{12}$, erroneously printed in our article), an enharmonic schifma from a femitone minimum, a linna from a femitone

major, a femitone major from a femitone maximum, a femitone

subminimum from a femitone minor, &c. The comma major

is equal to the following additions of intervals, in triples, viz.

two schismas, a medius residual and a major residual; three

schismas, a minor residual and a major residual; five schismas, a

kifer fraction and a major residual; ten schismas, a kifer fraction and a greater fraction; ten schismas, three kifer frac-
tions and a medius fraction, &c. See these several articles.

The curious, and those concerned in these kinds of calcula-
tions, will find a great variety of other relations, in which

the comma major illands, to the musical intervals, both great

and small. in the elaborate manuscript treatises on music by

the late Marmaduke Overend, organist of Ilfracombe, and by the

late Dr. Boyce, which Dr. Callcott lately presented to the

library of the Royal Institution in Albemarle-street; after

kindly permitting the writer of this article to peruse and ex-

tract from them the use of this work. The ratio of

the major comma may be resolved into the component

primes $\frac{2}{3}, \frac{3}{4}, \frac{2}{3}$, and then, according to the method of

Mr. Fary in the Philosophical Magazine, vol. xxvii. p. 195,

(see our articles Musical Primes, and Tuneable Intervals)

can be resolved into factors $\frac{2}{3}, \frac{3}{4}, \frac{2}{3}$ or two fifths ($\frac{2}{5}$) reversed, a fourth ($\frac{2}{3}$) and a major sixth ($\frac{2}{3}$); whence it appears, that

the interval of a major comma can be tuned on an instrument,

having sufficient number of limbs or tones, by taking two

fifths downwards in succession, and thence upwards a major

sixth, and a minor fourth in succession, or $\frac{2}{3} + \frac{2}{3}$

where it is observable, that two Veas might have been tuned

upwards, and a V and 4th downwards, which would also

produce the interval of a major comma; but above the

fifths k key note, instead of below it, as in the first case,

where $\frac{2}{3} + \frac{2}{3}$ is a negative quantity, as well as all the

following. The fraction $\frac{2}{3}, \frac{3}{4}, \frac{2}{3}$ does not at first appear capable of division into any other tuneable ratios, than
than the above; but, if we multiply the same by \( \frac{1}{4} \), it will then be resolvable into the factors \( \frac{1}{4}, \frac{1}{4}, \frac{1}{4}, \frac{1}{4} \), and may be tuned thus: \( 2 \times 161 = 322 \). If we multiply \( \frac{3}{4} \) by \( \frac{1}{4} \), we can obtain 2 fourths \( - V - 3 \); or if by \( \frac{1}{2} \), we can get 2 fourths \( + 3 \); or if by \( \frac{3}{2} \), we may get 3 fourths \( - 6 \); or if by \( \frac{3}{2} \), we shall have 2 fourths \( + 161 \); and thus, we have six methods of exactly tuning a major comma, either above or below any given note, by help of perfect intervals only.

The method above explained, of analysing musical ratios or intervals, and expressing them in different ways, by the use of tuneable intervals only, is calculated to instruct the musical student, in the curious and important relations which the several concordant intervals bear to each other: hence we see, for instance, that if in any chant, or passage in a melody, to be performed by voices, by violin, or other perfect instruments, any one of the above six successions of notes were to occur, and the intervals were all to be performed perfectly, or without temperament in the melody, the conclusion would not be in the key-note, or that set out from, but a comma different in pitch, which property of the musical scale is called divergency of time, see that article.

It is observable, that all of the above six successions or passages in melody, which diverge a comma, contain two fifths or two fourths, each moving the same way, and to which the divergency seems attributable, when the comma is not counteracted by a proper succession of other commas. Mr. Maxwell in his "Reformed or Complete Diatonic Scales for the Organ and Violin," &c., in his "Essay on Tune," and so does Overend in his manuscripts, proposes to mark the rise of a comma by the acute accent ('), and the fall of the same comma by the grave accent ("), and that when either of these is required to be taken off, this mark (°) is to be used in the writing of music, in the same way as the musical mark of use, to take off or destroy the effect of a & or b, which has gone before, either accidentally, or in the figure of the staff. Mr. Maxwell adds, how a violin performer may practically tune a comma upon his instrument, in a variety of ways.

Modern writers on the temperament of the musical scale, usually refer their temperaments, or small corrections, to be applied to the concords, to this major comma as a unit or standard, on which account we shall present our readers with some further particulars relating to this small interval of the scale. Dr. Robert Smith, in his "Harmonics," Lemma to the 9th proposition, cor. 4, has demonstrated, that if any part or parts of a comma \( c \), denoted by \( \frac{c}{p} \), be the interval of imperfect unisons (or temperament), the radius of the times of their single vibrations will be \( 161 \times p - q \) to \( 161 \times p + q \), extremely near: for example, if we want a finite or approximate ratio for a \( \frac{1}{2} \) of a comma, we have \( q = \frac{1}{4} \), \( p = 4, \) and \( \frac{161 \times 4 - 1}{161 \times 4 + 1} = \frac{643}{645} \) is the ratio, the complement arithmetical of its logarithm being \( 1.2387 \), which is true to the last of 7 places of figures: in like manner, \( \frac{161 \times 3 - 1}{161 \times 3 + 1} = \frac{483}{484} \) or \( \frac{241}{242} \) is the ratio answering to \( \frac{3}{4} \), or \( \sqrt{\frac{80}{81}} \), which is also true to the last of 7 places in the logarithm, and is sufficiently accurate for all purposes: but it must be noticed that these are not composed of musical primes.

It may be of use here to inquire, what proportion the major comma, or ratio of \( \frac{80}{81} \), bears, to the hemitone or ratio of \( \frac{15}{16} \); for which purpose we have the logarithm of the latter divided by the logarithm of the former, or \( \frac{80}{81} \) is \( 5 \times 0.9528 \), the number of major commas in one hemitone (or H) nearly: and as it may be useful on many occasions for the student to know, how many major commas make up any interval, we have added a short table, shewing very exactly how many major commas make up the different concords within the octave, and also some of the smaller discords.

</tbody>
</table>

From the above table it appears, that the octave, whose ratio is \( \frac{1}{1} \), contains something more than \( \frac{55}{2} \) major commas, the VI a little more than \( \frac{41}{2} \) commas, &c. We shall next consider the

**Comma Minor, or Less,** of Rameau, Overend, &c., being also the apotome minor of Salomon de Caus, Boccius, &c., the diatetis of Euler, and the major dieis of Maxwell. This interval seems first to have been noticed by the Greek writers, as the quantity by which two semitones major \( 2 S = \left( \frac{15}{16} \times \frac{15}{16} \right) \) exceeded the tone major \( T = \left( \frac{8}{9} \right) \). Its ratio is \( \frac{2025}{2048} \), and its value in Briggs's logarithm \( \frac{0.95058057575}{10} \), which reckoned downwards, by its arithmetical complement, is \( \frac{0.94940924751}{10} \); and its value in Euler's logarithms is \( \frac{0.16295}{10} \). It is equal to \( 1.005863 \) times the sphiema of \( \frac{5}{4} \), and in \( 0.9009707 \), or nearly \( \frac{15}{8} \)ths of the major comma. It is equal to the sum of ten sfhemeas and one minute (\( 10 \times \frac{15}{8} ) \times \\text{minute} \). And it refutes as the difference when a sphiema is taken from a major comma, a sphiema from two major commas, two major commas from a semitone minimum, a major comma from an enharmonic sfhema, a semitone minor from a limma, an apotome from a semitone maximum, a semitone minimum from two enharmonic sphiemas, a semitone median from a semitone major, a lesser fraction from a prisma, two

Grammar," this Nicola - —

Comma, Greater, has erroneously been afo to the interval 125 = 21 Σ + 2 m, which is the Embemotonic Diesis; see that article.

Comma, Minimum, according to some former writers, expresses the ratio 32768 = Σ, which is now called the Schisma; see that article.

Comma, Ancient, according to Galileo, had a ratio of 625 = 32 Σ + 3 m, which is now called the Semitone Minimum, which see.

Comma of Phidias is the ratio of 32 9 , intended as an approximation for 7th part of a tone major, but which it exceeds considerably; besides, the fraction 32 9 is not composited of the small or musical primes 2, 3, and 5, and cannot therefore be admitted into musical computations.

Comma of Boëtius, according to Gareanum, also of D.
 Nicol was 4th part of the tone major, or 11 2 9 + 2 f + m, whereof 5 made their semitone majus or apotome, and 4 made their semitone minus or limma; this interval was ancienly supputed by fome to be the fame with the modern diaphisma (12 Σ + m), but from which it differs, 4 11 9 f = 2 2 9 , or nearly half a schisma.

The ancients mention another comma of the tone minor, or 11 5 8 + + 4 1 f + m. (See Dr. Caiellott's "Musical Grammar," pages 119 and 49.

Comma, Artificial, of Nicholas Mercator, is the 72 part of the octave, or 11 2 5 3 1 f + m. (See Mercator's "Temperament of the Musical Scale").

Comma of Mercurinus. According to Holder's "Treatise on Harmony," page 104, Mercurinus divided the octave into about 58 parts, and called one of these a comma.

Comma of Galileo. The interval 32441 32488 called a comma in the writings of this author, was intended to have been the diaphisma or 33 48 , as Mr. Overend has shown, vol. i. p. 140, of his MS, before referred to; the error originated in an erroneous multiplication, in the second figure of Galileo's numerator, by which it was rendered unfit for the musical scale. (See Sir John Hawkins Hist. Mus. vol. i. p. 321.)

Comma and half of Galileo, has a ratio of 32 5 = 32 Σ + 3 m, which is the Semitone minimum; see that article.

Comma and half of Rameau. This interval refers from the addition of a major comma and a major residual, and is also the difference between a semitone subminimum and a hyperbole; its ratio is 3225125 , its common logarithm is 27505, whence it appears, from the process before explained, that 3 3 = 111, or five minor thirds upwards, and four major thirds downwards, furnish a practical method of tuning this interval above any note, and the reverse of this process or 111 = 4 would tune the fame below any given note.

Comma, Semi. See Semi-Comma.

Comma Redundant, or Superfluous, or deficient, or diminished; these terms are applied to such intervals, whether concords or discords, as exceed or fall short of the true ratio of that interval by a major comma, as a comma redundant fifth, a comma deficient third, &e. Sometimes the term comma is omitted in naming these intervals, as a redundant fifth, a deficient third, &e. See Fifth, Third, &c.

Commagene, or Commagene, Commagene, in Ancient Geography, a country of Syria, bounded on the west by mount Amanus, on the north by part of mount Taurus, on the eill washed by the Euphrates; and with regard to its southern boundaries, it is uncertain whether it is contiguous to Seleucia, Cyrrheftica, or both. It is near the north corner of Syria. This country is mentioned by Strabo, Ptolemy, Pliny, and Asmianus Marcellinus, but they assign to it different extents. Its chief cities were Samosata upon the Euphrates, its capital, Antiocia ad Taurum, Germanica, Singa, Chaonia, and several other cities, once of great note, but long since utterly destroyed. In the time of Antiochus the Great, Commagene was subject to the Syrians, and left to him by the treaty of peace which he concluded with Rome, after the famous battle of Magnesia; and hence it is probable, that it was feized by some of the princes of the Seleucan family, during their intestine wars, as no mention of the kings of Commagene occurs till the time of Pompey, and the names of those, who afterwards reigned there, are altogether Syrian. The first that is mentioned is Antiochus, who joined with Darius king of Media, in opposing the entrance of Pompey into Syria, after the defeat of Tigranes; but, being overcome in battle, he submitted to the conqueror, and was not only confirmed in his kingdom, but rewarded with part of Mesopotamia. In the civil war between Cesar and Pompey, he sent large supplies to the latter. Antiochus having been put to death by order of Augustus, for the affaffination of the Roman ambafador, was succeeded by Mithridates, on whom Augustus beffowed the kingdom of Commagene, in recompence of his services during the war with Antony and Cleopatra. Upon the death of Mithridates, Antiochus II., the son of Antiochus I., was permitted by Augustus to take possession
fot of the kingdom. This prince died in the reign of
Tiberius; and Commegane became a Roman province, and
due to the requests of the nobles, it was governed by a praetor.
But Caligula restored the kingdom to Antiochus III.,
the son of Antiochus II., adding to it the maritime parts of
Cilicia. He was succeeded by his son Antiochus IV., fur-
named Epiphanes, who distinguished himself under Vep-
phanes in his war with the Jews, and particularly at the
siege of Jerusalem. Vepphanes, however, having reduced Com-
megane to the form of a Roman province, would not allow
any of the sons of Antiochus to succeed him. This coun-
try was afterwards made part of the province called Augu-
stophratensis, or as Amminus has it, Euphratensis, and
was commonly known by the name of Euphratensis.

COMMAND, in French Commandement, in Military
Language; the act or action of him who commands; a thing
commanded; the right of commanding and making one’s
self obeyed. The movements of a battalion at exercise, are
performed by the words which the major or commanding
officer pronounces. Hence, the word of command is a phrase
in common use among military people.

COMMANDER, or COMMANDY, the person who
commands an army, a brigade, a garrison, a fort, castle,
regiment, company, &c.

COMMANDNE, a rope made use of for boats and pon-
toos.

COMMANDER, is a name given to a large wooden
mallet used in a ship.

COMMANDERY. See Command.

COMMAND in front, in Fortification, a height, or an
eminence, which is directly opposite to, or faces the work,
that it commands.

COMMAND in rear, an eminence or a height, which is
directly behind the work that it commands.

COMMAND in flank, or by enfilade, a height or an
eminence on the flank, or prolongation of any part of a
work, which is calculated and built

COMMANDMENT, Fr. A commanding ground,
an eminence or elevation, which overlooks a post or strong
place. There are three sorts of commandements; namely
the commandement in front, which faces a work, and batters
or fires on it in front; the commandement en revers, or in
revers, which is behind a work or place, and fires on
its rear either directly or obliquely; and the commandement
de courtine or en enflade, which is on the flank of a work,
and fires along the whole extent of a rectilinear part of
it. Nine feet in perpendicular height, constitutes a simple
command or commandement; 18 feet a double one; 27 feet
a triple one; and so on.

COMMANDMENT, Order of, among the officers of
infantry and cavalry. In France it was customary in a place of war,
and every inclosed city, for the officers of infantry to have
the command over those of the cavalry, and on the other
hand to be commanded by them in the open field.

COMMANDER, Fr. The commander of an order
of knights. In some orders of chivalry it is the title,
which a professed knight takes the moment he pronounces
the vows, that subjected him to celibacy without his
ceasing on that account to be military. There are, how-
ever, in some orders of chivalry, that do not require ces-
bacy on the part of the commanders.

Commandeur, in Orphicology, the French name of
Orpheus Phoenicis, which see.

COMMANDMENTS, FRUDERICK, in Biography, was born
at Urbino, in Italy, 1709. He was descended from a noble
family, and celebrated for his great classical learning,
and for his extensive acquaintance with the mathematical
sciences. He was patronized by Francis Moria, duke of Urbino,
and by his liberality enabled to publish translations of
various parts of the works of Archimedes: the Conics of
Apollonius; the Elements of Euclid, and many other
works of high reputation. He was also author of a book
titled "De Cento Gravissim Solidauro." Bologna,
1565; and of another entitled, "Horologiorum Descriptio"
Rome, 1562. He died in 1575; a funeral oration was

COMMANDMENT, in a Legal Sense, has various
uses as, Commandment of the king, when on his own mere
motion, and from his own mouth, he calls a man into prifon.

Commandment of the justices, is either absolute or ordinary;
absolute, as when, on their own authority, and their own
discretion, they commit a man for contempt, &c. to prifon,
as a punishment. Ordinary, as when they commit him
rather for fact custody, than punishment.—A man committed
by an ordinary commandment is releivable. Persons
committed to prifon by the special command of the king
were not formerly bailable by the court of king's bench;
but at this day, the law is otherwise. 2. Hawk. P. C.
c. 15, § 36.

COMMANDMENT, is also used for the offence of him who
directs or wills another to transgress the law; as by murder,
thief, and the like. See Accessory.

H. that commandeth any one to do an unlawful act, is
accursory to it and all the consequences, if it be executed
in the same manner as commanded: but if the command
revoke the command; or if the execution varies from it, or
in the nature of the offence; in such case he will not be
accursory. 3 Infl. 51, 57, 2 Infl. 132.

In another sense of this word, magistrates may command
others to afflict them in the execution of their offices, for the
doing of justice; and so may a judge of peace, to suppress
riots, apprehend felons; or any officer to keep the king's
peace, &c. Bro. 3.

A master may command his servant to drive another
man's cattle out of his ground, to enter into lands, to
seize goods, to disturb for rent, or to do other things;
if the thing be not a trepsa to others. The command-
ment of a thing is good; where he that commands hath
power to do it; and a verbal command is in most cafes
sufficient; unless he be, where it is given by a corporation,
or when a sheriff's warrant is to a bailiff to arrest, &c.

In trepsa, &c. the master shall be accountable for the
act of the servant done by his command; but servants shall
not be excused for committing any crime, when they act
by command of their master, who have no authority to
give such commands. The commands of infants and feme
coverts are void; but in forcible entries, &c. an infant or
feme covert may be guilty in respect of actual violence done
by them in person.

COMMANDMENTS, Ten. See Decalogue.

COMMANDRY, or Commandery, a kind of benefice.
or fixed revenue belonging to a military order, and conferred on ancient knights, who had done considerable service to the order.

There are *field* or *regular* commanderies, obtained in order, and by merit: there are others of *grace or favour*, conferred at the pleasure of the grand master.

There are also commanderies for the religious in the orders of St. Bernard and St. Anthony.—The kings of France have converted several of the hospitals or lepers into commanderies of the order of St. Lazarus.

The commanderies of Malta are of different kinds; for as the order consists of knights, chaplains, and brother ferritors, there are peculiar commanderies, or revenues, attached to each.

The knight to whom one of these benefices or commanderies is given, is called commander; which agrees pretty nearly with the *præfectus fecer* over the monks in places at a distance from the monastery, whose administration was called *decemviri* because depending entirely on the abbot who gave him his commissiou. Thus it is with the simple commanders of Malta, who are rather farmers of the order than benefices; paying a certain tribute, or rent, called *rentesfeo*, to the common treasury of the order.

The commanderies belonging to the priory of St. John of Jerusalem in England, confining of monasteries, lands, &c., such was that of New Eagle in Lincolnshire, Selbich in Pembrokeshire, and Shengay in Cambridgeshire, were given to Henry VIII. by statute 52 Hen. VIII. c. 20; so that the name of commanderies only remains, the power being long since extinct.

**COMMANNI.** In *Geography*. See **COMENDO**.

**COMMIPULARIS.** In *Ancient Military Language*, a Roman folder, who could not ride but with his own centur, nor fight but under its standard.

**COMMANDOES.** In *Geography*, one of the small Virgin isles in the West Indies, situated to the N.E. of Tortola. N. lat. 19° 25'. W. long. 65°.

**COMMONTAWANA**, a bay on the north coast of the island of St. Vincent, about one mile east of Tarraty point.

**COMMARCHIO, in *Antiquity*, the confines of the land, whence probably is derived the word марчер. "Impranii de nonibus landiumci," *Du-Cange*. **COMMARODES, in Ancient Geography*, a place of Thrace, in the vicinity of Constanitнопол.

**COMMEATUS, in Military Language*, a passport or permission granted to a Roman soldier to absent himself from the army for a fixed or limited time. The same name was also given to soldiers' provisions and their efforts.

**COMMELENIA, in Botany**, *commenis*, Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Ency. 398. Ill. Wild. 1. Dill. Ethb. tab. 78. Sp. Gart. tab. 15. fig. 1. Lam. Ill. tab. 35. fig. 1. Koofeici. Kempi Jap. 288. t-ab. 389. 3. *C. polgaena*, Roth. Catlelet. Bot. 1. p. 1. "Leaves ovate-lanceolate, acute, *fem*m creeping, fmoth." *Reed annual*. *Stems* several, two feet long, jointed, branched, leafy. *Leaves* alternate, nervd, supported by a membranous sheath with short hairs at its edge. *Flowers* axillary, two or three together, on short peduncles; two of the petals blue, the third white. *Capsule* egg-shaped, slightly compressed on each side, somewhat two-edged, two-celled, two-valved; valves thin, membranous, with the longitudinal partition on their inner side. *Stems* two in each cell, adhered to the valves near the infirnation of the partition, two adhering to each valve, gibbous and pitted on one side, flat and furrowed, with a longitudinal line on the other, truncate at the end where they are opposite to each other, umbilicated. A native of North America, Africa, and Japan. *ß* differs only in having polygamous diandrous flowers. In all other respects it exactly corresponds with *C. communis*, of which it appears to be only a variety. Wild. 2. *C. africana*. Linn. Sp. Pl. 2. Mart. 2. Lam. 1. Ency. 398. Ill. Wild. 2. Gart. tab. 15. fig. 3. Lam. Ill. tab. 35. fig. 3. "Leaves lanceolate, smooth; *fem*m deciduous." *Root* perennial. *Stems* about a foot long, branched, smooth. *Leaves* narrower, with ciliated or bearded sheaths, and a smaller one within the other. *Flowers* with two petals; yellow, unciated and roundish, or kidney shaped; the third small, oval, soft, and attention. He completed the work begun by his uncle, which he published in 1701. His next production was "Flora Malabarica, seu Horti Malabarici Catalogus," serving as an index to the Hortus Malabaricus. This was followed by "Prauludia Anatomica," 410. 1703; and the same year, "Prauludia Botanica," with figures for the benefit of students in those arts. In 1715, he published, "Icones Plantarum, pretierim ex Indiis Collectarum," 410; and, in 1718, "Botanographia Malabarica, a NOMI- num Barbarismis reviltuta," Lugduni Bat. folio. All useful to students in botany, but serving rather to flay the great industry, than the genius of the writer. Haller. Bib. Botan. Elyx. Dcl. Hilt.

Obscr. Linnaceus considers the spathae as the only calyx, and attributes six petals to the flower; three small, femelab, remaining small, and three interior, very large, coloured.

* Two petals larger; one small.

**Petals nearly equal.**

hairy; flowers panicled.” Stem a foot high, furrowed, paneled at the top. Leaves alternate, flattening, acute, smooth; lower ones three inches long; upper ones about an inch. A native of Japan. 17. C. spirata. Linn. Mant. II. 1:6 Hort. Kew. 77. (C. bracteolata; Lam.) “Leaves lanceolate; flowers panicled.” Linn. Leaves lanceolate-linear, undulated. somewhat curled; peduncles panicled, furnished with small bractes, half-embracing the stem. Linn. Root annual. Stem stem, ascending, somewhat scabrous; Linn. Stem six or seven inches long, very slender, bent at the joints, almost smooth, leafy, branched; Linn. Laves lanceolate, flatting, very minutely ferrated; upper leaf cordate-lanceolate; sheaths ciliated at the edge. Linn. Leaves narrow; sheaths short, ciliated; Linn. Flowers small, blueish; Lam. Peduncle terminal, divaricated, with small flatting bractes; Linn. Lam. Peduncles capillary, compound; Lam. Calyx three-leafed; leaves ovate-lanceolate, concave; Lam. Petals three, equal, orbicular-egg-shaped; Linn. Petals three, egg shaped, a little longer than the calyx. Linn. Filaments of the filaments three, bearded, naked above the middle. Linn. Almost entirely naked. Lam. Filaments of the villosa three, somewhat ciliated at the sides. Corpuscles crenatum, g lobular in the tips, whitish; Linn. corpuscles yellow: Lam. Style and stigma spirally convoluted, and evolved variously; Linn. Style permanent, a little spirally twisted when the flower is past; Linn. Found by Koenig in moist ground, by the side of rivulets in the East Indies; communicated to La Marek from the East Indies by Sonnerat. La Marek seems to have no good reason to doubt the identity of his plant with that of Linnaeus.

Ost. It is evident from the above descriptions, that this genus, as it now stands, is a very anomalous one. C. alexandra, if it had needeed filaments, would unquestionably be a tradescantia. C. vaginata, nudiflora, and spirata, approach to this genus, by their partially bearded filaments, but differ in the number of filaments; the third two have the additional anomaly of being chandraous, without a correponding diminution in the number of the other parts. Lam. The species in his second Mantissa, seems to have forgotten, or to have discarded, his original idea with respect to the flower; for he attributes to it, not a five petalled corolla, but a three-petalled one, with a proper three-leaved calyx. Gartner is of opinion that commelinia and tradescantia are one truly natural genus.

COMMELINA axillaris et triflata. Linn. See Tradescantia.

Propogation and Culture. All the species are propagated by seed. If the seeds of C. communis, which is an annual, be sown upon a warm border of light earth in the autumn, they will come up early in the spring and ripen their fruit. The roots of C. africana send out offsets, by which the plant is easily propagated; but they will seldom live through the winter in the open air. The other species are tender, and must be sown in a moderate hot bed in the spring; transplanted to a fresh hot-bed, when they are two inches high; and in June, again transplanted into a warm border of light earth. C. tuberosa may be preferred; it planted in pots, and placed in the bank-love in autumn; or its roots may be taken out of the ground in the autumn, kept in a warm place during the winter, and planted again in the spring; they will then more forward and stronger if placed on a hotbed.

COMMENORATION, the remembrance of any one; or something done in honour of a person's memory.

Among the Romanists, it is a practice for dying person
the introduction to the printed narrative, dedicated by permission to the king, is the following.

"It was in the year 1783, that the idea of this great enterprise was conceived in a conversation between Lord Fitzwilliam, the late Sir Watkin Williams, and Josiah Daines, late commissioner of the victualling office, on observing how much more London abounded with great musicians, vocal and instrumental, foreigners and natives, than any other city in Europe: but so disparaged and despised at the opereos, oratories, theatres, and public and private concerts, that they can never be heard in the aggregate, nor can the effects which may be produced by such a united band as our capital could furnish, ever be known, unless some plan was formed of a public periodical occasion for collecting and confounding them into one band; by which means a performance might be exhibited on so grand and magnificent a scale as no other part of the world could equal. The birth and death of Handel naturally occurred to three such enthusiastic admirers of that great master, and it was immediately recollected, that the next (now the present) year, would be a proper time for the introduction of such a custom: as it formed a complete century since his birth, and an exact quarter of a century since his decease.

The plan was soon after communicated to the governors of the Musical Fund, who approved it, and promised their assistance. It was next submitted to the directors of the concert of Ancient Music, who, with an alacrity which does honour to their zeal for the memory of the great artist Handel, voluntarily undertook the trouble of managing and directing the celebrity. At length, the design coming to the knowledge of the king, it was honoured with his majesty's sanction and patronage. Westminster Abbey, where the bones of the great musician were deposited, was thought the proper place for the performance; and application having been made to the bishop of Rochester for the use of it, his lordship, finding that the scheme was honoured with the patronage of his majesty, readily consented; only requiring, as the performance would interfere with the annual benefit for the Westminster Infirmary, that part of the profits might be appropriated to that charity as an indemnification for the loss it would sustain.

To this the projectors of the plan acceded; and it was afterwards settled, that the profits of the first day's performance should be equally divided between the musical fund and the Westminster Infirmary; and those of the subsequent days be solely applied to the use of that fund which Handel himself so long helped to sustain, and to which he not only bequeathed a 1000l., but which almost every musician in the capital annually contributes his money, his performance, or both, to support.

Imperfect with a reverence for the memory of Handel, no sooner was the project known, but most of the practical musicians in the kingdom eagerly manifested their zeal for the enterprise; and many of the most eminent professed, waving all claims to precedence in the band, offered to perform in any subordinate station, in which their talents could be most useful.

"By the latter end of February, the plan and necessary arrangement were so far digested and advanced, that the directors ventured to infuse in all the newspapers, the following advertisement.

Under the Patronage of His Majesty,
In Commemoration of Handel, who was buried in Westminster Abbey, on the 21st of April, 1759.

On Wednesday the 21st of April next, will be performed in Westminster Abbey, under the management of the Earl of Exeter
Earl of Sandwich
Viscount Dudley Ward
Viscount Fitzwilliam
Right Hon. H. Morrice
Sir W. Williams Wynn, Bart.
Sir Richard Jebb, Bart.

Directors of the concert of Ancient Music;

Some of the most approved pieces of sacred music, of that great composer.
The doors will be opened at 9 o'clock, and the performance will begin precisely at twelve.

And on the evening of the same day, will be performed, at the Pantheon, a grand miscellaneous concert of vocal and instrumental music; consisting entirely of pieces selected from the works of Handel.
The doors will be opened at 6 o'clock, and the concert will begin exactly at eight.

And on Saturday morning, April 24th, will be performed, in Westminster Abbey, the sacred oratorio of the Messiah.

Such is the reverence for this illustrious master, that most of the performers in London, and a great many from different parts of the kingdom, have generously offered their assistance; and the orchestra will consist of at least 400 performers, a more numerous band than was ever known to be collected in any country, or on any occasion whatever. The profits arising from the performances, will be applied to charitable purposes.

In order to render the band as powerful and complete as possible, the trombone, fagott, or double corde, and double kettle drums, were sought and their name revived.

In preparing Westminster Abbey for the reception of their majesties and the royal family, as well as the archbishops and bishops, judges, great officers of state, and principal nobility and gentry in the kingdom, to the amount of three or four thousand, Mr. James Wyatt, the admirable architect of the ill-fated Pantheon, furnished the elegant drawings for the orchestra, throne, and galleries.

As this commemoration is not only the first instance of a band of such magnitude being assembled together, but of any band, at all numerous, performing in a similar situation, without the assistance of a manufactory, to regulate the measure, the performances in Westminster Abbey may be safely pronounced, no less remarkable for the multiplicity of voices and instruments employed, than for accuracy and precision. When all the wheels of that huge machine, the orchestra, were in motion, the effect resembled clock-work in every thing, but want of feeling and expression.

And, as the power of gravity and attraction in bodies are proportioned to their mass and density, so it seems as if the magnitude of this band had commanded and impelled adhesion and obedience, beyond that of any other of inferior force. The pulsations in every limb, and ramifications of veins and arteries in an animal, could not be more reciprocal, simultaneous, and under the regulation of the heart, than the members of this body of musicians under that of the conductor and leader. The totality of sound seemed to proceed from one voice, and one instrument; and the powers produced, not only new and exquisite sensations in judges, and lovers of the art, but were felt by those who never received pleasure from music before.

This celebration was at first designed to be extended to no more than two performances on the same day; one at noon in Westminster Abbey, for sacred music; and the other in the evening of the same day at the Pantheon, for secular compositions, selected from the operas and miscellaneous works of the hero whose apotheosis was the efficient cause of this extraordinary undertaking. But being counseled by his majesty, the directors of the concert of ancient music,
the governors of the musical fund, and eagerly recognized by the public in general, while the plan was digressing, it determined the projectors, at the instigation of his majesty, to have three performances. The first and third in the morning, at Westminster Abbey, and the second at the Pantheon.

These performances having given such entire satisfaction to all that were present, and becoming, of course, the general subject of discussion and praise, excited a great desire in all lovers of music, and even of splendid spectacles, who were absent, to be enabled to judge and speak of transactions so memorable, from the conviction of their own senses. But even these were not more eager in wishing there might be a repetition of the performances, than those who had already attended them. Luckily for all parties, the wishes of their majesties coincided with those of their subjects; and as the seafaring was still standing, and the band not yet dispersed, two more opportunities were given for the display of Handel's wonderful powers, and the gratification of public curiosity.

The fourth day was supplied with a well chosen selection of Handel's most grand and captivating compositions, from his oratorios and anthems; and on the fifth, that sublime production, the Messiah, was repeated; and though it had been performed in the Abbey but a week before, in so perfect and magnificent a manner, that no rehearsal, previous to its repetition, was necessary to the band; yet, to gratify the wishes of many timid and infirm lovers of music, who dreaded the crowd that was likely to be assembled at a public performance, as well as to raise money for charitable purposes, another rehearsal would certainly have been announced, if it had not been prevented from taking place by the celebration of his majesty's birth day, on which occasion there was a certainty that the chief part of the performers and company would be engaged.

Those who attended this day's commemoration at the Abbey were, seemingly, of a higher class than had yet appeared there; so that though the crowd was somewhat less than at the preceding performance of the same oratorio, the exhibition was more splendid. Indeed, as a spectacle, it was so magnificent to the sight, and, as a musical performance, so melifluous and grateful to the ear, that it will be difficult for the mind's eye of those who were absent, to form an adequate idea of the show, or the mental ear of the found, from description. Every one present must have found full employment for the two senses which afford us the most refined pleasure; as it is from the eye and the ear that intellect is fed, and the mind furnished with its best intelligence.

At the first performance of the Messiah, his majesty expressed a desire to the earl of Sandwich of hearing the most truly sublime of all oratorics, "Alleluia! for the Lord God omnipotent reigneth," a second time; and this graciously was conveyed to the orchestra, by the waving of his lordship's wand. At this second performance of that matchless oratorio, his majesty was pleased to make the signal himself, with a gentle motion of his right hand, in which was the printed book of the words, not only for the repetition of this, but of the final chorus, in the last part, to the great gratification of all his happy subjects present; and, perhaps, the subjects of no sovereign prince on the globe were ever before so delighted with the effects of a royal mandate.

Thus ended the fifth and last of the performances for this memorable celebration; and so great and perfect was the pleasure which the audience had received, that those who had attended all the five exhibitions seemed most to regret this final close.

The whole receipts at the five performances of this most splendid and magnificent celebration amounted to £1,378 12s. 10d. Of which, after all disbursements for building, band, and other incidental expenses, to the amount of 57 12s. 10d. 6000l. remained for the fund of the society of decayed musicians, and 1000l. for the Westminster hospital.

At the end of the printed account of the first year's Commemoration of Handel, is added in the Appendix, a "History of the Rise and Progress of the Fund for the Support of decayed Musicians and their Families, established in 1786," which has been since landedly imitated by other professions, and in other countries; and it appeared in 1784, after these performances, that by the great accession to the fund from the commemoration, its capital became a serious and weighty concern, amounting to upwards of 22,000l., in South-sea annuities and three per cent.; which realizes and ascertains an income of 675l. a year, exclusive of benefits or subcription.

The path therefore which the governors and court of affidants have now to pursue, is perfectly plain and pleasant; the power of alleviating distresses and misery, of feeding the hungry, clothing the naked, and administering comfort to age and infirmities, is placed in their hands, without the trouble of providing the means.

COMMEMORATION, in Ancient Geography, a river of Asia, according to Arrian, who says that it ran into the Indus.

COMMENDAM, in the Canon Law, the charge, trust, and administration of the revenues of a benefice, given to a layman to enjoy, by way of dotation, for the space of six months, in order to its being repaired, &c. or to another bishop, or ecclesiastic, to perform the pastoral offices thereof, till such time as the benefice is provided of a regular incumbent. See Benefice.

Anciently, the administration of vacant bishoprics belonged to the nearest neighbouring bishop; which continued to be practised between the archbishopric of Lyons, and the bishopric of Autun: on this account they were called commendation bishopps.

This custom appears to be very ancient: St. Athanasius says of himself, according to Nicephorus, that there had been given him in commendam, i.e. in administration, another church besides that of Alexandria, whereas he was flated bishop.

The care of churches, it seems, which had no pastor, was committed to a bishop, till they were provided with an ordinary: the rector of pope Gregory I. is full of these commissions, or commendam, granted during the absence or sickness of a bishop, or the vacancy of a see. Some say, that pope Leo IV. first set the modern commendams on foot, in favour of ecclesiastics who had been expelled their benefices by the Saracens; to whom the administration of the vacant churches was committed for a time, in expectation of their being restored: though St. Gregory is said also to have used the same, while the Lombards defolated Italy.

In a little time, the practice of commendams became exceedingly abused: and the revenues of monasteries were given to laymen for their subsistence. The bishops also procured several benefices, or even bishoprics, in commendam, which served for a pretext for holding them all without directly violating the canons. Part of the abuse has been repressed; but the use of commendams is still retained, as an expedient to take off the incompatibility of the person, by the nature of the benefice.

When
When a parson is made bishop, his parsonage becomes vacant; but if the king by special dispensation give him power to retain his benefice, notwithstanding his promotion, he shall continue parson, and is said to hold it in commendam; but this must be done before consecration, for afterwards it comes too late. Because the benefice is then absolutely void. There are several forts of commendations founded on the flat.

25 Hen. VIII. cap. 21. as a commendam sempiterna, which is for the benefit of the church, without any regard to the commendatory, being only a provisional act of the ordinary, for supplying the vacation of 6 months, in which time the patron is to present his clerk, and only implies a quoad maxima of the cure and fruits till the clerk is presented: commendam retinere, by means of which a bishop retains benefices on his preeminent, which has operated for a certain number of years or even as long as the commendatory lived, and continued bishop; and these commendations are granted on the king's mandate to the archbishop, expressing his consent, which continues the incumbency, so that there is no occasion for institution: a commendam recipere, which is to take a benefice de novo. in the bishop's own gift, or of some other patron, whose consent is obtained; and for life, when it is equal to a presentation, without institution, or induction. But all dispensations beyond 6 months were only permis in at first; and granted to persons of merit; the commendam retinere is for one or two years, &c. and sometimes for three or six years, and doth not alter the clait which the incumbent had before; and this, as long as the commendatory should live and continue bishop, hath been thought good. Vaugh. 18.

The commendam recipere must be for life, as other patron's and vicars enjoy their benefices: and as a patron cannot present to a full church, so neither can a commendam recipere be made to a church that is then full. Show. 414.

A benefice cannot be commended by parts, any more than it may be presented unto by parts; so that one shall have the glebe, another the tythes, &c. Nor can a commendatory have a juris urum, or take to him and his Successors, free or be freed, in a writ of annuity, &c. But a commendam perpetua may be admitted to do it. 11 Hen. IV. Compl. Incumb. 360. (See Nell. Abr. 454.)

These commendations are now in fact seldom or never granted to any but bishops; and in that case the bishop is made commendatory of the benefice while he continues bishop of such a diocese, as the object is to make an addition to a small bishopric; and it would be unreasonabable to grant it to a bishop for life, who might afterwards be translated to one of the vacant sees.

Commendam, in populi countries, is a real title of a regular benefice; as an abbey, or priory given by the pope to a secular cleric, or even to a layman, with power to dispose of the fruits thereof during his life.

No benefice that has a cure of souls, i.e. no parsonage, or bishopric, can be given in commendam. This practice being entirely contrary to the canons, none but the pope, who has a power of dispensing with the canons, can confer it.

When the commendam becomes vacant by the death of the commendatory, it is not deemed vacant by his death; but as it was before the commendam was granted: that making no alteration in the thing: yet the pope gives the same benefice in commendam again, by a privilege which he still continues.

By the pope's bulls, a commendatory abbots has the full authority of the regular abbots to whom he is sublubilated. For this reason, the bulls expressly require, that he be a priest; or, if he have not yet attained the age of priest-
Little Commento; the Dutch distinguish both by the name of Great and Little Commento. This kingdom produces but little rice; nevertheless, the values are no lef: fertile than agreeable, and the hills covered with wood, which affords a very delightful prospect. Behind Little Commento, the land rises by a gentle ascent into little hills, beautifully sheltered with woods of a perpetual verdure; and at the bottom are meadows and plains diversified with various kinds of fruit-trees. The natives are warfare, and so numerous, that in this little kingdom, the sovereign is able to raise an army of 25,000 men. His ordinary body-guard is composed of 500 stout fellows, well armed, redoubt, and loyal. It has been said that Commento abounds in gold mines, but that the king, for fear of exciting the avarice of the Europeans, prohibits the working of them. This country is divided into two distinct provinces. We shall content ourselves with describing Little Commento. This province is called by the Portuguese Aldea das Terras, and by the natives Ikkia Tekki. The town is said to contain at least 100 houses. It is situated on the banks of a fine rivulet, that empties itself into the sea on the southward, which forms a kind of canal, or little oblong harbour for canoes. The N.E. side of the town, where the French had formerly a settlement, is bordered by little hills, at the foot of which lie rich meadows and pastures, as well as fertile fields, every where interfered with groves of fruit-trees. Little Commento, which was once a place of great note, and one of the finest towns in Guinea, has since exhibited only the remains of a town destroyed by fire, and the well-peopled ruins of a once flourishing and great city. The natives of Little Commento are in general turbulent, cunning, and deceitful; much addicted to lying and cheating. Their employment consists either in fishing or in commerce, and their neighbours employ them as brokers and factors, particularly the people of Akamen, who carry on a considerable trade. Every morning 70 or 80 large canoes may be seen upon the coast fishing, or trading with the European shipping in the road. About the middle of the day they put to shore when the south-west winds begin to blow, both for facility of unloading, and for securing a market for their cargoes, either at Great or Little Commento, where the inland negroes affemble with the commodities of their principal countries. No markets on earth are better furnished with all sorts of grain, roots, fruits, olive, and fish, than these, nor at a more reasonable price. Here the English and Dutch have factories. Next to Cape Coast, the English fort is said to be the principal which they possess in Guinea, at least on the Gold Coast. The Dutch fort of Wodenburg, lies at the distance of a musket shot, and was built in the year 1688. N. lat. 4° 34'. E. long. 2° 34'.

The principal commodities for which there is a demand by the negroes of Commento, are ghosts beads, brass bells, and buttons, long linen cloths and woollen stuffs. They are very dextrous in the adulteration of gold, and the practice is very common. When the people of Commento are at war, they have usually a slave-market at Little Commento, for the more quick dispatch of their bufiness. Here also they keep quantities of gold in the hands of certain agents employed to carry on trade, while the rest are fighting the enemy in the field. The gold trade, however, is not very considerable.

COMMENDONE. GIANN Francesco, in Biographia, an eminent prelate in the church of Rome, was born at Venice in 1524, and began, at the early age of ten years, to compose verses. He pursued his studies at Padua, and in the year 1530, he was introduced to pope Julius III., by whom he was made chamberlain, and afterwards employed on public business. In 1553, he accompanied the legate cardinal Bardin to Flanders, and from thence he was dispatched secretly to England, to inquire into the state of religion under queen Mary. Paul IV., made him bishop of Zart, and commissioned him to excite the different states of Italy to unite with him in a common league. By Pius IV., he was raised to the office of cardinal in 1562, while he was nuncio in Poland. He was employed in various other missions to foreign states, and in all these he acted with zeal for his church, and executed whatever was committed to his charge with the utmost dispatch and fidelity. Under Gregory XIII., he was prosecuted by the imperial faction for having too great a partiality towards France; his own party was, however, so strong, that he was not only acquitted, but upon a dangerous illness of the pope, it was projected to raise him to the papal crown. The pope, by recovering his health, disappointed his expectations, and Commentone himself died at Padua, in December, 1564. He is not celebrated as an author, having left behind him only some Latin poems, among those of the Academy of Occulti, of which he was the zealous patron, and some letters inserted in the notes to those of Giulio Poggiarino. Commentone was reckoned one of the ablest politicians of his own time, a man of great learning, and a friend to literature. He cultivated an intimate friendship with many of the most eminent scholars in Italy, and to him were addressed some letters of Annibale Caro. Gen. Biog.

COMMENSURABLE Quantities, in Geometry, are such as have some common aliquot part, or which may be measured or divided without leaving a remainder, by some measure or divisor, called their common measure. Thus, a foot and a yard are commensurable; there being a third quantity which will measure each, viz. an inch; which taken 12 times makes a foot, and 36 times a yard.

Commensurables are to each other as one rational whole number to another. In incommensurables it is otherwise. The ratio of commensurables, therefore, is rational; that of incommensurables irrational: hence, also, the exponent of the ratio of commensurables is a rational number.

COMMENSURABLE Numbers, in Arithmetic, whether integers or fractions, are such as have some other number which will measure or divide them without any remainder. Thus, 6 and 8, both divided by 2, are respectively commensurable numbers; and 6 and 8, 2 and 4, and 3 and 6, are commensurable fractions, because the fraction 3/6 or 2/4 will measure them both; and in this sense all fractions may be said to be commensurable.

COMMENSURABLE in Power. Right lines are said to be commensurable in power, when their squares are measured by one and the same space, or superficies.

COMMENSURABLE Surds, are such surds as, being reduced to their least terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational: such are 3√2 and 2√3 being one to the other as 3 to 2. See Surd.

COMMENTACULA, among the Romans, therof the flamens carried in their hands when going to sacrifice.

COMMENTARIENSIS, in Ancient Military Language, the person who was gazer of the soldiers' prison among the Romans, and kept its regifiers. He was subject to the "triumpvri capitales".

COMMENTARY, or Comment, a gloss, or interpretation, affixed to some ancient, obscure, or difficult author, to render him more intelligible, or to supply what he has left undone. The biblical student may find some judicious and useful remarks on commentaries, or those who have written commentaries on the Sacred Scripture, in Mr. Locke's Pre-
C O M M E R C E.

The situation and circumstances of the Phoenicians naturally led them to look to commerce as the only source from which they could derive opulence or power; and accordingly, the foreign trade carried on by them, particularly from Sidon and Tyre, became more extensive and important than that of any state in the ancient world. Their ships not only frequented all the ports in the Mediterranean, but they were the first who ventured beyond the ancient boundaries of navigation, and passing the straits of Gibraltar, visited the western coasts of Spain and Africa. They revived a commercial intercourse with Arabia and the continent of India, on the one hand, and with the eastern coast of Africa on the other; the cargoes which they purchased in Arabia, Ethiopia, and India, being landed at Elath, the safest harbour in the Red Sea towards the north; thence they were carried by land to Rhinocolura, the distance not being very considerable, and, being re-shipped in that port, were transported to Tyre, and distributed over the world.

The wealth which the Phoenicians acquired by monopolizing the commerce of the Red Sea, invited their neighbours, the Jews, under the prosperous reigns of David and Solomon, to aim at being admitted to some share of it. Solomon fitted out fleets, which, navigated by Phenician pilots and mariners, sailed from the Red Sea to Tarshish and Ophir, from whence they brought back valuable cargoes as suddenly diffused wealth and splendour through the kingdom of Israel. But the inquisitions of the Jews were by no means favourable to commerce, which was never carried to any great extent by them while they inhabited Judea.

The Carthaginians applied themselves to commerce and navigation with ardour, ingenuity, and success; but as the Phoenicians had encroached the commerce of India, their adventures were chiefly made to the west and north. Following the course which the Phoenicians had opened, they extended their voyages beyond the shores of the Mediterranean, visiting not only all the coasts of Spain, but those of Gaul, and penetrating at last to Britain. They made voyages of discovery in different directions, and thus established a commercial intercourse with places which before were wholly unknown; but whatever knowledge of this kind they acquired, it was concealed from the inhabitants of other states with the utmost care.

The Greeks, although their country was almost encompassed by the sea, which formed many fricas bays and commodious harbours, and though it was surrounded by a number of fertile islands, were notwithstanding such a favourable situation, a long time before they attained any degree of perfection in navigation. They fearfully carried on any commerce beyond the limits of the Mediterranean. Their chief intercourse was with the colonies of their countrymen planted in the island Aila, in Italy, and in Sicily. They sometimes visited the ports of Egypt, of the southern provinces of Gaul, and of Thrace, or passing through the Hellespont, they traded with the countries situated around the Euxine sea. The expedition of Alexander into the east considerably enlarged the geographical knowledge of the Greeks. He had observed the resources which commerce creates, in the exertions of the republic of Tyre, and therefore it became part of his plan to render the empire which he proposed to establish, the centre of commerce as well as the seat of dominion. With this view, he founded Alexandria near one of the mouths of the Nile, that by the Mediterranean sea, and the neighbourhood of the Arabian gulf, it might command the trade both of the east and west. This situation was so judiciously chosen, that Alexandria soon became the chief commercial city in the world. Not only during the subsistence of the Grecian empire in Egypt and
in the east, but amid all the succeeding revolutions of those countries, commerce, particularly that of the East Indies, continued to flow in the channel which the facility and foresight of Alexander had marked out for it, till the discovery of the navigation by the Cape of Good Hope opened a more expeditious and independent channel to all the maritime states of Europe.

In the early periods of the Roman history, commerce appears to have been much neglected and undervalued; it seems to have been thought a degrading employ by this military people, and to have been left almost entirely in the hands of the natives of the countries they conquered. The extent, however, of the Roman power, which included the greatest part of the known world, the vigilant inspection of the Roman magistrates, and the spirit of the Roman government, no less intelligent than active, gave such additional security to commerce, as animated it with new vigour; and, as soon as the Romans acquired a taste for the productions of other countries, commerce, particularly the trade with India through Egypt, was pushed with new vigour, and carried on to a greater extent. The pilots who failed from Egypt to India first ventured to quit the shores of the sea, and depending wholly on the trade winds, boldly sailed from Ocelet at the mouth of the Arabian gulph, across the ocean, to the coast of Malabar, returning with the eastern monsoon, and thus procuring the spices and other rich commodities of the continent and islands of the farther India, which were brought to the port of Memfis by the Indians themselves.

The commerce thus carried on will appear considerable even in the present age, as the trade with India is said to have drained the Roman empire every year of more than four hundred thousand pounds, and that one hundred and twenty ships sailed annually from the Arabian gulph to that country. The reign of Augustus was very favourable to commerce, as the peace which then prevailed over the civilized parts of the world, enabled the merchants to pursue it unmolested. Under Tiberius we find the Romans extending their protection to the north, and the town of Haven, the most ancient in Frieland, founded. Under Nero, the capital of England is first mentioned as a considerable place.

Tacitus, who lived for some time at London, says it was famous for its many merchants, and plenty of its merchants. Rome, however, as the seat of wealth and luxury, continued to be the metropolis of the commercial world, until the fourth century, when Constantinople removed the seat of empire to Constantinople, and made it the emporium of commerce. This city was undoubtedly well adapted for that honour; it was favoured by nature with a fine climate, and in a most advantageous situation for carrying on an extensive correspondence with every part of the world then known.

The invasion by the northern nations in the fifth century, not merely arrested the progress of commerce, but effectually dissolved all commercial connections, and deprived the merchants of any market for their commodities. Europe became parcelled out into many small and independent states, differing from each other in language and customs; no intercourse subsisted between the members of those divided and hostile communities; their mode of life was simple, they had few wants to supply, and few superfluities to dabble of. Cities, in which alone an extensive commerce can be carried on, were few, incommodious, and destitute of those commodities which produce security or excite enterprise. It became disagreeable and dangerous to visit any foreign country, and thus the knowledge of remote regions was lost; their situation, their commodities, and almost their names, were unknown. The preservation of Constantinople from the general destruction, however, prevented commercial intercourse with distant nations from ceasing altogether. In that city the knowledge of ancient arts and discoveries was preserved; a taste for splendour and elegance subsisted; the productions of foreign countries were in request; and commerce continued to flourish there, when it was almost extinct in every other part of Europe. The merchants of Constantinople did not confine their trade to the islands of the Archipelago, or to the adjacent coasts of Asia; they took a wider range, and following the course which the ancients had marked out, imported the commodities of the East Indies from Alexandria. When Egypt was torn from the Roman empire by the Arabsians, the industry of the Greeks discovered a new channel, by which the productions of India might be conveyed to Constantinople. They were carried up the Indus, as far as that great river is navigable; thence they were transported by land to the banks of the river Oxus, and proceeded down its stream to the Caspian sea. There they entered the Volga, and falling up it, were carried by land to the Tanais, which conducted them into the Euxine sea, where vessels from Constantinople waited their arrival. This extraordinary and tedious mode of conveyance, Dr. Robertson observes, is a proof not only of the violent passion which the inhabitants of Constantinople had conceived for the luxuries of the east, and of the ardour and ingenuity with which they carried on commerce, but it demonstrates, that during the ignorance which reigned in the rest of Europe, a knowledge of remote countries was still preserved in the capital of the Greek empire. Robertson's Hist. Amer. vol. i.

The devastations of the Huns in Italy induced many of the richest inhabitants of the country near the bottom of the Adriatic, to fly with their belt effects into the numerous small sandy isles lying amongst the shallow waters near the shores of the continent; on which isles, about seventy-two in number, they built such habitations as their circumstances would admit; and here by degrees arose the celebrated commercial city of Venice. Necessity first obliged them to devote themselves to commerce, the earliest branch of which was naturally the fisheries. Their next commercial object was the manufacture and exportation of salt. Thus by the application of its inhabitants, and the security of its situation, Venice gradually became the general magazine for the merchandise of the neighbouring continent, to which the many rivers that fall into the Adriatic sea greatly contributed; and as the Venetians in time became the carriers of this merchandise into distant countries, they were enabled to bring back raw materials for various manufactures which greatly enlarged their commercial dealings. In this manner, Venice first, and Genoa, Florence, and Pisa afterward, from inconsiderable places became populous and wealthy cities, and laid the foundation for the revival of commerce throughout the Mediterranean, which, in process of time, was extended to the countries of Europe without the straights of Gibraltar. The chief cities of Italy, were, for several centuries, the only places in Europe, west of the Eastern or Greek empire, which had any considerable commerce, or any valuable manufactures for the supply of other nations. Their merchants frequented Aleppo, Tripoli, Alexandria, and other ports of Syria and Egypt, where they procured the produce of India; and visiting the maritime towns of Spain, France, the Low Countries, and England, by distributing their commodities over Europe, communicated to its various nations some taste for the valuable productions of the east, as well as some ideas of manufactures and arts, which were then unknown beyond the precincts of Italy.
COMMERC.

The first mention of the city of Antwerp, afterwards so famous for its trade, is in the year 517, when Theodoric expelled the Danes from it. Some towns in England, as Chichester and Abingdon, are said to have been founded about this time, which shews that trade and manufactures were gaining ground in this country.

The unsettled state of Europe, arising from the fierce and ruthless disposition of the barbarous tribes who had taken refuge in the west, commended for several centuries a great flagellation of commercial intercourse. Venice however continued to improve its commerce, and London became "a mart town of many nations, which repaired thither by sea and land." Some of the Italian cities began to assume a degree of independence, and several towns were founded in Germany and Flanders, which afterwards became of much commercial importance. The commerce of Europe revived a little under the government of Charlemagne, who, among other endeavours to promote it, is said to have formed a project for uniting the two great rivers of the Rhine and the Danube, and thus forming a communication between the German ocean and the Black sea, without falling up the Mediterranean. But his engineers had not sufficient skill to overcome the difficulties they met with, and the undertaking was soon relinquished. In a letter from this prince to Offa, king of Mercia, he grants leave for such English as went in pilgrimage to Rome, to pass through his dominions free; but such as travelled for the purposes of trade were to pay the customary tolls; and promises that the merchants should have legal patronage and redress of grievances. These merchants were probably persons who carried their whole stock with them, which of course could not be of any very great amount.

The establishment of Christianity in Germany produced a much more intimate and regular correspondence between the north of Europe, and the earlier Christianized countries of Italy, France, Spain, and Britain; so that their superfluities and produce were mutually communicated to each other, while Germany received by degrees, from its intercourse with those countries, considerable improvements with respect to agriculture, mining, vine-dressing, manufactures, and the arts, more immediately conducive to the comforts of civilized life. It considerably increased the cities and towns, where cathedral churches and houses for the bishops and clergy were erected. Thus the propagation of Christianity greatly favoured the advancement of commerce in the north of Europe; while Charlemagne by his conquest of Italy, and by rebuilding and restoring many of the decayed cities of that country, inspired those cities with the spirit of commerce, manufacture, and navigation, for which they became in after times so jolly famous. This period may be considered as the first dawn of the revival of commerce in Europe; for although subsequent to this time the Saracens or Moors, and the Normans, by their ravages and conquests in various parts, greatly obstructed and retarded its progress, yet in spite of all opposition, the free cities in both the extreme parts of Europe in consequence of the increase of their wealth and population from the encouragement of commerce, gradually rose to very considerable importance.

In the tenth century, the commercial intercourse which the Germans had previously cultivated with the neighbouring states was much increased by the discovery of valuable silver mines at Gollar in Saxony, which occasioned other parts of Germany to be explored for mines with considerable success. The woollen manufacture of Flanders began to acquire some degree of importance, being much encouraged by Baldwin, third earl of Flanders, who invited into the country all manner of handcraftsmen for making all sorts of manufactures, to whom he granted great privileges. He also established annual fairs, and fixed markets on stated days of the week at Bruges, Courtray, Tournuit, Mont-Caffel, and other places, where merchants could exchange their goods for others; for by reason of the facility of money at that time, the Flemings dealt mostly by permission, or barter of one kind of merchandise for another; which we read also was the practice of almost all the Germans and Saracens.

The republic of Venice had now acquired so much wealth and strength by the great extension of her commerce, as to have become a formidable political state, and having annexed to their dominions many cities and towns on the east coast of the Adriatic sea, the doge of Venice assumed the title of duke of Dalmatia. They established a regular commercial intercourse with the Saracens of Egypt and Syria, "countries ever famous for the production of rice, sugar, dates, fauna, cassia, flax, linen, balm, perfumes, galls, wrought silk, wool, &c. besides the rich spices and precious stones of India, brought to those two countries; with all this rich merchandise, the Venetians now traded all over the western parts of Europe, and their immense profit." They obtained from the Greek emperors a freedom from all customs and taxes in their empire; and in the year 696 the emperor Otho III., likewise granted them various privileges, with a right to set up fairs in several parts of Germany, where they carried on a vail commerce. The crusaders contributed materially to the extension of commerce during the 11th and 12th centuries. The Genoese, the Pisans, and the Venetians, furnished the transports necessary to carry the vail armies that embarked on the wild enterprises; they also supplied them with provisions and military stores. Besides the immense sums which they received on this account, they obtained commercial privileges and establishments of great consequence, in the settlements which the crusaders made inPalestine, and in other provinces of Asia. From these sources they acquired great wealth, and a proportionate increase of power. By the expeditions into Asia, the inhabitants of all the states of Europe had an opportunity of observing the manners, the arts, and the accommodations of people more polished than themselves. The adventurers who returned from Asia communicated to their countrymen the ideas which they had acquired, and the habits of life they had contracted by visiting more refined nations. The Europeans began to be sensible of wants with which they were formerly unacquainted; and such a taste for the commodities and arts of other countries gradually spread among them, that they not only encouraged the return of foreigners to their harbours, but began to perceive the advantage and necessity of applying to commerce themselves.

The great commercial progress of the city of Lubeck soon caused other towns to be founded in the neighbourhood of the Baltic; which, suffering much from the occasional attacks of neighbouring powers, and the depredations of pirates, were induced to enter into an association for their mutual safety, and the protection of their navigation. Thus was gradually formed the famous Hanseatic confederation, which made to great a figure in the commercial history of several succeeding centuries, and of which Lubeck was from the first considered as the director or head. Werdenhagen fixes on the year 1169 for the first of this confederacy, which consisted of the twelve following towns on the Baltic shore: viz. Lubeck, Wismar, Rostock, Stralsund, Grypewald, Anslam, Stettin, Colberg, Stolpe, Danzet, Ebing, U and
and Koningsberg: though probably not all of them at the first; as some of them do not appear to have been founded till a later period. Lambeceur, librarian to the emperor Leopold, is of opinion, that the Han-ligue did not properly commence till after the league between Lubec and Hamburg in 1241, at which time the town comprehended in this association were in possession of all the commerce of the four shores of the Baltic, from Denmark to the bottom of the Gulf of Finland, besides an extensive commerce to more distant parts. About this time the commerce of Norway began to acquire some degree of importance, and in a treaty between the monarch of that country and Henry III. of England, in 1217, it was agreed that their respective states should be free for merchants and others on both sides.

At the beginning of the 13th century, the German merchants of the Steel-yard engaged all the foreign commerce which then existed in England, at that time had very few merchants, and fewer ships of her own. About 1250, however, a society of English merchants was formed, who were laid to have had privileges granted to them in the Netherlands, by John duke of Brabant; whither they had begun to refort with English wool, lead, and tin, bringing in return fine woollen cloths, linen, and other articles. From this society, the company styled "Merchant of the Baptist," took its rise. In 1274, a treaty was concluded with the earl of Flanders for the settlement of some commercial disputes which existed between the two countries.

France at this period possessed very little foreign commerce, but in the cities of Italy it had increased greatly. The republic of Genoa was in its meridian glory, being the greatest maritime power then existing. Even Venice, great as it was now become, was eclipsed by Genoa, which, towards the conclusion of this century, had reduced the republic of Pisa, till then also powerful at sea, to the lowest ebb of fortune, never again to rise to greats, and soon to lose her independence.

A new era was now about to commence in commercial history. The discovery of that valuable, but now familiar instrument, the mariner's compass, Dr. Robertson observes, may be laid to have opened to man the dominion of the sea, and to have put him in full possession of the earth, by enabling him to visit every part of it. But the effects of this discovery were not so sudden or extensive as might be expected. The use of the compass enabled the Italians to perform the short voyages to which they were accustomed, with greater security and expedition, but near half a century elapsed, before navigators ventured into any seas which they had not been accustomed to frequent. One of the first fruits of such adventures, was the discovery of the Canary islands by the Spaniards.

Many of the princes of Europe were now becoming more sensible of the importance of commerce, which led them to enter into treaties for its regulation and defence. Edward I. in 1302 published his famous charter styled Charta Mercatoria, by which "The merchants of Almaine, France, Spain, Portugal, Navarre, Lombardy, Florence, Provence, Catalonia, Aquitaine, Thouline, Flanders, Brabant, and of all other foreign parts, who shall come to traffic in England, shall and may safely come with their merchandize into his cities, towns, and ports, and fell the fame, by wholesale only, as well to natives as to foreigners." Some particular articles they were allowed to sell by retail; and they were to export any goods they might want from England on paying the usual customs, except wine, which could not be exported without a special licence. The countries here mentioned shew the parts to which the commerce of England was at that time chiefly confined; and a very good idea of its extent may be gained from the following account of the exports and imports, in the 28th year of Edward III. from a record in the Exchequer.

Thus, as Sir William Temple observes, "when England had but a very small foreign commerce, we were rich in proportion to our neighbours, by selling so much more than we bought." It is not very probable, however, that the exports of the commerce was generally so great as is here stated.

The materials of commerce were now increasing by the improvement of manufactures in various parts of Europe; while the discoveries of the Portuguese on the coast of Africa, and in the adjacent seas, excited a more enterprising spirit of mercantile adventure, and at length, in 1497, led to the discovery of the Cape of Good Hope, which they doubled about ten years after, and thus accomplished the first regular voyage to the East Indies. About the same time also was accomplished the great discovery of the western continent. These events, which filled the world with astonishment, and gave rise to an infinity of new speculations, have since supplied it with a prodigious increase of wealth, and with many new and excellent materials for the immense additional commerce which has thus accrued to all the states of Europe.

The whole of the vast regions discovered in the East and West, was by the papal authority divided between the Spaniards and Portuguese. The former first made herself mistress of the islands, and next of the principal part of the continent of America; in consequence of which the cities of Seville and Cadiz became the store-houses for the riches of the newly-discovered western world. Portugal pursued her commerce and rapid conquests in the East Indies, so that
COMMERCE.

Lisbon soon became (what the now declining city of Venice had been for many centuries paid) the great magazine for all the rich productions of the East. They had also discovered Brazil in South America, which soon became an almost inexhaustible fund of wealth to Portugal, which may be said to have been then at the height of its commercial greatness.

In the course of the 16th century many circumstances occurred which contributed greatly to the extension of commerce. The English in the pursuit of a north-west passage to India had discovered the whole coast of North America, where, after some years, they began to attempt settlements. They engaged in the Newfoundland fishery, and also in the whale fishery at Spitsbergen or Greenland. The continual jealousies and disputes between the English merchants and the German Hanseatic merchants of the Steer yard in London, were at length terminated by the abolition of the peculiar privileges of the latter. The discovery of a passage to Russia round the north Cape of Lapland, opened a field for other new discoveries, and new branches of commerce, in consequence of which a company for trading to Russia was immediately formed and incorporated. The commerce with Turkey was encouraged by the incorporation of a company; and the intercourse with Guinea and other places on the coast of Africa, was at first thought of sufficient importance to have a company established for carrying it on.

While the importance of the Italian cities was declining, and the commerce of the towns on the Baltic experiencing some diminution, the cities of Hamburg and Antwerp had risen into considerable importance. The latter in particular, from the convenience of its situation, might for some time be considered as the centre of the commerce of Europe, as well for the merchandise of both the Indies, as for the naval stores and other bulky commodities of the northern states. It was however soon to find a rival among its industrious neighbours in the United Provinces, who, from the time of their independence, applied themselves to manufactures and commerce with the utmost avidity. France was at this time beginning to encourage the cultivation of the vine, and the improvement of her broad silk manufacture; while Spain, by expelling the Protestants from the Netherlands, supplied England, Holland, and the Hanse towns with great numbers of wealthy and industrious manufacturers and artizans, as well as with an accession of many ingenious and beneficial new manufactures.

The 17th century was the period in which the principles were adopted, and most of the establishments formed, which have contributed to advance the commerce of Europe to its present astonishing height. The interests of nations became better understood than in any former age; the utility of commerce had become evident to every one, from the wealth and power it had conferred on the states which had encouraged it; and commercial treaties became frequent between the different nations. Navigation was improved; new settlements were formed, and many of those before made were rising into importance; manufactures were advancing in many parts of Europe; shipping was increasing, and the intercourse between distant places, from the accumulation of knowledge and experience, becoming more expeditious and secure.

The lucrative commerce of the East became one of the leading objects of mercantile pursuit. An English East India company was formed in 1600; and the Dutch companies, which were united in 1602, became one of the most celebrated commercial establishments ever formed. The French visited the East Indies in 1601, but did not establish a regular company for carrying on the trade till 1664. The Danes established an East India company in 1617, and in 1612 the king of Sweden issued letters patent for forming an East India company, but it was not carried into execution till some years after. The Spaniards and Portuguese, however, at this period, possessed by far the greatest share of the commerce of India, which had now become very considerable. The following account published by Mr. Munn, in 1651, of the quantity of Indian merchandise consumed annually in Europe, gives a very good idea of the proportion of the different articles of this branch of commerce: the prices affixed are the prime cost in India, including all charges till actually shipped for Europe.

This statement was probably meant to include only the principal articles; at least it is certain that about 1651 several other kinds of merchandise were usually imported from India, as taffalics, painted callicoes, drugs of various sorts, and China ware. Tea, the great object of commercial intercourse with China, was either not yet an object of commerce, or was imported in such small quantities, that in England at least, in 1660, it was not thought of sufficient consequence to be subjected to a duty.

Dr. Davenant, who published his "Discourses on Trade" in 1698, was of opinion, that from about the year 1550 to 1688, England had every year gradually increased in riches; and that about the last mentioned year, the increase or addition to the wealth, and general flock of the nation, arising from foreign trade and home manufactures, was at least two millions per annum. In this estimate the different branches of trade are stated as follows:

- The plantation trade may bring in £ 600,000
- The East India trade may bring in 500,000
- The European, African, and Levant trade, by our own product may bring in 600,000
- Ditto, by re-exports of plantation goods 120,000
- Ditto, by re-exports of East India goods 180,000

Total 2,200,000

This account is probably somewhat beyond the truth, with respect to the period to which it refers; but that there had been a considerable influx of wealth, is shewn by the observations of the same author, that from the year 1600 to 1688, the general rent of England was nearly trebled, and the produce of land half doubled; that the flock of the kingdom was multiplied above five fold, and the money in circulation above four fold. This rapid advance in wealth, can be ascribed to no other cause than the improvement of commerce, which was now becoming of the utmost importance to all the European states, particularly to such as were deficient in maintaining any degree of naval power.

The increase of wealth arising from the extension of commerce, gave rise to the establishment of banks, by which its operations have of late years been so much facilitated. The commercial cities of Venice and Genoa had long experienced the utility of such institutions, which were now adopted in other places. The banks of Amsterdam, of

Hamburg,
Hamburg, and of Rotterdam were established; and in 1694, the bank of England, and the bank of Scotland. The business of private bankers likewise took its rise, and had become considerable, when it received a fever check from the injudicious conduct of Charles II. in seizing the money which the bankers had advanced on credit of the state. This branch of mercantile intercourse has however been since carried to an extent which in former times would have been deemed wholly incredible.

But with its principles generally understood, with most of the establishments formed which are necessary to facilitate its operations; with laws and treaties in force for its encouragement and protection; markets established for the purchase or sale of commodities in almost every part of the globe; navigation brought to a high degree of perfection, salt improvements in arts and manufactures; and a great increase of artificial wants from the progress of luxury and refinement, the commerce of the world, and particularly of Europe, has during the 18th century, expanded in an astonishing degree, and become intimately connected with the political existence of almost every state.

Commerce of Great Britain. The most authentic materials from which an idea can be formed of the progress and extent of the commerce of Great Britain, are the accounts kept in the office of the inspector-general of exports and imports, at the custom-houses of London. These accounts do not show the current value of the commodities exported or imported, but are formed from their quantities, according to certain rates of value, fixed to the several articles of foreign trade in 1696, by which they have been rated ever since. It is evident, therefore, that, as the price of all kinds of merchandise is subject to great fluctuations, and in general has much increased in this country within the last hundred years, these accounts are far from shewing the actual values in the later years; they are, however, from this very circumstance of being uniformly made up at the same rates, the better adapted to a comparative view, and shew a progressive increase which has arrived to an amount never before known in the commerce of any nation. According to these estimates the total amount of the exports and imports of Great Britain have been as follows:

At the conclusion of the war, by the peace of Utrecht, a commercial treaty with France was likewise negotiated; but when the particulars of it came to be discussed, two of the articles, by which the produce and manufactures of France were to be admitted into this country on the same terms as those of the most favoured nation, excited such general disapprobation, that the bill for carrying it into effect was rejected by the house of commons. The strongest objection to the principle of the treaty, was that it might ruin the trade then carried on with Portugal, which was considered as the most valuable branch of our European commerce.

It is evident, that from the year 1705, notwithstanding the disadvantages it always labourers under in time of war, commerce had been gradually increasing; but when peace enabled it to return to its natural channels, and restored some branches which had been considerably interrupted, its general advancement became more obvious, and although from the mode then chiefly adopted, of judging of the profits of commerce merely by the excess of the value of the exports, the balance appeared less than it had been in former years, the wealth which flowed into the country from foreign trade, being no longer absorbed in public wars, soon enabled the government to make a permanent reduction in the legal rate of interest. The war with Spain in 1710 did not cause much interruption of commercial intercourse, except in the direct trade with that country.

At this period the judicious principle of promoting the exportation of British manufactures, which had hitherto been applied only to woollen goods, was extended to British manufactures and produce in general; which were allowed to be exported duty free, except a few articles chiefly materials for manufactures, the exportation of which it would not have been proper to encourage; while drugs and other materials used for dyeing, were, upon being first duly entered, to be imported duty free, but upon re-exportation were to pay specific duties. For this highly beneficial regulation, so simple in its principle, and so comprehensive in its extent, the country was indebted to the enlightened wisdom of Mr. Walpole: the experiment excited much doubt and solicitude as to its success, but it soon appeared that the loss of revenue in the duties thus given up, was more than compensated for by the greater stimulus it gave to manufactures and the consequent extension of commerce.

The above period was almost wholly a time of peace, during which the commerce of Great Britain was gradually advancing.
advancing, both from the improvement of several of the existing branches, and the acquisition of new ones. The South-Sea company undertook the Greenland whale fishery, which had been entirely relinquished by this country for some years past; and encouragement was given to fisheries on the coast of America. Attempts were made to obtain a share of the fur trade of North America, which was almost entirely in the hands of the French. The Holland East India company, which had been found prejudicial to the English trade in that part of the world, was suppressed; and while our trade with China increased considerably, particularly in the article of tea. The trade of the Levant company was very flourishing; as was likewise that of the Hudson's bay company, though the latter was but of small extent. The produce of several valuable commodities was at the same time augmenting, from an increased cultivation of rice in the American colonies, and of coffee in the West India islands, while great quantities of corn were annually exported from Great Britain to France, Portugal, Spain, and Italy.

The war which began in 1739, was occasioned chiefly by disputes respecting our commerce in the West Indies, which had been much interrupted by the Spaniards. It caused, at first, some decline of foreign trade, which however soon regained the extent to which it had been carried during the preceding peace.

At this time, a much greater proportion of the exports consisted of unmanufactured produce than it has since; as it appears there had been exported from England in five years, from 1744 to 1748, no less than 3,768,444 quarters of corn, which at medium prices was worth 8,007,948 l.

That a considerable increase of commerce had taken place, is evident from the quantity of shipping employed. The total tonnage of vessels that cleared outward on an average of three years preceding the war, had been 503,568 tons; the average of the three years, ending with 1751, was 661,184 tons. The encouragement of the fisheries, and the regulation of the Guinea or African trade, which had been in the hands of an exclusive company, but was now in a great measure laid open; caused some extension of foreign trade, although the Levant, or Turkey trade, which had been considered as one of the most valuable branches, was beginning to decline rapidly, from the French improving the natural advantages they possessed for a trade with those parts.

It is evident that commerce had not been very materially affected by the war. The years 1755 and 1756 marked the lowest point of its depression; whence it gradually rose, till it had regained a superiority over the unexplored traffic of 1750, a year of established peace and security.

By the peace of 1763, although many islands which had been taken in the West Indies were restored, Great Britain retained a number of newly acquired islands, perhaps more than could be immediately brought into cultivation with advantage. The arrangements respecting Africa were very favorable to the East India company, and in Africa an exclusive trade was secured in the article of gum Senegal, a material indispensably necessary to the perfection of many of our manufactures. The immediate consequence, however, of the acquisition of additional territories, was, that a wide field was opened for speculation and commercial enterprise, which caused much productive capital to be withdrawn from the trade and manufactures of Great Britain; yet our merchants were not only able to maintain their own credit, but also to affix their correspondents during the commercial embarrassments in Holland and other parts of the continent.

In 1765, the principles and measures which were adopted which soon involved the country in disputes with its American colonies. The violent restrictions were laid on a beneficial intercourse which had long subsisted between the British colonies and the Spanish West India settlements; which being soon followed by other causes of discontent, drove the Americans into public resolutions to make no further importations from Great Britain, but such as were unavailing necessary, and to encourage, to the utmost of their power, every kind of manufacture that was practicable among themselves. This step was taken by Great Britain; the merchants connected with America found themselves unable to fulfill their engagements by the copious ships now imported from the country; the whole list of their business was destroyed, and general distress spread through the whole of their relations; the manufacturers suffered by the want of regular payments from the merchants, while their materials, and made up goods, to an alarming amount, were becoming a dead stock upon their hands; in consequence of which, great numbers of workmen were thrown out of employ. Petitions were presented to parliament from all the trading and manufacturing towns, which probably had some effect in procuring a temporary adjournment of the dispute.

The non-importation agreement in America, was renewed in 1769 and 1770; yet the commerce of Great Britain, notwithstanding these interruptions of an important branch of its trade, continued to increase; and previous to the war which followed, had attained to a greater extent than in any former years.

1770
The prohibition of all trade intercourse with the American colonies excited serious alarms, not only on account of the loss of a valuable branch of trade, but from the supposed encouragement which the acquisition of it would give to the trade of those powers who afflicted the colonies. These apprehensions, however, in a few years appeared to be in a great measure groundless, many British manufacturers found their way to America, though not imported directly from hence; and Mr. Chalmers observes, that "there was an evident tendency in our traffic to rise in 1779, till the Spanish war imposed an additional burthen. There was a similar tendency in 1780, till the Dutch war added, in 1781, no inconconsiderable weight. And the year 1781, accordingly, marks the lowest degree of depredation, both of our navigation and our commerce, of our colonies. But with the same vigorous spirit, they both equally rose, in 1782, as they had risen in former wars, to a superiority over our navigation and commerce, during the year wherein hostilities with France began."

The opportunity of renewing the commercial connections between this country and America, from the conclusion of peace, was eagerly embraced; but subsequent experience proved, that a greater degree of caution had now become necessary to render it a beneficial trade. The arrangements relative to the commerce of Ireland, had a very beneficial effect in that country, which had hitherto been excluded from almost every species of commerce, and restrained from sending the produce of her own soil to foreign markets. The convention with Spain settled more accurately the limits within which British subjects were allowed to cut lumber on the Musquito coast, and consequently gave greater certainty and security to the trade with those parts. The commercial treaty with France, by discontinuing many of the prohibitions and prohibitory duties which had existed for almost a century between the two nations, opened a wide field for speculation and adventure. The confederation of the customs by the abatement of all the confused and complex duties which then existed, and the substitution of a single duty on each article in their stead, was a measure of great convenience to all persons engaged in mercantile transactions. Under all these circumstances, supported by the improvements which had taken place in several of the principal manufactures, the foreign trade of Great Britain increased greatly during the peace, and in the year 1792, had attained to an unparalleled height, both in point of value, and with respect to quantity of shipping employed in it.

The total number of vessels which belonged to the several ports of the British empire on the 30th September 1792, was 16,577; the amount of our merchant marine 4,543,143 tons; and the number of men and boys usually employed in navigating them 718,285. The number of vessels that entered inward at the several ports of Great Britain (including their repeated voyages) was as follows:

At this period, the commerce of Great Britain, was generally admitted to be in a very flourishing state. The application and improvement of machinery in almost every branch of manufacture, had reduced the charges of workmanship so far, as to enable our manufacturers to supply foreign markets on better terms than any other country could offer; while the increase of capital, arising from the accumulation of the profits of successful commerce during a period of peace, gave our merchants the means of allowing longer credit than could be obtained elsewhere. The high price of the public funds, led many persons to employ their money in discounting private securities, which greatly facilitated the extension of commercial credit, but probably tempted some to trade much beyond the amount which their capital justified, or to speculate largely without any real property of their own; so that when the apprehension of war produced a greater degree of caution, and began to affect particular branches of trade, many were involved in embarrassments; and on the commencement of the war in 1793, commercial concerns, in general, experienced a serious shock. The assistance afforded by government to such houses as appeared to be really solvent, by lending them exchequer bills for a certain time, operated very successfully, and averted the confidences that were apprehended; credit revived, and as the war in its progress almost annihilated the foreign trade of some of the powers engaged in it, the commerce of Great Britain received a considerable augmentation; and, protected by its naval superiority, continued to increase, notwithstanding all the measures which political animosity could devise to obstruct or destroy it.
The increase during the above period, though really very great, was not however equal to what it would appear from the above accounts to have been. This irregularity in the comparative view of the accounts of imports and exports generally furnishes with sufficient accuracy, of the commerce of Great Britain, arises from the article of coffee, the import of which was formerly little more than sufficient to supply its small consumption in the country. But the interruption of the trade of France, the conquest of their West India islands, and the greatly increased cultivation of coffee in Jamaica, caused nearly the whole supply of the continent with this commodity to depend during the war on Great Britain. In the inspector-general's book of rates, coffee is valued on importation at 7l. and on exportation, at no less than 14l. 10s. per cwt.; while, during the above period, the real average value was about 5l. per cwt. when imported, and 8l. 10s. when exported. The official account, therefore, from 1794, when coffee suddenly became a very considerable article of exportation, requires some correction; and if the un-estimated value of this article is deducted, the exports of the year 1803 will appear to have been 38,120,120l., and of 1804, 37,786,356l.

The short interval of peace in 1802, produced an immediate extension of foreign trade; and Mr. Addington thought himself justified "in pronouncing the commerce of the country to be in a state of unrivalled and unexampled prosperity." The value of British manufactures exported, considerably exceeded the preceding year, and the total amount of the exports, according to the official values, was 46,126,620l. But in this and the succeeding years, it will be proper to adopt the correction just mentioned, which will give the amount of the imports and exports as follows:

<table>
<thead>
<tr>
<th>Years</th>

</tbody>
</table>

The account of imports for the last year is not quite correct; the imports from the East Indies for that year being incomplete.

Almost every article being greatly under-valued in these accounts (except in one or two instances) the total must give a very inadequate idea of the real extent of the commerce of Great Britain. Some idea may be formed of the under-valuation of the imports by those of the East India company, taking the account of their fàles as the importation; the medium value of which, on an average of three years, was 6,100,000l.; whereas, the medium value by the accounts of the inspector-general, for the same three years, was 4,574,000l. Of the actual value of British produce and manufactures exported, which usually constitutes about two-thirds of the total export, we have more correct information. By an act passed in 1798, and revived in 1802, called the convoy act, the exporters were required to declare the real value of British manufactures exported, in order to ascertain the amount of duty chargeable thereon; and from these declarations, the actual value of British produce and manufactures exported has been ascertained as follows:

Considerable endeavours have been made to improve the manufactures of Ireland, but with little success, except in the linen manufacture, which probably proceeds from the want of sufficient capital, and from the facility with which British manufactures can be procured at a very small additional expense; the latter will, therefore, for a long time, continue to constitute a large proportion of the imports of Ireland.

The trade between Great Britain and Russia has been considered highly beneficial to both countries; to Russia in point of profit, and to Great Britain, as supplying articles essential to the support of its navy. The capital employed must be much greater than formerly, from the increased value of the principal articles; and the balance of trade, which is consider-
In favour of Russia, is paid by means of the commercial
transactions between Great Britain and other countries.
The articles imported are iron, hemp, flax, tallow, pat-ashes,
deals, and lath-wood, coarse linens, hog's bristles, &c.
The exports are principally broad-cloths and woolen stuffs,
refined sugar, cotton, lead, tin, iron and felt ware, earthen
ware and glafs, coals, alum, latt, horeses, London porters, with
articles of left importance.

Sweden, in the year 1806, was 333, of which 187 were Brit-
ish ships; the total number which cleared outwards was
363, of which 142 were British.

The imports from Prussia, consist of all kinds of grain,
hemp, flax, madder, linseed, goose-quills, bristles, pear-
stakes, mill-flours, and timber of various descriptions. The
exports are chiefly alum, copperas, coal, beer, salt, wrought
brails and iron, lead, tin plate, earthenware, glasses, woollen
and cotton goods, fome cotton yarn, India goods, raw and
refined sugar, drugs, dye-juices, pepper and other spices,
coffee, rum, tobacco, &c.

The total number of vessels which entered from
Prussia in the year 1805 was 1,946, of which 37 were Brit-
ish ships; the total number which cleared outwards was
1,657, of which only 482 were British. In 1806 the total
numbers were much less, in consequence of Prussia being
involved in the war.

The trade with Germany had not experienced any con-
siderable variation with respect to its extent, from the com-
mencement of the last century, till on the extension of the
war with France in 1794, it suddenly became the channel
through which the principal part of the continent received
the goods they had before obtained direct from Great Brit-
ain. The following account of exports to Germany shows
the rapid increase of trade with that country during the
war.

The total number of vessels which entered inwards from
Holland in the year 1804 was 709, and the number which
cleared outwards 521. The number which entered inwards
in 1805 was 709; outwards 323; which, from the two
countries being at war, were of course nearly all neutral
vessels.

France possess fuch natural advantages in the produce of
its soil, and the convenience of its situation for procuring the
commodities of all other countries, that while its manufac-
tures
COMMERCE.

The trade with Portugal was formerly a very beneficial branch of our commerce, but has declined very much. The imports consist chiefly of wine, cotton-wool, and indigo, with considerable sums in cash and bullion. The exports are almost wholly British produce and manufactures.

The total number of vessels which entered inwards from Portugal in the year 1800 was 340, of which 270 were British vessels. The number which entered inwards in the year 1801 was 468; outwards 332.

The extent of the trade with Spain, previous to the war in 1796, will appear from the statement of imports and exports.

The year 1806 being a year of war, the trade with Spain was of course confined to neutral vessels: the number which entered inwards was 222, and the number which cleared outwards 126.

The Mediterranean trade was subject to much interruption during the war which began in 1793, in consequence of which many of the goods usually imported from Venice and Italy were brought over-land through Switzerland and Germany to Hamburg and Tonnningen to be shipped for England. The Turkey and Levant trade was formerly one of the principal branches of English commerce, but it is now of much less importance. The chief articles imported, are cotton-wool, mohair, goats' hair, opium, fennel, and other drugs, palls, madder, valonca, and other dye-stuffs, currants, figs, raisins, goat skins, and box-wood; raw silk was formerly a principal article, but very little is now brought from Turkey, that of Italy being much superior. The exports consist of lead, tin-plates, wrought and cast iron, hardware, a considerable number of watches, some cotton goods, and a few woolen goods, India piece goods, coffee, sugar, cinnamon, cloves, pimento, and other spices. The extent of the different branches of the Mediterranean trade will appear from the following statements.

Vol. IX.
being principally intended for the purchase of slaves for the West Indies. They consisted of sugar, coffee, spirits of wine, coffee, press, guns and cutlasses, gunpowder, wrought brass, copper and iron, glass, cotton, hemp, rice, gr. cereals, specchecaries' ware, woollen, cotton, and linen goods, and large quantities of India piece goods. The total official value in the year 1800 was 4,017,357 l. 11s. 5d. of which 51,052 l. 19s. 11d. was British merchandise. The abolition of the infamous traffic in human beings, must cause a great revolution in the trade to this part of the world, as it appeared in the year 1786 that about 38,000 of the inhabitants of Africa were annually carried away in British ships for supplying the colonies with slaves, which of course employed a considerable number of vessels. The number of ships that cleared out from Great Britain for Africa, in the year 1801, was 176.

The East India trade furnishes a remarkable instance of the advantage of a branch of commerce carried on facetiously in the hands of an exclusive company, while most other commercial monopolies have made very small profits, and generally soon expired. The trade to India, however, since the immense territorial acquisitions of the English in that part, can no longer be considered as a mere commercial adventure, as it is now in a great measure a business of agency, for transacting in Europe the fortunes acquired by British individuals in the East. The quantity of merchandise brought from thence, consequently greatly, exceeds the value of the exports to India. The latter consists chiefly of woollens, metals, and naval and military stores; the remaining articles being of trifling amount in comparison, and almost wholly for the use of Europeans, as the natives are peculiarly attached to the use of their own produce and manufactures.

The exports to China include a considerable amount in bullion, the other articles are woolen cloths and camblets, lead, and tin; the articles exported in private trade are, cotton and flax, of various descriptions, jewellery, toys, and watches, cuttings of cloth, a very few woollens, some cutters, and hard ware, and silver. The amount of the company's exports to India and China, will appear from the following statements.

The imports from the East Indies consist of Bengal piece goods, coast and Surat piece goods, Bengal and China raw silk, tea, pepper, saltpetre, mahanen cloth, china, wrought silks, a small quantity of china ware, sugar, coffee, indigo, and various drugs. The total amount of the imports, on the company's account, and in private trade, according to the official rates of the inspector-general's office, was as follows:

<table>
<thead>
<tr>

But a more accurate idea of the real value of the imports from the East Indies, may be formed from the annual amount of the company's sales, which was

In 1801   £7,392,181
In 1802   £6,629,347
In 1803   £6,856,373

The East India trade is, in some respects, the most important branch of the commerce of Great Britain; as on the colonial produce which it supplies, much of the trade with different parts of Europe chiefly depends. The value of the British East India produce from the island islands, imported into Great Britain, is a medium of four years, preceding the 5th of January 1796, according to the current prices during that period, was estimated, exclusive of the duties, at about 6,800,000/. per annum. This sum is not wholly a return for goods exported, a part of it must be considered as remittances of the property of persons who posses titles in the East Indies, but who are wholly or occasionally resident in England; and of persons who have lent money on mortgage or otherwise in the East Indies, and receive their interest from the sale of the produce.

The total number of vessels which entered inwards from the West Indies, in the year 1804, was 721, containing 294,411 tons, and navigated by 1,119 seamen. The number of vessels which cleared outwards was 792. The value of British produce and manufactures exported to the British plantations in the West Indies, exclusive of the Conquered Islands, was £3,408,232.

The trade with the United States of America, has rapidly advanced to very considerable importance; and Great Britain now supplies them with commodities to a far greater amount, than in the most favourable years previous to their independence, although the number of British ships employed is considerably less. In the year 1789 the number of British vessels which entered inwards in this trade was 253, the number outwards 35; but in the year 1799, the number which entered inwards was only 42, the number outwards 57.

The total number of vessels which entered from the United States, in the year 1806, was 561, of which 33 were British; the total number which cleared outwards was 575, of which only 39 were British.

The remaining possessions of Britain in North America, being countries not very fertile or fully inhabited, the trade with them is not of very great extent. The following statement of the exports to those parts in the year 1809, will, however, show the trade is well worth preserving, independent of the consideration that it is the means of procuring articles of much importance to other branches of commerce.

With respect to the general balance of trade, or the ultimate profit which Great Britain derives from its commerce with all other countries, M. Living, the inspector-general of imports and exports, to whom the public have, for many years, been indebted for the judicious arrangement and explanation of the official documents relating to foreign trade, has justly remarked, that there are perhaps few questions to which the human attention can be directed more difficult to form an opinion upon, from the variety of considerations, and the various statements with which it is connected, and also from the materials on which conclusions are to be formed, being in some instances defective; he has, however, stated it as his opinion, that the balance of trade in favour of Great Britain, according to the true value of the goods exported and imported, amounted on a medium of the four years preceding 1798, to upwards of £650,000 per annum, exclusive of the profit derived from the East and West India trades, which he estimated at upwards of £450,000 per annum; and exclusive of the profits derived from the fisheries.

An accurate view of the progress and extent of commerce in all the European states, would furnish much information; but with respect to several, no authentic particulars of this kind have been made public, and the foreign trade of others has been so entirely turned out of its usual channels since the commencement of the war of the French revolution, that any account of its present state would be very incomplete and unsatisfactory.

With respect to domestic commerce, we may observe, that the king is the author of it; as it pertains to his prerogative to exhibit public acts, as markets and fairs, to regulate weights and measures, and to give money, which is the universal medium of commerce, authority and currency.

A great part of the foreign commerce of England is now carried on by collective companies: some incorporated by the king’s charters, with an exclusive privilege, as the East India company; others only private associations, as the Turkey and Hamburg companies. See Company.

COMMERCIA, Chambers f. Sce Chamber.

COMMERCIA, Characters in. See Character.

COMMERCIO, in Geography, a handsome town of France, and chief place of a district in the department of Meuse, on the western shore of that river. E. long. 5° 24' N. lat. 48° 29'. It has a sub prefet, and counts 3518 inhabitants. The district contains 181 communes, with a population of 73,123 individuals. There are several iron forges, paper mills, glue, and iron, and linen manufacturers. See BARKING.

COMMERCIO, in Botany. Somnus. See BARKING.

Gen. Ch. Cal. one-leafed, five-cleft, bearing the petals between the segments; segments egg-shaped, acute, larger and broader than the petals. Cor. Petals five, dilated at the base on each side, with an inflexed lobe, spreading. Stem. Filaments very short, setulose at the bale of the petals; anthers roundish, dilated. Nectary a five-cleft ring, between the petals and the germ, with five filiform villous small bodies between the divisions; divisions lanceolate, crested, shorter than the petals. Pyl. Germ superior, globular, villous, with five projections; styles five, filiform, approximating. Ber. Per. Capsule roundish, hard, ciliate with long soft bristle-shaped hairs, five-celled; two seeds in each cell. Seeds egg-shaped.

Sp. C. echinata. Linn. jun. Supp. 26. Mart. Linn. Gl. tab. 94. Lam. III. tab. 218. (Rehbtaria; Rumphi. Amb. 3. 167; tab. 119) A middle fixed tree. Trunk rarely the bulk of a man, with a diffuse head and smooth bark, easily separable from the wood; young branches woolly. Leaves alternate, petiolo, obliquely egg-shaped, acuminate, serrated, a little wrinkled, shining, dark green above
above, hoary underneath. *Flowers* very small, white, in axillary panicles. *Calyx* somewhat globular, with a coriaceous ciliate rind, five-locular, five-valved; cocii inversely egg-shaped, narrowing downwards, semilunar from the back, two-valved; valves of the contiguous cocii united and forming the proper partitions of the calyx. *Seeds* two in each cell, attached to the central angle of the cells, ovate-oblong, a little thicker upwards, slightly compressed, of a red-berruginous colour, blackish at the top, incompletely arilled; aril membranous, very thin, whitish, incised, fixed to the umbilicus of the seed, covering its hilum central, but not its dorsal part. *Gent.* A native of Othothe, the Friendly Isles, and the Moluccas.

A tree. *Leaves* alternate, lanceolate, quite entire, smooth, recurved. *Flowers* in axillary and terminal catkins. A native of Cochin-China. A white gum exudes abundant from its bark, which is sometimes used as a medicine in dropsies and obstructions, but is too violent in its effects to be taken without great caution.

**COMMINATORY,** a chafe infested in a law, edit, patent, &c. importing a punishment wherefor delinquents are menaced; which, however, is not to be executed in its rigour.

Thus, in France, when an exile is enjoined not to return on pain of death, it is deemed a comminatory penalty; hence, if he do return, it is not strictly executed; but a second injunction is then laid on him, which is more than comminatory, and from the day of the date thereof, imports death without remedy.

**COMMINES, PHILIP DE,** in Biography, a celebrated his- torian, was born of a noble family in Flanders in 1445. He spent the early part of his life in the court of Charles the Bold, duke of Burgundy; but in 1472 he went over to the service of Louis XI. king of France, who adopted him as a favourite, and employed him in various important negociations. He married an heiress of the house of Anjou, by whom he acquired considerable landed property. He accompanied his sovereign in many of his journeis and in some expeditions of a more fierce nature; and he attended upon his successor Charles VIII. to the conquest of Naples. Under this prince he was accused of having defrauded the excheque of the duke of Orleans, for which he was arrested, and imprisoned in an iron cage for eight months. He was afterwards transferred to a prison at Paris, where he was eighteen months without being able to obtain a trial. Commines was at length honourably acquitted, but it does not appear that, either in the remainder of this reign, or in that of the duke of Orleans who succeeded, and for whom he had suffered, he was afterwards publicly employed. He died at his seat of Argenton, in Poitou, of which he had been nominated the lord. Commines possessed various qualities well adapted to render him eminent as a statesman. He had a fine pen, and an excellent understanding: he was a complete master of many modern languages, and had so great a command of his own powers that he could dictate to four secretaries at once. As a literary character he is chiefly known for his "Memoirs," which contain an account of the principal events of the reigns of Louis XI. and Charles VIII. during a period of thirty-four years. This work is highly esteemed as an account of the personal knowledge and observation of the author, who united a sincere and candid disposition, with a simple and unaffected style. By the learned Lopitius, Commines is regarded as equal to the historians of antiquity; his "Memoirs" he recommends as the vade mecum of princes. They have gone through many editions, which have been illustrated with notes by different learned men; but the most esteemed impression is that of the abbé Lenglet du Plessy, 1747, in 4 vol. 4to, printed at Paris, with London in the title page. Nouv. Dict. Hist. Du Plessy.

**COMMININGES, in Geography,** (in Latin *Commines*,) was before the French revolution of 1789, a county in the province of Gascony, and forms now part of the department of Haute-Garonne in France.

**COMMINUTION,** the act of grinding, or breaking any matter into finer particles. — The effect of chewing, or malacifying our food is the comminution thereof.

**COMMIRE, JOHN in Biography,** a Jesuit, was born in 1625 at Amboife, where his father kept a tennis-court. He received a good education, and applied himself chiefly to classical literature. He acquired great reputation as a poet, by a collection of pieces in Latin which appeared in 1678, but he was, at the same time, diligent in his profession, as a teacher and director in theology. His poems contain paraphrases on various parts of the scriptures, od s. fabes, epigrams, &c. of which the general character is taciturn, copious, and amity. He is thought to have succeeded his father in his place, but his fables are in high repute. He died at Paris in 1702, leaving behind him the character of an open and upright disposition. An edition of his poems was published in 2 vol. 12mo, in the year 1734. Nouv. Dict. Hist.

**COMMIS, Fr.** A clerk, deputy, or subordinate person, who is employed in any of the war-departments of the French.

**Commiss general du parc des viviers; commis-general of the provision-park.** This officer exercises his functions under the orders of the director-general of provisions. His employment requires a good deal of capacity and zeal, as well as of probity. His duties and relations are multifarious and extensive. He should always encamp in the centre of the bagagg, to be able to have an eye to the whole, and to be left uninterrupted.

**Commiss General des travaux du parc des viviers, commis- general of labour and work in the provision-park.** The duties of this employment are troublesome, and require much attention. It should never be belowed on a man that does not possess experience, prudence, and firmness, without being too rigorous or severe, as he has authority over every thing connected with the different kinds of work in the park.

**Commiss des entrepreneurs pour la fourniture des Ets; clerks of undertakers for the furnishing of beds.** They have a right to visit and examine the beds and every thing connected with them, and to refuse or reject whatever is insufficient or defective.

**Commiss du tresorier de l'extraordinaire des guerres, clerks of the treasurer of the wars, or of the paymaster general of the army.** They deliver the certificates to the troops who leave lodgings or quarters. They were under the jurisdiction of the high comisiable.

**COMMISSIONERATION,** in *Pathology* and *Ethics,* is frequently used as synonymous with *compiission,* which term; but, in its general use, it is somewhat different. It is always preferred, when we wish to express our sympathy for misfortunes, which it is not in our power to remove, or for which there is no apparent remedy. Commissioning, diminishing upon the slate and suffering of others, induces a permanent concern. In such cases it may be said, that we commiserate the
the unfortunate sufferer, rather than that we have compas-
ッション upon him. But although this is a more helpfut, it is
not an ulelefs affection. It ftoths the mind of the afflicted,
and greatly alleviates their fOWors, when every other con-
volution faiis. Condolence is the expression of our commiser-
COMMISSAIRE, Fr. Commiffary. This word or term
was ufed in the old French service, to exprefs a variety of
occupations, and was annexed to a good many different ap-
pellations, of which the following are the principal.
COMMISSAIRE General des Guerres ou commiffaire General
des Armées, commiffary general of the wars. This charge,
office, or appointment, was created for Befangue, in 1637,
and did not long exift, being fupprefsed in his perfon, be-
cause it gave too much authority, and too many privileges,
to the perfon invested with it.
COMMISSAIRE General de la Cavalerie légère. Fr. He was
the third general officer of all the regiments of cavalry,
and he had a regiment of his own under the name of the
regiment of the commiffary general, or commiffary gen-
eral.
COMMISSAIRE Ordonnateur des Guerres. This appointment
was superior to that of an ordinary or provincial commif-
Sary of war. It was communi a fort of reconnoitres and
advancement granted in confideration of services rendered by
the one or the other commiffaries of war, whether of the
armies or in the interior of the state. The commiffary or-
donateur is charged with objects of the firft importance,
and with a greater variety of them than the other commif-
saries are.
COMMISSAIRE des Guerres, commiffaries of the wars, or
muiter-maifers general. They enjoyed peculiar privileges,
but were fubordinate to the governors and commandants of
towns and garrifons, without whom perfon they could not
muiter any regiment.
COMMISSAIRE Ordinaire des Guerres, ordinary commiffaries
of the wars, or deputy-muiter matters. Officers fubordinate
to the immediately preceding, who ought to affift at re-
views, who are charged with the conduct, police, and cli-
dipline of troops, and with making the men obferve the milita-
ry deccres. With the army, they have the detail of the hospi-
tals, bread, victories, &c. &c. They make inventories of pro-
inaries, and are charged with the management of convoys. Their
creation is very ancient: for there is mention made of them
under the reign of King Jenu I. in 1355. They were called at
fril conduiteurs des gens de guerre, (conductors of the people
of war, or of military men) a title or appellation which
they enjoyed for a long time under Louis XIII., and they are
still called fo in their commiffions. Thofe who were not
gentlemen, had the right of taking the rank of fquire, or
esquire; of enjoying all the privileges of the noblefle, and of
acquiring noble fiels.
COMMISSAIRE Provincial des Guerres, provincial commiffary
of the wars. There were no commiffaires provinciaux des
guerres before the year 1655. They were afterwards fupp-
refsed, and were re-callified in 1704, under Louis XIV.,
with the fame privileges, rights, attractions, and authorities
for the fervice of cities of war, that the ordinary commiffaries
of the wars enjoyed for the fervice of marches, and of the
armies.
COMMISSAIRE General des Fiores, commiffary general of
provisions. This officer has under him feveral other commi-
saries, who ought to know the number of men,
which each of them will have to fubfit, in order to
make choice of a proper place for causing the pro-
vifions to be brought to, as also to form magazines for the
duration of the campaign, and of course to procure a suffi-
cient number of bakers and workmen.
COMMISSAIRE d'Artillerie, commiffary of artillery. There is
one fuch officer in each department of the ordnance, who
keeps one of the three keys that belong to the artillery-ma-
gazine. It is at his requisition that the governor or com-
mendant of a place fends folders to remove, when nec-
chary, the pieces of artillery and ftores of war. He has the
superintendence and direction of every thing connected with
the cleaning and general management of the magazines.
COMMISSAIRES provinciaux d'Artillerie, provincial commif-
saries of artillery. These were of two sorts or descriptions.
The one had the names or titles of the provinces; the other
had merely the title of provincial. But on service, they
both received the fame pay.
COMMISSAIRES ordinaires d'Artillerie, ordinary commiffaries
of artillery. These were fubordinate to the provincial com-
miffaries, and were distributed among the forts, garrifoned
towns, navy, and dockyards.
COMMISSAIRES extraordinaires d'Artillerie, extraordinary
commiffaries of artillery. Under the monarchical of France, these
formed the third of ordnance-commiffaries, and they were
in like manner distributed on duty in garrifoned places, and
on board ships of war.
COMMISSAIRE Provincial de l'Arsenal de Paris, au departem-
ent de l'Isle de France, provincial commiffary in the arsenal
of Paris, in the department of the isle of France. This officer
receivcd his commiffion from the grand defanter, in whose
gift it was, and poifefled the exclusive privilege of being
made privy to every alteration or movement that took place
in the arsenal.
COMMISSAIRE General des Poudres et Salpêtres, commiffary
general of gun-powder and saltpetre. This appointment was
created in 1634, with that of superintendent general of
gun-powder and saltpetre. It was at ralt fupprefsed, and
the general matter of the ordnance appointed a perfon to ex-
cerfc its functions.
COMMISSAIRE General des Fontes, commiffary general of
the founderies. This appointment was the gift of the ma-
ter of the ordnance, and was invariablv bestowed on thofe
who had given convincing proofs of their abilities and skill
in the calling of cannon, &c.
COMMISSAIRE des Guerres entrepris dans l'Hôtel des Inva-
lités, commiffaries of war kept in the hotel des invalides.
The was a principal part of their duty to keep a regular roll on
list of all the names of the different officers, non-commif-
sioned officers, and foldiers, that might be detached on garrifon
duty, &c. from which they made a monthly return to the
secretary at war. Each commiffary, at every review or
inspection of the corps of invalids, had particular directions
to mark and point out thofe men who appeared to be ca-
Spable of ferving, of whom a regular return was made to the
secretary at war.
COMMISSAIRE General des Fortifications, commiffary ge-
eral of fortifications. This was an office of great im-
portance, as it was his duty to give the plans for places and
new works; to approve or condemn thofe that had been or-
dered by others; to visit the fortified places of the king-
dom; to order the repairation of works that had been di-
maged; to regulate the conduct of the engineers, and to
give them orders for the good of the service.
At a siege, he directed the tracing out of the lines of
circumwallation and counterwallation, and the fecturing of
the polls; he decided on attacks which were made accord-
ing to his plan; he directed the making of lodgments, lappes,
mines, the traverse of the ditch, the attack of the breach,
and after the place was taken, caused it to be repaired. In defending a place, he had the fame or equal power. His appointments amounted to about 30,000 livres per annum.

COMMISSARY, in Military Language of Britain, has various denominations, though he is generally a civil officer appointed to inspect the munitions, stores, and provisions for the army. The number of such officers is not limited in time of war. Commissaries general, and commissaries of accounts, in our service, are appointed by warrant under the king's sign manual, directing them to obey all directions given to them for the execution of their duty by the lords commissions of the treasury. These instructions are generally prepared by the comptrollers of the army-accounts, under the orders of the treasury, and subject to its subsequent inspection.

COMMISSARY General of the Mufters, or Muftar-mater general. This officer takes as an account of the strength of every regiment as often as he pleases; reviews them; sees that the horses are well mounted, and that all the men are well armed and clothed. He receives and inspects the mutton-rolls, and thereby knows exactly the strength of the army. A new officer has been appointed under the application of Inspector-general of Carriages, who performs the duties in that respect, which used to be performed by the munter mater general.

COMMISSARY General of Stores. A civil officer who has charge of ordnance stores, on which he is also accountable to the office of ordnance. He has other commissaries under him, as well as clerks and conductors, particularly in time of war.

COMMISSARY of the Train-horses. A civil officer of the ordnance, who has the inspection of all horses belonging to the train of artillery, the hospital, and the bakery. He has a number of conductors, drivers, &c. under him.

COMMISSARY of Accounts. A person of responsibility, who, with a proper establishment, attends as many armies, sufficiently large and numerous, to render it necessary for the purpose of taking, examining, and controlling accounts on the spot. All such commissaries make returns of their examinations, on which, as documents, the comptrollers of the army-accounts ground their inquiries into that branch of the public expenditure.

COMMISSARY General of Provifions. An officer who is charged with furnishing the army in the field and on service, with all sorts of provisions, forage, &c. generally by contract, and sometimes otherwise. He has a variety of commissaries, store-keepers, clerks, &c. under him.

COMMISSARY, in the Ecclesiastical Law, an officer of the bishop, who executes ecclesiastical jurisdiction in those parts of the diocese, which are so remote from the see that the chancellor cannot call the subjects thereof to the bishop's principal curia, without their too great molestation.

This officer, called by the canons commissarius, or officialis foratus, is appointed to supply the bishop's fice in the out-parts of the diocese, and in such parts as are peculiar to the bishop, and exempted from the jurisdiction of the archdeacon: for where the archdeacons have jurisdiction, as in most places they have, either by prescription or composition, the commissary is supefluous, and frequently vexatious, and ought not to be: yet in such cases, a commissary is sometimes appointed by the bishop, and takes prelummary of the archdeacon yearly pro exteriores jurisdictions, as it is ordinarily called. But this is held to be a wrong to archdeacons and the poorer sort of people. Cawel's Interp. 4. Int. 3. 8.

COMMISSARY Court, in Scots Jurisprudence. At the reformation, all episcopal jurisdiction exercised under the authority of the bishop of Rome was abolished, and the course of justice in ecclesiastical causes was thus stopped. Hence Queen Mary, besides naming a commissary for every diocese, did, by a special grant, establish a new commissary court at Edinburgh, consisting of four judges or commissaries. This court is vested with a double jurisdiction; one diocesan, which is exercised in the diocesan territory contained in the grant, viz., the counties of Edinburgh, Haddington, Linlithgow, Peebles, and a great part of Stirlingshire; and another universal, by which the judges confirm the sentences of all who die in foreign parts, and may reduce the decrees of all inferior commissaries, provided the reduction be pursued within a year after the decree. Bishops, upon their re-establishment in the reign of James VI., were restored to the right of naming their several commissaries. The commissaries retain to this day an exclusive power of judging in declarations of marriage, and of the nullity of marriage; in actions of divorce and of non-adherence, of adultery, bastardy, and confirmation of testaments; because all these matters are still considered to be properly confessional. Inferior commissaries are not competent to question divorce, under which are comprehended questions of bailiary and adherence, when they have a connection with the lawfulunts of marriage, or with adultery. Commisaries have now no power to pronounce decrees in absence for any sum above 40l. Scots, except in cases purely confessional; but they may authenticate titles and curatorial inventories; and all bonds, contracts, &c. which contain a clause for registration in the books of any judge competent, and protests on bills, may be registered in their books.

COMMISSION in Common Law, is the same with diarchy among the civilians, and is taken for the warrant, or letters-patent, which all persons exercising jurisdiction, either ordinary or extraordinary, have to authorize them to hear or determine any cause or action: such as the commission of judges, &c.

The term, however, is sometimes extended farther than to matters of judgment; as in the commission of purveyors, which seems to be only by the statute for taking away purveyance, 12 Car. II. and the high commissary court, which was founded in the statute 1 Eliz. and is also abolished by act of parliament at 16 Car. I. The persons charged with a commission are hence called commissaries or former times commissaries.

Commissaries of inquiry shall be made to the justices of oaths, or the other, &c., and to do lawful things are granted in many cases. Most of the great officers, judicial and ministerial of the realm, are made by commissaries. And by such commissaries, treasons, felonies, and other offences, may be heard and determined: by this method, brethren, oaths, cognizances of fines, and answers, are taken, warrants examine, &c. See Ab. 12. 1. c. 59. See flat. 42. E. III. c. 4. Most of these commissaries are appointed by the king under the great seal of England; but a commissary under the great seal may be determined by a privy seal; and by granting another new commission to do the same thing, the former commission determines; and on the death or demise of the king, the commissaries of judges and officers generally cease. See Commis. 2 Decr 289.

COMMISSION of Anticipation, was anciently a commission given under the great seal, to collect a tax or subsidy before the day. 15 Hen. VIII.

COMMISSION of Array. See MILITIA.

COMMISSION of Affidavit, is a commission under the great seal to allocate two, or more learned persons, with the several justices, in the several circuits and counties in Wales.

COMMISSION of Bankruptcy, a commission under the great seal,
CQM

feal, directed to five or more commissioners, to inquire into
the particulars of a man's circumstances, who hath tailed,
or broke; and to act according to certain statutes existing
in that behalf. See Bankrupt, and Petition of Bank-
ruptcy.

Commission of Charitable Uses go out of the chancery
of the bishop and others, where any lands given to char-
able uses are unemployed, or there are any fraud or dis-
putes concerning them, to inquire of and redress the abuse,
&c. 43 Eliz. cap. 3.

Commission of Delegates, a commission under the great
seal to certain persons, usually two or three temporal lords,
as many bishops, and two judges of the law, to sit upon
an appeal to the king in the court of chancery, where any sen-
tence is given in any ecclesiastical cause by the archbishop.
Stat. 35 Hen. VIII. c. 19. Now generally three of
the common law judges and two civilians sit as judges. See
Court and Delegates.

Commission to enquire of faults against the laws, an
ancient commission set forth on extraordinary occasions
and corruptions.

Commission of Lunacy, a commission out of chancery
in the care of his effate, &c. 17 Edw. II. c. 10.

Commission of Peace. See Justice of Peace.

Commission of Rebellion, or Writ of Rebellion, is issud
out when a man, after proclamation made by the sherif
upon a proceed out of the chancery, to present himself,
under pain of his allegiance, to the court by a certain day,
doing appear. See Rebellion.

This commission is directed by way of command to certain
persons; three, two, or one of them, to apprehend, or canle
be apprehended, the party as a rebel; and to bring him
to the court on a day assigned.

This writ or commission goes forth after an attachment re-
turned, non est inventus, &c.

Commission of Sewers, is directed to certain persons
to see drains and ditches well kept, and maintained, in
the marshy and fenous parts of England, for the better convey-
ance of water into the sea, and preserving the grazing
of the land. Stat. 6 Jac. I. c. 14. ordains, that all ditches, water-courses,
&c., within two miles of London, falling into the Thames,
shall be subject to the commission of sewers; and the lord-
mayor, &c., is to appoint persons who have this power.

Commission to examine witnesses, is sometimes appointed
by the court of equity in cases that require it, as when the
cast ances in a foreign country, and the witnesses are at
home, or when the witnesses are abroad, or soon to leave the
kingdom; or again, when they are aged and infirm.
This commission is empowered to exercise the same jurisdiction
as would have been exercised if the witnesses had at-
tended. See Suit.

Commission of Treaty with Foreign Princes, is where
leagues and treaties are made and transacted, between nations
and kingdoms, by their ambassadors and ministers, for the
mutual advantage of the kingdoms in alliance.

Commission to take up Men for War, was a commission
to pref or force men into the king's service. This power of
impressing has been heretofore doubted; but the legality
Com. r. 419. Comw. 517. See Impress.

Commission, Military. A brevet, or power, granted
in writing by the minister of war in the name of the sove-
reign, and sealed with the great seal, by which he, to
whom it is given, is authorized to the military charge commuted
in him, and who is to draw from the day of the date thereof.
Commission in military cases, in our laws, denotes any situta-
tions or places, which an individual may hold in the
regular army, militia, or volunteers. All commissions in
the line, guards, or volunteer-corps, must have the royal sign
manual. Commissions however in the militia do not bear the
royal sign manual, except that of the adjutant-general, who is
commonly called a king's officer. The lieutenants or
captains-lieutenants of counties affix their seals and signatures
to militia-commissions after they have been laid before the
king for his approbation. Fourteen days constitute the
time allotted for the royal approbation or disapprobation.
And if his majesty does not within that time disapprove
of the person to recommended, a notification of his pleasure
and acquiescence is left by one of the principal secretaries
of state to the lord lieutenant, or to those acting by com-
mussion in his absence.

Commission Military is also a momentary or temporary
tribunal appointed or ordered to sit for the trial of military
offences and crimes. When judgment is pronounced and
the duty is performed, for which it was appointed, its
authority, as well as its existence, ceases.

Commission of Array. Commissions issued to expe-
rienced officers to draw out and array the fitted men
in each county for service, and to march them to the
coasts, or to such other parts of the county as were thought
to be most in danger. There were hundreds of such com-
misions between the 36th of Henry III., and the reign
of Edward IV. The form of one is to be seen in "Rut-
worth's Historical Collection," published in 1642. Such
commissions were attempted to be revived by Charles
II., but they were voted illegal and unconstitutional by the
Parliament.

Commissioned is a term commonly employed to
designate a class of men, who, between the rank and file
of a battalion, and the commissioned and warrant officers,
are serjeants-major, serjeants for fatigue.

Commission Officers. See Officer.

Commissions, Book of. See Book.

Commission in Commerce. See Factorage.

COMMISSIONER, he who has a commission, cr. pr. a
patent, or other legal warrant, to execute any public
office. See Warrant, &c.

Such are, commissioners of hawkers and pedlars, commis-
sioners of alienation, commissioners of the flamps, &c.

Commissioners of Public Accounts. See Accounts.

Commissioners of the Customs. See Customs-house.

Commissioners of the Dock-yards. See Dock-yards.

Commissioners of Excise. See Excise.

Commissioners of the Navy. See Navy.

Commissioners, Lords, of the Treasury. See Treasury,
and Exchequer.

Commissioners of Trade, &c. See Board.

COMMISSUM Factore. See Factore.

COMMISSURE, a term used by some
authors for the junctures, or for the small interstices
of bodies; or the little clefts between the particles; espe-
cially when those particles are broad or flat, and lie contiguous
to one another, like thin plates, or lamelles.

The word literally signifies a joining, or connecting of
one thing to another.

COMMISSURE, in Architecture, &c. denotes the joint of
two plates; or the application of the surface of the one to
that of the other.
COMMISSURE. 

COMMISSURE Cordis, in Anatomy, are parts of the brain, which join together the right and left sides of this viscus.

There are three of these commissures: an anterior one which is directly under the anterior crura of the fornix; a posterior, which is behind the optic thalamus, and in front of the tuber cinereum; and a middle one, which joins together the opposed convexities of the thalami nuclei corporis quadrigeminarum.

For a further description of these parts, see Brain.

COMMITMENT, in Law, the lodging of a person to prison by warrant or order, who hath been guilty of any offence not bailable, or for which bail is refused. It may be by the king and privy council, or by the judges of the peace, and other magistrates, who have authority by the laws and statutes of the realm to do it, which must be exactly pursued.

As to the manner of commitment, it is enacted by 2 & 3 P. & M. c. 57, that justices of peace shall examine persons brought before them for felony, &c., or sufficition thereof, before they commit them to prison, and shall bind their accusers to give evidence against them. A justice of the peace may detain a prisoner for examination, and it is said that three days are a reasonable time for this purpose.

2 Hawk. P. C. c. 16. § 11, 12. 3 Leis. c. 125. 2 Inst. 52, 591.

Every commitment must be in writing, under the hand and seal, and shew the authority, of him that made it, and the time and place, and must be directed to the keeper of the prison. It may be either in the king's name, and only signed by the justice, or in the name of the justice. It may command the gaoler to keep the party in safe and close custody, which he is bound by law to do. 2 Hawk. P. C. c. 16. § 13, 14, 15. It ought to set forth the crime with convenient certainty, whether the commitment be by the privy council, or by any other authority: otherwise the officer is not punishable by reason of such imputum, for sufficing the party to escape; and the court before which he is removed, by Habeas-corpus, ought to discharge or bail him; and this holds not only where no cause at all is expressed in the commitment, but also where it is so loosely set forth, that the court cannot judge whether it were a reasonable ground for commitment or not. 2 Hawk. P. C. c. 16. § 17. See ARREST AND BAIL. A commitment for high treason or felony in general, without expressing the particular species, has been held good. (2 Hawk. P. C. c. 16. § 16.) But now, since the Habeas-corpus act, it feems that such general commitment is not good. Moreover, it is safe to set forth that the party is charged upon oath; but this is not necessary, for it hath been resolved, that a commitment for treason, or for sufficition of it, without setting forth any particular accusation or ground of the sufficition, is good. 2 Hawk. P. C. c. 16. § 17. Every such imputum ought to have a lawful conclusion, viz., that the party be kept till he be delivered by law, or by order of law, or by due course of law; or that he be kept till further order (which shall be intended of the order of law) or to the like effect; and if the party be committed only for want of bail, it feems to be a good conclusion of the commitment, that he be kept till he can find bail: but a commitment till the person who makes it shall take further order, feems not to be good: and it feems that the party committed by such or any other irregular imputum, may be bailed. 2 Hawk. P. C. c. 16. § 18.

A commitment grounded on an act of parliament ought to be conformable to the method prescribed by such statute. Where a man is committed as a criminal, the conclusion must be, "until he be delivered by due course of law;" if he be committed for contempt, it should be "until he comply."

All commitments must be to some prison within the realm of England; for by the Habeas-corpus act (c. 31 Car. II. cap. 2.) it is enacted "no subject of this realm, being an inhabitant or refugee of this kingdom of England, dominion of Wales, or town of Berwick-upon-Tweed, shall or may be sent prisoner into Scotland, Ireland, Jersey, Guernsey, Tangier, or into any parts, colonies, places, beyond the seas, which then were, or at any time after should be, within or without the dominions of his majesty." By § 14 Ed. III. c. 10, sheriffs shall have the custody of the gaol as before that time they were wont to have, and they shall put in such under keepers for whom they will answer. This is confirmed by § 19 Hen. VII. c. 10. It hath also been held, that regularly no one can justify the delivering of a prisoner in custody out of the common gaol, unless there be some particular reason for so doing, as sickness endangering life, or evident danger of a recusant from rebels, &c.: nevertheless continuance practice seems to authorize a commitment to a meffenger; and it is said, that it shall be intended to have been made in order for the carrying of the party to gaol. 2 Hawk. P. C. c. 16. § 8, 9. And it is said, that if a contable bring a felon to gaol, and the gaoler refuse to receive him, the town where he is contable ought to keep him till the next gaol delivery.

H. P. C. c. 114. 2 Hawk. P. C. c. 16. § 9. A prisoner in the custody of the king's meffenger, or on a warrant from the secretary of state, who is brought into K. B. by Habeas-corpus to be bailed, but has not his bail ready, cannot be committed to the same custody, under which he came; but must be committed to the custody of the marshal, which will prevent the necessity of putting out a new Habeas-corpus; as he may be brought up from the prison of the court, by a rule of court, whenever he shall be prepared to give bail. 1 Burr. 460. If a person arrested in one county for a crime done in it, fly into another county, and be retaken there, he may be committed by a justice of the first county to the gaol of such county. (H. P. C. 93.) But by the better opinion, if he had, before any arrest, fled into such county, he must be committed to the gaol thereof by a justice of such county. 2 Hawk. P. C. c. 16. § 8. 3 Dale. c. 118. It feems also to be laid down as a rule by some books, that any offender may be committed to the gaol next to the place where he was taken, whether it be in the same county or not. 2 Hawk. P. C. c. 16. § 8. By § 6 Geo. I. c. 19, vagrants and other criminals, and persons charged with small offences, may, for such offences, or for want of bail, be committed either to the common gaol or house of correction, as the justices shall think proper. By § 2, Geo. II. c. 55, if a person is apprehended, upon a warrant indorsed, in another county, for an offence not bailable, or if he shall not there find bail, he shall be carried back into the first county, and be committed, or if bailable, bailed by the justices in such first county.

With respect to the charges of commitment, it is enacted by § 3 Jac. I. c. 10, that offenders committed are to bear their own charges, and the charges of those who are appointed to guard them; and, if they refuse to pay, the charges may be levied by sale of their goods. And by § 27 Geo. II. c. 3, if they have no goods, &c., within the county where they are apprehended, the justices are to grant a warrant on the treasurer of the county for payment of their charges. But in Middlesex
Witness the same shall be paid by the overseers of the poor of the parish where the person was apprehended. By act 3 Hen. VII. c. 3, the sheriff shall certify the names of all prisoners in his custody to the judges of gaol delivery.

Prisoners, committed at first to the proper prison, ought not to be removed thence, except in some special cases; and in peculiar circumstances, specified by 31 Car. II. c. 2. A person, legally committed for a crime, which certainly appears to have been done by one or other, cannot be lawfully discharged by any other but the king, till he be acquitted on his trial, or have an ignorant found by the grand jury, or none to prosecute him on a proclamation for that purpose, by the judges of gaol-delivery. But if a person be committed on a bare suspicion, without any appearance of guilt, or indictment, for a supposed crime, when afterwards it appears there was none; as for the murder of a person thought to be dead, but afterwards found to be alive, it hath been held that he may be falsely dismissed without any farther proceeding. 2 Hawk. P. C. c. 16. § 23. But the safest way for the gaoler is to have the authority of some court, or magistrate, for discharging the prisoner. If the words of a statute are not pursued in a commitment, the party shall be discharged by Has. 31. G. 33. Jacob's Law Dict. by Tomlin. See Arrest, Bail, Imprisonment, Mitigation, &c.

COMMITTEE, in Law, one or more persons, to whom the consideration of any matter is referred, either by a court, or by consent of the parties concerned.

Committee of Parliament, is a board consisting of a certain number of members, appointed by the whole house for the examining of a bill, or making report of an inquiry, or proofs of the house, &c.

Sometimes the whole house is resolved into a committee; on which occasion each person has a right to speak, and reply as much, and as often as he pleases; an expedient they usually have recourse to in extraordinary cases, and where any thing is to be thoroughly canvassed. When the house is not in a committee, each gives his opinion generally, and is only allowed to speak once, unless to explain himself.

The standing committees, appointed by every new parliament, are those of privileges and elections, of religion, of grievances; of courts of justice, and of trade, though only the former sec. See Parliament.

Committee of the king, is used for a widow of one of the king's tenants; thus called, as being by the ancient law of the realm committed to the king's care and protection.

See Widow.

Committee of a Lunatic, idiot, &c. denotes the person to whom the care and custody of such lunatic, &c. is committed by the court of chancery. See Lunatic.

Committees of Corporations, &c. are such members who perform the general routine of business. See Corporations.

COMMODATE, Commodatum, in the Civil Jurisprudence, the loan or free concession of any thing movable or immoveable, for a certain time on condition of reverting again the same individual after a certain term.

The commodity is a kind of loan; there is this difference, however, between a loan and a commodity, that the latter is gratis, and does not transfer the property: the thing must be returned in effeuce, and without impediment; so that things which confine by use, or time, cannot be objects of a commodity, but of a loan; in regard they may be returned in kind, though not in identity.

COMMODAVIENSIS, an appellation given by some authors to a species of Iphis calamariae found in Bohemia.

But as it yields no zinc, Mr. Marggraf denies it to be true calamite.

COMMODORES. See Staple.

COMMODORE, in the British Navy, a general officer invested with the command of a detachment of ships of war detailed on any particular enterprise; during which time he bears the rank of a brigadier-general in the army, and his ship is distinguished by a broad red pendant tapering towards the outer end, and sometimes forked.

COMMODORE is also a name given to a select ship in a fleet of merchantmen, which leads the van in time of war, bearing a light in her top to conduct the fleet.

COMMUDUS, Lucius Aurelius Antoninus, in Biography, was the only son of the emperor Marcus Antoninus and Faustina, and born A.D. 161. He was educated with the utmost attention, and he enjoyed very superior advantages from the precepts and instructions of tutors appointed to preclude over his infantile studies and pursuits; but from the first openings of his mind, he displayed an untoward disposition, and a strong propensity for low and unworthy gratifications. He discovered an aversion from whatever was rational or useful, and a fond attachment to the sports of the cisterns, the combats of gladiators, and the hunting and destroying of wild beasts. To wean him from these pursuits, and with a view of engaging his mind in useful and manly occupations, his father made him a partaker of the sovereign power in his fifteenth year. This instance of parental affection did not produce the desired effect; it only furnished him with better opportunities of indulging every licentious gratification. Upon the death of Marcus, in the year 180; he succeeded to the quiet and undisputed possession of the throne; he law about him neither competitor to remove nor enemies to punish, and during the first three years of his reign, the influence of his father's virtuous counsellors restrained him from any acts of tyranny towards his subjects. During this period, however, he indulged in every species of licentiousness, and revelled in all the licence of sovereign and unrestrained power, but his hands were unstained with blood, and occasionally he displayed a generosity of sentiment worthy of a great mind; he had in one instance refused to see the proofs of a conspiracy formed against him, and it was hoped he might have followed the track of his illustrious father. A fatal incident decided his fluctuating character. An assassin was employed to destroy him; in making the attempt he explained "the senate sends you this." The deed was prevented, and Commodus from that hour encouraged a deep-rooted hatred for the whole body of senators. Spies and informers increased his suspicions and excited his jealousy of power in any other hands than his own. Accusation was regarded as proof, and the mockery of a pretended trial led only to certain condemnation. The execution of any considerable senator was ever attended with the death of all those who should attempt to revenge, or publicly dare to lament his fate, and when Commodus had tainted of human blood, he became incapable of pity or remorse. His ministers were one after another the victims of his fears or of his cruelty. Perennis was condemned to die for a charge of aspiring to the empire, and after his death the conduct of Commodus assumed the appearance of virtue. He repealed the most odious of his minister's acts, loaded his memory with public executions, and ascribed to his pernicious counsellors, all the errors of inexperienced youth. But his seeming repentance lasted only a short month, and then every sentiment of humanity appeared to be obliterated from his breast. He abandoned the reins of government to the most unworthy, and he valued nothing in sovereignty, except...
except the usual indulgence in indulging his indulgent appetites. Histories were spent in a rhapsody of bawdy women and boys, selected from all ranks of the people, and toms every province of the empire. The intestines of but were filled up with the half-felt amusements. The servile crowd, whole fortune depended on their monarch's voice, applauded these vile perfumes. Having by long practice attained great skill in the use of the bow, he exhibited his talents before the people, and animals of the rarest species were collected from the remotest part of his dominions in order to serve as marks for the spectated archer. The pernicious voice of flattery reminded him that by exploits of the same nature, the Grecian Hercules had acquired a place among the gods, and an immortal memory among men. He accordingly assumed the title and insignia of Hercules; in this character he exhibited all the helpmens and dismayed of the city, and causing them to be wrapped up in fantastical habits, like dragons and mulehers, and armed with sponges instead of stones, he rushed upon them with his club and laid them all dead at his feet. He exhibited himself more than 500 times in the character of a slaver, and in all his combats he was victorious, but his amusements in this way were frequently fatal to his antagonists. It would take more of our work than can be allotted to this article to describe all the cruelties and acts of savage barbarity which disgraced the reign of Commodus. At length his detestable career came to its mentor end. Opposition to his bloody deluges was given by some of his bolom counsellors, among whom was Marcia, his favourite confederate. He resolved to put them to death, and entered their names in a long list defined to the same fate. Marcia discovered his intentions, and apprized her friends of their common danger. They resolved to anticipate the blow, and Marcia mixing some poison in wine, presented it to him as he came from the bath. He soon fell asleep, but the dose not being sufficiently strong, he awake; while, however, he was labouring under the effects of the poison, a robust youth, by profession a wrestler, entered his chamber, and strangled him without resistance. The body was secretly conveyed out of the palace, before a funeral was entertained either in the city or the court of the emperor's death. Such was the fate of Commodus, and "so faly," says the historian, "was it to destroy a tyrant, who, by the artificial powers of government, had oppressed, during thirteen years, so many millions of subjects, each of whom was equal to their master in personal strength and personal abilities." Gibbon.

COMMOIGNE, in Law, a word signifying a fellow-mosaic, that lives in the same convent. 3 Bl. 15.

COMMON, in Agriculture, an open piece of ground, made use of equally by different persons who occupy lands in the parish to which it belongs or in which it lies.

It is remarked by Mr. Marshall in his "Treatise on Landed Property," in regard to the origin of commonable lands, "that a very few centuries ago, nearly the whole of the lands of England lay in an open, and more or less in a commonable state. Each parish, or township, (at least in the more central and northern districts) comprised different descriptions of lands; having been fued, during successive ages, to specified modes of occupancy, under ancient and strict regulations, which time has converted into law. These parochial arrangements, however, varied somewhat in different districts; but, in the more central and greater part of the kingdom, not widely. Under this ingenious mode of organization, each parish or township was, he says, considered as one common farm, though the tenantry were numerous. Round the village in which the tenants resided lay a few small inclosures or plat yards for rearing calves, and as baiting and muniting grounds for other farm stock. This was the common farmstead or bungfel, which was generally placed as near the course of the more cultivated lands of the parish or township as water and shelter would permit. And that "round the homestead lay a suit of arable fields, including the deep and boundless of the lower grounds, situated out of the water's way, for raising corn and pulse; as well as to produce fodder and litter for cattle and hawks in the winter season." While in the lowest situation, as in the water-reformed base of a rivered valley, or in swampy dips, shooting up among the arable lands, lay an extent of meadow grounds or inges, to afford a supply of hay for cows and working flock, in the winter and spring months.

That on the outskirts of the arable lands, where the soil is adapted to the purlieus of cattle, or on the springy slope of hills, less adapted to cultivation, or in the sandy leazes of valleys, which were tunnel or gravelly water-formed lands, which were too dry to produce an annual supply of hay with sufficient certainty, one or more ighted fylons, or homesteads, were laid out, for milking cows, working cattle, or other flock which required superior purlieus, in summer.

While the b caked, word-foiled, and most distant lands of the township were left in their native wild state, for timber and fuel, and for a common fylon, or suit of purlieus, for the more ordinary flock of the township, whether horses, rearing cattle, sheep or swine, without any other stint, or reflection, than what the arable and meadow lands indirectly gave; every joint tenant, or occupier of the township, having the nominal privilege of keeping as much live flock on these commons, in summer, as the appropriated lands be occupied would maintain, in winter.

Further, that the appropriated lands of each township were laid out with equal good fence and propriety. That each occupier might have his proportionate share of lands of different qualities, and lying in different situations, the arable lands more particularly were divided into numerous parcels, of sizes, doublets, according to the size of the given township, and the number and rank of the occupiers.

And that the whole might be subjected to the same plan of management, and be conducted as one common farm, the arable lands were moreover divided into compartments, or "fields," of nearly equal size, and generally three in number, to receive, in constant rotation, the triennial succession of fallow, wheat (or rye), and spring crops, (as barley, oats, beans, and peas), thus adopting and promoting a system of husbandry, which, howsoever improper it is become in these more enlightened days, was well adapted to the state of ignorance and villagile of feudal times, when each parth or township had its sole proprietor; the occupiers being at once his tenants and his fielders, or maner writhe. The lands were in course liable to be more or less deferted by their occupiers, and left to the freetailed of the young, the aged, and the weaker sex. But the whole township being, in this manner, thrown into one system, the care and management of the live flock at least would be easier and better than they would have been under any other arrangement. And at all times, the manager of the estate was better enabled to detect bad husbandry, and enforce that which was profitable to the tenants and the estate, by having the whole spread under the eye at once, then he would have been had the lands been distributed in detached inclosed farneata, besides avoiding the expense of inclosure. And another advantage, he thinks, arose from this more social arrangement: in barbarous times the tenants, by being concentrated in villages, were not only better situated to defend each other from predatory atta,
COMMON.

But where the common is unfenced; or in other words, where the farmers possess right of pasturing any number and species of live stock which they choose to feed, and without restraint of any kind, the value of such right is confirmed by many farmers in inconsiderable as not to be worthy of their attention. Such farms as possess improved troops of horses, cattle, and in ep. felde, indeed, if ever, are convenient to some neighbouring farmers or drovers, who have no objection, in the view of profit, of running the risk of their cattle meeting with accidents, or being infected with disease, as much naturally be expected to happen on these extensive commons, where so many cattle are promiscuously collected together.

It has been remarked by a late able writer, that "the commons in Middlesex, as in most other places, are three fourths of them covered with heath and furze, from which a little of the worse sort of firing is obtained by the poor. The trifling quantity of food which cattle consume from these shrubs, does not, and indeed cannot, improve them, as it is barely sufficient to keep them from starving. Much of the remainder is occupied by roads, gravel pits, and ponds, yielding nothing. After the mott mature consider of, he is inclined to think, that about 4,500 acres of the commons in the above county are employed in the production of grass for the feeding of cattle, affording indeed but a miserable pasturage, as the greater part is under water during winter; and, from being poached and trodden down by cattle while wet, is rendered hard, lumpy, full of holes, and parakes of the thriftiness of manuring during summer. The grass is mostly of the dwarf kind, and of scanty produce, with a large proportion of the carnation and other grasses which are known to be rather more dangerous than nourishing; so much so, as to induce some of the most observing farmers in various parts of the kingdom, possessing extensive common rights, after a fair trial to refrain altogether from turning their cattle on such commons.

On such authority it may well be, he says, be questioned, whether commons are of any more use to the community than they would be were they confined to the bottom of the deep. But without attempting the solution of such a question at present, he may be allowed to observe, that the value of commons, considered solely as to their power of increasing animal food, and as totally unconnected with the adjoining inclosures, is extremely small indeed. But when considered as affording an opportunity to the neighbouring farmer to turn his flock out, at certain seasons of the year, they become an object of some importance. For in the spring quarter of the year, by receiving the flock during these months, the growth of hay is encouraged, they answer the purpose of pâturage, and the farmer is thereby enabled to mow all his grass land: which must sensibly increase the quantity of hay to be sent to market; as at Finchley and Harrow, and in this county; or being applied during the winter months to the support of a greater quantity of live stock in places more distant from a good hay-market; and in others, for the purpose of folding on the arable land."

It is further stated, that "on estimating the value of the commons in the same county, including every advantage that can be derived from them in pâturage, locality of situation, and the barbarous custom of turnip, it appears, he says, that they do not produce to the community, in their present state, more than four shillings per acre! On the other hand, they are, in many instances, of real injury to the public, by holding out a lure to the poor man for procuring the means of materials..."
The benefits and advantages that would be derived from a general inclosure of commons, are, he thinks, so numerous, as far to exceed his powers of description or computation. The opportunity it would afford of separating dry ground from wet, of well draining the latter, and liming the rotten parts, is of infinite consequence; as such an arrangement would, with the aid of intelligent breeders, be the means of raising a breed of sheep and neat cattle far superior to the present race of wretched half-starved animals now seen in such situations. It would have the effect of supporting a more numerous flock upon the same quantity of food by repressing the cattle and sheep within due bounds. Their refuse and rambling disposition not only tramples the grass off the ground, but also takes the drift off their bones. This renders the attendance of a shepherd necessary, and requires likewise that they may be driven to and from the fold. Further, the live-flock would by this means be rendered many hundreds per cent. more valuable to individuals and the community than it has hitherto been, or can possibly be, without inclosure; and, what is of the last, the greatest importance, it would tend to prefer such improved breeds from that deplorable malady, the (rot) which makes such terrible havoc among our fleeks. Add to this, that the markets would be more plentifully supplied with beef and mutton, and the price of these articles considerably reduced.

It does not, he says, appear necessary to state with precision (nor indeed is it capable of being so stated) what would be the encrease or value of the commons of this country on their being inclosed and well and properly cultivated. It may, however, with safety be stated at upwards of 15 times their present value to the proprietors, and 40 times their present value to the public. But increasing the rental of such land to 15, or perhaps 20 times, its present amount, is by no means the greatest advantage that may be expected to result from an inclosure of commons. The general salubrity and healthfulness of the country would essentially be improved, while industry would be largely encreased among the most useful classes of society, beggary and robbery much lessening, and the general stock of corn and cattle almost inconceivably augmented. And wherever inclosures are made with due attention to the interest of the poor (as they ought always to be), they will be found to ameliorate their condition, as much as they increase the property and the comforts of the rich.

It is further observed, that "the commons of this kingdom being, with very few exceptions, without ridges, furrows, or drains, have not the means of discharging that superfluous water from the surface of them, which is well known to be of great detriment to vegetation in general.

Many commons in low situations, and where the soil happens to be of a retentive quality, hold water like a sponge, which being always flagrant, as well as excursive in quality, renders the soil of such commons much too wet for the pasturage of sheep, and is, no doubt, the cause of many of the disorders which that animal is subject to, particularly that fatal malady, the rot. From the same cause, also, the neighbourhood of most commons must be particularly unfriendly to the health and longevity of man. Only let us, says he, reverse the scene, and for a moment suppute these commons to be inclosed, the necessaries ditches and drains sunk, and the land brought into tillage, and we shall see all the superabundant moisture got rid of; and the water, being kept in constant motion, by trickling down the sides of the ridges into the furrows, and from thence into the ditches and rivulets, will be found to fertilize the very soil which in its present flagrant state it serves to injure;
injure; while, by leaving the land dry, it will be rendered more healthy both for men and cattle. The effects of such a measure would soon shew themselves in many districts of this island, which, at present, are very unpropitious to the health of man, in the much greater longevity of the inhabitants. It may also be further noticed, that commons are entirely defective in the great article of labour; but no sooner does an inclosure take place, than the scene is agreeably changed from a dreary waste, to the more pleasing one of the same spot, appearing all animation, activity, and bustle. Every man, capable of performing such operations, is furnished with plenty of employment, in sinking ditches and drains, in making banks and hedges, and in planting quicks and trees. Nor are the wheelwright, carpenter, smith, and other rural artificers, under the necessity of being idle spectators of the scene, since abundance of work will be found for them, in the creation of farm houses, and the necessary appendages thereto; and in the forming and making of roads, bridges, gates, files, implements of husbandry, &c. Even after a few years, when this kind of temporary exertion is over, by the whole being brought into a regular syrum of husbandry, it will still continue to provide both food and employment for a very increased population.

"It is highly probable, he thinks, that if the legislature should pass an act for the general inclosure of waste land, it would increase the quantity of rural labour so much as to advance its price considerably, and thereby have the good effect of drawing a vast number of hands out of the unwholesome confinement of manufactories; where, in addition to the life-shortening effects of such confinement, the morals of the people are exposed to certain contamination."

With respect to the effect produced by inclosures on the population of the country, it may be observed, that the inclosing of 1000 acres in any one parish would probably require 100 different labourers, many of whom would undoubtedly be drawn from such of the adjoining parishes as had less work than workmen. Thus it must follow, that the neighbouring towns and villages would diminish, just as much as the parish in which the inclosure is going forward, would increase its numbers; yet the amount of the community will evidently be the same. But although the inclosing of waste land certainly does not immediately either increase or lessen population, as some writers seem to have supposed, yet, that inclosures ultimately affect population, and that as to its increase, in such a manner as the district is thereby made more conducive to health, is, he says, sufficiently evident. Every thing that has a tendency to make a nation more healthy and productive, must, of necessity, operate as a stimulus to population. The certainty of a man's being able, with ease and comfort, to provide for himself and family, by the increase of rural labour, is at once an inducement to marriage, and a consequent increase of population.

The inhabitants wholly supported by agriculture in England and Wales, appear, the same writer says, to be nearly, or perhaps quite, six millions, (while it supplies provisions for near two millions more,) or one to every five acres and a half of cultivated soil. The estimation is made in this manner.

**Estimate.**

| Cultivators of farms, fix persons to every 100 acres, is | 2,340,000 |
| Ditto of gardens, hop-grounds, nurseries, &c. | 300,000 |

Smiths, wheelwrights, bricklayers, masons, carpenters, painters, plumbers, glaziers, various manufacturers of furniture, woollen cloth, and making it up, linen, and making it up, leather, and making it into shoes, boots, &c. hats, hams, and saddlery; as many of each of this description of persons, as are wholly employed by the cultivators of the soil; men, women, and children, about seven persons to each farm, of 100 acres, is 2,800,000

The like of millers, bakers, maltsters, brewers, dressers, fashions, makers, dealers in corn, and persons employed in the commerce of corn - 500,000

The landlords of farms - 49,000

Perfons supported by taxes on the produce of land - 120,000

Not but that the extremes vary much, as there are some few grazing farms, with only one soul to fifty, and arable farms that are peopled in the proportion of one person to three acres of land. In point of produce, the commons, in their present state, apparently, though, he thinks, not rationally afford entire support to human beings, in the proportion of one to an hundred acres. But by being inclosed, and brought into the present ordinary cultivation of the country, every fix acres and a half might do the same.

Should agriculture experience a rapid advance towards perfection, as there is reason to imagine it will, both from the exertions of the board, and of intelligent individuals, every three or four acres, would, in a few years, be capable of supporting its inhabitant; and, as from its nature, it might certainly be carried on from one degree of perfection to another; it may even arrive at such a pitch of excellence, as that every acre of land shall support its man.

It has long since been well observed by Dr. Anderson, that while land is in the condition of common, man is debased from ever being able to embellish the soil, and thus to augment its product to the state; but that he is not prevented so essentially from deteriorating it. While, in the state of a common, the surface of the ground may be broken by him in such a way, as not to recover for ages a sparrow equivalent to that which was originally upon it. It may be cut up and link into pits; it may be converted into wet and rotten marshes, by casual obstructions being thrown in the way of the water, which no one finds it his interest to remove; it may, in short, while a common, be abused in a thousand ways, by reason of the obstinacy, indulgence, or caprice of individuals, but it never can be benefited by the industry of man; and not only may this be done, but these things actually are done, in innumerable instances; so that to a person who contemplates the loss that the nation must suffer by these deplorable abuses, nothing can afford a more melancholy train of reflections, than that which the frequent recurrence of these deplorable commons suggest to his mind, as he travels over the otherwise delightful country of England. When he flaps to inquire more minutely into the effects of this kind of property upon the morals and domestic economy of the individuals who claim a right to these commons, he only finds additional causes, he says, of regret. He frequently discovers that the quiet and industrious cultivator, having a right upon a common, is obliged to aban-
COMMON.

It is evident from every one of the agricultural surveys which have been yet made, he says, that in every county in England and Wales, there are extensive tracts of land of this description (for commons and wastes may be considered as nearly synonymous terms, although it is a truth that many of these commons confit of land naturally as good as any in the kingdom). Of the extent of these lands, were it necessary, a tolerably accurate knowledge, he thinks, might be obtained; but as to the amount of improvement, it is impossible for any person to form at present an idea of it, without the prosperity of the country be permitted to go forward for a considerable length of time in that accelerating ratio into which it would naturally fall, if the general tranquility of the nation were preserved, and the obstructions which have heretofore required exertions in agriculture removed. It is enough here to say, he thinks, that it would be an object of immense magnitude. He has had occasion to observe, that in some favourable situations, it is well known that land, in the course of a very few years, has been made a thousand times at least more productive than in its original state.

Many commons are at present hung waste in situations equally favourable as these; and many other situations may become equally favourable by an extension of those modes of facilitating intercourse, which are now in contemplation, and are only prevented from being carried into effect by barriers that judicious laws may easily remove. See Waste Land.

In regard to the appropriation of comonable lands, it has been observed by Mr. Malthus, that the species of unappropriated lands in this country are, at present, 1st. Forest lands, and other extensive wastes, on which several manors, or adjacent townships, have a right of common paturage.

2d. Commonland of distinct townships, or manors, whose appropriated lands are wholly inclosed, and in a state of mixed cultivation.

3d. Commonland of townships, whose arable fields, are partially inclosed.

4th. Commonland of townships, whose arable fields remain wholly open.

And in respect to the principles on which the appropriation of such lands requires to be conducted, it may be observed, that as, by an established principle of the general law or constitution of the country, immemorial custom establishes right, neither the original rights and regulations, respecting such lands, nor the changes which may have taken place during a succession of centuries, from the origin of forests and townships, to the latest periods of time, are objects of investigation or inquiry; but many acquired rights which exist in any certain case at the time of appropriation, and which would continue to exist were it not to take place. "The poiffessor of a cottage," says the same writer, "which has enjoyed, since immemorial and without interruption, the liberty of paturage, though such cottage was originally an encroachment of a freeholder or an untenur, has indisputably as legal a claim to a proportionate share of the comonable lands, as the poiffessor of the demesne lands of the manor has (merely as such), although they may have descended from father to son from the time of their festivity. For it is evidently on the estimated values of the respective rights which exist, and which can be rightfully exercised in time to come, and on these alone, that a just and equitable distribution can be effected."

It is, however, stated, that before the distribution of comonable lands among the owners of common paturage can take place, the more affrait rights which belong to commons require to be estimated, and the just claims of their poifforors to be satisfied. These are, he says, principally manorial rights, and the rights of tithes.

The manorial claims are to be regulated by the particular advantages which the lord of a given manor enjoys, and which he will continue to enjoy, while the commons remain open and unappropriated; whether they arise from mines, quarries, water, timber, alien tenants, fuel, fowage, pannage, or game? And that his claim, as guardian of the soil, as productive
productive of pasturage only, is in most cases only honorary; he cannot as such (unless through ancient custom) profit by the herbage or the browse that the soil produces. But that the claim of the lord of the manor, in right of the soil on which thriving timber is standing, is substantial. For out of this, he has, in effect, a real yearly income, equal to the annually incrating value of the timber: a species of advantage which, if the commons remain open and unappropriated, he will in course continue to enjoy, so long as the timber continues to increase in its value. His claim, therefore, in this respect, depends on the quantity of timber, and its state of growth taken jointly. Young thriving timber not only affords an annual increase of value at present, but will continue its benefits for many years to come, if it be suffered to remain undisturbed on the soil which supports it, during the elimated period of its future increase; whereas, dotard*, and flinted trees which afford no increase of value, do not entitle their owner to any share of the soil they stand upon. The trees themselves, or their intrinsic value, are all the lord of the manor can have a right to claim."

And further, in like manner, the claims of the crown, or of hereditary rangers (if any), on the forest lands, ought, he conceives, to be satisfied.

But the claims of tithe owners, aggregately considered, are more complex and obscure. In a case where the great and small tithes are united, where the tithes of wool and lamb, and that of grain, roots, and herbage, belong to the same owner, and where no modus vivendi, it may seem to be reasonable that he should have the option of receiving land of equal value to the existing value of the whole of the tithes, or of taking the chance of their value, in the state of cultivation. But facing the evil tendency of corn tithes, and the impropriety of laying on so harmful a burthen, as they are now become, upon lands that have never borne it, there can be little risk in saying that it would be at least politic in parliament to prevent it. Besides, it stands part of the statute law, he believes, that the lands which have never been under tilage, shall not pay tithes during the first seven years of their cultivation; during which time, the incumbent's income might, by leaving the tithe to take its course, be materially abridged, and his circumstances thereby be rendered diftrefling.

It is therefore concluded, that, on the whole, it appears to be proper in this case, that the law should infract commissioners to set out lands equal to the existing value of the tithes at the time of appropriation; and, where much common land (land fit for corn) shall be appropriated, to set out a farther quantity, equal to the reversion of the extra value of the tithes to arise from such corn lands, seven years after the appropriation shall have taken place, above the value of the tithes that exist, provided any such extra value shall appear by the estimates.

And further in cases in which the tithes of land and wool, and the tithes of corn, &c. belong to separate owners, the line of rectitude and strict justice to all parties, appears, he says, to be still more difficult to draw. The former is clearly entitled to land, or a money payment equal to his lots of tithe; but the right of the other is less obvious. To cut him off entirely from any share of the lands, and likewise from any share of tithes to arise from them after they shall be appropriated, may seem unjust; he may be a lay rector, and may have lately purchased the tithes, or a clerical rector who has recently bought the advowson under the expectation of an indue. On the other hand, it appears to be hard that the proprietors of the parish should first give up land for the tithes of wool and lamb which will no longer exist, and then be liable to a corn tithe on the same lands, after they shall have bestowed on them great expense in clearing and cultivation. Indeed the injustice of such a measure is evident. A middle way, therefore, he thinks, requires to be sought; and it will be difficult, perhaps, to find one which has more justice in it than that which is proposed for the first case."

It may, however, says he, be urged that, admitting the foregoing regulation to be the true ground on which a remuneration in lieu of tithes of commomable lands ought to be elivated, the difficulties of cultivation would in some cases be great, and might be the cause of dispute and delay in the general work of appropriation; and a more practical method, though less reconcileable to theory, presents itself. Thus, let a certain proportion in value, of the lands to be appropriated as one, be allsized in lieu of the whole of the tithes of the township or manor, supposing the whole be payable in kind; and if there are more than one tithe owner in the manor or township, let the commissioners divide such aggregate allotment among the several owners and claimants, as the rector, the vicar, &c.; and the owners of land, &c. who pay the by ancient modus not in kind: such owners being entitled to a share of the said as the tith owners, in proportion to the advantage they receive, by such ancient privilege.

And if any other abstract claim on the lands to be appropriated be fairly made out, or any alien right, as that of a non-parishioner, or extra manorial occupier who has acquired by ancient grant, or by prescription, the privilege of depafluring them, be fully proved, its value requires to be accurately elminated, and land to be allsized in lieu of it."

When this has been done, the remainder of the unlimited commons of a given township or manor belongs to the owners of its common right lands and houses; but in what proportion may be difficult to determine with mathematical precision. Nevertheless, by adhering strictly to the general principle, on which alone he conceives an equitable appropriation can be conducted, viz. that of determining each man's share by the benefit which he has a right to receive at the time of appropriation, and which he may continue to receive, were it not to take place, truth and justice may be sufficiently near approached.

He considers that one of the first steps towards an equitable distribution of unlimited commons, is to ascertain the common right houses, and to distinguish them from those which have no right of commonage, and which therefore can have no claim to any share of the lands of the unlimited commons, further than the right of the lands they stand upon.

By ancient, and, he believes, pretty generally received, though somewhat vague idea, respecting the rights of commonage, the occupier of every common right house has the privilege of depafluring as many cattle, sheep, or other live stock, on the common in summer (provided, it must be understood, that it is large enough to permit every occupier to exercise this right), as the grounds he occupies within the township or manor can properly maintain in winter; and no one can exceed that proportion, for the surplus of the paflarge (if any) belongs to the lord of the soil, according to Fitzherbert and Blackstone.

Under this regulation, the appropriated lands of a common field township, which are not occupied jointly with a common right house, may be said to be deprived, during the time they are so occupied, of their right of commonage. And in some of the private bills of inclosure, which have been suffered to pass through parliament, the lands which happened to be in this state of occupancy at the time of passing
passing the bills, were deprived of their interest in the common lands, for ever: Notwithstanding, perhaps, they had a few years preceding their accidental circumstance, an undetermined right to their portion of them; a right which, a few weeks or a few days afterwears, might have reverted to them, without the smallest slight, by the temporary alienation. If any of the appropriated lands of a township or manor have been estranged from its commons, during time immemorial, have never been occupied jointly with a common right house, or in any way enjoyed of right the common pastureage, within memory, they may, with some reason, be said to have lost their right, and be excluded from a participation.

It is stated, that by this ancient, and in a degree essential, usage, common right houses have a clear right to the land of the commons, superior to the ground they stand upon; especially if they rightfully enjoy a privilege of partaking of the fuel and pannage they afford; for their properly belong to the houses, not to the lands; and still especially if they are not conveniently situated for enjoying the several benifits which the commons afford in their wild state. And whatever a common right house is worth, merely as such, that is to say, whatever it will let or sell for, over and above a common right house of the same intrinsic value, it certainly ought to participate, in the distribution, according to such extra value.

"The true proportionate shares of the common right lands are to be ascertained on the same principle. For although the ancient regulation respecting common right may continue in force while the commons remain open and unappropriated, it would be found troublesome, or unmanageable, as a rule to their just appropriation. There are few, if any, commons of common-field townships at least, that now afford pastureage in summer for all the flock which the appropriated lands are capable of maintaining in winter; so that their several proportions only could be used; and these proportions may be calculated with much greater certainty and dispatch, on the respective rental values of the lands, than on the more vague and troublesome estimation of the quantities of flock they would winter, which indeed would be best calculated by the rental value of the land. Consequently, in adopting this as the basis of calculation, the ancient rule is in effect complied with.

But still there is another circumstance, he says, of some importance, which requires attention, before an equitable distribution can be made. For although each common right occupier may have a right to flock in proportion to the productivity or rental value of his appropriated lands, every one could not do this with equal profit, and of course could not receive equal benefit. Lands situated on the side of a common, are much more beneficial in this respect, than lands which lie a mile or two from it, with bad roads between them. And it is the real advantage which an occupier can freely receive that is the true guide in the partition; which consequent ought to be conducted, not on the rental value of the land, abstractly confidered, but on this and its situation with respect to the commonable lands, jointly. In other words, it is the rental values of the common right lands while the commons remain open, not what they will become after the commons are inclosed, which he conceives to be the proper ground-work of appropriation. And that in cases where commonable lands are wholly attached to manors, and not common to the parih or township in which they are situated, as in forests and woodland districts, the self-same principle of distribution is applicable. The remainder of the commons (after the owners of abstract rights have been satisfied) belong to the common right lands and houses, no matter whether such lands and houses belong to copyhold tenants exclusively, or to copyholders and freeholders jointly, provided the immemorial custom of the manor make no distinction in their respective rights; the well established customs of manors being in all cases rules of conduct and unerring guides to commissioners."

With these he supposes, end the great difficulties as to the principles of appropriation; the rest he considers as merely technical; the works of admistration, election, and calculation; operations that are familiar to professional men in every district, and which require nothing but application and integrity to render them sufficiently accurate. It is however a matter of vital importance to have persons fully conversant with the subject as commissioners in all such cases.

Through the uncertainty and ex pense attending private acts, a great portion of these unlimited common lands remain nearly as nature left them,—appearing in the present state of civilization and science, as blotsches on the face of the country, especially when seen under the threatening clouds of famine, which have now repeatedly overcast it.

COMMON-FIELD Land, signifies a description of land of a somewhat similar kind to vast of commons, only lying in extensive fields. There is a large proportion of this sort of land in almost every county of the kingdom. It has been observed by Mr. Mallet, that the common arable fields in the county of Middlesex are about 22,000 acres; and in that, as well as in most other counties, are divided into too small properties to be advantageously cultivated. He says he has known thirty landlords on a field of 200 acres; and the property of each so divided as to lie in ten or twenty pieces, containing from an acre or two downwards to fifteen perchés; and in a field of 300 acres he has met with patches of arable land, containing eight perchés each. In this instance the average size of all the pieces in the field was under an acre. In all cases, he observes, they lie in long, narrow, winding, or worm-like slips. Land so distributed occasions great lots of time to the farmer, in removing his teams and labourers; and what is of equal importance, he can neither cross-plough nor harrow and clean such land in a workmanlike manner. And another great inconvenience attending common-field land is, the farmer cannot crop with that which béd fuels his coi, but is confined to few such grain as must be cut with his neighbours. An act to include common-field land would be advantageous to the farmer, and make the estates compact, and of more value to the owners. Neither can he sow any green or mellowing crops, vary the usual impove-riishing succession, or even destroy the vermin. In short, the cultivator of these lands finds his expenses double, and his crops only half of what they might be, if the land were laid together and well fenced."

By including the common-fields, says he, which consist of a turnip and barley field, both the landlord and the farmer are freed from the shackles of an exhausting and obsolete rotation of crops, and placed at liberty to distribute for cultivation the soil in the most improved manner, keeping it clean, in better heart, raising such roots and green crops as are in the greatest demand at market, and only growing a crop of corn for the sake of renewing the course of green and root crops. In this manner intelligent men, after inclusion, can double the produce of their land.

It is added that the invariable rotation of crops in all the common-fields is, first year a fallow, second year wheat, third year peas or oats, then begin again with a fallow. This, he says, is the destructive system of arable management that mostly prevails in this kind of land, and by which some
some of the belt land in the kingdom is condemned to be unemployed every third year; and the farmer who occupies it is compelled to pay three years rent in taxes, for two years use of it, and of course to maintain his family, farmers, cattle, and implements of husbandry, every third year, without having any return from the land. It is, therefore, impossible that lands of this sort can ever be cultivated to the greatest advantage, while they remain in their present state. See Inclosing.

It is observed by Mr. Marshall that "abund as the common field system is, in almost every particular, at this day, it was admirably suited to the circumstances of the times in which it originated, the plan having been conceived in wisdom and executed with accuracy as appears in numberless instances, even at this distance of time."

It is remarked that in the western extreme of the island the common field system has never, perhaps, been adopted; has certainly never been prevalent, as in the more central parts of England. There, a very different usage would seem to have been early established, and to have continued to the present time; when lords of manors have the privilege of letting off the lands of common pastures, to be broken up for corn, the tenant being restricted to two crops; after which the land is thrown open again to pasture in a manner more convenient for the several proprietors, and is laid each man's portion, which had confided of numberless narrow plots, in one or more well-shaped grounds, or by alt of parliament, whereby not only common fields, common meadows, and foisted pastures, but unlisted commons also, have been appropriated, by commissioners named in, or chosen in pursuance of, each respective act, who, throwing back the entire township to its original state, laid it out afresh, according to the directions of the act and their own judgment.

Common Field Husbandry, that sort of cultivation which is practiced in common fields. See Husbandry. It has been observed in the "Agricultural Report of Wiltshire," that the introduction of the common field husbandry seems to have been very slow and progressive; and that the imperfection in the smallness of the pieces, of the common field lands now in cultivation, evidently shows that the occupiers began with tilling a single acre, as one day's work for a plough, or perhaps only half an acre each; and that, as a want of corn increased, this cultivation was augmented until they had cultivated all that was most proper for that purpose, still leaving those parts which were less fit for the plough, or more distant from home, in a constant state of commonage, but by mutual agreement keeping the cattle out of the cultivated parts till after harvest. This was, probably, the origin of common fields. It does not seem probable, that any improved methods of cultivation can be adopted on common field lands, until the system of common field husbandry is abolished. See Common and Common Field Lands.

Common Meadows and Pastures, are such meadows and pastures as are held in a state of commonage. It is remarked, by the author of the "Agricultural Survey of Wiltshire" that, by the same kind of mutual agreement, as is stated in speaking of common field lands, those who have rights shut up, as in some cases included, such parts of their common pastures as were most proper to mow for hay, dividing them into certain specific quantities, either be land-marks, or by lot, for mowing, and suffering the common herd of cattle to feed there again as soon as the hay was carried off, till it was time to lay them up for a new crop; and that this was the origin of common meadows. And that the mutual agreements, originally founded in necessity, because, when approved by the lords, and ob served for a length of time by the tenants, what are called a custom of manors, constituting the very essence of the court baron, or manorial court, by which both lord and tenants were and are still bound; and of which, though the lands or his plate is the judge, the tenants are the jury, the custom of the manor equally binding both.

Common, Communes, in a general sense, something that belongs to all alike; is owned or allowed by all; and is not confined to this more than that.

In which sense, common bounds opposed to proper, peculiar, &c. Thus, the earth is said to be our common mother; in the first, or golden age, all things were in common, as well as the sun and elements; the name animal is common to man and beast; that of substance to body and spirit. Philosophers dispute whether there be any such thing as common notions, innate, or impressed on the mind by nature herself; or whether our ideas are all adventitious. See Idea.

Common, Communis; (i.e. quod ad omnes pertinent) in Law, signifies that that foil, the use whereof is common to a particular town or lordship; or it is a profit that a man hath in the land of another person, usually in common with others; or a right or privilege, which one or more persons claim to take or use, in some part or portion of that which another man's lands, or his plate, is; that is, they produce without having an absolute property in such land, waters, wood, &c. It is called an incorporeal right, which he in grant, as if originally commencing on some agreement between lords and tenants, for some valuable purposes; which by age being formed into a pretension, continues, although there be no deed or instrument in writing which proves the original contract or agreement. 4 Co. 37. 2 Nill. 67. 1 Vent. 387. And there is not only common of pasture, which the word common, in its most usual acceptation, signifies; but also common of piscary, common of estovers, common of turbary, &c. And in all cases of common, the law doth much respect the custom of the place; for there the rule is, confutudo loci ob observanda. 7 Rep. 5.

Common of pastures, is a right of feeding one's beast on another's land; for in those waste grounds, usually called commons, the property of the soil is generally in the lord of the manor; as in common fields, it is in the particular tenants. This kind of common is divided into common in gross, common appendant, common appurtenant, and common per eau des vicinage.

Common in gross, is a liberty to have common alone, that

Vol. IX.
COMMON.

is without any land or tenement in another man’s land, granted either to a person for life or to him and his heirs. This is commonly passed by deed, or by warranty, or by use, and claimed by prescriptive right.

Common appurtenant, and Common appurtenant to, are usually confused; both being defined to be a liberty of common appertaining to, or depending on, such or such a freehold; which common must be taken with beasts commnurable as hores, oxen, &c. being accounted fittest for the plowman; and not with goats, geese, and hogs. Others differing between the two, thus; common appurtenant may be severed from the land whereof it appertains; and is where the owner of land has a right to put in other beasts not commnurable as hogs, goats, &c. which neither plough nor manure the land. Whereas common appurtenant, according to lord Coke, had its original in the following manner:

"When a lord enfeoffed another in arable lands to hold of him in fociage; the foecifee, to maintain the service of his plough, had at harl, by courtesy of his lord, common in the wales, for necessity beasts to eat and comprop his lands; and that for two canes; 12. Because it was tacitly implied in the fociage; by reason the foecifee could not till, or comprop his palture; by consequence, therefore, the foecifee had, as a thing necessary, or incident, common in the wales, or lands of the lord. 2. For the maintenance and advancement of tillage."

Common appurtenant belongs only to ancient arable land, and not to a house, meadow, palfure, &c. and it is of common right. But it is not common appurtenant, unless it hath been appurtenant time out of mind. 1 Danv. 746. It may be upon condition, for all the year, or for a certain time, or for a certain number of beasts, &c. by usage; though it ought to be for such cattle as plough and comprop the land to which it is appurtenant. 1 Danv. 757. Common appurtenant may be to common in a field after the corn is ferred, till the ground is relown, and it may be to have common in a meadow after the hay is carried off, till C dumbas, &c. Yelv. 185. This common, which in its nature is not restricted by number, may be limited by a common to the wales, whereas every beast to an appurtenant ought always to be for thole levant and conchant, and may be farnumber. Plowd. 161. A man may preferbe to have common appurtenant for all manner of cattle, at every seafon in the year. 25 Aff. 8. He who hath common appurtenant or appurtenant can keep but a number of cattle proportionable to his land; for he can common with no more than the lands to which his common belongs is able to maintain. 3 Saik. 93.

Common parc de vicinage, i.e. by reason of neighbourhood, is the liberty that the tenants of one lord in one town, have to common with the tenants of another lord in another town.

But it is to be observed, that those who claim this kind of common, (which is usually called intercommunining) may not put their cattle into the common of the other lord, for then they are disfrainable; but, turning them into their own fields, if they stray into their neighbour’s common, they must be filled-red.

The inhabitants of one town or lordship may not put in as many beasts as they will, but with regard to the frehold of the inhabitants of the other; for otherwise it were no good neighbourhood, upon which all this depends. Terms de Ley. If one lord excludes the common, the other town cannot then common; but though the common of vicinage is gone, common appurtenant remains. 4 Rep. 38. 7 Rep. 5. Every common parc de vicinage is a common appurtenant. 1 Danv. Abru. 799. This is indeed only a permissive right, intended to excuse what in friesians is a trespass in both, and to prevent a multiplicity of suits. And therefore either township may enclose and bar out the other, though they have intercommenced time out of mind. Black. Com. 34.

The property of the soil in the "common" is entirely in the lord; and the use of it jointly in him and the commoners. Lords of manors may departure in commons where their tenants put in cattle; and a prescription to exclude the lord is against law. 1 Inl. 122. The lord may agit the cattle of a stranger in the common by prescription; and he may license a stranger to put in his cattle, if he leaves sufficient room for the commoners. 1 Danv. 775, 2 Mod. 6. The lord may also forcharge, &c. an overplus of the common; and if, where there is not an overplus, the lord forcharge the common, the commoners are not to detain his beasts; but must commence an action against the lord. F. N. B. 125. The lord may detain when the common is free charge and bring an action of trespass for any trespass done in the common. 9 Rep. 113. A lord may make a pond on the common, though he cannot dig pits for gravel or coal; the statute of appropriation extending only to incluirae. 3 Inl. 104. 9 Rep. 112. 1 Sld. 106. If the lord makes a warren on the common, the commoners may not kill the comme; but are to bring their action, nor they may not be their own judges. 1 Rol. 92. 405. By statute of Morton (20 H. III. c. 4.) lords may "approve" against their tenants, viz. inclose part of the wale. &c. and thereby discharge it from being common, leaving common sufficient; and neighbours as well as tenants, claiming common of palfure, shall be bound by it. If the lord incloses on the common, and leaves not common sufficient, the commoners may not only break down the inclosures, but may put in their cattle, although the lord plowes and lowes the land. 2 Inl. 88. 1 Rol. Abru. 406. By lit. 29 Geo. II. c. 36. Owners of commons, with the consent of the majority, in number and value, of the commoners; the majority of the commoners, with consent of the owners, of all peruns, with the consent of the owners, of all fainly and Macklum; for the growth of wood. If the wood be delivered, the offender may be punished according to lit. 1 Geo. I. c. 48.; if not convicted in six months, the owner shall have satisfaction from the adjoining parishes, &c. as for fences overthrown by lit. Wedm. 2. Persons cutting wood on commons shall incur the same penality. And by lit. 31 Geo. 2. c. 41, the recompence is to be paid to persons injured, in proportion to their interest. A commoner hath only a special and limited interest in the soil, but yet he shall have such remedies as are commensurare to his right; and therefore he may detain beasts damage-faunt, bring an action on the cache, &c. but not being absolute owner of the soil, he cannot bring a general action of trespass for a trespass done upon the common. A commoner cannot do any thing on the soil which tends to the melioration or improvement of the common, as cutting down of beeches, fern, &c. 1 Sld. 251. 12 Hen. VIII. 2. 13 Hen. VIII. 115. Therefore, if a common every year in a field is inundated with water, the commoner cannot make a trench in the soil to avoid the water, because he has nothing to do make that trench, but only to take the grass with the mouth of the cattle. 1 Rol. Abru. 405. 2 Bull. 116. Every commoner may break the common if it be inclosed; and although he does not put his cattle in at the time, yet his right of commongage shall excuse him from being a trespasser. Lit. Rep. 38. 1 Rol. Abru. 406. If a tenant of the freehold ploughs it, and lays it with corn, the commoner may put in his cattle, and with them, eat the corn growing upon the land: so if he lets his corn
COMMON.

Coercion in the field, beyond the usual time, the other commoners may, notwithstanding, put in their beasts. 2 Leon. 202, 203. The commoner cannot use common except with his own proper cattle; but if he hath not cattle to manage the land, he may common another cattle to manage it, and use the common with them; for, by the loan, they are in a manner made his own cattle. 1 Danv. 708. A commoner may detain beasts put into the common by a stranger, or every commoner may bring action of the waste, where damage is received. 9 Rep. 11. But one commoner cannot detain the cattle of another commoner, though he may those of a stranger, who hath no right to the common. 2 Lew. 1238. See Surcharge of Common, and Disturbance of Common.

Upon agreement between two commoners to inclose a common, a party having interest, not privy to the agreement, will not be bound; but one or two wilful persons shall not hinder the public good. Chan. Rep. 48. Commons must be driven yearly at Mechachmas, or within 15 days after; infected heifers and stone-horses under size, &c. are not to be put into commons. under forfeiture, by 15 Hen. VII. c. 13. New erected cottages, though they have four acres of ground laid to them, ought not to have common in the waste. 2 Inh. 740. In law-proceedings, where there are two distinct commons, the two titles must be shown: cattle are to be alleged commensal; and common ought to be in lands commensal; and the place is to be set forth where the meadows and lands lie, &c. to which the common belongs. 1 462, 463. By 15 Geo. III. c. 81, in every parish where there are "common field-lands," all the arable lands lying in such fields shall be cultivated by the occupiers, under such rules as three-fourths of them in number and value (with the consent of the land and tenants) shall appoint, by writing under their hands; the expense to be borne proportionally, under the management of a field-matter, or field-revee, to be appointed annually in May. For other particulars, see Jacob's Law Dict. by Tomlins.

COMMON, in Geometry, is applied to an angle, line or the like, which belongs equally to two figures, or makes a necessary part of both.

COMMON, in Grammar, denotes the gender of nouns which is equally applicable to both sexes, male and female.

Such is that of parent, parent; which is either masculine, or feminine, as it is used to signify either father, or mother.

The Latin grammarians, besides this, which they call the common of two, also make a common of three; which extends to masculine, feminine, and neuter.

COMMON, Communis, in Ancient Music, was an appellation given to the seventh species of the diapason. See Diapason.

COMMON Bail. See Bail.

COMMON Barrator. See Baratry.

COMMON Bench. The court of Common Pleas was anciently called Common Bench, because the pleas of controversies between common persons were there tried and determined.

In law books and references, the court of Common Pleas is written C. B. from communis banco, or C. P.: and the justices of that court are styled justiciarii de banco. See Court and Common Pleas.

COMMON Centre of Gravity, in Mechanics. See Center of Gravity.

COMMON Chord, in Music, is sometimes used to denote the third, fifth, and octave of any note, considered as a bass. It will afford some light into the composition of chords, to exhibit all the possible variations in the order or arrangement of the concord, major third (III), minor third (3d), and minor fourth (4th), constituting the common chord in the following manner, viz.

\[
\begin{align*}
\text{VII} & : & \text{V} & : & \text{VI} & : & \text{V} \\
\text{V} & : & \text{V} & : & \text{VI} & : & \text{V} \\
\text{VI} & : & \text{V} & : & \text{VI} & : & \text{V} \\
\text{V} & : & \text{V} & : & \text{VI} & : & \text{V} \\
\end{align*}
\]

By a comparison of the several chords in the first arrangement above, it will appear, that when the four notes, C, E, G, and C, constituting the common chord, are founded together, all of the seven concords, viz. 3d, III, 4th, V,
COMMON.

51 Hen III. concerning general days in bank. Blount and Cowel.

COMMON, Disturbance of. See Disturbance of Common.

COMMON Dwell, in Anatomy. See DucTus CommuNus.

COMMON Estate in. See ESTATE.

COMMON of Estates. See Estates.

COMMON Field-land. See Common Fugs.

COMMON Fine, in Law, a certain sum of money, which the reiant within the liberty of some peers pay to the lord thereof; called in some places, head-deser; in others, cer-

Cious, or certain fees, and head-pace.

It was first granted to the lord towards the charge of his purchase of the court-let; whereby the reiants have now the convenience of doing their suit within their own manors, without being compelled to go to the sheriff's turn.

COMMON in Grofs. See Common Fugs.

COMMON Hunt, the chief huntsman belonging to the lord mayor and aldermen of London.

COMMON Informer. See Informer.

COMMON Intention, in Law, the common understanding, meaning, or construction of any thing, without examining it to any foreign remote or particular sense; and Bar to Common Intention, is an ordinary, or general bar, which is commonly an answer to the declaration of the plaintiff. See Bar and Intendment.

COMMON Jury. See Jury.

COMMON Law, that body of rules generally received, and held as law in this nation, in contradistinction to the statute, or written law, and including not only general customs, or the common law properly so called; but also the particular customs of certain parts of the kingdom, and likewise those particular laws, that are by custom observed only in certain courts and jurisdictions.

The common law is grounded upon the general customs of the realm, and comprehends the law of nature, the law of God, and the principles and maxims of the law; it is founded upon reason, and it is said to be the perfection of reason, acquired by long study, observation, and experience, and refined by learned men in ages. It is justly regarded as the common birth-right, which the subject has for the self-guard and defence, not only of his goods, lands, and revenues, but also of his life, and liberty, and estate, and even his life. Co. Litt. 97, 143. Treasury of Laws, 1, 2.

According to Hale, the common law of England is the common rule for administering justice within this kingdom, and affects the king's principal prerogatives, and likewise the rights and liberties of the subject. It is, in general, that law which by the determinations of the king's "Ordinary courts" are guided; and this directs the course of defendants; of lands; the nature, extent, and qualifications of estates, together with the manner and ceremonies of conveying them from one to another; the forms, solemnities, and obligations of contracts; the rules and directions for the exposition of deeds, and acts of parliament; the processes, proceedings, judgments, and executions of our courts of justice; also the limits and bounds of courts, and jurisdictions; the several kinds of temporal offenses and punishments, and their application. &c. Hale's Hist. of the Common Law, p. 24, 44, 45.

As to the origin of the common law, which, adopting the expression of lord chief justice Hale, is as undeniable Commus the head of the Nile; our ancient, both, the customs, which constitute our common law, are as old as the primitive Britons, and that they have been continued down, through
the several mutations of government and inhabitants, to the present time, unchanged and unadulterated. This, says judge Blackstone, may be the case as to some; but, in general, as Mr. Selden observes, this assertion must be understood with many grains of allowance; and ought only to signify, as the truth seems to be, that there never was any formal exchange of one system of laws for another; though, doubtless, by the intermixture of adventitious nations, the Romans, the Picts, the Saxons, the Danes, and the Normans, they must have infensibly introduced and incorporated many of their own customs with those that were before established; thereby in all probability improving the texture and wisdom of the whole, by the accumulated wisdom of diverse particular countries. Accordingly, lord Bacon observes, that our laws are as mixed as our language; and, as our language is so much the richer, the laws are the more complete. And, indeed, our antiquaries and early historians do all positively assure us, that our body of laws is of this compounded nature.

After the decay of the Roman empire, it has been said, Britain became invaded by three kinds of German people, viz. the Saxons, Angles, and Jutes. From the Jutes descended the men of Kent, and those of the Isle of Wight; from the Saxons came the people called the East, South, and West Saxons; and from the Angles came the East Angles, Mercians, and Northumbrians.

Now, as each people had its peculiar customs, so each inclined to different laws; whereas, those of the West Saxons and Mercians, who inhabited the midland counties, were, upon the diffusion of the heptarchy, and establishment of a monarchy, preferred to the rest, and acquired the common appellation of Jux Anglorum. Their particular names were Welf Saxon leges, and Mercenlages.

The first Saxon laws published in England were those of king Ethelbert, in the sixth century. Three hundred years after, king Alfred, whom our historians call magnus juris Anglicani conditor, having united the heptarchy, and rendered himself master of the whole nation, made a collection from among the numerous laws and customs of the several provinces of his dominions, which were grown so various; and commanded them to be observed throughout his kingdom. This collection was denominated folk right, and soon after the common law; as being common to the whole nation.

This was written in Alfred's dome-book, or liber judicidii, which was designed for the general use of the whole kingdom.

This book is said to have been extant in the reign of king Edward IV.; but has since been unfortunately lost. It contained, as we may reasonably imagine, the principal maxims of the common law, the penalties for misdemeanors, and the forms of judicial proceedings.

By these laws the nation was governed for a considerable time, till, being at length subdued by the Danes, the customs of those people were introduced, and incorporated with the rest. Hence the code of Alfred in many provinces fell into disuse, or, at least, was mixed and debased with other laws of a clearer alloy; and thus a new form of common law arose, called Danelage.

The three systems of law above recited, viz. the Danelage, principally maintained in several of the midland counties and also on the eastern coast; the Welf Saxon leges, which was much the same with the code compiled by Alfred, and which obtained in the counties to the south and west of the island, from Kent to Devonshire, being the municipal law of the far most considerable part of Alfred's dominions, and particularly of Berkshire, the seat of his peculiar residence; and the Merchenlages, observed in many of the midland counties, and those bordering on the principality of Wales, the retreat of the ancient Britons, and therefore probably intermixed with the Britifh or Druidical customs; were in use about the beginning of the eleventh century. The northern provinces were at this time under a distinct government. In proofs of time king Edgar began what his grandson Edward the Confessor, on this account called regum Angliearem refiduum, completed; viz. to form one digest or body of laws. This seems to have been only a new edition, or fresh proclamation of Alfred's dome-book, with such additions and improvements as the experience of a century and a half had suggested.

The Danes being afterwards, in their turn, overcome by the Normans; the Conqueror, on a review of the several laws and customs that then obtained, abrogated some, and abolished others; adding some of his own country laws.

His son, William Rufus, broke through the ancient laws and customs which his father had established; but his next son, Henry I. excluded the civil customs which his brother had introduced, and restored the laws of Edward the Confessor, with those amendments made by his father, under the advice of his barons. These were afterwards confirmed in succeeding reigns.

Hence is derived that system of maxims and unwritten customs, now known by the name of the common law, which is of Saxon parentage; though the customs and maxims themselves are of higher antiquity than memory or history reach; many of them being as old as the primitive Britons. The name of common law was given to it, either in contradistinction to other laws, as the statute law, the civil law, the law merchant, and the like; or, more probably, as a law common to all the realm, the jus commune or folk-right mentioned by king Edward the Elder, after the abolition of several provincial customs and particular laws.

The common law of England is, properly, the common customs of this kingdom; which, by length of time, have obtained the force of laws.

The goodness of a custom depends upon its having been used time out of mind; or, in the solemnity of our legal phrase, time whereof the memory of man runneth not to the contrary. This gives it its weight and authority; and of this nature are the maxims and customs which compose the common law, or lex non scripta, of this kingdom. This unwritten, or common law, is properly distinguished into three kinds; 1. General customs, which are the universal rule of the whole kingdom, and form the common law, in its stricter and more usual signification. 2. Particular customs, which for the most part affect only the inhabitants of particular districts. 3. Certain particular laws; which by custom are adopted and used, by some particular courts, of pretty general and extensive jurisdiction. See Custom.

Some have divided the common law into two principal grounds or foundations; viz. 1. Established customs; such as that, where there are three brothers, the eldest brother shall be heir to the second, in exclusion of the youngest; and, 2. Established rules and maxims; as, that the king can do no wrong; that no man shall be bound to accuse himself; and the like. But judge Blackstone observes, that these are one and the same thing. For the authority of these maxims rests entirely upon general reception and usage; and the only method of proving,

COMMON.
proving, that this or that maxim is a rule of the common law, is by showing that it hath been always the custom to observe it. See Custom.

It is called lex non scripta, the unwritten law: not but that we have most of it written in the old Norman dialect, and the monuments and evidences of our legal customs are contained in the records of the several courts of justice, in books of reports and judicial decisions, and in the treatises of learned fages of the profession, preserved and transmitted from times of the highest antiquity, but because it does not appear to be made by charter, or parliament; for those are always matters of record. Its original institution and authority are not set down in writing, but it receives its binding power and the force of law, by long and immemorial usage, and by universal reception through the kingdom. See Authorities and Reports.

Besides the common law of England in general, there are in divers parts of the nation particular customs, and common usages, which have the force of common law among those people, who have retained them: such as the Borough-English, Gavel-kind, &c.—Where the common law is silent, there the Statute-law speaks. See Statute.

All trials at common law are by a jury of twelve men. Among the ancient and most eminent writers on common law we may select and enumerate the following. Britton wrote his learned book of the common law of this reign by the king’s command, and it runs in his name, corresponding to the institutions of the civil law, which Justinian assumes to himself, though composed by others. He thus describes the king in six books, of which the last is of the Roman law. Britton, a great lawyer in the time of Henry III., wrote a very learned treatise of the common law of England, held in great estimation; and he was said to be lord chief-justice of the kingdom. The famous and learned Glanville, lord chief-justice in the reign of Henry II., wrote a book of the common law, which is said to be the most ancient composition extant on that subject. Besides these, in the time of Edward IV. the renowned lawyer Littleton wrote his excellent book of “English Tenures.” In the reign of king James I., the great oracle of the law, Sir Edward Coke published his learned and laborious Institutes of our law, and commentary on Littleton. About the same time likewise Dr. Cowl, a civilian, wrote a short institute of our laws. In the reign of king George I., Dr. Tho. Wood, a civilian and common lawyer, and at last a divine, wrote an institute of the laws of England, somewhat after the manner of the Institutes of the civil law. And to mention no others, the late learned judge Blackstone, in the reign of George III., published his Commentaries on the laws of England, the best analytic and most methodical system of our laws, which was ever published; and equally adapted for the use of students, and of those gentlemen who wish to acquire that knowledge of our laws, which is, in fact, essentially necessary for every one. See biographical articles Britton, Bracton, &c. &c.

Common measure divisor, in Arithmetic, a number that exactly measures two other numbers, without a remainder. And the greatest number that can measure any two other numbers, is called their greatest common measure; thus 4 is the greatest common measure of 8 and 12.

To find the greatest common measure of two numbers, divide the greater by the less, and if there be no remainder, the less number is the measure required. If there be a remainder, divide the last divisor by it, and thus proceed, till there be no remainder left, and the last divisor is the greatest common measure.

E. G. To find the greatest common measure of 816 and 1438.

\[
\begin{array}{c}
816)1438(1 \\
816 \\
672)816(1 \\
672 \\
144)672(4 \\
568 \\
104)672(6 \\
648 \\
124(10 \\
96 \\
28 \\
0
\end{array}
\]

Common measure - 28

For algebraic quantities, the remainders are to be divided by their simple divisors, and the quotients will be the quantities required.

E. G. Let the quantities be \( a^2 + 2ab + b^2 \) and \( a^2 + 2ab + b' \).

Divide the latter of these by the former in the following manner:

\[
a^2 + 2ab + b^2 | a^2 + 2ab + b' (a + b + b')
\]

The remainder is \( a^2 - b^2 \), which being divided by \( b' \), its greatest simple divisor, given \( a + b \) and by this divide \( a^2 - b^2 + b' \), and the quotient will be \( a + b \), exactly, which is the common measure required. And if fractions are divided by their greatest common measure, they will thus be reduced to their lowest terms.

E. G. Let the fraction be \( \frac{816}{1438} \); then divide the numerator and denominator by 48, the greatest common measure, and the fraction will be reduced to \( \frac{17}{31} \), its lowest terms.

Let the algebraic fraction be \( \frac{a^2 + 2ab + b}{a^2 + 2ab + b'} \); then, dividing the numerator and denominator by \( a + b \) the greatest common measure, and it will be reduced to \( \frac{a + b}{a^2 + b} \), its lowest terms.

These operations are founded on this principle, viz. that whatever quantity measures the whole and one part of another, must afo measure the remaining part. For that quantity (whatever it is) which measures both the divisor and dividend, must evidently measure \( a^2 + 2ab + b' \) being a multiple of the former; whence, by the above-cited principle, the same quantity, as it increases the whole dividend, must also measure the remaining part of it, \( a^2 + b' \) but the divisor, which we are seeking, being a compound one, we may call off the simple divisor \( b' \), as not answering our purpose; whence \( a + b \) appears to be the only compound divisor which the case admits of; and this must be the common measure required, if the proposed example admits of any such.

Common Place Book. Adversaria, among the learned, denotes a register, or orderly collection of things which occur worthy to be noted, and retained in the course of a man’s
man’s reading, or study; so disposed, as that among a
multiplicity of subjects, any one may be easily found.

Common place-books are of great service; they are a
kind of promptuaries or storehouses, wherein to repose the
most valuable parts of authors, to be ready at hand when
wanted. Several persons have their several methods of or-
dering them: but that which comes best recommended, is
the method of that great matter of order Mr. Locke. He
has thought fit to publish it in a letter to M. Toftnard; de-
termined thereto, by the great convenience and advantage
he had found it in twenty years experience; as well as
by the recommendations and intracacies of many of his friends,
who had likewise proved it.
The fabulosity of this method we shall here give the
reader; whereby he will be easily enabled to execute it him-
self.
The first page of the book you intend to take down the
common places in, is to serve as a kind of index to the whole;
and to contain references to every place, or matter there-
in: in the commodious contrivance of which index, so
that it may admit of a sufficient copia, or variety of ma-
terials, without any confusion, the whole secret of the me-
thod consists.

In order to this the first page, as already mentioned, or
for more room, the two first pages that front each other, are
to be divided by parallel lines, into twenty-five equal parts;
whereof every fifth line is to be distinguished, by its colour,
or some other circumstance. These lines are to be cut per-
pendicularly by others, drawn from top to bottom; and in
the several spaces thereof the several letters of the alpha-
bet, both capital and minuscule, are to be duly written.

The form of the lines and divisions, both horizontal and
perpendicular, with the manner of writing the letters
therein, will be conceived from the following specimen;
which is what is to be done in the book for all the letters
of the alphabet, is here shewn in the first four, A, B, C,
and D.

The index of the common-place book being thus formed,
matters are ready for the infection of any thing in it.
In order to this, consider to what head, the thing you
would enter is most naturally referred; in this head, or
word, regard is had to the initial letter, and the first vowel
that follows it; which are the characteristic letters on which
the whole use of the index depends.

Suppose, e. g. I would enter down a passage that refers
to the head beauty: B, I consider, is the initial letter, and
e the first vowel; then looking upon the index for the par-
tition B, and therein the line e (which is the place for all
words whose initial letter is B, and first vowel e; as Beauty,
Beneficence, Bread, Bleeding, Blemishes, &c.), and finding
no numbers down already to direct me to any page of the
book where words of this characteristic have been entered,
I turn forward to the first blank page I find, which in a
fresh book, as this is supposed to be, will be page 2, and
here I now write what I have occasion for on the head
beauty; beginning the head in the margin, and indenting
all the other sublervent lines, that the head may stand out,
and show itself; this done, I enter the page where it is
written. viz. 2, in the index, in the space B e, from which
time, the class B e becomes wholly in the possession of the
2d and 3d pages, which are configured to letters of this cha-

Had I found any page or number already entered in the
space B e, I must have turned to the page, and have written
my matter in what room was left therein: so, if after
entering the passage on beauty, I should have occasion for
benevolence, or the like, finding the number 2 already pos-
sessed of the space of this characteristic, I begin the pas-
tage on benevolence in the remainder of the page; which
not containing the whole, I carry it on to page 3, which is
also for B e, and add the number 3 in the index. When
the two pages defined for one class are full, look forward
for the next backside that is blank; if it be that which im-
mediately follows, write at, the bottom of the margin of
the page filed, the letter υ for vertic, turn over; and the
same at the top of the next page: and continue from this
new page as before. If the pages immediately following
be already filled with other classes, then write at the bottom
of the page last filed, the letter υ, with the number of the
next blank page; and at the top of that page, the number
of the page last filled; then entering that head in this new
page, proceed as before. By these two numbers of refer-
ce, the one at the top, and the other at the bottom of the
page, the discontinued matters are again connected. It
may not be amiss, every time you put a number at the bot-
tom of a page, to put it likewise in the index. Now, if
the head be a monosyllable beginning with a vowel, the
vowel is at the same time both the initial letter, and the
characteristic vowel; thus the word art is to be written in
A n. Mr. Locke omits three letters of the alphabet in
his index, viz. K, Y, and W; which are supplied by C,
I, U, equivalent to them: and as for Q, since it is always
followed by an u, he puts it in the fifth place of Z; and so
has no Z u, which is a characteristic that very rarely occurs.
By thus making Q the last in the index, its regularity is
preferred, without diminishing its extent. Others choose to
retain the class Z u, and affix a place for Q u below the
index.

If any imagine, that those hundred classes are not suffi-
cient to comprehend all kinds of subjects without confusion,
he may follow the same method, and yet augment the num-
ber to five hundred, by taking in one more characteristic to
them.

But the inventor assures us, that in all his collections, for
a long series of years, he never found any deficiency in the

index as above laid down. Other contrivances for common-place books have been proposed; but they are such as will naturally occur to persons conversant with the subject, and accustomed to orderly arrangement: and it is, therefore, needless to extend this article.

COMMON Pleas. See Court of Common Pleas. Compound Prayer, is the liturgy of the church of England. Clergymen are obliged to use this liturgy in the service of the church; and refusing to do so, or using any other public prayers, is punishable by 1 Eliz. cap. 2. and every incumbent refusing on his living and keeping a curate, is obliged, once every month at least, to read the common prayer in his parish church, in his own person, under a forfeiture of 5l. for every failure, by the act of uniformity, 13 and 14 Car. II. cap. 4; and by the same ft. every church is to be provided with a book of common prayer, under the penalty of 3l. a month, and the common prayer is to be read before every lecture. Every minister who speaks any thing in derogation of this book, shall, if not benefited, be imprisoned for one year for the first offence, and for life for the second; and, if he be benefited, he is liable to six months imprisonment, and the forfeiture of a year's value of his benefice; for the second offence to deprivation and one year's imprisonment; and for the third offence to deprivation and imprisonment for life: and any person convicted of reviling it in plays, songs, or other open words, or of forcibly preventing its being read, or of causing any other service to be read in its stead, shall forfeit for the first offence an hundred marks; four hundred for the second; and for the third offence all his goods and chattels, and suffer imprisonment for life. Common Wealth denotes "bonum publicum," or the public good, and is much favoured in our laws, and therefore many things are legally tolerated, with a view to the public good, which otherwise might not be done. Hence it is that monopolies are void in law, and that bonds and covenants to refrain free trade, tillage, and the like, are adjudged void. 11 Co. Rep. 50. Plowd. 25. Shep. Epit. 270. Common Year. See Year. COMMUNABLE LANDS, in Agriculture, are such lands as are generally in some measure arable, and which belong, in property, to individuals who are known, and the limits of whole property are ascertained: but which, in regard to their culture and mode of cropping, are subject to certain regulations, which common, for time immemorial, has established, so as gradually to have acquired the force of law, to which rules every individual occupying such property must adhere, until these old customs shall be abrogated, either by the unanimous consent of all the individuals having a right to such communable lands, or by an express statute, obtained with their consent, for the purpose of annulling them.

In some countries, Dr. Anderson says, it appears that not much less than one half of the whole arable lands are in this state; although it is evident, by the concurring testimony of all the agricultural reports, that taking all these lands at an average, they do not afford half the produce the same lands would do, if they were put under the ordinary management that appropriated farmers are subject to in their respective districts: and not perhaps one tenth part of what they might easily be made to afford, within a very short period of time, should all other obstructions to improvement be removed. It would be timefome, he says, to enumerate all the facts that occur in the different agricultural surveys, tending to point out the pernicious tendency of this mode of tenure: but a few of them may be mentioned. In one place it is stated, that a few inclosures had been made, seemingly with the concurrence of all the parties concerned; but when the hedges had advanced nearly to become a fence, one of the communable tenants went deliberately and pulled them up by the roots, and eradicated them entirely. In another case the parishioners having come to an agreement to plant clover, after that practice has been universally acquiesced in for the space of eighteen years, one of the farmers, occupying extensive acres of land, bought a large flock of lean sheep in the month of May, and turned them on the clover crops, which were nearly in bloom, and no one could hinder him. In another case, where customs had established the practice of having one corn crop, and one fallow, alternately, the occupier of the district came to an agreement to have two crops and a fallow alternately; but before the expiration of ten years, one of the farmers broke through the arrangement, and turned his cattle upon the crops of beans, oats, and barley: in which plan he was followed by the rest of his neighbours; and the crops were, in consequence, totally destroyed on that part of the field, which, agreeable to the ancient custom, should have been that year in fallow. These notices, while they tend to illustrate the nature of this particular kind of tenure, at the same time, he says, clearly demonstrate its pernicious tendency to the public. No one, who has considered the subject for a moment, but will readily admit, that it were much for the interest of Britain that no such practice existed in it: and that, of course, no time should be lost in endeavouring to eradicate it; for, were this effectually done, it must appear evident from the facts stated, that the total produce of the kingdom would be greatly augmented and improved. See Common. COMMONALTY, comprehends one division of the civil state; the nobility being the other; and like the nobility, includes several degrees of rank and condition. In Art. super Chartera, 28 Ed. 1. c. 1., the words "Tout le commune de l'Engletterre," signify all the people of England. 2 Inf. 539. But the term is generally used for the middle rank of the king's subjects, such of the commons as are ranked above the ordinary fort, and having the management of offices, are by that means one degree below gentry, who are superior to them in order and authority, and companies incorporated are said to consist of masters, wardens, and commonalty, the first two being the chief, and the others such as are usually called of the livery. The ordinary people, and freeholders, or at least knights and gentlemen, under the degree of baron, have been, in late years, called "communitis regni," or "tota terra communitas;" yet anciently, if we credit Edward the barons and tenants in capite, or military men, were the community of the kingdom, and those only were reputed as such in our most ancient histories and records. Brady's Gloss. to his introd. to Eng. Hist. COMMONE, in Ancient Geography, the name of an island
in the Mediterranean, placed by Pliny on the coast of Ionia.

COMMONER, is used for a student in some universities, entered in a particular rank.

The word is also applied to a member of the house of commons, in contradistinction to a peer.

COMMONI, in Ancient Geography, a denomination given by Ptolemy to a people of Gallia Narbonensis, who inhabited the country, including the town of Tarraconensis, the promontory of Cithareides, the town of Olbia, that of Forum Julii, &c.

COMMONS, in a general sense, consists of all such men of property in the kingdom, as have not seats in the house of lords; every one of whom has a voice in parliament, either personally, or by his representatives. In a free state, says judge Blackstone, every man who is supposed a free agent, ought to be in some measure his own governor; and, therefore, a branch at least of the legislative power should reside in the whole body of the people. And this power, when the territories of the state are small, and its citizens easily known, should be exercised by the people in their aggregate or collective capacity; as was widely ordained in the petty republics of Greece, and the first rudiments of the Roman state. But this will be highly inconvenient, when the public territory is extended to any considerable degree, and the number of citizens is increased. Thus when, after the Social war, all the burghers of Italy were admitted free citizens of Rome, and each had a vote in the public assemblies, it became impossible to distinguish the frivolous from the real voter, and from that time all elections and popular deliberations grew tumultuous and disorderly; which paved the way for Marius and Sulla, Pompey and Caesar, to trample on the liberties of their country, and at last to diffuse the commonwealth. In so large a state as ours, it is therefore wisely contrived, that the people should do that by their representatives, which it is impracticable to perform in person; representatives chosen by a number of minute and separate districts, wherein all the voters are, or easily may be, indiscriminately.

COMMONS, in parliament, are the lower house, consisting of knights elected by the counties, and of citizens and burgesses by the cities and borough-towns. See Borough, Burgess, and Knight.

In these elections, anciently, all the people had votes; but in the 8th and 9th of King Henry VI. for avoiding tumults, laws were enacted, that none should vote for knights but such as were freeholders, did reside in the county, and had forty shillings yearly revenue; equivalent to near 20l. a year of our present money: the persons elected for counties to be miles notabiles, at least esquires, or gentlemen fit for knighthood; native Englishmen, at least naturalized, and twenty-one years of age: no judge, sheriff, or ecclesiastical person, to sit in the house for county, city, or borough.

The house of commons, in Fortescue's time, who wrote during the reign of Henry VI. consisted of upwards of 300 members: in Sir Edward Coke's time their number amounted to 493. At the time of the union with Scotland, in 1707, there were 513 members for England and Wales, to which 45 representatives for Scotland were added: so that the whole number of members amounted to 558.

In consequence of the union with Ireland, in 1801, 100 members were added for that country; and the whole house of commons now consists of 658 members; viz. 80 knights for 40 counties in England; 50 citizens for 25 cities (Edinburgh none, and London four); 334 burgesses for 167 boroughs, and 5 burgesses for 5 boroughs, viz. Abingdon, Banbury, Beverley, Higham Ferrers, and Monmouth + Vol. IX.

burrigesses for the two universities of Oxford and Cambridge; 16 barons for the 8 cinque-ports, viz. Hullings, D. Berwick, Sandwich, Romney, Hythe, and their three branches, Ryde, Weymouth, and Seaford; 12 knights for 12 counties in Wales; 12 burghers for 12 boroughs in that county; 50 knights for the shires of Scotland, and 15 burghers for its boroughs; 64 knights and 36 burghers for Ireland. For an account of the privileges of members of the house of commons, and other particulars, see Parliament.

COMMONS is also used in opposition to noble or peer, viz. for all sorts of persons under the degree of a baron; including the orders of knights, esquires, gentlemen, the sons of the nobility, and yeomen. See under each its proper article, Esquire, Gentleman, Yeoman, &c.

COMMONS, Doctors. See College of Civilians.

COMMONS, Prior of the. See Proctor.

COMMONS is also used for the stated and ordinary diet or eating, of a college; an inn of court, or other society. See Inn, &c.

COMMONWEALTH. See Republic.

COMMONWEALTH of England, in History, a form of government introduced after the dissolution of the monarchy by the death of Charles I., in 1649. The change of government seems to have been suggested in the preceding year by a council of officers, who took into consideration a scheme called "The Agreement of the People!" being the plan of a republic to be established in the place of that government which they were demolishing; but the commonwealth was not established till after the tragic event of the king's death. Soon after this event, the house of commons published an act to forbid the proclamation of Charles Stewart, eldest son of the late king, or any other person, on pain of high treason. On the same day the lords desired a conference with the commons about settling the government and the administration of justice, the commissions of the judges having been determined by the king's death. The commons, without answering the message, voted the house of lords to be useless and dangerous, and therefore to be abolished. They only left the lords the privilege of being elected members of parliament, in common with other subjects. Thus, the parliament, which at first was composed of the king, 120 lords, and 513 commoners, was reduced to a house of commons, consisting of about 30 members, few of whom at the beginning had 500l. yearly income. Nevertheless, these few and inconsiderable members assumed the name of a parliament, and acted as if their body had been invested with the authority which had before reposed in the king, lords, and commons. But they were previously disqualified and prepared for the business which they undertook to execute, and they were aided and supported by an army of near 50,000 men, formidable from its discipline and courage, as well as its number, and actuated by a spirit that rendered it dangerous to the assembly, which had assumed the command over it. It must be confessed, however, that in this parliament there were some men of dignified capacity and integrity, and that if they adopted erroneous principles, or purified those that were just and reasonable to an unwarrantable extent, they were deluded neither of talents nor of influence to defend and support them. The sovereign authority, as they maintained, reposed originally in the people, by whom a part of it was committed to the kings, chosen to govern them according to law; and they alleged, that the king's abuse of this trust had broken the original contract between king and people, and that, in consequence of this violation, the contract had lasted no longer, but the sovereign power reverted to the people, as to its original source. Considering themselves as the representatives of the people, they conceived that they had
had a right to change the form of the government, without any regard to the original contract annulled by the king in his violation of the laws. Upon these principles, the commonwealth, assuming the name of parliament, voted, and afterwards enacted, that the kingly office should be abolished as unnecessary, burdensome, and dangerous, and that the state should be governed by the representatives of the people in a house of commons without a king or lords, and under the form of a commonwealth. The former oaths of allegiance and supremacy were abolished, and a new oath was prepared, called "The Engagement," by which every man swore, that he would be true and faithful to the government established, without king or peers. Justice was no longer to be administered in the king's name, but the name, style, and title of the state were to be, "catholica libertatis Angliae, authoritative parliament." A new great seal was to be made; new money to be coined; and, in a word, every thing was to be detached and abolished, that bore any marks of royalty. A great seal was therefore made, on one side of which was seen the parliament sitting, with this inscription: "the great seal of the parliament of the commonwealth of England." And on the other side, the arms of England and Ireland, with these words, "the first year of freedom by God's blessing restored." This seal was committed to a certain number of persons, who were styled "keepers of the liberties of England." And it was ordained, that, for the future, all public orders should be dispatched in the name of the state, under the direction of the parliament. The parliament also made choice of 20 persons to form a council of state for the administration of public affairs under the parliament; to this council all addresses were made; they gave orders to all generals and admirals, executed the laws, and digested all business before it was brought into parliament. They professed to employ themselves entirely in adjusting the laws, forms, and plan of a new representation; and as soon as they should have settled the nation, they avowed their intention of restoring the power to the people, from whom they acknowledged, they had wholly derived it. The parliament also erected a high court of justice, consisting of 60 members, to try some persons of distinction, who were in their power. The commonwealth, thus formed and established, found England composed into a feeming tranquillity by the terror of its arms. Foreign powers, occupied in wars among themselves, had no leisure nor inclination to interpose in the domestic diffections of this island. The young king, poor and neglected, living sometimes in Holland, sometimes in France, sometimes in Jersey, indulged the hope, among his present difficulties, of better fortune at some future period. The situation alone of Scotland and Ireland occasioned any immediate inquietude to the new republic. As to the Scots, they were all-well for the present to take their own measures in setting their government; but Ireland demanded more immediately their efforts for subduing it. Cromwell, having obtained the appointment of lieutenant in that country by his interest in the council of state, left no time in passing thither; and he proceeded with much uninterrupted success, that in the space of nine months he had almost entirely subdued it. Afterwards, leaving the command of Ireland to Ireton, who governed that kingdom in the character of deputy, he hastened home, and was declared captain-general of all the forces in England. Having received this honourable appointment, he immediately marched his forces and entered Scotland; where Charles, who had been invited thither, was making considerable progress, with an army of 16,000 men. Cromwell having gained a decisive victory over the Scots in the battle of Dunbar, and having taken possession of Edin-
which had filled all Europe with the renown of its actions, and with atrocity at its crimes, and the commencements of which was not more ardently desired by the people than its first dissolution. Parliament having been thus dissolved, Cromwell might have assumed the administration of the government by an authority similar to that with which he had dismissed the parliament. But he chose to proceed in his assumption of the sovereign power by more cautious steps, and with some appearance of respect for the popular opinion. Accordingly, by the advice of his council of officers, he sent summoners to 128 persons of different towns and counties of England, to five of Scotland, and six of Ireland; and he pretended by his sole act and deed to devolve upon himself the whole authority of the state. This legislative power they were to exercise during 15 months; and they were afterwards to choose the same number of persons, who might succeed them in that high and important office. They immediately voted themselves a parliament, called by way of derivation from Barebone, a leather-seller, one of their number, "Barebone's parliament;" and having their own consent, as well as that of Oliver Cromwell, for their legislative authority, they now proceeded very gradually to the execution of it. The members of this legislative assembly, of which Cromwell himself was a member, though he had introduced into it several members entirely devoted to his own interest, found themselves unequal to the burden imposed upon them; and having met, by consent, at an early hour, they agreed to dissolve themselves and to resign the sovereign authority into the hands from which they had received it. They hastened, therefore, to Cromwell, along with Roufe, their speaker; and by a formal deed of alignment referred to him the supreme authority. The council of officers now proposed to adopt another scheme of government, and to temper the liberty of a commonwealth by the authority of a single person, who should be known by the application of protector. Without delay, Lambert, who made this proposition, prepared what was called "the instrument of government," containing the plan of this new legislature; and as it was supposed to be agreeable to the general, it was immediately voted by the council of officers. Cromwell was declared "protector," and with great solemnity installed in that high office. The chief articles of the aforesaid instrument are these: a council was appointed, the number of which was not to exceed 21, nor to be less than 13 persons. They were to enjoy their office during life or good behaviour; and in case of a vacancy, the remaining members named three, of whom the protector chose one. The protector was appointed supreme magistrate of the commonwealth; in his name all justice was to be administered; from him were all magistracy and honours derived; he had the power of pardoning all crimes, excepting murder and treason; to him the benefit of all forfeitures devolved. The right of peace, war, and alliance rested in him, with the advice and assistance of his council. The power of the sword was vested in the protector jointly with the parliament, while it was sitting, or with the council of state in the intervals. He was obliged to summon a parliament every three years, and allow them to sit five months without adjournment, prorogation, or dissolution. The bills which they passed, were to be presented to the protector for his assent; but if they were not obtained within twenty days, they were to become laws by the sole authority of parliament. A standing army for Great Britain and Ireland was established, of 20,000 foot and 10,000 horse; and funds were assigned for their support. These were not to be diminished without the consent of the protector; and in this article alone he assumed a negative.

During the intervals of parliament, the protector and council had the power of enacting laws, which were to be valid till the next meeting of parliament. The chancellor, treasurer, admiral, chief governors of Ireland and Scotland, and the chief justices of both the benches, must be chosen with the approbation of parliament; and in the intervals, with the approbation of the council, to be afterwards ratified by parliament. The protector was to enjoy his office during life, and on his death, the place was to be in m. duly supplied by the council. Such was the instrument of government bestowed by the council of officers, and solemnly sworn to by Oliver Cromwell. The council of state, named by the instrument, consisted of 15 persons; men entirely devoted to the protector, and by reason of the opposition among themselves in party and principles, not likely ever to combine against him. The military force of the country was exerted under this government with vigour, conduct, and unanimity; and never did the kingdom appear more formidable to all foreign nations. In September, 1654, a new parliament was summoned. Of 400 members, which represented England, 275 were chosen by the counties; the rest were elected by London, and the more considerable corporations; at the small boroughs having been deprived of their right of election, because they were the most exposed to influence and corruption. The lower populace, in easily guided or deceived, were also excluded from the elections; an estate of 200/. value was necessary to entitle any one to a vote. The elections of this parliament, says Mr. Hume, were conducted with perfect freedom; and excepting, that part of the royalists which had borne arms against the parliament and all their sons were excluded, a more fair representation of the people could not be desired or expected. Thirty members were returned from Scotland, and as many from Ireland. This parliament, having heard the protector's speech of three hours length, and having chosen Lenthall for their speaker, immediately entered into a discussion of the instrument of government, and of that authority, which Cromwell, by the title of protector, had assumed over the nation. The greatest liberty was used in arranging this new dignity; and even the personal character and conduct of Cromwell shaped not without censure. The protector, surprised and enraged at the refractory spirit of the parliament, sent for them to the painted chamber, and authoritatively reproached against their conduct. He obliged the members to sign a recognition of his authority, and an engagement not to propose or consent to any alteration in the government, or the protection of his person and parliament; and he placed guards at the door of the house, who allowed none but subscribers to enter. Most of the members, after some hesitation, submitted to this condition; but retained the same refractory spirit which they had manifested in their first debate. Cromwell hastened to the dissolution of this dangerous assembly, and having ordered their attendance, he delivered to them a speech, composed, angry and rage, and disinherited them.

In 1656, Cromwell, having pleased by his administration so much labour and success abroad, and to such order and tranquility at home, ventured to summon a parliament, having taken previous measures for filling the house with his own creatures and party. The period, however, that the majority would not be favourable to him. For, there were, let guards on the door, who permitted none to enter, but such as produced a warrant from his council; and the council rejected about a hundred, who either refused to recognize the protector's government, or were on other accounts obnoxious to him. These protected against a violence which was subversive of all liberty; but every application.
tion for redress was neglected both by the council and parliament. In this parliament a motion was made to level the crown on Cromwell; and no surmise or reluctance was discovered on the occasion. A formal motion was afterwards made to the same purpose; but it produced great disorder, and divided the house into parties. The bill was however voted by a considerable majority; and a committee was appointed to reason with the protector, and to over come those terrors which he pretended against accepting a liberal offer. Cromwell's chief difficulty arose from the opposition of the officers; and he justly dreaded a mutiny in the army. At length he determined to decline the acceptance of that crown, which the representatives of the nation, in the most solemn manner, had tendered to him. The parliament, when Cromwell had rejected the royal dignity, found themselves obliged to retain the name of a commonwealth and protector; and as the government had hitherto been a manifest usurpation, it was thought proper to function it by a leening choice of the people and their representatives. Accordingly, instead of "the instrument of government," which was the work of the general officers alone, an "humble petition and advice" was framed, and offered to the protector by the parliament. This was represented as the great basis of the republican establishment, regulating and limiting the powers of each member of the constitution, and securing the liberty of the people to the most remote posterity. By this deed, the authority of protector was in some particulars enlarged; in others, it was considerably diminished. He had the power of nominating his successor; he had a perpetual revenue assigned him, of a million a year for the pay of the fleet and army, and 300,000L. for the support of civil government; and he had authority to name another house, the members of which should enjoy their seats during life, and exercise some functions of the former house of peers. But he abandoned the power affirmed in the intervals of parliament, of framing laws with the consent of his council; and he agreed, that no members of either house should be excluded but by consent of that house, of which they were members. The other articles were much the same with those contained in the instrument of government. This model of government, the humble petition and advice, was accepted for the voluntary deed of the whole people in the three united nations; and Cromwell, as if his power had just commenced from this popular consent, was anew inaugurated in Westminster Hall, after the most solemn and pompous manner.

In 1653 the parliament was again assembled; confounding, as in the times of monarchy, of two houses, the commons and the other house: Cromwell, during the interval having lent his hand to the house of peers, which confounded 60 members. Upon the death of Cromwell in 1658 (see Cromwell) the council recognized the succession of his son Richard. A parliament was called; and in hopes of obtaining greater influence in elections, the ancient right was restored to all the new boroughs; and the counties were allowed no more than their usual members. The house of peers, or the other house, confounded of the same persons that had been appointed by Oliver. All the commons, at first, argued an engagement, without hesitation, not to alter the present government; but next proceeded to examine "the humble petition and advice," and after much debate it was confirmed. But though parliament acquiesced, cabals were formed against the new protector by the army. Richard, who professed neither penetration nor resolution, was prevailed on to give an unguarded consent for calling a general council of officers; but as soon as they were assembled, they voted a remonstrance; and they proposed that the whole military power should be entrusted to some person, in whom they might all confide. The protector, who was in his disposition gentle, humane, and generous, was justly alarmed at the movements of the officers; nor was the parliament less alarmed at the military cabals. They voted that there should be no meeting or general council of officers, except with the protector's consent, or by his orders. This enraged the officers, who hastened to Richard, and demanded of him a dissolution of the parliament. The parliament was dissolved; and by the same act, the protector was, by every one, considered as dethroned. Soon after he signed his dismission in form: and withdrawing into retirement, extended his peaceful life to an extreme old age. The council of officers, now possessed of supreme authority, deliberated what form of government they should establish. It was agreed at last to revive the long parliament, which had been expelled by Cromwell. The members of this parliament did not exceed 70; but they resolved, since they enjoyed the title of the supreme authority, and observed that some appearance of a parliament was requisite for the purposes of the army; not to act a subordina part to those who acknowledged themselves as their servants. They chose a council consisting of 7 persons, who should nominate to such commands as became vacant; and they voted, that all commissions should be received from the speaker, and be assigned by him in the name of the house. The general officers were disfranchised by those precautions; but the state of the country prevented their manifesting their disgust. As soon as an interval occurred, they renewed their hostility, and expelled the parliament. The officers, again possess'd of supreme authority, elected a committee of 23 persons, of whom 7 were officers, whom they pretended to invest with sovereign authority; and they called them "the committee of safety." On the approach of danger, Lenthall the speaker was invited by the officers to summon the parliament, which had twice before been expelled, with so much reproach and ignominy. But general Monk was advancing with his army, and having sent a message to the parliament from St. Albans, deposing them to remove from London those regiments, which had so lately offered violence to their assembly; he marched towards London and took quarters at Westminster. He afterwards required parliament, in the name of the citizens, soldiers, and whole commonwealth, to issue writs for the filling of their house, and to fix the time for their own dissolution, and the assembling of a new parliament. The parliament attempted to conciliate the general, and dispatched a committee to him for this purpose; but he refused to hear them, except in the presence of some of the seceded members. These members, upon the general's invitation, were restored; and the long parliament, after having passed some resolutions for the compoΨure of the kingdom, dissolved itself, and issuing writs for the immediate assembling of a new parliament. When the parliament met, measures were taken for the recall of Charles II.; he was proclaimed in the presence of the two houses, on the 8th of May, and on the 26th, which was his birth-day, the king entered London. Rapin's Hist. vol. xi. Ham's Hist. vol. viii.

COMMORTH, from the Brit. Cymmorf, q. d. subfiubium, a contribution which was gathered at marriages, and when young priests said or sung the first missal, &c. See deat. 4 Hen. IV. c. 27. But deat. 26. Hen. VIII. c. 6. prohibits levying any such in Wales, or the marches, &c. Covel.
COMMOTAU, or CHUMSTON, in Geography, a town of Bohemia, in the circle of Saaz. Large quantities of alum are prepared here. It is distant 10 miles N. W. of Saaz. 49° 8' of Drefden, and 42° N. of Prague.

COMMUTE, an ancient term in Wales, denoting half a hundred, or hundred; containing fifty villages, Stat. Wallia, 12 Ed. I.

Wales was ancienly divided into three provinces; each of these sub-divided into cantred; and every cantred into two commotes, or half hundreds.

Silvretta Girald, however, tells us, in his Itinerary, that a commote is but a quarter of a hundred. Commote also signifies a great dignitary or lordship, and may include one, or divers manors. Co. Litt. 5.

COMMOTION, an interline motion, or inclination in the parts of any thing.

In medicine, the term is chiefly used for a blow, or shake of the brain. A convulsion is a commotion of the fine medullary fibres of the brain. A fall occasions a commotion, whence frequently arises a counterfeit stroke on the opposite part; which occasions sometimes a contra-fall, and at other times a rupture of the veils, and an impulsion, by shaking the whole mass of the brain.

COMMUNA, or COMMUNES. See APPROPRIE, &c.

COMMUNANCE, a name formerly given to the commoters, or tenants and inhabitants, who had the right of common or communing in an open field, &c. Cowley.

COMMUNE, in the present organisation of France, denotes the subdivision of a canton, including sometimes a single town, and sometimes an union of several villages, possessing a mayor, and a communal munificence. All the considerable cities are divided into several communes.

COMMUNE Concilium Regni Anglie, denotes the common council of the king and people assembled in parliament.

COMMUNE Rectum. See Rectum.

COMMUNEM Legem, Writ of Entry ad. See L. GEN.

COMMUNIA Placita non tenenda in fececarion, an ancient writ directed to the treasurer and barons of the Exchequer, forbidding them to hold pleas between "commun perpons," (i.e. not debtors, to the king, who alone originally sued and were sued there) in that court, where neither of the parties belong to the same. Reg. Org. 187. But little obedience would be now paid to such a writ, if any officers were to dare to issue it? for the court of Exchequer seems, by precept, to have attained a concurrent jurisdiction in civil suits with the other courts in West munster-hall.

COMMUNIBUS Locis, a Latin term, in frequent use among philosophical, &c. writers; implying some medium, or mean relation between several places.

Dr. Keil supposes the ocean to be one quarter of a mile deep, communibus locis, q. d. at a medium, or taking one place with another.

COMMUNIBUS Annis, has the same import with regard to years, that communibus locis has with regard to places.

Mr. Derham observes, that the depth of rain, communibus annis, i.e. one year with another, were it to fluctuate on the earth, would amount to, at Townly in Lancashire, 4 3/4 inches; at Upminster, in Essex, 1 1/4; at Zurich, 3 1/2; at Pisa, 3 1/2; and at Paris, to 19 inches.

COMMUNICANS Arteria Cerebri, in Anatomy, is a branch of the internal carotid artery, which joins with a branch of the profunda cerebri, to form the circle of Willis. See Arteries.

COMMUNICATING, in Theology, the act of receiving the sacrament of the Eucharist.

Those of the reformed, and of the Greek church comme-
always be made within the line of circumvolution, for the safety of those who partake and receive.

Communication of Idioms. In Theology, the act of imparting the attributes of one of the natures in Jesus Christ to the other.

The communication of idiom is founded on the supposed union of two natures in the person of Christ: by this communication of idiom it is, that some divines say, God suffered, died, &c., which is strictly understood of the human nature; and signifies that God suffered in his humanity, that he died as to his human nature, &c.

The Lutherans carry the communication of idiom so far, as to say, that Jesus Christ is not only in his divine nature, and by reason of his divine person, but also really and properly in his humanity, immortal, &c., &c.

Communication of Motion, that act of a moving body, whereby another body at rest is put by it in motion, or a body already in motion is accelerated.

F. Malebranche looks on the communication of motion as something metaphysical; i.e., it is not necessarily arising from any physical principles, or any properties of bodies, but flowing from the immediate agency of God: there being, according to him, no more connection, or dependence, between the motion or rest of one body, and that of another, than between the form, colour, magnitude, &c., of one body, and those of another. The motion of one body, therefore, on his principle, is not any physical cause of that of another. See Cause.

The communication of motion results from, and is an evidence of the impenetrability and inertia of matter as such: unleas we admit the hypothesis of penetrable matter, advanced by M. Boerovitch and Mr. Michell, and ascribe to the powers of repulsion those effects which have been usually attributed to its solidity and actual resistance. See Matter.

Action, and re-action, sir Isaac Newton demonstrates, are equal and opposite; so that one body striking against another, and thereby occasioning a change in its motion, does itself undergo the very same change in its own motion, the contrary way. See Motion.

Hence, a moving body striking directly against another at rest, the one loses just as much of its motion as it communicates to the other; and they will proceed with the same velocity as if united into one mass. For the laws and quantity of motion so communicated, either in elastic or non elastic bodies, see Collision.

Communication, communicatio, in Rhetoric. See Anacolouasis.

COMMUNI Custodia, in Law, a writ which recently lay for the lord, whose tenant holding by knight's service died, and left his escheat fon under age, against a stranger that entered the land, and obtained the ward of the body. F. N. D. 80. Reg. Orig. 1611. Since the 11th 12. Car. II. c. 24, hath taken away wardships, this writ is of no use.

COMMUNION, in Theology, an uniform belief in several persons; whereby they are united under one head, in one church. See Unity, Uniformity, &c.

In this sense, the Lutherans, Calvinists, &c., are said to have been cut off from the Romish communion.

This is the primitive use of the word communion, as appears from the canons of the council of Elvira.

Though the term has been more extensively applied to denote a general agreement in matters of doctrine, discipline, and worship. And unless the term be understood in this large sense, so various are the opinions of men, there could be no communion among the members of any one church on earth.

Communion is also used for the act of communicating, or participating of, the sacrament of the Eucharist. The fourth council of Latrun, in acts, that every baptister shall receive the communion, at least, at Easter; which seems to import a tacit desire, that they should do it oftener; as, in effect, they did it much oftener in the primitive days. Gratian, and the master of the sentences, prescribe it as rule for the laity to communicate three times a year, at Easter, Whitsune, and Christmas. But in the thirteenth century, the practice was got on foot, never to approach the eucharist except at Easter; and the council thought fit to enjoin it then by a law, left their coldnesses and remissnesses should go farther still.

And the council of Trent renewed the same injunction, and recommended frequent communion without enforcing it by an express decree.

In the ninth century, the communion was still received by the laity in both kinds; or, rather, the species of bread which dipped in the wine, as it was owned by the Romanists themselves. Acta S. Bened. Sec. III. M. de Marca observes, that they received it at first in their hands. Hift. de Bern, and believes the communion under one kind alone to have had its rise in the West under pope Urban II. 1096, at the time of the conquest of the Holy Land. And it was more solemnly enjoined by the council of Constance in 1414.

The twenty-eighth canon of the council of Chalons enjoins the communion to be received under both kinds, distinctly; adding, however, two exceptions; the one of necessity, the other of caution, nijp fer necessitatem, & cautelam; the first in favour of the sick, the second of the sick, illtious, or those who had an aversion from wine.

It was formerly a kind of canonical punishment, for clerks guilty of any crime, to be reduced to lay communion, i.e., only to receive as the laity did, viz. under one kind.

They had another punishment of the same nature, though under a different name, called foreign communion; to which the canons frequently condemned their bishops, and other clerks. This punishment was not confined to the communion, or dispensation; but a kind of suspension from the functions of the order; and a degradation from the rank they held in the church. It had its name because the communion was only granted to the criminal on the foot of a foreign clerk, i.e., being reduced to the lowest of his order, he took place after all those of his rank, as all clerks, &c., did in the churches to which they did not belong. The second council of Agnada orders every clerk that abandons himself from the church, to be reduced to foreign communion.

Communion, Monstrance. Some instances occur in the early ages of the church, of the practice of adorning the eucharist to infants; and some few have imitated this practice in more modern times. Mr. Pfeiler pleads the use of it even to this day among the Greeks, and in the Bohemian churches till near the time of the Reformation; and he refers to the usage of the ancient churches, recorded by Phinis, Augutin, and Cyprian. He urges from Scripture the right which children have to all the privileges of which they are capable, as well as the Jewish children under the law, who were allowed to eat of the passover, and other sacrifices. To which it has been answered, that the sacrifices, of which they were allowed to partake, were chiefly peace offerings, which became the common food of the family, and were not considered as acts of devotion in such a degree as the eucharist. He replies to the objection founded on the incapacity of infants to examine themselves and discern the Lord's body, by observing that the precept extends only to those who were capable of understanding and complying with it; on the same ground that faith is required previous to baptism. Bishop Bedell suggests the following inquiry relative to this subject; what necessity of baptising infants.
infants, if their baptism produces no effect till they come to years of discretion? To which he replies, though the most principal effect be not attained presently, the less principal are not to be refused: fo children were circumcised, who could not understand the reason of it, and the same also did eat the passover: and fo did children baptized, in the primitive church, communicate in the Lord's supper: which I know not (says he) why it should not be so still: de quo phatis. It has been alleged, that the foundation of this practice was a mistaken apprehension of the absolute necessity of this ordinance in order to salvation, resulting from an erroneous interpretation of John vi. 53. See Bishop Newby's Letter to Dr. Ward, in p. 442 of Archbishop Usher's Life by Parr. Pierce's Essay on the Escorial. Wall's Hist. of Infant Baptism, part ii. chap. 9. § 15 and 16. Waterland's Review of the Doctrine of the Escorial, and preface to his two volumes of Poliphrenous Sermons, p. 35, &c. and Inquiry concerning Infant Communion, vol. ii. p. 75, &c.

Communion service, denotes that part of the liturgy of the church of England which relates to the administration of the sacrament. See Liturgy.

Communion table. See Altar.

Communis capsula. See Capsula.

Communis dutia cholecocius. See Ductus.

Communis digitorum manus extensor. See Extensor.

Communis latusorum depressor. See Depressor.

Communis latusorum elevator. See Elevator.

Communis mifericordia. See Misericordia.

Community, a society or body of men united together under certain common laws, agreed on among themselves, or imposed by a superior. The Romans, who seem to have given the first hint of communities to the several nations into which their empire was divided, doubtless borrowed it from some rules of their neighbours: they call them collegi; which term, among them, had nearly the same signification with community among us. For an account of the introduction and establishment of communities in Europe, see Charters of Community and City. See also Corporation and Coadjuration.

Communities now are of two kinds, ecclesiastical and laity; the first are either secular, as chapters of cathedral and collegiate churches; or regular, as convents, monasteries, &c.

Lay communities are of various kinds; some contracted by a fixed abode of a year and a day in the same place; others formed by the discharge of the same office, the profession of the same art, or attending the same place of worship, as those of parishes, fraternities, &c.

Accordingly, the word is commonly understood of pious foundations for the support of several persons, either in a secular or regular life; as colleges, abbeys, convents, priories, seminaries, hospitals, inns, &c.

Community is more particularly used in the French law, for the joint property in goods between the husband and the wife: the result of which is, that during marriage they are equally entitled to all effects, and liable to all debts, contracted either before or under marriage.

Community is a species of succession, and the acceptance of community refumbles an additio hereditatis.

Community was fet on foot in favour of the wives, to enter them as sharers in their husband's effects.

In countries where the civil law obtains, this community has no place, nor even in several customary countries, as being reputed a burden on the man.

Antiquity, the woman's share in the community was only one-third; and this appears till the fente of the law among us, the widow at the decease of her husband, being only intituled to one-third part of the moveables.

Community, continued, in the French Law, is that which subsists between the survivor of two persons joined in marriage, and the minor children of that marriage, when the survivor has not made an inventory of the effects in possession during marriage. The widow may either renounce community with her children, or continue it.

Community, tacit, is a community contracted between a man and woman, by the mere meeting of their effects, provided they have lived together the space of a year and a day: this community, being, indeed, is now abolished.

Community, Charters of. See Charters of Community.

Community of Goods, as it has been sometimes denominated, signifies a practice which was adopted for a short time in the primitive church, and which consisted principally in a common use, derived from an unbounded liberality, that induced the opulent to share their riches with their indigent brethren. The rich supplicated the wants of their numerous brethren with such liberality and promptitude, that, as St. Luke tells us (Acts ii. 4. iv. 32.) among the primitive disciples of Christ, all things were in common. This expression, however, has been greatly abused, says Molheim (E. H. vi. p. 60), and has been made to signify a "community of rights, goods, and possessions," than which interpretation nothing is more groundless, nothing more false. From a multitude of reasons, as well as from the express words of St. Peter (Acts v. iv.) it evidently appears, that the community which is implied in mutual use, and mutual liberality, is the only thing intended in this passage. This is very clearly and satisfactorily proved by Molheim, in a dissertation concerning the true nature of the community of goods, which is said to have taken place in the church of Jerusalem. This learned discourse is to be found in the second volume of his excellent work entitled "Discertationes ad Historiam ecclesiasticam pertinentes." Mr. Gibbon (see Hist. Decl. and Fall of Rom. Emp. vol. ii. p. 541) has given a very uncandid and unjust statement of this ancient Christian practice, and instead of considering it as honourable to the liberality and mutual benevolence of the first disciples, he seems to attach reproach and cenfure to it; when he suggests that the community of women, and that of temporal goods, may be considered as inapplicable parts of the same system. He also observes that it was of the same kind with that which had so agreeably amusèd the imagination of Plato, and which furnished in some degree the idea of the aulcrea fecl of the Elymians; although it was undoubtedy of a very different nature. This author further adds, that the progres of the Christian religion relaxed, and gradually abolished this generous institution, which, in hands less pure than those of the apostles, would too soon have been corrupted and abused by the returning selfishness of human nature; and the converts who embraced the new religion were permitted to retain the possession of their patrimony, their legacies and inheritances, and to increase their separate property by all the lawful means of trade and industry. Bishop Watson (see his "Apology for Chriftianity," 1708) has justly observed, that the expression "permitted to retain," in ordinary acceptance, implies an antecedent obligation to part with; but, as he adds, we have no account in scripture of any such obligation being imposed upon the converts to Chriftianity, either by Chrift himself, or by his apostles, or by any other authority: nay, in the very place
where this community of goods is treated of, there is an expext proof to the contrary. When Peter was about to insemi
ity as an exemplary punishment upon Ananias (not for keeping back a part of the price, as some men are fond of representing it, but) for his lying and hypocrisy, in offering a part of the price of his land as the whole of it; he said to him, "Whilst it remained (unfold) was it not thine own? and after it was sold, was it not in thine own power?" From this account it is evident, that Ananias was under no obligation to part with his patrimony; and after he had parted with it, the price was in his own power; the apostle would have permitted him to retain the whole of it, if he had thought fit; though he would not permit his prevarication to go unpunished.

Pythagoras not only taught his disciples to be contented with a little, but even deprived them of all command over their own property, by ceding the possessions of each individual to a common flock, to be distributed by proper officers, as occasion should require. From the time of this equitable division of their goods, as long as the natural inhabitants of this spot, and they lived upon the footing of perfect equality, and sat down together daily at a common table. If any one, however, repented of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution.

**COMMUNITY of the kingdom. See Commonalty.**

**COMMUTATION, in Aeronomy. Angle of Commutation.** is the distance between the sun's true place seen from the earth, and the place of a planet reduced to the ecliptic. See PLACE.

Thus the angle ESR (Plate V. Aeronomy, fig. 11.) subtended between the sun's true place, E, viewed from the earth at S, and that of a planet reduced to the ecliptic, R, is the angle of commutation. The angle of commutation, therefore, is found by subtracting the sun's longitude from the heliocentric longitude of the planet R; or contrary.

**COMMUTATION, in Law, a change of a penalty, or punishment, viz. of a greater for a less, &c. as when death is commuted for, by bonds, as long as the natural inhabitants of this spot, and they lived upon the footing of perfect equality, and sat down together daily at a common table. If any one, however, repented of the connection, he was at liberty to depart, and might reclaim, from the general fund, his whole contribution.**

Some doubt whether the word be properly applied to any change but that of punishment; others will have it indifferently serve for the exchanging, or trucking of any thing.

**Commutation Act.** an act passed during the session of parliament in 1784, as part of a system for the prevention of smuggling; so called because, whilst it gave up the existing duties and excise on teas, it proposed an additional tax on windows, not as a new tax, but as a commutation for the portion of the duties on tea which it surrendered. The plan of the framers of this bill was to take off all the excise duty on tea, and impose a custom duty of 1 l. 10 s. on Bohea tea, which, it was apprehended, would ruin the smuggling trade in that article. On the finer kinds of tea, a higher duty would be laid; 15 l. per cent. on fouchong, &c.; 20 l. on fingo and hyfon; and 30 l. on congo. The total annual importation of teas into Europe amounted to about 15,000,000 lbs., above two-thirds of which quantity were consumed in Great Britain and Ireland, though the legal importation was not quite 6,000,000; consequently the quantity annually smuggled must have been above 7,000,000 lbs. According to this calculation, the people of England were considerably under-rated at the number of 6,000,000. Of thofe it was said that 9,000,000 would be relieved from the payment of the present duty on tea, without being obliged to contribute a farthing towards the tax which would be proposed as a substitute: the other 4,000,000, it was calculated, would, one with another, consume 3 lbs. of each tea in the year, for each pound of which, they, at this time, paid on an average 8 l. 7 d. duty; this duty, or the principal part of it being taken off, they, of course, afford to pay a substituted tax, which was proposed to be raised in the following manner:

On every house with seven windows, which house was also rated to the house tax, it was intended to lay an additional tax of 3 l. and 10 s. for every house of eight windows; 4 l. for those of nine windows; 6 l. 8 d. for those of ten windows, and so on, adding 2 l. 6 d. for each window up to 14, and full rising up to 180 windows, for which 20 l. per annum should be paid, over and above the duty at present paid on windows and houses. This regulation was calculated to produce above 700,000 l. so that with the new duty on tea, the produce would be near 900,000 l.

It was suggested that, according to this plan, the public revenue would be a considerable gainer, and the people at the same time have no reason to complain of additional burdens. In England, Scotland, and Wales, it was calculated that there were about 609,000 houses, which might be divided into the following classes:—286,593 houses under seven windows; 211,493 houses having from 8 to 10 windows; 38,524 of 11 windows; 24,170 from 12 to 15; 67,672, from 14 to 19; 52,625, of 20 windows and upwards; and 17,732 houses in Scotland. Of these about 200,000 as being excluded from the house-tax would pay nothing to this new tax, and the inhabitants being of the poorer sort, would be wholly delivered from the duty on tea. This regulation, it was supposed, would check, or rather absolutely ruin, the smuggling trade; besides being productive of other benefits to the fair trader, and particularly to the East India Company. Against this bill, which, however, passed into a law, many objections have been urged. To the East India Company, it has been argued, this with the new duties on teas, the house which the public were to derive from it are less obvious and certain. It has been said that those householders who were to be charged with the new rate for windows were precisely the persons who should have received the reciprocal benefit of the commutation; but that the reverse of this is undoubtedly the case; they who do not pay the new window-tax, or indeed any window-tax at all, being the only persons who share among them any little advantages that have accrued from the agreement. The facts are these:—Of the five different sorts of teas consumed by the public, there are three which are chiefly used by those who pay the new window-tax, viz. congo, fouchong, and hyfon. The price of the two former of these (which are the most used of the three) has been so incomparably reduced, as to afford nothing like a pecuniary compensation for the additional window-tax, and the price of the third sort, hyfon, which is the dearer and the least used, though rather more reduced, is still wholly disproportionate to the promised commutation. The only two sorts of tea, therefore, where the reduction of price is at all considerable, are bohea and fingo; and those are in general consumed by the lower orders of people only. From these facts it has been inferred, that they who pay the new tax consume those sorts of tea, from which not one-fifth of the proposed faving arises; while they who do not pay any tax at all, or at most a small portion of it, consume those species of tea upon which almost the whole of the faving, or at least upwards of four-fifths of it arises. The act has been deemed, by those who
who frenzously opposed it, unjust in its principle, and oppre- 
sive in its operation.

COMMENA, Anna, in Biography, daughter of the em- 
peror Alexius Comnenus, flourished about the year 1175, 
and wrote fifteen books upon the life and actions of her 
father, which she called the ‘Alexiad.’ She has been 
acclaimed of a too great partiality in favour of her hero, 
for which, considering her near relationship, the may claim an 
indulgence. This work was published with a Latin transla-
tion in 1691, and again in 1670; to this last edition are 
added notes historical and philological by the learned Du 
Trefn.

COMMENO, in Geography, a town of European Tur-
key, in the province of Albania; 35 miles S.E. of Alba-
nano.

COMO, Da, Fra. Emanuella, in Biography, so 
called from the place of his nativity, a considerable town in 
the state of Milan, was an historical painter, whose tale for 
the art was first called forth upon his seeing some painters at 
work in the cathedral of Como. Without the direction of 
any master, he afterwards attained some degree of eminence.
His works, however, are of very unequal merit; he painted 
in the refection of a convent at Como a ‘Last Supper,’ 
by which but an indifferent idea of his talents could be 
formed, were not his character retrieved by an excellent pic-
ture in the church representing a Pietà with Santo. He 
died aged 76, in the year 1521. Orlandi. Lanzì, Storia 
Pittorica.

Como, in Geography, a strong, populous, and commer-
cial town of Italy, and capital of a district in the Milanese, 
built by the Gauls, under the conduct of Brennus, situated 
at the south end of a lake to which it gives name, in a plain, 
almost surrounded with mountains. The town is encom-
passed by a wall, guarded with picturesque towers, and 
backed by a conical eminence, on which stand the ruins of 
an ancient wall. The houses are almost wholly built of 
one; and the cathedral is a handsome edifice of white 
marble, hewn from the neighbouring quarries. The inhabi-
tants have established several manufactories of cotton 
and silk, and carry on some trade with the Genoese. This 
town being distinguished as the birth-place of Pliny the younger, 
his statue is placed in a niche on the outside of the church, 
and has a Latin inscription bearing the date of 1193. It is 
distant 20 miles N. of Milan, in lat. 45° 44' E. long. 
8° 57'.

Como, Lake of, a lake in Italy in the Milanese, on the 
confines of Switzerland, about 32 miles long and 88 in cir-
cumference. At first it is scarcely a quarter of a mile broad, 
but it widens near a neck of land upon which is situated the 
small village of Turin. Towards the south it is divided into 
two branches, at the end of one of which stands Como, and at 
the end of the other Lecco. The river Adda passes through 
it, and several country houses and villages are situated on 
its banks, which are adorned with vines, chesnuts, and 
almend-trees. The neighbourhood of Turin, and the dis-
tricts bordering the lake of Como, supply, for the moat part, 
those Italian emigrants, who wander through Europe 
vending barometers and thermometers, of whom numbers 
annually resort to England.

COMOCLadia, in Botany (from Κόμος, comus 
fun; and Κλάδος, ramus; so called because the branches 
have a tuft of leaves at the end, bearing a fancied refer-
blance to a head of hair.) Linn. Gen. 49. Schreb. 66. 
Lam. Ill. 67. Willd. 82. Juss. 370. Vent. 3. 444. Clas 
and order, trilandra ungenymin. Nat. Ord. Terebinthacca; 
Jull. Vent. 

VOL. IX.

COM

Gen. Ch. Calyx one-leaved, three or four cleft, spread-
ing, coloured; segments roundish. Cor. Petals three or 
four, roundish-egg-shaped, acute, flat, widely spreading, a 
little larger than the calyx. Stam. Filaments three or four, 
awl-shaped, shorter than the corolla; anthers roundish, in-
cumbent. Pfyl. Germ superior, egg-shaped; style none; 
fruit obtuse, simple. Peric. Drupes oblong, somewhat 
curved, marked at the top with three dots; membrana-
ous, the form of the drupe. Seed single.

Eff. Ch. Calyx three, rarely four-cleft. Petals three 
or four. Drupe oblong; with one seed.

Bigna superior, pendulous, always with a few quadri-
foil-translucent flowers intermixed with the others. A native 
of Jamaica, and St. Domingo. It abounds in a watery, 
flightly glutinous juice, which grows black when exposed 
to the air, and stains the hands so far as scarcely to be wash-
ed off. The wood is hard, of a fine grain, and reddish 
tab. 253. fig. 2. "Leaves egg-shaped, acute, toothed, 
shortly pubescent, venous and villous underneath." A tree 
much like the preceding Trunk upright with few branches. 
Leaves a foot and half long, in tufts at the ends of the 
branches; leaves from thirteen to twenty-one, oblong, 
cuneate, blunting above, edged with prickly teeth. A 
native of Cuba. It's juice is milky, glutinous, turning very 
black in the air, durably masting woollen and linen cloth, 
corrodin the 4em and rendering it scaly, smelling like 
liver of sulphur, or the human excrement. The nati-
ves have an idea that to sleep under it is dangerous. 3. 
I11. tab. 27. fig. 2. (C. triculifolia; Nouv. Act. Acad. 
Paris, 1784, p. 347; 'lex dodonae; Linn. Dodonae; 
Plum. Gen. 20. tab. 118. fig. 1.) "Leaves roundish angu-
ar-spinous, smooth on both sides." Leaves leafy, rigid, 
in crowded pairs terminated by an odd one. Flowers com-
paratively few; panicule very slender; racemes generally 
simple. A native of the West Indies. La Marec's figure 
was taken from a dried specimen. Wilkerson has both an 
illucifolia and an angulofia, quoting for the latter La Marec's 
figure in opposition to La Marec himself. His error seems 
to have been occasioned by mistaking the synonym from 
Plumier, given by Linnaeus, as a spinelike variety of his lex 
dodonae, which Wilkerson read D. aquifolii folio angulofia 
aculeata, instead of non aculeato, as it stands in the spe-
cies plantaram.

Propagation and Culture.—The first two species have 
been propagated in England, by seeds obtained from their native 
climate. They require the same treatment as other tropical 
plants.

COMO, Andrea, in Biography, an historical painter, 
who was born at Florence in 1560. He became at once the 
disciple and companion of Ludovico Cigoli, and was ranked 
amongst the best Florentine artists of his time, but the ex-
Bb
treme difficulty which he found in satisfying himself with his own productions, has occasioned their number to be very small, considering the great age to which he lived. After having gone through the regular routine of academic study, he went to Rome, where he spent many years, and painted several frescoes, particularly one in the tribunal of the church of St. Vitale, a composition of many figures, representing Christ bearing his cross, and on each side figures of martyrs. One of his most celebrated easel pictures was a "Magdalen in the Desert," for which the cardinal Barchini presented him with five hundred crowns, a very large price in those times. His pictures of "Madonas" are very highly esteemed for the beauty of their colouring and the delicacy with which they are finished, and above all for an elegance and lightness of form, joined to an expression of virgin modesty peculiarly their own. His numerous copies of the pictures of Coreggio, and other great masters are much esteemed. He died in the year 1658. Baldinucci.

LANZI, Storia Pittorica.

COMOMBO, in Geography, of the hill of Ombo, anciently Onobor, a town of Egypt, situated to the south of Thebes and on the same side of the river, where are still seen considerable ruins of an ancient temple. The inhabitants of this place were famous for the worship of the crocodile, which they fed in their ponds (according to Plutarch), where they became so tame, as to obey when they were called.

COMONAYA, a town of European Turkey, in the province of Macedonia; 66 miles N.N.E. of Akra.

COMORIS, in Ancient Geography, a town of Affyria, according to Ptolemy.—Allo, a town of Asia Minor, famenamed Abodora.—Allo, a town of Asia Minor, in Phrygia Sultaris, famenamed Merus, the same with Myrus.

COMORA ISLE, in Geography, are African islands in the Indian ocean, between the north-end of the island of Madagascar and the coast of Zanguebar, generally reckoned five in number, Johanna, Mayotta, Mohilla, Angazi, Comora, though some enumerate three, others four, and others eight, between the 41st and 46th degree of E. long. and the 10th and 11th of S. lat, at an equal distance from Madagascar and the continent of Africa. The largest is Johanna, which is. As the Comora isles abound in horned cattle, sheep, hogs, a variety of fruits and rice, they strive to refresh the European shipping to and from India. The inhabitants are negroes of the Mahometan religion; but they entertain the European seamen with great humanity.

COMORA, one of the fore-mentioned islands, which gives name to the whole cluster, about 6 leagues long, and three wide, but little known. S. lat. 11° 50'. E. long. 42°.

COMORIN, CAPS, the southernmost part of the southern Hindooftan, N.W. of the island of Ceylon. Though not above nine miles in extent, this promontory unites the two opposite seaboards of the year, owing to a ridge of mountains called the Ghauts, on the south side of which trees are laden with blofdom and fruit, while on the north side, the same fort of trees are stripped of all their leaves. N. lat. 8°. E. long. 77° 32'.

COMORN, COMORRA, LAT. a town of Hungary, and capital of a district, to which it gives name. It is so well defended by a fortress that the Turks could never take it. Its chief inhabitants were Hungarian, or Rascians, who belong to the Greek church. In 1783 it was almost wholly destroyed by an earthquake; 36 miles S.E. of Pecsburg, and 24 S.E. of Vienna.

COMORTH. See COMMORTH.

COMOSI, in Botany, the thirty-sixth natural order in the Philosophia Botanica of Linnaeus, which he afterwards abolished. It contained only spirea, filipendula, and aruncus. These are now all united in spirea, and the genus referred to the order rosacea.

COMOSANDALOS, in Antiquity, a crown of flowers worn in the festival CTHONIA.

COMOUCKS, in Geography, the Tartar inhabitants of Comania or Daghastan in Asia, under the protection of Persia. They are ferocious robbers. Every town has a chief named Myso, and the head of those chiefs chosen from among themselves is called Schmbul.

COMPACH, a rivet of Carnithia, which runs into the Moil, near Vellach.

COMPACT, in Physics, is a relative term, denoting a body to be close, dense, and heavy; having few pores, and those small ones. The heaviest metals, as gold and silver, are the most compact. See Gravity.

COMPACT, in a Legal Sense, signifies an agreement, or a contract, stipulated between several parties. A compact carries with it an obligation equal in point of confidence to that of a law; but the original of the obligation is different. In compacts, we ourselves determine and promise what shall be done, before we are obliged to do it; whereas in laws, we are obliged to act without our selves determining or promising at all. See Contract.

COMPACT is also the name of a celebrated bull, confirmed by pope Paul IV. relating to the cardinals.

In virtue of the bull of compa&c, cardinals can only confer benefits in their natural state; i.e. regular benefits on regulars.

COMPAGIES circularis montium, a term devised by Kircher to express what he in other places calls the annularity, or annual disposition of Mountains, which he says are in continued chains, forming belts or ridges in the manner of spines, all round the globe of the earth, from north to south, and so on from that point to north again, and in the same manner from east to west, and from west to east again.

COMPAGNE, Fr. The cabin of the commander or chief of a galley.

COMPAGNIES aux Garde. These were the companies of infantry that composed the regiment of French guards, making part of the householf troops of the king for the exterior guard. And it was usual to say captive aux Garde, lieutenant aux Garde, &c.

COMPAGNIE Ecossese. See Gendarmerie aux Garde du Corps.

COMPAGNIES d'Ordonnance. These were companies that never formed corps or regiments, like the gendarmeries, the light horse, the musketeers, &c.

COMPAGNIES des Garde. The four companies of horse-guards made part of the troops of the householf of the kings of France for the interior guard. Thus, in speaking of that corps, it was usual to say, a captain of the guards, a lieutenant of the guards, &c. It was customary to speak in the same manner of Swiss guards.

COMPAGNIES Francaises. Fr. These free companies were not regimented, but in time of war were put on a certain establishment. Each of them had a chief, who commanded it. They were generally composed of dragoons, hussars, and foot soldiers. All those who served in these corps or companies were called partisans. They were employed in making incursions into the enemy's country, and laying it waste as much as they could. An officer, who had served some campaigns as a partisan, could not easily afterwards serve with regular troops. They are a sort of voluntary pirates, who know no kind of subordination but that which is peculiar to themselves. When these troops have chiefs that
that are hardy, brave, and intelligent, they render important
services to armies.

**COMPAGNIE du Gout a pied.** See the article **MARÉ-
chaussée**.

**COMPAGNIE du Lieutenant criminel de Robecourt.** See also
the article **MARÉCHAUSSEE**.

**COMPAGNIE d’Ordinance a cheval.** See the same ar-
ticle.

Independent company is one that is not incorporated into
a regiment. Two such companies generally belong to each
regiment in England, for the purpose of supplying the regi-
mants with recruits.

**COMPAGUS, in Antiquity, a kind of summer-floé worn
by the Roman senators, consisting only of a sable at the bot-
tom; it was fastened with fasteners, crossed one ano-
other many times about the leg.

Rubenius makes the *compagn* to have been a sort of caige
worn by the roman generals as well as senators. Under the
later emperors, in the middle age, we read of the same worn by
popes, bishops, and abbots.

**COMPANION of the Garter, an appellation distingui-
ishing one of the knights of that most noble order, at the
head of which is the king, as sovereign. Stat. 24 Hen.
VIII. c. 13. See Garter.

**COMPANY, a collective term, understood of several
persons assembled together in the same place, or with the
same design. See Society.

The word is formed of the French compagnie, and that of
companions, which, Chifflet obseres, are found in the Saic law, tit. 65. and are properly military words, understood of soldiers, who, according to the modern phrase, are comrades, or men-mates, i.e. lodge together, eat to-
together, &c. of the Latin cum, with, and panis, bread.

It may be added, that in some Greek authors under the West-
ern empire, the word *kubernai* occurs in the sense of fo-

**Company, in Commerce, is an association of several mer-
chants, or others, who unite in one common interest, and
contribute by their stock, their counsel, and study, to the
felling on foot, or supporting, of some lucrative estab-
ishment.

Though company and society, or fellowship, be in effect,
the same thing, yet custom has made a difference between
them; society, or partnership, being underlaid of two, or
three dealers, or not many more; and company usually of a
greater number. See Society.

A second difference between companies and societies is,
that the first, especially when they have exclusive privileges,
cannot be established without the concurrence of the prince;
and need letters patent, charters, &c. Whereas, for the
latter, the consent of the members, fixed and certified by
acts and contracts, and authorized by bye-laws, is suf-
ficient.

The several professions and trades exercized in the city of
London, being incorporated into distinct fraternities, govern-
ed by their particular laws, a tabular view of them may not
be unacceptable.

The abridgment of their incorporations, and particular pri-
vileges, is taken from the records of the Tower, &c. and
from the Firma-Burgi of Madox, the king’s historiographer;
the account of their charters from those eminent historians
Stow and Strype; and the lines of the livemans on ad-
million, are taken from the returns to the clerks of the
parliament, and the fictery-books made after the several
polls for the magistrates and representatives of the city.

The companies are here placed according to their prece-
dence, beginning with the twelve principal ones, of one or
other of which the lord mayors have generally made them-
theselves free at their election, if they were not so before; for
they are not only the oldest, but the richest, many of them
having had the honour of kings and princes to be their mem-
ers, and the apartments of their halls being fit to enter-
tain a monarch.

This stock consists of shares, which are distributed in different proportions among those who have lived, or served the office of renter-wardens: who, if they die married, devolve to their widows. They pay above 200l. a year in pensions and other charities. They are likewise trustees for the disposal of the considerable legacies of Mr. William Bowyer, a learned printer, (who died Nov. 18, 1778) consisting of 30l. a year to the most learned journeyman that can be met with; and 180l. a year in annuities of 20l. each to nine necessitous printers of sixty-three years of age or upwards; besides other charities.</td>

**CARMEN,**

have no hall, nor charter, nor livery: but are a fellowship by act of common council, with the title of Free Carmen of the city of London, and have a master, 2 wardens, and 41 affiliates, under the direction of the lord mayor and aldermen. The cats that belong to this fellowship, which are betwixt 4 and 500, are, by an act of common council, subject to the rule of the president and governours of Christ's Hospital; to whom the owner of every cart pays 17s. 4d. a year for a licence to work it, and every cart is brought to the hospital to have a number in brass put upon it.

</table>
From the foregoing list, it appears on the whole, that there are ninety-one companies, forty-eight halls, and that the number of liverymen, according to the most exact account that could be procured, in 1779, was 8934, but this number is variable. The sums of money yearly distributed in charity by only twenty-three of the companies, amounts to more than 23,655 l.; and if but forty pounds each be annually given by the remaining sixty-eight companies, the whole will much exceed 26,575 l. per annum.

Company seems more peculiarly appropriated to those grand associations, yet on foot for the commerce of the remote parts of the world; as the English and Dutch East India company, South Sea company, Mississippi company, &c.; the rife and establishment of which, we shall here let before the reader.

However injurious companies with joint-stock, and incorporated with exclusive privileges, may, at this time, be reckoned to the nation in general; it is yet certain that they were the general parent of all our foreign commerce; private traders being discouraged from hazarding their fortunes in foreign commerce, until the method of traffic had been first settled by joint-stock companies. From this principle it is, that we find several nations that are now endeavouring to improve their trade, and to establish or increase marine power, by the means of joint-stock companies.

But since the trade of this kingdom, and the number of traders have increased, and the methods of assurance of shipping and merchandise, and the navigation to all parts of the known world have become familiar to us; these companies, in the opinions of most men, have been looked upon in the light of monopolies; their privileges have therefore been lessened from time to time, in order to favour a free and general trade; and experience has shewn, that the trade of the nation has advanced, in proportion as monopolies have been discouraged. When companies do not trade upon a joint-stock, but are obliged to admit any person properly qualified, upon paying a certain fine, and agreeing to submit to the regulations of the company, each member trading upon his own Stock, and at his own risk, they are called regulated companies. When they trade upon a joint-stock, each member sharing in the common profit or loss in proportion to his share in this stock, they are called joint-stock companies. Such companies, whether regulated or joint-stock, sometimes have, and sometimes have not, exclusive privileges. Regulated companies resemble, in every respect, the corporations of trades, so common in the cities and towns of all the different countries of Europe; and are a sort of enlarged monopolies of the same kind. As no inhabitant of a town can exercise an incorporated trade, without first obtaining his freedom in the corporation; so in most cases no subject of the state can lawfully carry on any branch of foreign trade, for which a regulated company is established, without first becoming a member of that company. Of companies of this kind we have had, or still have, in Great Britain, the Hamburgh company, the Ruffia company, the Eastland company, the Turkey company, and the African company. Regulated companies, as Sir Joshua Child has observed, though they had frequently supported public ministers, had never maintained any forts or garrisons in the countries to which they traded; whereas joint-stock companies frequently had. And in reality, says Dr. Smith, (Wealth of Nations, vol. iii. p. 116,) the former seem to be much more unit, for this sort of service than the latter; partly, because the directors of a regulated company have no particular interest in the prosperity of the general trade of the country, for the sake of which such forts and garrisons are maintained; whereas the private interest of the directors of a joint-stock company, is connected with the prosperity of the general trade of the company, and with the maintenance of the forts and garrisons which are necessary for its defence; and partly, because the directors of the latter company have always the management of a large capital, the joint-stock of the company, a part of which they may frequently employ, with propriety, in building, repairing, and maintaining such necessary forts and garrisons; whilst the
the directors of a regulated company, having the management of no common capital, have no other fund to employ in this way, but the casual revenue arising from the admission of goods, and from the corporation duties imposed upon the trade of the company for its benefit. A joint-stock company, established either by royal charter or by act of parliament, differ, in several respects, not only from regulated companies, but from private copartnery. In a private copartnery, no partner, without the consent of the co-partners, can transfer his share to another person, or introduce a new member into the company. Each member, however, may, upon proper warning, withdraw from the copartnery, and demand payment of his share of the common flock. In a joint-stock company, on the contrary, no member can demand payment of his share from the company; but each member can, without their consent, transfer his share to another person, and thereby introduce a new member. 2dly. In a private copartnery, each partner is bound for the debts contracted by the company to the whole extent of his fortune; whereas, in a joint-stock company, each partner is bound only to the extent of his share. The trade of a joint-stock company is always managed by a court of directors, which is frequently subject to a variety of respects, to the control of a general court of proprietors; but these proprietors, being for the most part totally exempted from trouble and from risk, beyond a limited sum, receive contentedly such half-yearly or yearly dividends, as the directors think proper to allot; and many persons are encouraged to become adventurers in joint-stock companies, who, would, upon no account, hazard their fortunes in any private copartnery. The directors of such companies being the managers rather of other people's money than of their own, it cannot well be expected, that they should watch over it with the same anxious vigilance with which the partners in a private copartnery frequently watch over their own. Negligence and profusion must always prevail, more or less, in the management of the affairs of such a company. It is upon this account that joint-stock companies for foreign trade have seldom been able to maintain the competition against private adventurers. They have, accordingly, very seldom succeeded without an exclusive privilege, and frequently have not succeeded with one. Without an exclusive privilege, they have commonly mismanaged the trade; with an exclusive privilege, they have both mismanaged and confined it. For other appropriate and just observations on this subject, in its reference to the African company, the Hudson's Bay company, the South Sea company, and the East India company, see Smith's Wealth of Nations, vol. iii. chap. 1.

When a company of merchants undertake, at their own risk and expense, to establish a new trade with some remote and barbarous nation, it may not be unreasonable to incorporate them into a joint-stock company, and to grant them, in case of their success, a monopoly of the trade for a certain number of years. It is the ancient and most natural way in which the trade can reconcile them for hazarding a dangerous and expensive experiment, of which the public is afterwards to reap the benefit. A temporary monopoly of this kind may be vindicated upon the fame principles upon which a like monopoly of a new machine is granted to its inventor, and that of a new book to its author. But upon the expiration of this term, the monopoly ought certainly to terminate; the forts and garrisons, if it was found necessary to establish any, to be taken into the hands of government, their value to be paid to the company, and the trade to be laid open to all the subjects of the state. Without a monopoly, however, a joint-stock company, as experience has shown, cannot carry on any branch of foreign trade. An eminent French author, of great knowledge in matters of political economy, the abbe Morelet, gives a list of 55 joint-stock companies for foreign trade; which have been established in different parts of Europe since the year 1660, and which, according to him, have all failed from mismanagement, notwithstanding they had exclusive privileges. Although he has been misinformed with regard to the history of two or three of them, which were not joint-stock companies, and which have not failed; yet there have been several joint-stock companies, which have failed, and which he has omitted.

The only trades which it seems possible for a joint-stock company to carry on successfully without an exclusive privilege, are those, of which all the operations are capable of being reduced to what is called a routine, or to such an uniformity of method as admits of little or no variation. Of this kind is, first, the banking trade; secondly, the trade of insurance from fire, and from sea-risk and capture in time of war; thirdly, the trade of making and maintaining a navigable cut or canal; and fourthly, the similar trade of bringing water for the supply of a great city. To render the establishment of a joint-stock company perfectly reasonable, with the circumstance of being reducible to strict rule and method, two other circumstances ought to concur. First, it ought to appear with the clearest evidence, that the undertaking is of greater and more general utility than the greater part of common trades; and, secondly, that it requires a greater capital than can easily be collected into a private copartnery. In the four trades above-mentioned both these circumstances concur.

The joint-stock companies, says this judicious writer, which are established for the public spirited purpose of promoting some particular manufacture, over and above managing their own affairs ill, to the diminution of the general stock of the society, can, in other respects, fear no evil to do more harm than good. Notwithstanding the most upright intentions, the unavoidable partiality of their directors to particular branches of the manufacture, of which the undertakers mislead and impose upon them, is a real discouragement to the rest, and necessarily breaks, more or less, that natural proportion which would otherwise establish itself between judicious industry and profit, and which, to the general industry of the country, is of all encouragements, the greatest and the most effectual.}

**COMPANY, African; sometimes called "Royal African Company,"** the name of the original institution. The first commercial voyage from England to the coast of Guinea was in 1556, but nothing like a company was formed till the year 1588, when queen Elizabeth granted a patent for ten years to come, to some merchants of Exeter, and other perfsons for an exclusive trade to the rivers Senegal and Gambia. In 1618, king James I. granted a charter for establishing a joint-stock company; but separate traders continuing to resort to the coast, the company was soon disdolved. Another company was erected by charter in 1631, which met with little success; and in 1651, the parliament granted a charter for five years to the East India company, for trading to the Gold coast in their way to India. The demand for negroes in the West India and American plantations increasing considerably, another exclusive African or Guinea company was incorporated in 1662, at the head of which was the duke of York, joined with many persons of rank and distinction. This company, like those that had preceded it, was unsuccessful, and its charter was soon after revoked by consent of the parties associated in the enterprise, in consequence of which another exclusive company
was incorporated by letters patent in 1672. They raised a capital of 111,000l. and improved the trade considerably; but at the revolution, the West India planters joined the separate trakers in asserting that they were always belved served with fites when the trade was free to all persons; and exclusive companies, whose privileges had not been sanctioned by parliament, were considered inconsistent with the declaration of rights, and the trade became open again; but all private traders were to pay 10 per cent. to the company, towards maintaining the forts and factories on the coast. This contribution was however found insufficient, and in 1730 parliament granted 10,000l. for the purpose, which was continued annually till 1744, when, in consequence of the war, 20,000l. was granted, and in almost every year since, a sum has been appropriated by parliament to this purpose.

As all the joint-stock companies which had been established for this trade had appeared incompetent to carry it on with advantage, it was in 1750 (3 Geo. II. c. 21.) transferred to a regulated company, the members of which are deemed a body corporate and politic, under the title of The Company of Merchants trading to Africa, but are prohibited from trading in their corporate capacity, from having any joint or transferable stock, and from borrowing money under their common seal. Any person intending to trade to Africa, may become free of this company on payment of forty shillings; and out of the monies thus received, a sum not exceeding 800l. is allowed for the salaries of clerks and agents at London, Bristol, and Liverpool, the house-rent of their office at London, and all other expences of management, commission, and agency in England. What remains of this sum, after defraying these different expences, they may divide among themselves, as compensation for their trouble, in what manner they think proper. The forts, factories, &c. possessed by the old company on the coast of Africa, are vested in the present company, who continue to receive an annual sum from parliament (generally about 13,000l.) for the support of these establishments: the sum granted in the year 1806 was 18,000l. For the proper application of this sum, the committee is obliged to account annually to the curator baron of the exchequer, which account is afterwards to be laid before parliament.

The company is under the management of a committee of nine persons, three being chosen for London, three for Bristol, and three for Liverpool, annually. The committee are enjoined to lay an annual account of the application of the money granted to them before parliament.

Although by the 4th of Geo. III. c. 20. the fort of Senegal, with all its dependencies, had been vested in this company, yet in the year following (by the 5th of Geo. III. c. 44.) not only Senegal and its dependencies, but the whole coast from the port of Saltee, in South Barbary, to Cape Rouge, was exempted from the jurisdiction of that company, and vested in the crown; the trade to it being declared free to all his majesty's subjects.

Before the establishment of the Royal African company, there had been three other joint-stock companies successively erected one after another, for the African trade. They were all equally unsuccessful. They all, however, had exclusive charters, which, though not confirmed by act of parliament, were in those days supposed to convey a real exclusive privilege.

Companies, English. The East India Company was established by charter dated Dec. 31, 1600, by which the earl of Cumberland and 215 other persons were authorized to carry on an exclusive trade to all parts of the East Indies, for 17 years; under the title of "The Governor and Company of Merchants of London trading to the East Indies." They raised 72,000l. in shares of 50l. each, and fitted out five ships, which accomplished their first voyage very successfully, in two years and seven months.

Having carried on the trade for about ten years, with different degrees of success, they obtained another charter dated May 31, 1610, by which the company was made perpetual. They had not yet adopted the mode of trading under one joint stock, but carried it on in several co-partnerships and lesser stocks. In 1613 the proprietors of the several separate stocks, united them into one general joint-capital; and notwithstanding some opposition to their trade, both at home, and abroad, they preferred and extended it, having at this time established factories at about twenty different places in India. In a vindication of the East India Company before the privy council, at a subsequent period, among other remarks for shewing the great difficulties attending an East India trade, it was asserted, that although they had a stock of 1,500,000l. yet in fifteen years time, viz. from 1617 to 1632, their whole profit was no more than 12 and one-half per cent.

In 1637, Charles I. established a new company to trade to China and Japan, but it was soon ruined. The old company likewise from its differences with the Dutch East India company, the encroachments of private adventurers, and other causes, fell into decay, and in 1655 it was dissolved by Cromwell, and the trade laid open. The merchants who followed obliged him to re-establish the company about three years after; their joint stock was now 7,595,824l., of which only one-half, or 3,796,912l. was paid in, and was properly their capital. The total exports of the company in three years, ending with 1660, was 227,828l. in bullion, and 23,763l. in merchandise. After the reformation, they obtained a new charter from Charles II. dated April 3, 1661. By this charter it appears that the company had not then one sole transferable joint-stock, but that every one, who was free of this company paid a certain sum of money to the company on the quitting out of their fleet, for which he had credit in the company's books, and received his proportionate dividend on the profits of the respective voyage. The whole investments were made by the company in their corporate capacity; but they were not established as an irrevocable corporation, as they might be dissolved in three years notice.

In 1664, the company's stock fell at only 73 per cent., but in consequence of an inquiry into the state of their affairs, the result of which was very favourable, the stock soon got up considerably. New charters were granted in 1669 and 1676, confirming all their privileges. In the latter year, the company having made a considerable profit by their trade, agreed, instead of making a dividend thereof, to add it to their capital stock, so as just to double the same, by which their capital became 7,595,824l. 102. In consequence of the extension and success of their trade, which enabled them to make large dividends, their stock in 1680 sold from 280 to 300 per cent; but these great profits, and the doubtful authority under which they held their exclusive privileges, (not having the sanction of parliament) being a great temptation to individual adventurers, interlopers, who had often given them much trouble, became again very numerous, and attempts were made to get the trade laid open, or to have it vested in a regulated company similar to those by which the trade with Turkey and with some other countries was then carried on. The company, however, in 1683 found means to obtain another charter, by which all their former privileges were confirmed, and they were empowered to seize the ships and merchandise of all interlopers, to raise and maintain military forces, to exercise martial law, and
and to establish a court of judicature for determining all mercantile causes, within their limits. In 1686 they obtained another charter granting them still greater powers and privileges.

Soon after the revolution much popular clamour was raised against the East India company; and in 1691 the house of commons addressed the king to dissolve the company and incorporate a new one; an opportunity for which soon occurred, as in 1693, the charter of the company became void, from their not paying the duty which had been imposed on their flock within the time limited by the act; but a new charter was granted them, on condition of submitting to such regulations as should be ordained before the 29th of September 1694 and which were contained in two charters soon afterwards executed.

In 1698 the complaints of the weavers of London against the importation of India wrong'd silks, and the company having been prevented by lollies from making any dividend for several years, brought it into much disrepute, and the house of commons thought it necessary to take the state of their affairs into consideration. The company thought it prudent to offer an advance of 700,000l. for the public service at 4 per cent. interest, provided the exclusive trade was legally settled on them; but a number of merchants, numerous, and in 1691 the company was incorporated in the exchequer, proposed to advance 2,000,000l at 8 per cent. interest, for similar privileges. The latter proposal was approved, and an act passed by which a new company was established; many difficulties however appeared, with respect to their engaging in the trade, till the expiration of the three years notice for determining the old company. During this unsettled state, the East India trade, the old company's stock had in about five or ten years fluctuated from 530 per cent. to only 37 per cent.

The great contentions which ensued between the old and new companies, soon rendered it obvious that little benefit would be derived from the trade, unless a coalition between the two rival corporations was effected. This was accomplished in 1702, by an agreement that the old company should purchase an equal proportion of stock in the new company, and that the separate traders, who had subscribed to the new company, but not to their joint-stock, should be included in the union. The old company was to keep their stock in the new company, in their corporate capacity for seven years, then to transfer it to their respective members, and resign their charter to the crown, from which time the new company comprehending the proprietors of both, assumed their present title of "The United Company of Merchants of England trading to the East Indies." In 1698 the term of their exclusive trade to India, which was determinable upon three years notice after 1711, and repayment of the sum they had advanced, was prolonged to three years notice after Lady-day 1726; for which they advanced to government 1,200,000l. without any additional interest. In 1712 they obtained an act for continuing the trade and corporation capacity of the company, although the sums they had advanced to government should be repaid; which repayment or redemption of their annual fund, was not to be made till the expiration of three years notice after Lady-day 1733.

The act of parliament being liable to a different construction from what was probably intended, and the term granted being near its expiration, a very powerful opposition to its renewal, was raised in 1730, and specious proposals were made to parliament for redeeming the fund of the company, and transferring the trade to a regulated company, with similar privileges. After a very full discussion of the subject, a new agreement was entered into with the company, who agreed to pay 200,000l. towards the service of the current year, and to have the interest payable to them by government reduced from 3 to 4 per cent.; in consideration of which all their exclusive privileges were continued till the expiration of three years notice, to be given after Lady-day 1766, when upon re-payment of their entire capital of 3,200,000l. their exclusive privileges were to cease, but the company to continue a corporation for ever, to enjoy the East India trade in common with all other. In consequence of this, the situation of the interest received from government, they thought proper to reduce the dividend payable to their proprietors from 3 to 7 per cent. and soon after to 6 per cent.

In 1743 the company proposed to advance 1,000,000l. for the service of the year 1744, at 9 per cent. interest, on having the term of their exclusive trade enlarged for fourteen years, and being permitted to borrow a million on bonds. This proposal being accepted, the debt from the public to the company became 4,200,000l., and the exclusive trade was now extended to three years notice, to be given by parliament after Lady-day 1780, with the former proviso, that, after such determination, the company should continue to have a common right with other subjects in the trade to India.

The company not subscribing to the reduction of interest proposed in 1749, the speaker of the house of commons was ordered to give them notice that the fund due from government would be paid off, unless they subscribed before May 30, 1750: with this it was deemed prudent to comply, but in consideration of the company having reduced their bond debt, they should be empowered to raise money by the sale of 5 per cent. annuities, to the amount of the debt of government to the company. The annuities thus sold were known by the title of 3 per cent. India annuities, and were for many years payable at the India house, but are now consolidated with the 3 per cent. reduced bank annuities.

Hitherto the company had not aspired beyond their original character of merchants, and merely possessed factories at the principal ports to which they traded; these factories were, for the safety of their merchandise and the protection of their freights, converted into forts, which rendered it necessary to maintain a military establishment. Thus possessed of the means of offence as well as defence, they made considerable exertions to oppose the progress of the French in those parts and as the two companies each endeavoured to procure the affiliation of the neighbouring native princes, the field of interest and ambition became much enlarged. In 1751, the company lent a considerable military force into the province of Arcot to support the nabob against his rival, who was powerfully assisted by the French; in which contention they were engaged with little intermission for several years. In Bengal, the company had carried on their commercial intercourse without any connexion with territorial authority, till the death of the nabob Ali-Verdi-Khan, in 176. This prince had viewed their increasing opulence and power with great jealousy, and a short time before his death gave a remarkable charge to his successor, in which he cautioned him to keep in view the power of the European nations in his country, and to free himself from their influence as soon as possible. "The power of the English is great; reduce them first; the others will then give you little trouble. Suffer them not to have forts or soldiers; if you do, the country is not yours." In attempting to put
this advice into execution, Son-Rajah-Dowla was completely defeated by the company's forces, and the new sultan of the appointment, besides paying to the company a very large sum for their loffs and expenses, ceded to them a considerable territory in the vicinity of Calcutta. On the coast of Commanded, hostilities were carried on against the French settlements with unequal success, but ultimately to the advantage of the English, upon which the sultan of the Deccan concluded a treaty with the company, and ceded to them the entire cree of Mysalipatam. In 1768, the company's forces completely defeated those of France, and in the following year captured Pondicherry, the chief of the French settlements in India; since which events the power of France in India has been very insignificant.

Such was the commencement of the company's acquisition of territory, which they have seized every subsequent opportunity of extending, till the sovereigns of India, whose protection they formerly courted, have sunk into the situation of their dependents, and hold their precarious dignities at the will and pleasure of a society of foreign traders.

The annual sales of the imports of the company for sixteen years preceding 1777, amounted on an average to about 2,055,000l.; and for the same period, the exported goods and stores amounted, at their prime cost, to 2,800,000l.; the bullion exported to 690,000l. per annum, and they paid in discharge of bills of exchange 192,000l. per annum.

Early in 1764, on the receipt of some unpleasant news from Bengal, India stock fell 14 per cent. The general administration of the company's affairs, both at home and abroad, became soon after the subject of much discussion; and on 29th August 1766, the court of directors received a notice from the secretaries of state, that an investigation would take place in the next session of parliament. The administration laid claim to the territories which the company had acquired in India, with the revenue arising from them, as of right belonging to the crown; but as the company were very unwilling to have this new source of wealth taken out of their hands, a temporary agreement was made for two years, by which the company, in consideration for this claim, agreed to pay to government 200,000l. a year. In 1769, the agreement was renewed for five years, and the territorial acquisitions and revenues in India leased to the company for that term, with a stipulation that the company should be allowed to increase their dividend to 12½ per cent. But not to increase it to more than one per cent. in one year.

They now became involved in a war with the famous Hyder Ali, in consequence of which, and of the misfortune of their servants in India, the concerns of the company, from the most flourishing situation, were brought into the greatest embarrassments. Select and secret committees of the house of commons were appointed to investigate the state of their affairs; and in 1773, it appeared, not only that they were unable to make the stipulated annual payment to government, but that it was necessary to withdraw a loan of 1,450,000l. Till this sum should be repaid, the dividend to their proprietors was not to exceed 6 per cent, and afterward not to exceed 7 per cent. till their bond debt was reduced to 1,500,000l. From these circumstances, the price of the company's stock fell considerably from the latter part of 1772 till February 1774, when their affairs began to wear a brighter aspect. In 1776, the loan from government had been repaid, and their situation being otherwise improved, the dividend on their stock was raised to 8 per cent.

On an average of ten years, ending with 1777, the company's exports in goods were about 400,000l. in bullion, 110,000l. and the sum paid in discharge of bills of exchange, 400,000l. per annum. By the aid afforded from the revenue, their impositions were increased, so as to produce about 3,200,000l. per annum.

In 1779, an act was passed for continuing the territories and revenue in India in the possession of the company for one year, which in 1780 was continued for another year. In June 1780, it was agreed to offer to pay to the exchange 400,000l. in full discharge of all claims of the public upon the company up to the 1st of March; and as, in the preceding year, they had received notice that the 4,200,000l. due to them from government would be paid off on the 1st of April, 1783, it became necessary to enter into a new agreement, the conditions of which were, that the company should continue to enjoy their exclusive privileges to the 1st of March, 1794, then to cease and determine, upon the former conditions of three years previous notice, and the repayment of all sums due to them. The surplus of their nett profits, after paying their dividends, were appropriated, three fourths for the service of government, and one fourth to be retained by the company; and they were restricted not to increase the dividend of 8 per cent. more than 1 per cent. in any year. This restriction was, however, soon found unnecessary; for the nett profits of the company for the year ending 31st March, 1782, did not amount to so much as a dividend of 8 per cent. on their stock by 22,023l.; in consequence of which, it became necessary for government to allow a further time for the payment of 296,400l. 21. 6d., which was due from the company for customs, besides a part of the sum which they had agreed to pay in 1781; and they were at the same time empowered, notwithstanding the above deficiency, to continue their dividends at 8 per cent. In the following year, the war in India, and other circumstances, increased the embarrassment of the company's affairs; and, by a statement of their accounts to the 1st of March, 1783, it appeared that the
the nett profits of that year did not amount to a dividend of 8 per cent. by 255,813l., which dividend they were nevertheless authorized by parliament to continue; and, to enable them to do, government issued exchequer bills to the amount of 300,000l., which the bank undertook to lend money upon to the company.

The long and expensive war in which the company had been engaged in India, terminated in March 1784, by the ratification of peace with the Mysorean government; but the conseqence of this war, in addition to the war in Europe, was the general derangement of the company's affairs both at home and abroad. In December 1783, February and May 1784, the directors laid before parliament such accounts as they then possessed, respecting the general state of their finances. But the impossibility of drawing any satisfactory information from statements made up in such a situation of their affairs, with the apprehensions which the measures then in agitation, relative to the future government of India, had excited in the public mind, reduced the credit of the company to the lowest ebb. Their Stock fell as low as 11s. 3d.; their bonds at home, bearing 5 per cent. interest, were negotiated from 2½ to 4 per cent. discount; their bonds and certificates, at Bengal and Madras, bore from 18 to 40 per cent. discount; at Bombay 50 per cent.; and orders on the treasury there sold at 5s., and upwards, per cent. discount.

It now became a general conviction, that the company was incompetent to the political government of the extensive territories which they had acquired. A Board of Control was therefore established, composed of a certain number of commissioners to be appointed by the king, and removable at his pleasure. This board was authorized to check, superintend, and control, the civil and military government and revenues of the company. The dispatches transmitted by the directors to the different préficiencies were to be previously subjected to the inspection of the Board. The appointment of governor-general, president, or councilor in the different préficiencies, was made subject to the approbation and recall of his majesty; and such other regulations adopted, as in a great measure deprived the company of that political and civil authority which they had suffered to be so grossly abused.

In 1786 some further regulations were made respecting the government of India; and, as the company's trade was increasing, particularly in the article of tea, their import of which had been greatly augmented by a rearrangement of the commutation act, they were said to require a greater capital, and were authorized to create 800,000l. new stock, on which they raised 1,240,000l. at the rate of 15½ per cent. In 1789 they obtained another act, enabling them to add 1,000,000l. to their capital, which thus became 5,000,000l.

In the beginning of 1793, the term of the company's exclusive privileges being nearly expired, the subject of laying open the trade to India was again discussed, and though it was not thought proper to risk the loss and confusion which must unavoidably attend any attempt to take such an immense concern out of the hands in which it has so long continued, a bill was made in the agreement for the renewal of the charter, that such regulations should be adopted as to admit of a free exportation by private persons on their own account, of any goods of the growth, produce, or manufacture of Great Britain or Ireland; and of a free importation of such sorts of the raw materials of the East Indies as are used in the manufacturies of Great Britain or Ireland; that the company should be obliged to provide shipping for the carriage of the private trade, at as low a freight as it could be furnished by private merchants; and that they should license a proper number of agents to reside at the company's settlements, under their protection, for the management of the private trade. On these conditions the company's term in the exclusive trade was enlarged for 20 years, or to the 1st of March, 1814, with the former provision, that if, after the expiration of the term, their right to the sole trade shall cease, in consequence of three previous notice being given by parliament, and the repayment of such sums as may be then due from the public, they shall continue a corporation, with power to carry on a free trade in common with other persons.

On this occasion, the total income of the company, arising both from their territorial revenues and their commercial concerns, was stated as follows:

The nett annual income in rents and profits of trade, taken in the most unfavourable light to the company, and supposed to be considerably under the mark, was rated at £2,329,164.

Subject to the following payments, viz.

Interest of 3,000,000l. on bonds, at 4 per cent. £1,550,000.
Interest of 6,660,000l. debt in India, at various rates of interest, on a medium about 9½ per cent. £561,876.
Dividend of 8 per cent. on their capital of £5,000,000l. £400,000.

Leaving a nett annual surplus of £1,239,241.

Of this surplus it was proposed to appropriate 550,000l. per ann. to the reduction of the debt in India, to pay 500,000l. per annum to government in half-yearly payments, and to pay an increased dividend of 10 per cent. to their proprietors on 6,000,000l. to which sum their capital was now raised.

This annual surplus, if it really existed at the time to which the above account refers, was of very short duration. In 1795 the company found themselves unable to continue the proposed contribution to government; and the intrigues of Tippoo Sah with the French, and with some of the native powers, which obliged the company to keep up a large military establishment, and soon after to engage in another expensive war, not only reduced the surplus of their revenues, but occasioned a considerable increase of debt in India, which has since been further augmented in consequence of hostilities with Dowlat Rao Scindia and Jefwunt Rao Holkar.

In order to furnish some idea of the extent of the company's commercial and financial concerns, the following accounts are subjoined.

The amount of all goods sold at the East India Company's fairs, from the 1st of March 1785 to the 1st of March 1806.

The va$t concerns of this company are under the management of twenty-four directors, who are formed into different committees; each committee having the superintendence of a particular department of the company's business. At the general courts of proprietors, persons pofting 1000l. Rock have one vote; 3000l. two votes; 6000l. three votes; and 10,000l. four votes. The number of proprietors entitled to vote, on the 8th of April 1800, was 12193, and the number of votes 3812.

COMPANY, Hamburgh, is the oldest trading establishment in the kingdom; though not always known by that name, no ascribed to those narrow bounds under which it was afterwards confined. It was first called the Company of Merchants trading to Cassis, Holland, Zealand, Brabant, and Flanders; then it acquired the general title of Merchant-adventurers of England; as being composed of all the English merchants who traded to the Low Countries, the Baltic, and the German ocean. Lastly, it was called the Company of Merchant-adventurers of England trading to Hamburgh.

This company was not a society of dealers, each furishing a part of the sum to constitute the capital flock of the company; but a mere association, or body of merchants, who had nothing in common, but the grant and privilege of trading to Hamburgh, and some other cities of Germany; each managing his own commerce, and trading on his own foundation; only observing a certain discipline, and some regulations, which none but the company could establish or change.

This company was first incorporated by Ed. I. in 1296; and established again, by charter, in 1462, under the reign of Henry IV. It was afterwards confirmed and augmented with divers privileges, by many of his successors; among the rest, by Henry V. in 1413; Henry VI. in 1422; Henry VII. in 1493, 1505, and 1506; Henry VIII. in 1509, 1517, and 1526; Edward VI. in 1547; Queen Mary, in 1553; Elizabeth, in 1564, and 1566; James I. in 1607; and Charles II. in 1661. But of all these charters, none but those of Henry IV. Henry VII. Elizabeth, James, and Charles, were of any importance, or gave the company any thing new; the rest being only confirmations. Before the charter of Henry IV. all the English merchants, who trafficked out of the realm, were left to their own discretion, and managed their affairs with foreigners as might be most for their respective interests; without any regard to the general commerce of the nation.

Henry observing this disorder, endeavoured to remedy it, by uniting all the merchants in his dominions into one body; wherein, without losing the liberty of trading each for himself, they might be governed by a company; and be subject to regulations, which should secure the general interest of the national commerce, without prejudice to the interest of particulars. With this view, he granted all the merchants, of his states, particularly those of Calais, then in his hands, a power of associating themselves into a body politic, with directors...
dircctors and governors, both in England and abroad; to hold assemblies both for the direction of business and the deciding of controversies among merchants; make laws, punish delinquents; and impose moderate duties and taxes on merchandizes and merchants to be employed in the service of the corporation.

These few articles of the charter of Henry IV. were afterwards much augmented by Henry VII. who first gave them the title of Merchant-adventurers to Calais, Holland, &c. gave them a power of proclaiming and continuing free fairs at Calais; and ordered, that to be reputed a member of the society, each person should pay twenty marks sterling; and that the several members should attend the general meetings, or courts, appointed by the directors, whether at London, Calais; or elsewhere.

The inexecution of this last article and contempt of some of the rest, occasioning great inconveniences to the company's affairs, another charter was procured, whereby the pain of imprisonment was menaced, for those who should absent themselves from the meetings without lawful cause, or should disobey the laws. A petition being made to queen Elizabeth, in 1564, for an explanation of certain articles in the charter of Henry VII. and a confirmation of the rest granted by other kings; that princes, by a charter of the same year, declares, that to end all disputes, they should be incorporated anew under the title of "Company of Merchant-adventurers of England," that all who are members of the former company should, if they desire it, be admitted members of this; that they should have a common seal; that they should admit into their society what other persons, and on what terms, they please; and expel them again on misbehaviour; that the city of Hamburg, and neighbouring cities, should be reputed within their grant, together with those of the Low Countries, &c. in that of the former company; that no member should marry out of the kingdom, nor purchase lands, &c. in any city beyond sea; and that those who do, shall be 15% faith excluded for ever.

Twenty two years after this first charter, queen Elizabeth granted them a second; confirming the former, and further granting them a privilege of exclusion, with a power of erecting in each city within their grant, a flandering council.

The woollen manufacture being the principal object of their application, they met with great opposition; first, from the Hanse, who forced them frequently to change their mart, or staple; and afterwards under king James I. who having erected a corporation in 1616, in favour of some private persons, who offered to set up a manufacture for dyeing and preying cloths, &c. under pretence thereof the company of merchant-adventurers were prohibited dealing therein. But that project not succeeding, and the charter being revoked two years afterwards, the merchant adventurers, whose company had been dissolved two years before, were restored in 1617, to their ancient privileges, and a new charter was given them, confirming their exclusive rights; and allowing them to have officers in the several custom-houses, to have an eye that they were not prejudiced in their woolsens, under pretence of the like merchandizes, which others were allowed to fend to other parts. This charter of king James, is the last of those confirmed by Charles II. in the grand charter of 1661.

The revolutions which had happened in the Low Countries towards the end of the sixteenth century, and which laid the foundation of the republic of Holland, having hindered the company from continuing their commerce with their ancient freedom; it was obliged to turn it almost wholly to the side of Hamburch, and the cities on the German ocean; from which change some people took occasion to change its name to that of the Hamburch company, though the ancient title of Merchant-adventurers is still retained in all their writings.

This society was greatly reduced, when its trade was left open by William III. and the company is now extinct.

Company of Merchants of the Staple was incorporated by Edward III. Their factory was at Middleburgh, in Zealand; but the staple being removed, in 1390, to Calais, it was soon after, viz. in 1392, removed from thence to England.

Company, Ruffia. This was first projected towards the end of the reign of king Edward VI. executed in the first and second years of Philip and Mary; but had not its perfection, till its charter was confirmed by act of parliament, under queen Elizabeth, in 1566. It had its rise from certain adventurers, who were sent in three vessels on the discovery of new countries; and to find out a north-east passage to China; these, falling into the White sea, and making up to the port of Archangel, were exceedingly well received by the Muscovites; and at their return, solicited letters patent to secure to themselves the commerce of Ruffia, for which they had formed an association.

The charter was promised them by Edward VI. but he dying, was first dispatched by queen Mary, in 1555. By this charter, the association was declared a body politic, under the name of the "Company of Merchant-adventurers of England, for the discovery of lands, territories, islands, &c. unknown or unexplored." Their privileges were to have a governor, four consuls, and twenty-four afflictions, for their commerce; for their policy, to make laws, inflict penalties, send out ships to make discoveries, take possession of them in the king's name, set up the banner royal of England, plant them; and lastly, the exclusive privilege of trading to Archangel, and other ports of Muscovy, not yet frequented by the English.

This charter, not being sufficiently guarded, was confirmed by parliament in the eighth year of queen Elizabeth; whereby it was enabled, that in regard the former name was too long, they should now be called "Company of English Merchants for discovering new trades," under which name, they should be capable of acquiring and holding all kinds of lands, manors, rents, &c. not exceeding a hundred marks per annum, and not held of her majesty; in no part of the continent, island, harbour, &c. not known nor frequented before the first enterprize of the merchants of their company, situate to the north, or north-west, or north-east of London; or any part of the countries, islands, &c. under the obedience of the emperor of Ruffia, or in the countries of Armenia, Media, Hyrcania, Persia, or the Calpian sea, should be visited by any subjects of England, to exercise any commerce without the consent of the said company, on pain of confiscation. The said company shall use no ships in her new commerce, but those of the nation; nor transport any cloths, ferges, or other woollen stuffs, till they have been dyed and privileged. That in the case the company discontinue of itself to unload commodities in the road of the abbey of St. Nicholas, in Ruffia, or some other part, on the north coasts of Ruffia, for the space of three years, the other subjects of England shall be allowed to traffic to Narva, while the said company discontinues its commerce into Ruffia, only using English vessels.

This company suffered with reputation almost a whole century, till the time of the civil wars. It is said, the ear then reigning hearing of the murder of king Charles I. ordered all the English in his states to be expelled; which the Dutch taking the advantage of, settled in their room After,
After the restoration, the remains of the company re-established part of their commerce at Archangel, but never with the same success as before; the Russians being now well accustomed to the Dutch merchants, and mercurialize.

This company fulfills its end on the coast of that of Hamburgh, and the northern and Turkey companies; i.e., each member thereof traffic for himself, and on his own foundation; only paying an acknowledgement as fine for admission, which was reduced by 20 and 11 W. III. c. 6, to five pounds besides some other dues imposed, from time to time, for the occasions of the company, and the commerce in general. It is under the direction of a governor, four counsellors, and a treasurer.

Company England is established on similar ground with that of Hamburgh; from whence it appears to have been dismembered.

Its charter is dated in the year 1679. By the first article the company is erected into a body politic, under the title of the "Company of Merchants of the East," to confit of Englishmen, all real merchants, who have executed the business thereof, and trafficked through the Sound, before the year 1668, into Norway, Sweden, Poland, Livonia, Prussia, Pomerania, &c., all also Reiel, Koningberg, Danzig, Copenhagen, &c., excepting Narva, Mutcovy, and its dependencies. Most of the following articles grant them the usual prerogatives, of such companies; as a seal, governor, courts, laws, &c.

The privileges peculiar to this company are, that none shall be a partner of a member who is already a member of any other company; nor any retail dealer at all. That no merchant qualified, be admitted without paying 6l. 13s. 6d. By 29 C. II. c. 7, the fee of admission into this company was reduced to 2l. That a member of another company, deferring to renounce the privileges thereof, and to be received into that of the East, shall be admitted gratis; provided he procures the same favour for a merchant of the East, willing to fill his place. That the merchant adventurers who never dealt in the East, in the places express'd in the charters, may be received as members of the company on paying forty marks; that, notwithstanding this union of the adventurers of England with the company of the East, each shall retain its rights and privileges. That they shall export no cloths but what are dyed and pressed, except a hundred pieces per annum, which are allowed them gratis.

This charter was confirmed by Charles I. in 1629, with this addition; that no person of what quality, ever, living in London, should be admitted a member, unless he were free of the city.

This company was complained of as a monopoly, and first curtailed by legal authority in 1672; and since the declination of right in 1693, exiles only in name; but they still continued to elect their annual officers, who are a governor, deputy, and twenty-four assistants.

Company, Turkey, or Levant. This once flourishing body had its rise under queen Elizabeth, who, in 1580, incorporated a small number of merchants, with the privilege of an exclusive trade to Turkey for seven years. James I. in 1605, confirmed their charter, with the addition of some new privileges. During the civil wars some innovations were made in the government of the company; many persons having been admitted members, not qualified according to the charter, or who did not conform to the regulations prescribed, in consequence of which Charles II., upon his restoration, endeavoured to place it upon its ancient basis, for which purpose he gave them a new charter, containing a confirmation of the old one with some additional articles. By this charter the company was declared to be a body politic, capable of making laws, &c., under the title of "The Company of Merchants of England trading to the Seas of the Levant." The number of members was not limited, but no person residing within twenty miles of London, excepting noblemen and gentlemen of quality, was to be admitted into the company, unless first made free of the city of London; those under 26 years of age were to pay 23l. for their admission, and those above that age 53l. These fines were reduced by an act passed in 1753, (26 G. 11. c. 18) by which it is directed that every subject of Great Britain deferring admission into the Turkey company, shall be admitted within thirty days after such request, and shall enjoy all the liberties and privileges of the company, on paying for such admission the sum of 20l.

All persons free of the company may, separately or jointly, export any goods or merchandise (not prohibited) from any place in Great Britain, to any place within the limits of the company's charter, in British or plantation built ships, navigated according to law, at any time, and to any persons whoaver, being free of the company, or to the sons or apprentices of freemen; long as they shall remain under, and submit to, the direction of the British ambassador and consuls for the time being; and may also import, in like manner, any commodities purchased within the company's limits, on payment of the government duties; and such importations shall be subject to all merchandise exported orimported, or upon ships laden thereafter, with, for defraying the necessary expenses of the company.

The company is under the management of a governor, a deputy governor, and fifteen directors; they have also a deputy governor in every city and port where there are any members of the company. They present the ambassador which the king is to keep at the Porte, and elect two consuls for Smyrna and Constaninople; allowing a fixed salary or pension to the ambassador and consuls, and even to their chief officers, as secretary, chaplains, interpreters, and janitors, that they may not have any pretence for raising any sum whatever on the merchants or merchandise. For defraying these charges the company have power to levy duties on the merchandize imported or exported by their members; but of late years they have frequently found it necessary to apply to parliament for pecuniary assistance.

The commerce of this company was formerly very considerable, having been estimated nearly equal to that of the East India company in extent, and much more advantageous to Great Britain; but the convenient situation of the French ports in the Mediterranean for the Levant trade, gives that country such a decided advantage, that the commerce of Great Britain with Turkey has long been on the decline. In 1797, in order to avoid the hazard to which British vessels in the Levant trade were exposed in consequence of the war, an act was passed giving permission to the members of the Turkey company to import the goods usually brought from Turkey, Egypt, or other parts of the Turkish dominions in the Levant seas, from any port whatsoever, either in British vessels or vessels belonging to any friendly nation, on paying, if in British vessels, the same duties which would have been payable if the goods had been imported directly from the place of their growth, and, if in foreign vessels, the duties to which they were subject liable; but no entry of such goods was to be made at the custom house till the importer produced a certificate of his being a member of the Turkey company, and that he had paid the company's duties, and in all respects conformed to the company's regulations.

Company,
COMPANY.

Company, South Sea, originated in a project for relieving the government from the embarrassment of a large amount of unfunded debts, and considerable deficiencies in the funds appropriated for the payment of others; the proprietors of these debts being incorporated for the obvious purpose of establishing a trade to the south seas and the N.W. coast of America. The capital of the company was £177,677 l. 154. 4.; but this being subscribed wholly in government securities, they issued bonds in 1712, for raising 200,000 l. in cash in order to fit out their first mercantile adventure. In the following year, they obtained the Affiento contract, by which they agreed to import into the Spanish West Indies 144,000 negroes, within the term of 30 years. At the rate of 4000 in each year, and were allowed to send a ship of 500 tons yearly to trade with the Spanish settlements, on condition that the king of Spain should have a fourth part of the gain by each ship, and receive five per cent. on the nett gain of the other three parts. See Assiento.

The first voyage of their annual ship was in 1717, and the company were again empowered to borrow money under their common seal, for carrying on their trade, or to enable them to fulfill an engagement with government to advance two millions towards carrying into execution a proposed reduction of interest on the public debts. On the war breaking out in the following year, a fleet was put to their trade with the Spanish West Indies, by the seizure of their effects, by which they sustained a very considerable loss.

Soon after this interruption of their commercial concerns, they engaged in a scheme for converting some of the government terminable annuities into redeemable debts. They had, in 1715, for the accommodation of government, agreed to increase their capital to 10,000,000 l., which, by the annuities now purchased, and an advance to government, became £11,746,844. 8 s. 10. 4.; and although the scheme did not completely succeed, it prepared the way for the more extensive project of taking in all the public debts, and thus reducing all the public funds which then existed into one.

The mere rumour of this mercantile project raised the price of the company's flock to 126 per cent.; and, in the beginning of 1720, while the bill for carrying it into execution was depending in parliament, their flock got up from 117 to 319 per cent. As the transaction consisted merely in taking the public debts at a fixed price, and giving the proprietors, in exchange, a certain quantity of the company's capital flock, at prices agreed upon between the company and the subscribers, it is evident that the great gain which the company expected to make, could arise only from the current price of their flock being considerably above its real value. By a variety of artifices, and a general flock jobbing infatuation, it was carried up to the enormous price of 1000 per cent.; the rapidity of its fall, however, exceeded that by which it rose, as it was in a few weeks down to 130 per cent.; involving in ruin pensions of all descriptions who were engaged in the wild speculations of the time. Had the transaction completely succeeded, the capital of the company would have amounted to £43,411,399. 6 l. 113. 4.; but from some of the debts remaining unsubscribed, it became £27,802,483. 14. 2.; of which four millions were purchased in 1722 by the bank, and in the following year the remainder was divided into two equal parts, one of which was to be called the trading capital of the company, and the other to be distinguished by the title of "The joint-flock of South Sea annuities," since called old South Sea annuities.

In 1724, the company undertook the Greenland white

filhers, which turned out very unprofitable; after eight voyages, they sold their ships, stores, and utencils, and found that their whole loss upon this huf mains, capital and interest included, amounted to £237,142 l. 61. 2. d.

In 1733, three fourths of their trading capital, which had been reduced by fines paid off in 1727, 1729, and 1732, to £1,451,203 l. 8 s. 1. d.; was converted into an annuity flock called "New South Sea Annuities," only one fourth remaining as their trading flock; and, in the following year, they petitioned the king to be allowed to dispose of the trade and tonnage of their annual ship under the Affiento contract, on account of the little profit they made by it, and to accept of such equivalent as they could obtain from the king of Spain, who, at length, put an end to the many disputes which had arisen from this contract, agreed in 1750, to pay 100,000 l. to the company, as a compensation for their being unable to get a legal charter under the Affiento contract, and from that period they have not carried on any trade whatever. The whole benefts of the company, therefore, now consists in the management of the following public funds:

<table>

<tr>
<td>Three per cents.</td>
<td>£1,919,600</td>
</tr>
</tbody>
</table>

The interest received from government on all these funds, is 3 per cent., but the dividend paid to the proprietors of the company's flock, is 3% per cent.; on the old and new annuities, 3% per cent.

The company is under the management of three governors, and 21 directors; the qualification required for a governor, is the possession of 5000 l. in the company's flock; for sub-governor, 4000 l. : for deputy-governor, 3000 l. ; and for a director, 2000 l. Five hundred pounds flock, gives a right to one vote at the general courts; 1000 l. to two votes; 3000 l. to three votes; 5000 l. to four votes.

Company, Scotch Darien. This was established with good prospect at Edinburgh, in 1697; for the commerce of South America. In 1698, they sent an armament and a colony, which they endeavoured to establish in the illums of Darien, which parts North and South America; but the English ministry not thinking proper to avow and support the first successes of the company, which had alarmed Spain, ever jealous of this part of her territories, the Scotch colony was dispossessed by the Spaniards in 1699, and thus vanquished the belt project that ever was formed for disputing with that nation the possession of those countries, from which she pretends to exclude all other nations.

Company, Hudson's Bay, was incorporated by charter, dated the 2d of May, 1670, under the title of "The Governor and Company of Adventurers of England, trading into Hudson's Bay," with the exclusive privilege of trading to all parts within the entrance of the freight commonly called Hudson's freights. The charter, however, not being confirmed by act of parliament, the company possesse all exclusive rights. However, any British subject being at liberty to fall into Hudson's Bay, to fish or traffic with the Indians as freely as the company; all the advantage the company have over other adventurers thither is merely the benefit of their own forts, such as they are, by which their agents can reside in so inhosipitable a country during the winter, preparatory to their trading with the Indians against the arrival of their ships in the summer. According to the evidence given before a committee of the house of commons in 1749, the company then possessed four small factories, erected at the mouths of the principal rivers, in which they employed about 130 per-
COMPANY.

The capital of the company, it is said, does not exceed £10,000, which is divided among a very small number of proprietors. The commerce carried on by them is not of great extent, but seldom employs above four or five ships of about 500 tons each. The articles exported by them are coarse druffe cloth or blanketings, guns, pistols, sword blades, hatchets, powder and shot, spirits, tobacco, bras kettle, button, fish hooks, looking glasses, &c.; the imports consist of large quantities of Beaver skins, and peltry of all kinds, bed feathers, quills, calafornia, whalefin, oil, and a few smaller articles.

The company is under the management of a governor, deputy governor, and a committee of seven members.

The company, Sierra Leone, was set on foot in the year 1791, with the philanthropic view of introducing civilization into Africa. The principal means proposed for effecting this end was the establishment of a secure factory for carrying on an extensive commercial intercourse with the interior; but before the arrangements for this purpose were completed, the reception into the settlement of near 100 blacks, who had taken part with Great Britain in the American war, and had petitioned the government to be removed from Nova Scotia on account of the coldness of the climate, involved the company in considerable difficulties, and gave it a new character to the undertaking. Their exposure, from various causes, became much greater than could have been foreseen, amounting in the first two years and a half to 111,500, and were still further increased in 1793 by the war, which at the same time greatly interrupted their trade, and subjected them to depredations. In October 1794, the colony was attacked by a French squadron, and all the moveable property of the company was either carried off or destroyed, every building belonging to them burnt, and several ships captured. The company's losses on this occasion have been estimated at £5,000. This calamity, combined with their previous expenses, so greatly diminished the company's funds, as to lay them under a necessity of contracting their trade, and reducing considerably the scale of their establishment, which had been at all times so limited as scarcely to afford sufficient means of transacting the business and attending to the various wants of an infant settlement.

In the year 1798 the colony had made considerable progress, notwithstanding the many obstacles to its advancement. The town consisted of about three hundred houses, with the necessary public buildings, and had become a place of considerable respect. It was estimated that from one to two hundred natives visited the settlement every day, many of them coming from a distance of eighty or a hundred miles, for the purpose of exchanging articles of African produce, for British manufactures. The total number of inhabitants of the colony at this time was about 1200.

In 1800 the company obtained a charter, creating their settlement an independent colony, and authorizing the directors to frame laws for its government, to appoint a governor and council, and to make other arrangements for the administration of justice; a small military force was at the same time lent for the defence of the colony. The sum of £7000 being part of the sum granted by parliament for the maintenance of African forts, was paid to the company for the erection of a fort; £10,000 was about the same time received from government as a partial indemnification for the expense to which the company had been put in settling the Nova Scotians; £4000 was also granted for the support of the civil government of the colony. About this time the company agreed to receive in their colony the Maroon Indians, and soon after their arrival, employed them to quell an insurrection among the Nova Scotians, who had endeavoured to pollute themselves of the government. A more serious attack on the colony was afterward made by some of the native chiefs in the neighbourhood, which rendered it necessary to adopt additional means of defence.

The sums since granted by parliament for defaying the charges of the civil establishment of the company, and for the erection of fortifications, have been as follows:

For the year 1801 £ 4,400
1802 10,000
1803 14,000
1804 14,000
1805 14,000
1806 18,000

The trade of the company appears to have been successful, supposing it to have been hitherto only with those charges which are chiefly commercial, and to have been exempt from the extraordinary losses by fire, and the destruction of the settlement which it has had to sustain. The abolition of the slave trade will remove some great obstacles to the success of this laudable undertaking, and probably enable it to improve and extend its commercial intercourse with the natives very considerably.

COMPANY, for the Manufacture of Flour, Meal, and Bread. During the difficulties occasioned by the great scarcity of corn, in the year 1800, a number of persons formed themselves into a company, for the purpose of establishing in London a manufactury of flour, meal, and bread, to be sold out at reasonable prices. They were incorporated by parliament, and empowered to subscribe a joint capital, not exceeding 120,000l. in shares of 25l. each; their profits being limited to 10 per cent., and the surplus, if any, to be at the disposal of parliament. They were limited to sell only 120,000 sacks of flour, or meal in a year, to make only 200 sacks into bread in a week, and to sell not more than 1000 quarters of wheat in any one week. The managers of the company were prohibited from dealing in corn, flour, or bread, for their own private account; and were required to lay before parliament an annual statement of their receipts and payments, of the quantities of grain purchased, with the prices paid for the same, of the quantities of grain and flour in store, of the quantities of flour and bread manufactured by the company, and of the debts and credits of the company, with the names of all the members of it, and the number of shares held by each. By these regulations sufficient publicity is given to the concerns of the company, to prevent it from ever being perverted from the original principle of the establishment, and made subservient to schemes of monopoly or speculation; and though upon the scarcity ceasing, they discontinued making bread, they have carried on the manufacture of flour and meal, and probably contributed to prevent their essential articles from being unnecessarily enhanced in price.
The total quantity of wheat purchased by the company in the year 1836, was 9,182 quarters, for which they paid £25.6.5d. 19s.; the quantity of flour manufactured was 15,757.55 bushels. The number of proprietors of the company was 370.

The king by an order in council may dissolve this company on six months previous notice being given.

Company, Dock. See Dock.

Company, Dutch East India, had its rise in the midst of the struggle that people had for their liberty; for the Spaniards having forbid all commerce with them, and shut up all their ports, necessity inspired some Zealanders to seek a new north-east passage to China.

This enterprise proving unsuccessful to three several armaments in 1594, 1595, and 1596, a second company was formed under the name of the "Company of remote Parts," which, in 1595, took the ordinary route of the Portuguese to the Indies, and returned in two years and a half's time, with little gain, but good hopes.

This company, and a new one just established at Amsterdam, being united, equipped other fleets; and these occasioned other companies at Amsterdam, Rotterdam, in Zealand, &c., infomuch that the flates soon began to apprehend they might be prejudicial to each other. Under this concern they called all the directors of the several companies together, who all confined to the union, the treaty whereof was confirmed by the flates in 1602, a very remarkable epocha, as being that of the most solid and celebrated establishment of commerce that ever was in the world.

At this time they obtained a charter from the flates; and prevailed upon that body, by administering to its exigencies in the Spanish war, to grant them the exclusive privilege of trading to the southern parts of Africa, for a short term of years. The company's capital of 6,500,000 florins (about 2,521,833 l. sterling) was divided into transferable shares, or acciones, as they are called on the continent, of 3000 florins (about 1764 l. sterling each), which were all speedily bought up. The superiority of their trading capital, together with their greater skill in commerce and navigation, enabled them to under sell all other nations, even in the foreign markets of Europe. As they also fixed the prices of their merchandise to all consumers, their profits for some years were enormous. The annual dividends for the 6 years ending in 1610 were as high as 36 per cent.; and in a short time, the actions rose from 3000 to 15,000, and at one time floated as high as 24,500 florins, 8 times the amount of their prime cost. The charter, first granted in 1602, and since renewed from time to time, conferred upon them, besides the exclusive right of trading to the East, the sovereignty (under the superintendence of the states-general) of all the territories which they might acquire in that part of the world, by parcells, tracts, or conquest, with the full power of appointing their own servants, of raising whatever force they might deem necessary for the defence of their territories; and of enacting laws for the internal administration of their dominions. In consequence of this charter, the most extensive that was ever granted to any trading corporation, the company proceeded to arrange their establishment, both in Europe and the East Indies. Their affairs were under the management of 56 directors, divided into several chambers; twenty in that of Amsterdam, twelve in that of Zealand, fourteen in that of Delft and Rotterdam, and a like number in those at Sluys and Hoorn. As each grant expired the company was obliged to procure a new one, which it has already done, four times since the

The first vis. one in 1623, for forty-one years, like the first; another for twenty-one years, commencing in 1645; and a third in 1665, for forty years; a fourth in advance, commencing in 1698, to end in 1740. Each grant cost the company a considerable sum; that of 1647 cost 1,600,000 guilder, and the two following ones more; that of 1698 was confirmed by a placard of the states general, granted them an exclusive privilege, which was prolonged in 1761, for thirty years more. The average premium paid for these renewals was about 270,000 l. sterling, or three millions of florins.

Their factories, refidences, &c. in the East Indies, were very numerous; reaching from the Persian gulf to the coast of China; the principal was that of Batavia, the centre of their commerce: here resided the general, with the flate and splendor of a sovereign prince; making war and peace with the eastern kings and emperors at pleasure. They had also several other considerable factories on the coast of China, in Japan, Malacca, Surat, Amboyna, Bandi, Sum, Moluccas, &c., several on the coast of Commandel, and on Ipanah, Cape of Good Hope, &c. in all, they numbered forty factories, and twenty-five fortresses. They engrossed the whole trade of the figery in their own hands.

At an early period as the year 1616, this company had no less than 45 large vessels engaged in war and trade, with 10,000 soldiers and sailors in their service, and 4,000 pieces of artillery. However, the florishing state of their affairs was of short duration. The mismanagement and plunder of the company's servants, and the disputes in which their cruelties, avarice, and imprudence involved them with the native powers during the 17th century, and the difficulties which arose among the different chambers of the general direction at home, greatly reduced the trade, wealth, and power of the institution. The expense of the military establishment also increas'd; so that at the end of the 18th century, it amounted to 80 vessels, carrying from 50 to 60 guns, and 25,000 men, soldiers included, while the whole dominions in Java, and its dependencies, were farmed for 301,263 dollars. The directors acknowledged that, in 1782, their losses in the war had exceeded 10 millions of florins, nearly twice the amount of their original capital. In the 18th century, the Dutch East India company excited the jealousy of the Dutch company. In 1721, a law was passed by the former, prohibiting their subjects from falling under the East India colors, upon pain of death; and in 1731, this unfortunate affair was dissolved in consequence of representations from the different European states interested in the East Indian trade; among which Holland, that is the Dutch company, took the lead. Various precautions have been used to support the credit of this company, some of which were oppressive to the country; nevertheless, its shares have continued to fall with augmented rapidity. In the period from 1605 to 1779, the dividends have varied from 75 to 10 per cent.; and in many years no dividend at all was given. From 1605 to 1610 (both inclusive), the dividend was, at an average, 56 per cent. From 1610 to 1613, the average was only 21; and from 1777 to 1780, it was no more than 12.4 per cent. The price of the actions, which had at first risen to 500, and even 800 per cent. of the prime coin, fell, in the period from 1770 to 1780, to about 340 per cent., and during that time continued regularly to fall. The last dividend this once flourishing company made to its proprietors was in the year 1798; but it was not paid till 1816, as their commerce, which had been rapidly declining for the last 30 years, was entirely suspended.

D d

Cum
The Company, Dutch West India, was established in 1621, with an exclusive privilege to trade twenty-four years along the coasts of Africa, between the tropic of Cancer and Cape of Good Hope; and in America, from the south point of Newfoundland, through the Straits of Magellan, that of Le Maire, or others, to the Straits of Anian, both in the north and south Sea.

Besides these commercial privileges, the shares conferred upon the corporation the right of governing and defending any new colonies which it might acquire; and made it a present of several large vessels, well manned. They retained to themselves, however, the nomination of the company's governor-general abroad. The original capital of this association amounted to 72,000 florins, in transferable shares, or actions, of 600 florins each.

The 74 directors were divided into five chambers (as in the East India company), out of which, eighteen, with a deputy appointed by the states, were chosen for the general direction of affairs. In 1647, the company renewed its grant for twenty-five years; but it was scarce able to hold out the term, on account of its great losses and expenses in taking the bay of Todes land, Staten, Feramboc, and the greatest part of Brasil, from the Portuguese. The weakness of the company, which had several times in vain attempted to be joined to that of the East Indies, occasioned its dissolution at the expiration of its grant.

In 1674, a new company, composed of the ancient proprietors and their creditors, was settled in the same rights and establishment with the former. It was to undertake the burden of the old company's debt, amounting to six millions, but reduced to 50 per cent.; and was to accredit in its books the proprietors of the old company's stock, at the rate of 15 per cent. The creditors, on their part, were to advance an addition of 8 per cent. on their loans; and the stockholders were to advance 4 per cent. on their shares. The new capital, thus scraped together, amounted only to 600,000 florins. The exclusive commerce of the company was limited to a certain part of the African coast, besides the commodities they should make; and its principal establishments were at Cape Verde, on the Gold Coast, at Togo, Curafalco, &c. in America. The roll of the trade amounted to the former company; and the former commerce was thrown open to all the subjects of the republic. In 1720, when the charter was renewed, the African slave-trade was made free, on condition of a certain tribute being paid to the company; and in 1724, the whole African trade was laid open upon the same terms. As the united privileges of the company were not sufficient to counterbalance the various disadvantages under which all fresh institutions labour, they obtained, in 1632, the exclusive management of the colony of Surinam, for the trilling sum of 200,000 florins paid to the states-general. This grant was accompanied by certain conditions, framed with the manifest view of preventing the abuses common to trading corporations. Under these restrictions, the company was not able to delay the essence of the original purchase-money paid for the charter; and, therefore, in the next year, one-third share was sold to the city of Amsterdam, and another to the rich family of Sommelsdyk, retaining the remaining third to themselves. These three co-proprietors have since continued to form a society or partnership, under the name of the "Surinam Company," regulated by the charter originally granted to the West India company. Except in the government of Surinam, this association has had no connection with the West India company, which, of course, continued to furnish negroes to the settlement, in its capacity of African company, until the year 1730.

The progress of the dividends and prices of West India stock will enable us to judge concerning the prosperity, not only of the Surinam society, but also of the concerns of the West India company. The average dividend in ten years, ending 1690, was 2½ per cent.; and from 1721 to 1779 inclusive, nothing at all was divided. The actions have never been at par; their price has varied from 92½ to 18 per cent. since the year 1733. The average price during ten years, ending 1732, was about 81½ per cent. During ten years, ending 1779, it had fallen to 32½ per cent. The settlements of Essequibo and Demercy have been always under the charter of the West India company, as well as Surinam, and governed in the same manner. Berbice, though within the company's charter, owed its origin to the speculations of the family of Van Peere; and all the cultivated part of the colony belonged to them. In 1687 they obtained a perpetual grant of it from the company, which was confirmed in 1703, and when the French attacked it in 1712, the colony bought them off with a considerable composition. The money was paid by their great mercantile houses, and one fourth of it by the Van Peeres, who thus transferred three-fourths shares of the colony to the other merchants as co-proprietors; and the four houses together formed a company or company at Berbice, administered exactly in the same manner with the Surinam society. The proprietary governments of North America differed from the company administrations of Guiana in many important particulars. They were the consequence of large and thoughtless grants, made by the court to favourites, of waste and uninhabited lands. As the British colonies were subservient to the legislature of the mother-country, the Dutch colonies owed the same allegiance, not to the states-general, but to the proprietors. The ill success of the West India company furnishes an useful example of the manifold evils of company government. This company must in great part be ascribed to the capture of all their settlements.

Company, Dutch North, has no exclusive privilege; the advantage of its patent being of another kind, and very considerable.

There are also, in Holland, companies for the Baltic sea, the fifty of New Zealand, Davis's Straights, and Greenland; yet none of their fisheries are interdicted to private traders; all the difference between the and the companies confining in this, that the former may not go a shore to cut their fish in pieces, and meet their lord: but must bring their cargo to Holand.

Company, Dutch Levant. In Grecia, there is no Levant company in Holand: but the commerce of the private traders is so considerable, that the state has taken the regulation thereof on itself.

To this end, they have established a chamber of direction at Amsterdam, composed of six deputies, and a regular who, under the burgomasters, take care of every thing relating to the commerce of the Mediterranean; especially that of Smyrna and Constantinople.

This company names the consuls, appoints the number and strength of convoys, terminates differences among the traders, and has also a right, on occasion, to add new regulations to the old ones; though these be of no force, till confirmed by the states general.

Company, French East India, was established in 1664, with an exclusive privilege to trade for fifty years in all the seas of the East Indies and South Sea; no adventurer to be admitted without a thousand livres in stock; and foreigners, who have twenty thousand livres in stock, to be reputed speculators.

The patent grants them the island of Madagascar; and the
the king to be at one fifth of the expense of the three first armaments, without interest; the principal to be refunded in ten years; or, if the company finds it loses on the whole, the loss to fall on the king's side.

The capital fund of the company, which was mostly furnished by the king, was ten or eight millions of lives, but was to have been fifteen millions.

In effect; though no means were wanting to support the company, yet it did drop off, and still shrunk; till, having subsisted ten years without any change in its form, and being no longer able to discharge its engagements, there were new regulations concerted, but to little purpose. At length, things not being disposed for a new East India company, nor much good to be expected from the old one, in 1708, the ministry allowed the directors to treat with the rich traders of St. Malo, and resign to them their privilege under certain conditions. In the hands of these last, the company began to flourish.

Its chief factory was at Pondicherry, on the coast of Coromandel; this was the residence of the director-general; the other factories were inconsiderable. The merchandizes which the company brought into France were, flax, cottons, spices, coffee, rice, salt-petre; several kinds of gums and drugs, wool, wax, printed calicoes, muslins, &c. The trade was laid open in 1769, which soon reduced the company to a sort of mere holders of the government funds. A new company was established in 1785, with the privilege of an extensive trade to all parts of the East Indies, except the island of France and its dependencies. This exception must have prevented the company from succeeding; but the experiment had scarcely been made when the trade was again laid open by the national assembly in 1790. As for the other French companies, such has been the fate of the country, they are all, we presume, extinct; and it is needless to give any account of them. Such were the French West India company, established in 1664, and possessing by their charter the property and sovereignty of Canada, Acadia, the Antilles island, the Isle of Cayenne, and the Terra Firma of America, from the river of the Amazon to the coast of Oroono; with an exclusive privilege for the commerce of these places, as also of Senegal, and the coasts of Guinea, for 40 years, on condition of paying half the duties; but in 1674 the grant was revoked, partly on account of the poverty of the company, and partly because it had an unfavourable effect on the commerce of the West Indies from the Dutch:—the French Missipipi company, first established in 1684, in favour of the eleveur de la Salle, who failed in search of the Missipipi, but mis-carried with his colony, and came to an untimely death. He was succeeded by M. Hibernelle, who found the Missipipi and settled a colony there; but this adventurer being poisoned, M. Crozat obtained in 1712 the sole privilege of trading to the French territories called Louisiana, granted to him for 15 years:—Company of the West, formed in 1717, when M. Crozat surrendered his grant before mentioned; and obtaining besides every thing granted to the former company the commerce of beaver, enjoyed by the Canada company from the year 1706, but expiring in 1717:—India company, formed by a junction of the former company with that of Canada and with that of Senegal in 1718, and also by an union with the East India company, and with those of China and St. Domingo, with the two first in 1719, and with the third in 1720:—the Biflot company, arising from the association of two merchants of Marille and in the 17th century for fishing of coral in the gulf of Stora-Courcoury on the coast of Barbary, on the frontiers of Algiers and Tunis: so called from a small port called the "Bantion of France," built in 1591, but it funk in 1633;— and several other companies, which either fell of themselves, or upon the expiration of their grants, and which it is therefore needless to mention.

Company, Danijb North, was established at Copenhagen in 1647. Its establishments are very considerable in Norway, Sweden which, it lends itself to Warangal, where they convey their merchandizes by land into the Danish Lapland; and by fedges drawn by rein-deer into the Munifico Lapland. It also lends others for Barandai and Siberia: where its agent takes them up, and conveys them, in like manner, on fedges, to Panigarod, the capital of this port of the Munifico empire.

The commodities it lends thither are rix-dollars, tobacco, and linens; it returns nothing but furs and skins.

Company, Danijb Iceland, established in the same year with the North Company, its chief factory is at Kirkebar, a large town in that island.

Company, Danijb East India, established in the year 1616, and involved not only with the exclusive privilege of trading to the East, but with the powers of civil and military administration; their chief factory was at Tranquebar. In 1634 this corporation was dissolved, and another, with similar privileges, substituted in its place. This also rapidly declined; and in 1686, a third institution was tried for the same purposes; but this too failed in about 23 years; and the project was tried for the fourth time in 1732. The new company was provided with ample privileges and powers; and the submission of these preferred its existence, and increased the profits of the flock holder, at the expense of the country, and of the Indian settlements. In 1772 the charter expired, and was renewed under restrictions which proved ruinous to the prosperity of the company. In 1777, the king purchased the rights of the company, and the private trade began to flourish. When the charter was renewed in 1792 for 20 years, the private trade was rendered still more free; all Danish subjects, and all foreigners were permitted to trade with the Indian settlements, upon receiving passports, either from Copenhagen or the Atlantic seaports of government, and upon condition of returning with the cargoes to Copenhagen.

Company, Levant. of the Genoves, established in 1664, and confirmed by the Pope; notwithstanding the opposition of the French. From 1670 this company has languished and sunk.

For a more particular account of the rise and progress of most of the above mentioned and other companies, see "Anderson's Hist. of Commerce."

Company, New River. This corporation consists of a governor, deputy governor, treasurer, and twenty-six directors, who hold a weekly board for appointing officers, granting leases, and redressing grievances. The projector of this canal for bringing water to London, with the assistance of king James I. and the corporation of London, is supposed to have expended 100,000l. upon it: the profits, which are divided into twenty-two shares, for the first thirty years admitted of little more than five pounds to each share; but their value is much increased, and its original shares of 100l. are now estimated at upwards of twelve thousand pounds each.

Company, in French compagnies. A certain number of people of war under the inspection and command of a chief called captain. The number, however, is never fixed, but varies. In the guards, as in the artillery, a company consists of 120 men. In the Artillerie service a company consists of 200 men. A compagnie d'ordonnance was originally composed of fourteen companies of gens d'armes of a hundred hommes. 

D 2
cluded the company of infantry, and the word cavale the company of cavalry. A company seldom consists of fewer than 50 men. It generally has three or four ferrnants, three or four corporals, and two drums.

Company, Artillery. See Artillery.

Company of Musicians, in the city of Wellminster. See Charter.

Company, in Sea Language, denotes the whole crew of a ship, including her officers.

Company of Ships, is used for a fleet of merchant vessels, who make a kind of charter-party among themselves; whereby, under several clauses and conditions tending to their common safety, they engage not to quit one another, but to defend each other reciprocally, during their voyage.

These associates, in the Mediterranean, are called consorts. The chief conditions of the charter-party are, that such and such shall be owned admiral, vice admiral, and rear-admiral; and those that bear no guns, shall pay so much percent. of their cargo, for the expenses of the admiral; that such and such signals shall be observed; that if they be attacked, the damages shall be reimbursed by the company in general, &c.

Company, Rule of, or Fellowship, in Arithmetic, is a rule whereby we discover or ascertain the share of the profits, or duties, belonging to the several partners, or associates, in any enterprise, in proportion to the stock each contributed thereto, and the time that stock was in bank. See Fellowship.

COMPARATE, Comparada, in Logic, the terms or subjects of a comparatid; or the two things compared to each other.

COMPARATIONE—Punctum ex COMPARATIONE. See Punctum.

COMPARATIONIS, Homogeneum. See Homogeneum.

COMPARATIVE Anatomy. See Anatomy.

COMPARATIVE Degree, in Grammar, is an inflexion between positive and superlative degrees; whose effect is, to set a thing above or beneath the level of another.

The Latins expressed their comparative degree by a particular termination of their adjectives, and particles; wherein they are followed by the English, though by few others of the modern languages.

The French form most of their comparatives by adding the particles plus, moins, and aussi; the Italians, by più, meno, &c. as the thing is to be raised, lowered, or equaled to another.

COMPARE, Valdi, in Geography, an island in the Ionian sea, anciently called Ithaca, noted for having been the country and kingdom of Ulysses.

COMPARISON, the relation of two persons or things, considered as opposed, or set against each other, in order to find wherein they agree or differ; or wherein one has the advantage of the other.

COMPARISON of Ideas, an act of the mind, whereby it compares its ideas one with another, in respect of extent, degree, time, place, or any other circumstances. This operation of the mind is the ground of relations.

Brutes from not to have this faculty in any great degree; they have, probably, several ideas distinct enough; but cannot compare them rather than as to some fableable circumstances an exed to the objects themselves: the power of comparing general ideas, which we observe in men, they have not, as we may probably conjecture.

COMPARISON, in Rhetorics, is a figure, or rather place, in speech, whereby two things are considered with regard to some third, which is common to them both.

Thus, Cicero, "Catoni licuit extundi bellum civile, igitur et Ciceroni hec est." "It was allowed Cato to engage in the civil war, therefore it may be allowed Cicero," where, to engage in the civil wars is common to both.

There are three kinds of comparison; the first a majus, i.e. from the major to the minor, as that of Cicero against Antony, "Quid feci? domi tua, cum alii teneat, quae, in soto?" Or that of Terence, "Quis erat, si parentem non fuisse?" From the same place, Ovid endeavours to appem Cæsar.

"Cur ergo esse negant leniri Caesarivrat
Cum videam mitis holibustus effe Deos?"

The second, à minore, i.e. from the minor to the major; thus Cicero, "Majoris nihil esse mercatoribus, ae navigatortibus injuriosus et fastidiosus, habet constitutum, vos tot civium Romanorum millibus uno nuntio atque uno tempore necatis, quos tandem animo effe debitis?"

The third à pari; as when we contend, that what obtains in one thing, ought to obtain in another of the same kind: "It was a law that he who killed his father should be hanged up in a sack, and thrown into a river; therefore, he who killed his mother deserts the same punishment."

COMPARTMENT, or COMPARTMENT, a design composed of several different figures, disposed with symmetry, to adorn a parterre, a cycling, panel of joinery, or the like.

The term of compartment is also used in painting. The Turkish and Moorish paintings are only compartments; the fine bindings of books are in compartments, &c.

COMPARTITION, in Architectura, the useful and graceful distribution of the whole ground plot of an edifice, into rooms of office, and of reception, or entertainment. Compartment makes one of the great divisions of the art of building.

COMPARTMENTS, in Gardening, are beds, plats, borders, and walks, laid out according to the form of the ground, and depend more on a good fancy, than on any set of rules, for their construction. They are also sometimes merely diversities or knots of flower-gardens or parterres, of which there is an infinite variety, according to the fancy of the designer. Plain compartments are pieces of ground divided into equal squares and flower beds, marked out by lines, and made of regularly equal length and breadth. Some allow to these squares borders of two feet broad, if the plot of ground be small, and if larger of three feet, and edge the borders with box, or with upright hardy thyme; the alleys up between are to be laid with sand or gravel, and kept clean weedless.

COMPARTMENT of tiles, is an arrangement of white and red tiles varnished, for the decoration of the covering of a roof.

COMPARTMENT, alley of. See Alley.

COMPARTMENT, in Heraldry, is the term for a partition in coat armour, when the arms of several families are borne by one, either on account of intermarriages or otherwise.

COMPASS, the Mariner's or Nautical. A period of about 500 years is now elapsed, since an admirable property of a natural production was either discovered by, or intro-
COMPASS.

duc'd amongst the nations of Europe. To the simple application of this remarkable property, mankind is indebted principally for the discovery of a new continent nearly equal to the old one, for an extensive commerce between the most distant nations, and for an accurate knowledge of the shape and size of the world we inhabit. The magnet is the natural production, and its directive property forms the active part of that wonderful guide, the mariner's compass, or as it is more commonly called, simply the compass; probably from its moving in a circle, or from its compelling the whole horizon. Whatever relates to the history, the construction, the use, and the defects, of this singular machine, is rendered extremely important by the curiosity, the interress, the security, and the wants of the human species.

The time when the attractive property of the magnet was first discovered, is by no means known. The opinions are various, but they are not established upon historical documents of sufficient accuracy and authenticity. Certain however it is, that mankind was acquainted with it at a very early period. Father Kircher, in his work, De Magnetis, l.t. cap. v., endeavours to prove that the Hebrews were acquainted with the magnet's singular property of attracting iron; and from Plutarch it appears, that the Egyptians were not ignorant of it. Pythagoras, Eolomy, Hippocrates, Empedocles, Democritus, Leucippus, Epicurus, and several other ancient philosophers, knew and admired this wonderful property of the magnet. Thales and Anaxagorae were so struck with it, as to imagine that the magnet had a soul; and Plato said that the cause of its attraction was divine. Aristotle, Theophrastus, Dioscorides, Galen, and others, were likewise acquainted with this property of the magnet. But its directive property (viz. that property by which, if placed upon a piece of cork, or wood, &c. to swim on the surface of water, or if it be suspended by a very flexible thread, so as to have sufficient freedom of motion, it will constantly place itself in a certain situation with respect to the cardinal points of the world) does not appear to have been known to the ancients; and though the time of the discovery of this property is of a much more recent date, yet this too is involved in much doubt and obscurity. It seems, however, that the use of this property, or (what amounts to the same thing) the use of the magnetic needle, was not known in Europe before the thirteenth century. The honour of its discovery has been much contested. The Spanish Jefuit Pineda, and Kircher, affirm that Solomon knew the use of the compass, and that his subjects actually used it in their navigations. Plantus in Mercator, aet v. scene ii., has the following remarkable passage, Hoc secundus venus eft, cape modo werforiam. Now some authors are of opinion, that by the word werforiam or werforiam, is meant the mariner's compass; but some learned critics affirm that werforiam or werforiam, meant a particular rope. And Dr. Lorimer is inclined to believe that it only meant the helm.

By the consent of most writers, it seems that a certain Flavio, or Johns, de Gioja, or Giova, or Gira, a Neapolitan, who lived in the 13th century, has the bell title to the discovery. Flavius Blond affirms that about the year 1302, the above-mentioned John de Gioja, a noble citizen of Amalphi, a town of Principato, in the kingdom of Naples, first discovered the mariner's compass; and he quotes the following verse from Antony of Palermo, recorded by the Neapolitan historians, viz.

Primo dedit nautis usum magnetis Amalphi.

The arms of the territory of Principato have, it appears, ever since been a mariner's compass. See Collins, et From belleu de aevii magnetica inventore. Infl. Acad. Bonon. tom. ii. p. 3, p. 372.

Dr. Gilbert, an English writer of the 16th century, in his book De Magnetis, affirms that Paulus Venetus (the Venetian Marco Paulo) brought the invention of the compass to Italy in the year 1260, having learned it of the Chinese. But this cannot be true; for Marco Paulo did not set out for the first time before the year 1269, and did he return before the year 1295 (see Purchas's Pilgrim, vol. iii.); whereas the directive property of the magnet, and the communication of that property to felce, was known in Europe before that time; though in all probability it was not used in navigation till some time after, which may very reasonably be attributed to the clumsy mode of suspending the magnetic needle's, which must at first have been practised. Ludii Veromannus affirms, that when he was in the East Indies, about the year 1350, he saw a pilot direct his course by a magnetic needle, fastened and formed like those now in use. And Mr. Barlow, in his Navigator's Supply, anno 1597, relates, that in a personal conference with two East Indians, they affirmed that, instead of our compass, they used a magnetic needle of about six inches in length, suspended upon a pin in a dish of white China earth filled with water, in the bottom of which were marked two cross lines to indicate the principal winds; the roll of the divisions being left to the skill of their pilots. But these two last observations, being of a date much posterior to the use of the magnetic needle in Europe, conclude nothing with respect to its original discovery; since the use of that magnetic property might have been introduced into Asia by some European.

P. Duhalde, in his General History of China, vol. i. in the annals of the Chinese monarchy, speaking of the emperor Hongti, when he gave battle to Tchi T'ou, says, "He perceiving that thick fogs favored the enemy from his puruit, and that the soldiers rambled out of the way, and loft the course of the wind, made a carr, which showed them the four cardinal points. By this method he overtook Tchi T'ou, made him prisoner, and put him to death. Some say there were engraven in this carr, on a plate, the characters of a rat and a horse, and underneath was placed a needle to determine the four parts of the world. This would amount to the use of the compass, or something very near it, being of great antiquity and well attested." And in another part of the same book, speaking of certain ambassadors, he says, "After they had their audience of leave in order to return to their own country, Tchiou Kung gave them an instrument, which on one side pointed towards the north, and on the opposite side towards the south, to direct them better on their way home, than they had been directed in coming to China. This instrument was called Tchi Nan, which is the same name as the Chinese now call the sna-compas by: this has given occasion to think that Tchiou Kung was the inventor of the compass." This happened in the 22d cycle, above 1040 before Christ. Renautod adds strong reasons against the knowledge of the mariner's compass amongst the ancient people of China, and of Arabia. See Kircher, De Magnetis, lib. i. cap. v.

In the works of Claude Fauchet, entitled, Renseil de l'origine de la Langue et Pays Francs, fol. 555, there is a quotation from an old French poem, called le Biblie Guiet, in which the mariner's compass is evidently mentioned. This same passage is likewise quoted by Muichenbrock, in his Differtatio de Magnete. The passage in which the compass is mentioned forms part of the abovementioned poem, contained in a curious quarto manuscript of the 13th century, on vellum, belonging to the royal library at Paris, which was never published. The poem entitled la Biblie Guiet,
Cuius, forms the first article of the volume; the author of
which, viz. Cuius de Provincis, as mentioned in the poem it-
self, was at the court of the emperor Frederic Barbarossa,
held at Mentz in the year 1281, when the emperor’s two
sons were knighted. See Chron. Abbot. Ufperg. p. 311.
Here follows this remarkable passage in its antiquated
language, to which is subjoined a literal translation made by
a native of Provence.

Extrae from la Bibil Cuius.
Iecile efoie ne fe muet,
Une arts font qui mentir ne puet,
Par la virtu de la manete
Une piee laide et brune,
On il fers volantz fe joint.
Ont regardent lor droit point.
Puez eune agileu dont touchye,
Et en un felto dont fillie,
En longue la mette tens plus,
Et il faitu la tient desus;
Puis fe torne la pointe toute
Contre leoftoie faire douce;
Quunt il nus ent tenche et brune
Con ne soit efoie ne lune,
Lor font a laguille alunier
Puiz ne puent ils asserer,
Contre leoftoie vers le pointe;
Par ce font il mariner conto,
De la droite voie tenir;
C’est uns ars qui ne puett mentir.

Literal Translation of the preceding.

This same (the pole) star does not move, (and)
They (the mariners) have an art which cannot deceive,
By the virtue of the magnet
An ugly brownish star
To which iron adheres of its own accord.
Then they look for the right point,
And when they have touched a needle (on it)
And fixed it on a bit of straw
Lengthwise in the middle, without more,
And the straw keeps it above;
Then the point turns just
Against the star undoubtedly,
When the night is dark and gloomy,
That you can see neither star nor moon,
Then they bring a light to the needle;
Can they not then allure themselves
Of the station of the star towards the point (of the
needle?)
By this the mariner is enabled
To keep the proper course;
This an art which cannot deceive.

Francis Cabeus, a Jesuit of Ferrara, says, that the first
thing he knew professedly written respecting the directive
property of the magnet, was an epistle of Petrur Peregrinus
Gallus, about the latter end of the 13th century. A few
years after, this epistle was digested by one John Tainier,
who published it in his own name, under the title of Opus-
culum perpetua memoria dignifimum de natura et effectibus
magnetis. Some years ago, Mr. Senebeer of Geneva sent
the following memorandum concerning this letter to Dr.
Lorimer in London.

"Epifola Petri Peregrini de Marcour,
Ad Sigierum de Fomancourt, Militem.
de Magnete."

"The work contains a description of that star, the
means of finding the poles, its property of attracting iron,
and proves that the part of the magnet which is turned
towards the north, attracts that which is turned to the south.
It then teaches the manner of employing the magnet in
navigation, and of playing tricks thole of Compas. It des
erves to be remarked, that the author knew not that
the magnet could be employed in navigation; for though he
frequently speaks de fella nautica, he never speaks of the
star, which might be made of the magnetic needle in sea
Catalogue of the manuscripts in the library of Geneva, by Se-
nebeer. p. 272."

Among the manuscripts of the university of Leyden,
there is a volume containing several scientific tracts, one
of which is a Latin letter of Peter Adiger, on the properties
of the magnet. It is, in fact, a little methodical tracts,
divided into two parts, the first of which is subdivided into
ten, and the second into three chapters. This letter, which
seems intended for the instruction of some particular friend,
is dated in the year 1260. A few years ago, Mr. Cavallo
obtained an exact copy of this curious letter, of which he
inferred very ample extracts, both in the original Latin
and in English, in the supplement to the second and third
editions of his treatise on magnetism, from which it appears
that the writer, at that early time, was acquainted with all
the principal properties of the magnet. The following is
the translation of the most remarkable part of the above-
mentioned letter, which describes the compass, and men-
tions the declination of the magnetic needle.

"Part II. Chap. 2. On the construction of a better in-
strument to answer the same purpose, viz. to find out the Az-
imuth of the Sun, the Moon, or any Star upon the Horizon.

"In the present chapter, you will be informed of the
construction of another instrument of more certain effect.
A vessel must be made of wood, copper, or any other ma-
terial, and let it be turned like a box of small depth, and
competently wide. Let a cover of some transparent sub-
te, as glass or crystal, be adapted to it; and if the whole
be made of some transparent matter, it would be still better.
A slender axis of copper or silver must be adapted to the middle of this vessel, applying its extremities
to the upper and lower parts of the box, viz. to the cover
and to the box; the axis, however, must not be so firmly
fastened, as not to be capable of moving very freely.
Two holes must be perforated in the middle of the axis, at right
angles to each other, and an iron style, like a needle, must
pass through one of these holes, while another style of sil-
ver or copper passes through the other hole in a direction
crossing the iron one. The cover must first be divided into
dark four parts, and each of these into ninety parts, agreeably
to the instructions given concerning the other instrument
in the preceding chapter, and upon it mark the north and the
south, the east and the west, points; and let a ruler of some
transparent substance, with lights on its extremities, be
adapted to it. Then place whichever part of the magnet
you please, viz. the north or the south, near the glass, un-
til the needle be moved towards the Said magnet, and ac-
quires the virtue from it; after which, the magnet being
removed, the extremity of the needle will turn itself towards
the pole. This being done, turn the box until one extre-
mity of the needle remains directed towards the north part
of the instrument, or the north part of the heaven; then
turn the ruler towards the sun in the day time, and towards
the stars in the night time, after the manner mentioned in
the preceding chapter. By means of this instrument, you
may direct your course towards cities, and islands, and all
other
Compass.

Other parts of the world, either on land or at sea, provided you are acquainted with the longitudes and latitudes of those places; for, if the town or island to which I intend to go is in a lower latitude than the place in which I am, I shall go straight before me, towards that end of the ruler which is directed to the sun or star; but if the latitude of the place be greater, I shall proceed in the opposite way, viz. in the direction of the other extremity of the ruler. Observe, that the south part of the needle, which is to be used as a guide, must be made to decline towards the west by one point; and this must be done by the declination of the north part towards the call, because the south part of the instrument is definite of divisions.

"Take notice that the magnet, as well as the needle that has been touched by it, does not point exactly to the poles, but that part of it which is reckoned to point to the south, declines a little to the west; and that part which looks towards the north, inclines as much to the east. The exact quantity of this declination I have found, after numerous experiments, to be five degrees. However, this declination is no obstacle to our guidance, because: we make the needle itself decline from the true south by nearly one point and a half towards the west."

To this letter, Mr. Cavallo, in his treatise, subjoins the following observation. "It appears that the suspension of the needle in the above description, is a very clumsy one; and that the beautiful suspension by a cap upon a pin, which is now universally used, was unknown to the author. It is likely, therefore, that for want of this suspension, the needles at that time not moving sufficiently, were not actually used in navigation, at least in Europe, though the suspension by means of a cap upon a pin, seems not to have remained long unknown after the date of this letter."

Sir G. Wheeler says, that he had seen a book of astronomy older than the year 1522, which mentions the use of the needle in astronomy, but not in navigation.

Caffè d'Ascase, as an argument of the French having been the inventors of the mariner's compass, that the north point of it is always marked with a flower-de-luce. Lib. x. Diag. Lat. t. 1. p. 139. As for Gorgopius's pretence, that the compas must have been invented by the Danes, Dutch, or Germans, because the 32 points on it are written and pronounced in the Dutch, or Teutonic language, it is hardly deserving of a reply. Dr. Wallis attributes it to the English, for no other reason, but for its being called compass. Vincentius Belloncinius, and Albertus Magnus, who lived about the year 1245, allo Lavinius Lemnianus, make mention of the direction of the poles of the magnet, as from a tract de Lapidibus, which had been attributed to Aristotle; but is, with more probability, supposed to have been written by some Arabic author, not long before their own time. This tract has been since lost.

Notwithstanding the foregoing remarks, it is still very doubtful whether the use of the compass in navigation, or even the directive property of the magnet, was known by any people before the Europeans, or about the 15th century; and it appears, that in the same century, or soon after, the above-mentioned Neapolitan, Flavio, or John de Giaja, if not the original discoverer, was at least the first who used the mariner's compass, or constructed it for the use of vessels in the Mediterranean.

The principle of the construction of the compass is extremely simple. A magnet, or a piece of steel that has been rendered magnetic by means of natural or artificial magnets, must be freely suspended, so as to be able to move without obstruction; for such magnet or piece of steel will, in that case, direct itself to certain parts of the world, which will of course indicate to the observer the direction of any other place, provided its situation on the surface of the earth be known. Suppose, for instance, that you are at sea near Portsmouth, and wish to go towards Newfoundland, which lies to the west. By looking at the magnetic piece of steel or magnet, one extremity of which looks nearly towards the north, and turning your face to that part of the world, you proceed towards your left hand, at right angles to the direction of the needle; for in that direction Newfoundland is to be found. And after the same manner, you may proceed in any other direction. Such is the simplicity of the principle; but the practical application of it, especially in the present accurate mode of constructing instruments, and of making observations, requires a great degree of mechanical nicety, and a considerable degree of attention to a variety of circumstances, upon which the accuracy of the instrument, and its various applications, absolutely depend.

On account of those particulars, and in consequence of various contrivances made at different times, the compass or magnetic needle has undergone innumerable alterations, both in shape and size; and every kind of construction is attended with peculiar advantages, as well as defects; the most essential of which we shall endeavour to point out in the following species. See 1. The land compass, which is used either for the pocket, or is adapted to the odolites, to celestial and terrestrial globes, &c.; 2. The steering compass for the use of vessels at sea. 3. The animal compass, which serves to find the sun's or star's azimuth, whence the actual or true direction of the magnetic needle may be ascertained (this seldom being due north and south); and 4. The variation compass, which, being situated in a proper place on land, shows the daily variation of the magnetic needle from its ordinary direction. See Magnetic Declination, and Magnetic Variation.

A common seaviging needle rendered magnetic, and simply laid upon water, or fastened to a cork, or draw, &c., and so laid upon water, in a glass, or earthen or wooden cup; or else suspended by a very flexible thread, which must be fastened to its middle, forms a simple but imperfect compass; and such, in a 1 probability, was one of the first modes of constructing the compass, whence the magnetized steel, wire, or bar, has, ever since, been called the magnetic needle. The defects of the last-mentioned construction are too evident to need any particular remarks. The needle laid upon water is continually running to the side of the cup, the water is liable to be split, or if a thread be used, the likeness of it will always influence the action of the needle. To avoid these inconveniences, an excellent contrivance was substituted. It is a conical cavity made in the middle of the iron or steel bar, as shown in Plate, Magnetical, fig. 1. the open of which rests upon a pointed wire a, which enables the needle to move with the greatest freedom imaginable. The open of this cavity should come as near as possible to the upper surface of the needle, or rather a little above it, as in fig. 2. in which case the upper surface of the middle part of the needle is left a little more elevated than the rest. But in order to avoid any irregularity in the shape of the needle, as well as any difficulty in the mechanical formation, the needles are mostly pierced quite through, with a pretty large hole; a piece of hammerd brass is riveted into this hole, so that the open of it may stand even with, or very little above, the upper surface of the needle. The upper part of the wire upon which the needle rests, is generally made of hard steel, whilst
whilst the lower part is made of brass. This construction answers very well for a considerable length of time; yet, by continual rubbing, a small proliferation or irregularity of the cavity, is at length produced, which will in some degree obstruct the free motion of the needle; hence, in the bevel needles, the upper part of the above-mentioned cavity is formed in a piece of agate, which is not in the brass piece, as shown in fig. 3., where AB is the needle, d, of the brass piece riveted in a hole in the middle of it, and B is the piece of agate. These needles that constructed are said to have an agate cap. The defect to which those agate caps are subject, is, that on account of the hardness of the stone, the cavity in it seldom runs to a point; the consequence of which is, that the pin which supports the needle is apt to shift from one part of the agate cap to another, and of course the centre of the needle cannot always coincide with the point of suspension.

The forms of the needles have likewise been very numerous. Some are flatter and longer, others broad and short; several needles of the common fort are made broad towards the end, but tapering towards the middle, or they terminate in two very sharp points. Sometimes that extremity of the needle, which points towards the north, is formed like a crescent; but the most objectionable of all, are those which consist of two wires, and may be frequently met with on board merchant ships. Two pieces of steel wire, each bent in the middle so as to form an obtuse angle, and when fixed under the cards in the centre of which the brass cap is fastened, form a longitude. All those shapes may, in great measure, answer for common purposes; but they differ from being accurate or regular in their performance, the reason of which is, that a piece of steel of irregular form generally has more than two magnetic poles; almost every corner or protuberance being a south or north magnetic pole; in consequence of which the axis of the needle never coincides with its magnetic axis, the latter of which changes its situation in proportion as some of the above-mentioned poles become stronger or weaker than the rest; and this is continually the case.

In order to avoid every irregularity of shape, and even the perforation, needles, for certain purposes, have been suspended in the following manner: AB (fig. 4.) is the magnetic needle of a parallelopipedical form, which is fastened to a piece of brass C D. In the middle of this piece of brass at g, there is a small conical cavity, wherein an agate cap is set. In order to suspend this needle, a bar FH (fig. 5.) of brass, or copper, or wood, is made fast to a box KL; in the middle of this is a short point wire is fixed, which, when the bar is made to pass through the brass piece C D of fig. 4. viz. through g, cuts the agate cap, and supports the needle. Fig. 5. represents the whole together, where F H is the bar fastened to the box, A B is the brass piece, seen lengthways, or in the direction of the needle, which passes through the hole A B, and moves below the bar F H. It is evident that in this construction the needle cannot turn quite round, consequently this form of suspension is not useful for navigation.

The Chinese method of suspending the magnetic needle is exceedingly ingenious (see fig. 6 and 7.), the first of which represents a section of this suspension as viewed in the direction of the needle, and the second exhibits a lateral view of the same. The letters refer to the same parts in both figures. I is a brass cap very thin and light, and towards the edge of it there are two holes, opposite to each other. B D is a very slender blade of brass, the upper part of which A, is shaped like a ring, through which the needle C D passes. The extremities of this blade of brass go through the holes in the lower part of the cap, and are fastened to it by being turned over its edge. The magnetic needle C D consists of a cylindrical steel wire about an inch long, and not above a fortieth part of an inch in diameter; having its northern extremity only painted red by way of distinct. All this is supported by the pin E, which is fastened to the bottom of the box, and upon which it moves very freely. In this construction the needle is above the point of suspension, yet the centre of gravity of all the three pieces (viz. cap, needle, and of brass) taken together, is below the point of suspension, which prevents the cap, &c. falling off from the pin when the compass is fixed in an horizontal position; but to prevent the cap with the needle being shook off by any sudden jar, or by inverting the instrument, there is a very thin brass plate fixed to the box, a fiction of which is indicated by FG. It has a hole through the middle, which, being smaller than the diameter of the aperture of the brass cap, prevents its falling off. It appears, from a variety of experiments, that the perforation through the magnetic needle is not attended with any bad consequences. The external shape of the needle requires to be formed with greater attention, this being more apt to produce a multiplicity of poles. A very broad needle seldom has its magnetic axis coinciding with the axis of its figure. A very flatter and long needle almost always has more than two magnetic poles. There is a certain breadth, proportionate to the length of a needle, which is left sufficient to an irregular dispersion of the magnetic virtue; this proportion, however, cannot be accurately determined. The little swelling generally left about the middle of the magnetic needle in order to give them strength, where the perforation for the cap would otherwise weaken them, has not been found to produce multiplicity of poles, provided it be made smooth and free from corners. The lengths of the needles commonly used at sea are from three to six inches, but those that are ned or variation needles are generally made longer, though they need not, however, exceed eight or at most nine inches. With respect to the fulness of the needle, it must be observed that certain kinds of steel are more apt to acquire the magnetic virtue than others; but this must be determined by actual trial. The common forts of magnetic needles are brought down to what is called by the workmen a blue temper, because in that state they are easily magnetized; but it must be observed that if in that state they are easily magnetized, they are at the same time liable to lose that power very easily; therefore the magnetic needles, if they are made too hard for that cause, when once rendered magnetic, which is easily done, they will retain that power almost for ever after. The magnetic needles, though perfectly balanced before they are magnetized, will, after that operation, incline one of their extremities towards the horizon, which is in consequence of the dipping property of the magnet. See MAGNETISM, and DIPPING NEEDLE. Therefore after the communication of the magnetism, it becomes necessary to balance the needle again; but this must not be done either by grinding off part of that extremity of the needle, or by adding a fixed weight to the opposite extremity of it, because the quantity of that dipping varies according to the change of situation on the surface of the earth. The best way of adding this weight is by placing a small piece of brass on one arm of the needle, capable of being slid nearer to, or farther from, the centre of the needle, by which means the balance of the needle when left may be easily restored. Upon all these considerations, a needle of the best form and size is exhibited at fig. 8. and 9., the former of which represents a vertical, and the latter a lateral, view of it. A D
The needle of hard steel, $C$ is the agate cap let in a piece of bone, $D$ a mark made on that extremity which points towards the north, in order to distinguish it from the other, and $E$ is the piece of bone which may be fixed upon the arm $C D$, for the purpose of balancing the needle.

The frames and sizes of the compasses used upon land are very numerous: some being of the usual size of a watch-ceil, and they are actually fixed in such cases; others are of the size, and externally in the form of a pocket watch; others again are made in a wooden box, square on the outside, but circular within; some are of a larger size, in a brass box. Sometimes a little funnel is affixed to some compass boxes, and so forth. But though the shape be different, the principle of the construction is the same in them all. The box, whether of wood, or brass, or silver, or other substance, must have no particle of iron or steel in its construction; and even the brass, when that metallic substance is used, must be tried by pressing the extremity of a very delicate magnetic needle to every part of it; for if any attraction be observed, that brass must be rejected, otherwise the needle would not move with sufficient freedom. Brass is frequently magnetic, especially after being hammered, which is generally done by the workmen, for the purpose of rendering it hard. A pin of hard steel is fixed in the centre of the box, upon the point of which the needle rests; and a glass plate covers the cavity. This glass plate rests upon a shoulder, and there is very little above the piece $C$ (fig. 9), so as not to touch that piece, whilst at the same time it prevents the needle's falling from over the pin. In several of the compasses a little piece of wire with a button is affixed to the box, which is formed so as to stop the motion of the needle when the compass is not intended to be in action, as when it is carried in the pocket, &c.

The friction which must naturally take place in cleaning the glass cover of a compass, frequently excites its electricity, in which case the needle is attracted more or less by the glass, and its free motion is thereby partly or entirely obstructed, Phil. Trans. N.S., 480, p. 243. This inconvenience may be removed by pulling a wet finger in various directions over the surface of the glass. Few needles of land compasses are furnished with cards like those which are used at sea. In general the principal points of the horizon are marked in the bottom of the box, and a divided circle is added to the box, so that the edge of it may be even with, and so near as almost to touch, the extremities of the needle.

The compasses used at sea for ascertaining and directing the course of vessels, differ from the former principally by their having a circular card, whose diameter is equal to the length of the needle, fixed upon the needle, so as to turn with it, and by the box being let in a mechanism on four cross centres, called gimbalts, the office of which is to keep the compass box always in a horizontal position, whilst the external box moves with the ship, as the latter rolls and pitches. This construction will be easily understood, by observing fig. 10, which exhibits a feeing compass as viewed by an eye placed perpendicularly over it. A B C D is the external wooden box, which is fastened to and moves with the ship. E F is a brass circle having two pivots or axes, G H, which turn in two holes in the opposite sides of the wooden box; i.e., in the compass box, which is likewise furnished with two pivots or axes. $r, u$, and these turn in two holes made in the brass ring $E F$. Now as the direction of these last pivots, $r, u$, is at right angles to the direction of the pivots, G H, it will be easily understood, that in whatever direction the vessel, and the box $A B C D$, which is fixed to it, may incline, the compass box, i.e., represents always in an horizontal position, for it will turn either upon the pivots, $r, u$, or upon the pivots, G H. K is the card which is fixed to the magnetic needle and moves with it, under the glass cover, through which it may be distinctly seen. The outer edge of this card is divided into 360 degrees, and within the circle of those divisions it is again divided into 32 equal parts or arches, called the points of the compasses, or rhumbs. These rhumbs are usually divided into quarters. Their names, beginning from the north point, and going all round, are as follows: the letters standing $N$, for north; $E$, for east; $S$, for south; and $W$, for well.

The construction which has been more generally used in the royal navy, is an improvement of the above. Dr. Knight, a gentleman of very extensive knowledge in magnetism, in this construction the weight of needle, card, &c. is removed considerably below the point of suspension or centre of motion, by the addition of a brass circle, whose diameter is equal to that of the card, which is made very thin. This ring being fixed below the card, and the needle above it, the centre of gravity of the whole comes low enough to admit of the cap being situated below the needle; hence the needle needs not be perforated. This needle is a perfect parallelepiped. The figs. 11 and 12 represent the lower and upper parts of this (Dr. Knight's) card, needle, &c. about one half of the real size. A B is the needle, and $C$ represents the outer part of its cap, situated below it. The under part of the cap is seen at $G$; $A D B$ is the card. The brass edge, or circle, is represented by $F E O$, and is fastened to the extremities of the needle, (the card being interposed) by means of two screws. $H, I$, are two sliding weights to balance the card.

A few years ago another sort of construction was contrived by Mr. K. McCulloch, for which he obtained a patent. The figs. 13 and 14 represent this compass, the former being a fection, and the latter a perspective view of it. In this compass, both the compass-box and the needle, with the card, are suspended upon points, the extremities of which come very near to each other; which construction keeps them horizontal without any gimbals, as will be easily manifest by the following description. Fig. 13, $A a a a$, is the common wooden box, with its lid; $b b$ the brass compass box; $c c$ the glass cover to it; $d d$ the hollow conical bottom; $e e$ the prop, upon which the compass is supported instead of gimbals; the spherical top of which is finely polished, and the apex of the hollow cone is fitted to receive it; $f f$ is a quantity of lead run round the bottom and cone of the compass box, to balance and to keep it steadily horizontal; $g g$ is the card, and the magnetic needle, bent in such a manner as to bring the point of the conical pivot, on which it moves and is supported, very near to the centre of gravity, as well as to the centre of motion; $h h$ are two guards, which, by means of the two pins $i i$, affixed to the compass-box, prevent its turning round, and deceiving the freightman. In fig. 14, both the lid and $E e$ the
the front of the box are removed; \( b \), \( b \) are the guards; \( b \) the compass-box, and \( e \) is the prop which supports the box.

The greatest inconvenience that attends the use of the compass at sea is the irregularity of motion induced by shocks of sudden impulsion. In those cases the needle is suddenly moved out of its direction, and the card of the compass takes a vibrating for a considerable time, during which the observations are not correct. Methods have been tried for the purpose of removing this inconvenience, and the above-described compacts of Mr. M'Culloch's convenience was supposed to accomplish this end in a considerable degree; but the experience of some years shows that this is not the case. The least suffered by them suffer too powerfully magnetized, because, they say, then the needles are not steady. The fact is, that when the needle is not strongly magnetic, it follows the irregularities of the ship's motion in a great degree; which renders it apparently more steady; but the very same cause which enables it to follow the irregular motion of the ship, prevents at the same time its placing itself in the magnetic meridian. With the same degree of inappropriateness, some persons have endeavored to prevent the irregular shocks or vibrations of the magnetic needle by increasing the friction between the cap of the needle and the painted wire which supports it. Sometimes pieces of paper, like wings, have been stuck to the lower surface of the card which, by offering a resistance against the air in the box, check in some measure the irregular movements of the card.

In the year 1779, Dr. Ingenhousz presented a paper to the Royal Society, which is published in the 46th vol. of the Philosophical Transactions, and in which he describes some experiments, made by magnetic needles in water, where he found that a strong magnetic needle placed itself in the magnetic meridian, nearly as well under water as in the open air, and that by the resistance of the medium, much of its too great veratibility was taken away. In consequence of these experiments the Dr. proposed to enclose the magnetic needle in some fluid for the use of vessels. "Common water," he says, "would be, perhaps, the best medium for these different contrivances, if kept not so easily touched by it, and if in cold weather water was not so apt to freeze; therefore, I think, that some of the thinnest expressed oils would answer the purpose better. The glass season containing such a compass should be full of the liquid to the cover, to obstruct undulating motion." But though this proposal appeared at first very promising, and some eminent philosophical instrument-makers were much struck with it; yet it does not appear that it was ever adopted.

The use of the compacts in general is to direct a person along any required track, which makes a known angle with the direction of the magnetic needle; and this renders the compacts applicable to a variety of purposes; thus it guides travellers in defects, as in Arabia, in the woods of America, &c.; it enables the navigator to proceed in any required track; it is highly useful to the miner, by showing the direction of subterranean places; it serves for measuring horizontal angles; hence it is useful in land surveying, taking plots, finding bearings in dialling, &c. And briefly it serves to set fun-dials, and other astronomical instruments when no great accuracy is required. The application of the compacts to these purposes is too obvious, as not to require any further illustration. But for some of these purposes, sights must be applied to it, in the azimuth compacts.

The azimuth compacts is a fleeting compacts of any of the above-mentioned contractions, to which two sights are adapted, through which the sun is to be seen, in order to find its amplitude or its azimuth, whence the declination of the magnetic meridian from the true or astronomical meridian may be determined; those two meridians follow coinciding. At present (1807) in London, the declination of the magnetic needle is about 24° west; that is, the northern extremity of the magnetic needle, points to a part of the heavens, which makes an angle of about 24° with the true North, but the declination is different at different times in the same place; as well as at different places at the same time.

The more usual fort of azimuth compacts is represented in fig. 15, where \( F, \ G \), are the sights, or sight-vcnes, in one of which, \( G \), there is an oblong aperture, with a perpendicular thread or wire through its middle; and underneath it, \( F \), there is a narrow perpendicular slit. A thread or wire, \( H, I \), is stretched from one side of the edge of the box to the other. The ring \( A \) of the gimbals rests with its pivots on the semicircle \( CD \), the foot, \( E \), of which turns in a socket, \( D \), that whilst the box, \( KLM \), remains steady, the compacts may be turned round, in order to place the sights, \( F \), \( G \), in the direction of the sun, or other celestial object. The pivots of the gimbals of this, as well as of the fleeting compacts in general, should lie in the same plane with the point of suspension of the needle or card, for the purpose of avoiding the irregularity of its vibrations as much as possible. In the inside of the box there are two lines drawn on its sides perpendicularly down, from the points where the thread, \( H, I \), touches the edge of the box. These lines serve to show many degrees the north or south pole of the needle is distant from the azimuth of the sun; on which account the middle of the apertures in the sight-vcnes, \( F \) and \( G \), the thread \( H, I \), and the above-mentioned two lines must stand exactly in the same vertical plane. The use of the thread \( H, I \), which is sometimes omitted in compacts of this sort, is to show the degrees between the magnetic meridian and the azimuth, &c., when the eye of the observer stands perpendicularly over it. On one side of the box of the azimuth compacts, there generally is a nut or stop, which, when pulled in, bears against the card and stops it; and this is done for the purpose of reading that degree, half degree, &c., of the card, which coincides with one of the perpendicular lines in the inide of the box.

Mr. M'Culloch's azimuth compacts is represented in fig. 16, where \( b \) is the compacts-box, \( b \) one of the guards, \( e \) the prop, which stands in a brafs socket, and may be turned round at pleasure, \( r \) is a brafs bar upon which the sight-vcnes are fixed; 2, a dark glass, which moves up or down on the sight-vcne \( 3 \); 4 is a magnifying-glass, which is also moveable on the other sight-vcne; 5 is the nunus or vernier; 6 is a file for moving the vernier so as to flop the card in taking the azimuth; and 7 a double convex glass, through which the divisions on the vernier may be read with accuracy.

In order to observe at sea the magnetic amplitude of a celestial object (via its bearing by the compacts when in the horizon) with the azimuth compacts, place the instrument on a steady place, whence the horizon may be clearly seen; and looking through the sight-vcnes of the compacts, turn the instrument round, until the centre of the sun's disk, or other celestial object, may be seen through the narrow slit in one of the sight-vcnes exactly on the thread which bisects the other sight-vcne; and at the instant that the centre of the celestial object, whether rising or setting, is in the horizon, push the flop in the side of the box, so as to flop the card, then read the degree, half degree, &c. of the card, which stands against one of the perpendicular lines in the inside of the box, and this is the magnetic amplitude sought. — In this observation, some allowance must be made for the height of the observer's eye, above the level of the sea.
then

The true amplitude of the celestial object is an arch of the horizon contained between the east or west points of the horizon, and that point of the horizon which the centre of that celestial object cuts in its rising or setting. In order to find the true amplitude of the celestial object, the latitude of the place of observation, and the actual declination of that object, must be known; then lay, as the cosine of the latitude is to radius, so is the sine of the declination to the cosine of the amplitude sought.

To observe at first the magnetic azimuth of a celestial object, (viz. its bearing by the compass when above the horizon,) situate the instrument in a steady place, and looking through the narrow slit in one of the right vanes, turn the box r. and until the centre of that object appears to coincide with the thread in the slit of the other right vane, or till the shadow of that thread, when the sun is observed, falls exactly along the line on the surface of the compass-box, and at that instant drop the card; then read the degree, &c. as above directed with respect to the amplitude, and thus you have the magnetic azimuth of that object. The true azimuth of that object is an arch of the horizon intercepted between the north or south point, and that point in which a plane passing through the zenith and the celestial object, cuts the horizon. In order to find this azimuth, the latitude of the place of observation, the declination of the celestial object and its altitude must be known; and hence to determine the declination of the magnetic needle, this true azimuth of a celestial object must be taken at the same time that its magnetic azimuth is taken; therefore the altitude of that object must be taken with a sextant, at the very instant that its magnetic azimuth is taken, and at the time the card is dropped; then proceed in the following manner: If the declination and latitude be both north or both south, call the declination $A$; but if they be one north and the other south, add $90^\circ$ to the declination, and call the sum $A$. Call the difference between the co-latitude and co-altitude $B$. Let the half of the sum of $A$ and $B$ be called $D$; and the half of their difference be called $C$; then add together the four following logarithms, viz. the arithmetical complement of the logarithmic sine of the co-latitude, the arithmetical complement of the logarithmic sine of the co-altitude, the logarithmic sine of $D$, and the logarithmic sine of $C$. Half the sum of these four logarithms is the logarithmic sine of half the azimuth sought.

Now, having shown how to find the true and the magnetic amplitudes as well as azimuths, we shall briefly add the method of determining from them, the declination of the magnetic needle for the time and place when and where the observations are made. Let the amplitudes, as well as the azimuths, be all reckoned from the north point, which is affected by intracting the amplitude from $90^\circ$ when it is on the northward of the east or west points; or by adding it to $90^\circ$ when it is southward of the east points. Then the magnetic amplitude is either smaller or greater than the true amplitude. When the magnetic amplitude is less than the true, and they are both on the same side of the north point, their difference is the declination of the magnetic needle towards the contrary side of the north point. But if they be on different sides of the north point, then their sum is the declination towards the same side with the true amplitude. When the magnetic amplitude is greater than the true, and they are on the same side of the north point, their difference is the declination towards the same side with the true amplitude. But if they be on different sides, then their sum is the declination towards the same side with the true amplitude. Thus, for example, if the magnetic amplitude is $80^\circ$ eastward of the north point, and the true amplitude is $82^\circ$ towards the same side; then the declination is $2^\circ$ east. And if the magnetic amplitude be $50^\circ$ eastward of north, whilst the true amplitude is $50^\circ$ westward of north, then the declination is $80^\circ$ west. The same directions, mutatis mutandis, are to be followed for finding the declination from the magnetic and true azimuths.

Ever since the discovery of the declination of the magnetic needle from the true meridian, which appears to have been first observed by Columbus in his first voyage towards the continent of America, in the year 1492, the cause of that phenomenon has been earnestly sought after by inquisitive persons in the scientific world; and especially when it was found that this declination varies continually, in a manner, which has not, as yet, been reconciled to any theory. The most promising method of investigating the subject appeared to be that of observing attentively the daily, and even the hourly, variation of the declination, in order to discover, if possible, any period in it, or any dependence of it upon other natural phenomena. And in fact, the late ingenious Mr. Canton, who made numerous observations relative to the subject, found a periodical increase and decrease of the magnetic variation, in great measure corresponding with the temperature of the different parts of a natural day. For this purpose accurate compasses were fixed in various observatories, and the variation of the magnetic needle has been observed, at least once every day, for a great many years; such observations having frequently been inserted in meteorological journals, and elsewhere.

The variation of the needle being intended to show the daily variation of the magnetic needle upon land, is generally made longer than those that are used at sea; and, as it is not necessary to turn it round, the box generally is of an oblong form, so that the angular motion of the needle on it may amount to about $40^\circ$ or $50^\circ$. The divided arches are either within the box, concentric with the point of suspension of the needle; or out of it, on a frame, the particular construction of which will appear from the description of the variation compass of the Royal Society of London, which will be given presently. When the divided arches are within the box, in which case a nonius is often placed on one extremity of the needle, the variation is known by observing the division which coincides with the axis of the needle. In either construction, it is evident that the beginning of the divisions of the arch or arches must be placed exactly in the meridian of the place; or else its deviation from the meridian must be accurately known and allowed for in reading the degrees of magnetic variation. And it is almost superfluous to add that such compasses must be situated in very steady places, out of the influence of iron; so much so that it will be proper for the observer, when he examines the compass, &c. to take out of his pocket, keys, knives, or any other article of iron and iron; for otherwise the needle will feebly alter the direction of the needle. We shall now finish the particular descriptions of two variation compasses of the best construction, viz. of that which is used at the Royal Society, and is described by the honourable Henry Cavendish, in the 66th vol. of the Philosophical Transactions; and of that which was contrived by Mr. Cavollo, and is described in his "Treatise on Magnetism," the former of which, being much larger, is well calculated for a fixed observatory, whilst the latter is smaller, more compact, and may be fixed in any place.

Fig. 17, is a plan of the Royal Society's variation compass. "In this instrument, the box which holds the needle is not fixed, but turns horizontally on a centre, and has an index attached to it, pointing to a divided arch on the brass frame on which it turns; and the method of observing is to move
move the box, till a line drawn on it points exactly to the end of the needle; which being done, the angle that the needle makes with the side of the frame is shown by the index. \(A Bb a\) is the frame, the sides \(A B\) and \(ab\) being parallel: \(E E\) is a circular plate fastened thereto, on which \(CD/e\), the box which holds the needle, turns as on a centre; \(N n\) is the needle, the pin on which it vibrates being fixed in the centre of the plate \(E E\); \(B b\) is the division on the frame; and \(G G\) the index fastened to the box, \(CD/e\), furnished with a vernier division; the division and vernier being connected so as to show the angle which the line, \(F G\), makes with \(A B\), or \(a b\). The instrument is placed in the meridian by the telescope, \(M M\), the line of collimation of which is parallel to \(A B\), and is pointed to a mark fixed due north of it. \(F g. 18\), is a vertical section of the instrument passing along the line \(F G\); \(A B\) is the frame; \(C D/e\) is the box which holds the needle; \(E E\) is the circular plate on which it turns; \(N n\) is the needle; \(P\) and \(p\) are small plates of brass fixed to the ends of it, on each of which is drawn a line serving as way of index. These pieces of brass are raised to such a height that their tops are on a level with the point of the pin on which the needle turns. The use of them is, that it is much easier observing this way, than when the lines, serving as way of index, are drawn on the needle itself, as this means the inconvenience proceeding from one kind of vibration in the needle is avoided. \(S\) and \(s\) are two brass plates, on each side of which is drawn a line, to which the index at the end of the needle is to point; there is also a line parallel to these, drawn on the bottom of the box; these three lines form the line, \(F G\), in \(f g. 17\). \(R\) is a double microscope intended to aid us in judging when the index, \(P\), points exactly to the line, \(F\), that is, to the line drawn on the plate \(S\). It is placed so that a wire, \(W w\), in its focus, appears to coincide with this line; and in observing, the box is moved till the wire appears also to coincide with the index \(P\). The cap in the centre of the needle is made to take on and off readily, and to fit on upon either face; so that we may on occasion observe with the under face of the needle uppermost. The intention of inverting the needle is to show whether the axis of the figure of the needle coincides with its magnetic axis.

The figures 19 and 26, exhibit a vertical view, and a section of Mr. Cavallo's variation-compass, and those representations are two thirds of the real size of the instrument. The letters of reference indicate the same parts in both figures. \(A B D\) is a brass frame with a circular brass piece, \(cei\), screwed fast upon it. \(F G H K\) is a rim likewise of brass, that slides on the outside of the circular piece \(cei\), and to which the flat glass, \(M\), is fastened; so that when the rim is removed, the glass comes off with it. The shape of the needle is clearly indicated by the figures. It has a hole in the middle to receive the agate cap, which is burnished into a brass socket, and is so situated into the needle, that the upper surface of the eye lens does not rise higher than the surface of the needle; hence the point of tinfoil upon the pin, \(B\), is even with the upper surface of the needle. By this means the pendulum-like oscillations cannot disturb the direction of the line of the fine lines marked on the extremities of this needle. The upper and lower surfaces of this needle are quite alike, and the brass socket, which contains the agate cap, is made so as to admit of the needle's being turned with either of the surfaces uppermost. The hole in the middle of the needle is one, cylindrical, and so is the outside of the brass socket, which fits the said hole exactly, but projecting a little way beyond the needle, has a few cut on that projection, upon which another circular piece of brass is screwed to fix it, as may be seen in fig. 20. It is evident, therefore, that when the last-mentioned piece of brass is unscrewed, the socket with the agate cap, may be put in on either side of the needle, and may be fastened on the opposite side of it. By this means a great source of error may be avoided, namely what arise from the magnetic axis of the needle being not in the axis of its figure, which is frequently the case; for, if the direction of this needle be observed with one side of it upwards and then (the needle being turned) be observed again with the other side upwards; either the second observation coincides with the first, and then we may conclude that the magnetic axis of the needle is truly in its middle; or the observations differ, and hence we shall know that the magnetic axis of the needle is not in the axis of its figure; but in this case we may have the real magnetic direction by taking a mean of the two observations; or we may thereby ascertain, once for all, how much the line of direction of the needle deviates from its magnetic axis, which, when once ascertained, becomes a fixed quantity to be either subtracted from, or added to any other observation."

"The upper side of the circular piece \(cei\) is silvered, and divided into degrees and half degrees; but those divisions, being too minute, are omitted in the figure. The bottom \(A D D\) has two projections, \(A\) and \(D\), opposite to each other, and on each of their chamfered edges a line is marked, which, being drawn at the same time that the circle, \(cei\), is divided by the circular dividing engine, coincide exactly with the commencement of the numerator of the degrees on the opposite sides of the circle, from which places the degrees run on both sides as far as 90°. The needle, therefore, which lies with its upper surface even with the divided circle, points to the same degree and part of a degree with both its extremities."

"We come now to describe the method of measuring the parts of a degree on the circle, which is only divided into half degrees. This is obtained by means of the microscope, \(f g. 21\), which is furnished with one of my mother-of-pearl micrometers. (Phil. Trans. vol. 71.) The external construction of the microscope, and likewise the manner of placing it perpendicularly upon the compass box, are indicated by \(f g. 21\), at \(N\) in \(f g. 19\); and by the dotted lines at \(K\) in \(f g. 20\). \(P\) is a short tube supported by the uprights \(P, R\), the lower parts of which project horizontally. These horizontal projections, \(O, O\), are notched at \(Y\), so as to fit the mouldings, \(H, K\), of the rim \(F G H K\), when the parts, \(O, O\), rest upon the glass. By this means the microscope may be moved all round the compass-box, whilst it keeps some of the divisions of the circle always in the field of view. The body of the microscope may be moved up and down in the tube \(P\), in order to adjust it for distinct vision. It consists of the tube \(S S\), into the upper part of which slides a short cylindrical tube \(T\), and at its lower extremity, \(H\), a lens is fastened. Two other lenses are fixed into the tube \(T\), which is about nine-tenths of an inch long, and within it; viz. exactly in the focus of the eye-lens, the mother-of-pearl micrometer is situated. Those three lenses are all of the plano-convex sort. The focus of the upper one is about four-tenths of an inch, and the focus of the second and third is about five-tenths of an inch. The divisions of the micrometer are about four-thousandths of an inch, and when viewed through the microscope, and the micrometer is placed upon the compass, all of them appear to be exactly equal to half a degree on the circle \(cei\). But there is no need for these divisions to be exactly
COMPASS.

Three of an inch. It is sufficient if they are nearly so, as, for instance, from about 280 to 320 in an inch; because by pulling the tube T more or less out of the tube S, and by moving the said mentioned tube up or down into P, the divisions of the circle may be magnified more or less, till 15 divisions of the micrometer appear to be exactly equal to the space between any two contiguous divisions on the circle; viz. to half a degree. When the micrometer has been once so adjusted, it requires no farther alteration, excepting to be moved round the box until it comes over the end of the needle, in which situation the field of view appears as shewn in fig. 22, where the middlemost part is occupied by the micrometers 1, 2, 3, 4; the other large divisions are the magnified divisions of the circle, and W is the extremity of the needle, with its directive line pointing to some division on the micrometer.

"Fifteen divisions of the micrometer being equal to half a degree, or to 30', it follows that each division is equal to two minutes, and as it may be easily discerned whether the line on the end of the needle is directed exactly to one of those divisions or midway between two of them, therefore the direction of the needle in this compass may be read off to a single minute. In order to observe the daily variation, when this compass is properly fixed, the micrometer need not be moved, because its field of view takes in about two degrees, which is a much greater space than the needle will go through in ten years time. In moving the micrometer round the box, care must be taken to place it so that the divisions of the circle may appear to coincide with some of the long divisions of the micrometer. — N. B. This micrometer inverts the objects; therefore what appears to be on the right hand must be understood to lie on the left, and vice versa."

"In order to observe the real direction of the magnetic needle, or the daily variation, the compass must be placed so as that the two lines marked on the projections A and D, fig. 19, may coincide with a meridian line drawn upon a board, a stone, a block, &c. and then the degrees and minutes, to which the extremity of the needle is directed, will shew the required variation."

Having, in the preceding paragraphs, mentioned all the important particulars relating to the discovery, the construction, and the use of one of the most remarkable, and the most useful, philosophical instruments, we shall conclude by mentioning a deception which has sometimes been offered to the credulous and unskilled part of mankind. It is a compass, or a magnetic needle which was pretended to point due north and south, without any variation at any time or place; and compasses apparently of this description have actually been offered for trial and have even been sent abroad. But upon examination it has been found either that the north and south points of the card were not placed over the north and south points of the needle; or that the needle, having been made purposely broad, had been magnetized so that the direction of its poles made an angle with the axis of its figure, just equal to the magnetic declination at that particular time and place. The consequence of this artifice is, that though the needle may appear to have no declination at that particular time and place; yet at any other time, or if moved to another place where the magnetic declination is different, its direction will deviate from the true meridian. The declination or variation, like the attraction and repulsion, belongs to every piece of magnet, be it natural or artificial, and the magnetic needle is of the latter sort; nor can, at the same time and in the same place, one needle point to one part of the heavens whilst others point to a different part; provided they be freely suspended, and be uninfluenced by iron or other magnets.

COMPASS of voices, in Music. In early times of counterpoint, human voices of different compass, occasioned by age, sex, and natural organ, were cliified and divided into four distinct kinds, at the distance only of a third above each other, which the base, or F clef, placed from one line to line, expressed. The lowest of these was called the tenor, the next contratenor, motetus the third, and tripulum the highest, or treble; of which term this was the origin.

After this, about the middle of the fifteenth century, as different parts began to be multiplied, the scale received fix divisions: base, baritone, tenor, contralto, mezzo soprano, and soprano. The natural pitch of these is about three or four notes above each other, as their several clefts, which originally served as barriers, will discover.

It seldom happens that a voice has more than ten real, steady, and full, natural notes, in its compass, without a mixture of falset, which, being of a different register, is easily discovered. The following are the names and usual extent of the several species of human voice.

But as there are sometimes base voices which go down to double F, and even lower; so there are in the treble, among modern vocal phenomena, fingers that go higher than E in altissimo; which make the whole diapason of voices exceed four octaves. And there is at present 1802 in England, a German buffo finger with a base voice that goes down to double gammut in real musical tones; and in falset, up to G on the second line in the treble. No public use was made of this extraordinary voice. He arrived in autumn, when no theatres were open, and remained but a short time.

But though parts in choral music were multiplied, not only to fix, but even thirty-six, before the clef of the fifteenth century; yet the general, and established number, in the pope's chapel, by which probably all other choral service was regulated, amounted to no more than four: cantus, altus, tenor, and base; which fee severally.

If it be asked why so many clefs are used? It may be answered, to keep the melody of these several voices within the compass of the five line staff; to prevent the perplexity of a great number of leger-lines, which in singling and playing at sight, frequently alarm and embarrass the performer.

Of all the expedients proposed by speculative and ingenious men, for the abolition of tenor clefs, the only one that seems practicable, and has the merit of great simplicity, was published in our own country in the time of Charles II. under the title of "An Essay to the advancement of Music", by clearing away the perplexity of different clefts; and uniting all arts of music, lute, viols, viols, organ, harpsichord, voice, &c. in one universal character, by Thomas Salton.
This book is well written, and, though very illiberally treated  
by Locke, Playford, and some other professors, contains nothing  
that is either absurd or imprecaibilis: nor could I discover,  
says Dr. Burney, any other solid objection to its doctrines  
being adopted, than the effect it would have upon old  
music; by soon rendering it unintelligible. At present  
the tenor cliff alone is thought an insuperable difficulty in our  
country, by Diletanti performers on the harpsichord; but  
if Salmon's simple and easy musical alphabet were chiefly  
in use, the basic cliff would likewise be soon rendered as obso-

tele and difficult as the tenor; so that two parts or cliffs out  
of three, in present use, would become unintelligible. The  
author's plan was simply this: instead of the eight or nine  
ciffs that were then in use, as,  

\[ \begin{align*}

\end{align*} \]

Compass of proportion. See Sector and Proportion.

Compass dials, are small dials, fitted in boxes, for the  
pocket, to shew the hour of the day by direction of the  
neddle; which indicates how to place them right by turning  
the dial about, till the cock or style stand directly over  
the needle, and point to the northward; but these can never  
be very exact, because of the variation of the needle itself.  
See Dial.

Compass Screw. See Saw.

Compasses, or pair of Compasses, a mathematical  
instrument, used for the describing of circles, measuring  
lines, &c. The common compasses consist of two branches  
or legs, or iron, brass, or other metal, pointed at bottom;  
and joined by a twist, whereon they move, as on a centre.  
These are reckoned the best, p’ot of whole joint is steel,  
and where the pin or which the joint turns is a steel screw.  
The points should also be made of hardened and polished  
steel. In some the points are fixed; in others they may be taken  
of a drawing-pen, pencil, or dotting wheel,  
embedded in their room.

The invention of compasses is ascribed to Talus, nephew  
of Dædalus, by his flider, whom, the poets say, Dædalus  
killed out of envy. We have compasses now of various  
kins and contrivances, accommodated to the various uses  
they are intended for; as,

Compases of three legs, or triangular compasses. Their  
structure is like that of the common compasses, letting aside  
the excess of a leg, which has a motion every way; their  
use is to take three points at once, and so to form triangles:  
to lay down three positions of a map to be copied at once,  
&c. Two of the legs A, B (Plate, Compasses, fig. 1.)  
are jointed together like a common pair; the pin a, which  
connects them, has another leg D, jointed to it; the legs,  
A, B, are first set to two of the points, and the leg D is  
then moved farther from, or nearer to, the other legs by  
bending its joint; or it is turned round the pin a of the  
other legs as a centre, as occasion may require.

Fig. 2, is another construction of the triangular  
compasses. A, B, C, are three arms, at whose ends are jointed  
the arms a, b, c, carrying steel points; they are of such  
lengths, that when closed they shall nearly meet in one  
point; by opening them as in the figure, they can be made  
to coincide with any three points within the reach of the arms.  
Compasses, Beam, consist of a long branch, or beam,  
carrying two or three cursors; the one fixed at one end, the  
other sliding along the beam, with a screw to fasten it, on  
occasion. To the cursors may be screwed points of any  
kind; whether steel, pencils, or the like. To the fixed  
cursor is sometimes applied an adjusting or micrometer  
screw, by which an extent is obtained to vary great nicety.  
Mr. Ramírez constructed compasses of this kind whose  
micrometer screw shows very perceptibly a motion of 1/1000  
part of an inch. It is used to draw large circles, to take  
great extents, &c. See Plate, Compasses, fig. 3, which  
exhibits a common pair of beam compasses. A A is a fixed  
branch, or mahogany, made very straight and true; B, D  
are two frames of brass, sliding on the bar, that can be  
separated at any place by a clamp screw a b, at the top of  
each; e f are two pieces into which are inserted the points,  
and are fastened by a screw; the sliding frame B has a  
colar g screwed to it, in which the screw h, with a divided  
head, turns; this screw is tapped into a piece of brass  
fastened at the end of the mahogany bar, so as to move  
the point at f very slowly when the screw is turned.

Compasses, Bow, or Boxes, are a small sort of com-

\[ \begin{align*}  
& \text{G in every part of the scale being on the first line, } a \text{ on the}  
& \text{first space, } b \text{ on the second line, &c. the letters preceding}

& \text{keyed-instruments; of which we have already pointed out}  
& \text{the inconvenience. See Accompaniment and Cliff.}  
\end{align*} \]
COMPASSES, that shut up in a hoop, which serves for a handle. Their use is to describe arcs, or circumferences of circles of very small radius. Fig. 4, is a small pair of compasses, with a screw for measuring small distances very accurately, and describing small circles: a is one of the points fastened to a socket, in which the screw b works; d is a steel-bar attached to the same socket; e is a piece sliding on the bar d, and carrying the other point; it has a projection above it, in which the screw works; f and g are two pieces jointed to the points at one end, and to a small handle h, at the other, which is used to hold them by. The head f of the screw is divided into equal parts, which divisions are read against a projecting part of the piece, holding the point a, and by turning it round one of the divisions, the points are moved some fractional part of an inch, as 1/16, or 1/16, according to the number of threads in an inch of the screw's length, and the number of divisions on the head of the screw.

COMPASSES, Caliber. See Caliber.

COMPASSES, Clock makers. Are very subtiltantial, serving to cut paperboard, bras, &c. jointed like the common compasses with a quadrant, or bow, as the spring compasses, only its use is different; as serving here to keep the instrument firm at any opening. See Clock.

COMPASSES, cylindrical and spherical, used in taking the diameter, thickness, or caliber of round or cylindrical bodies, such as cannon, balls, pipes, &c. They consist of four branches joined in a centre, two of them circular, and two flat, a little bent at the ends.

To use them, one of the flat points is put within the cannon, the other without; the two opposite points show the thickness. See Caliber Compasses.

There are also spherical compasses, differing in nothing from the common ones, but that their legs are arched, serving to take the diameters of round bodies, &c. Another sort of compasses has been lately invented, for measuring the diameter of round bodies, as balls, &c. which consist of two flat pieces of metal, set at right angles, in a straight bar or beam of the same; the one being fixed, and the other sliding along it, so far as just to receive the round body between them; and then its diameter, or distance between the two pieces, is shown by the dividers marked on the beam.

COMPASSES, Elliptic. Their use is to draw ellipses, or ovals of any kind: they consist of a beam A B (Plates, Compasses, fig. 5,) about a foot long, bearing three cursors; to one of which may be fixed two points of any kind: to the bottom of the other two are riveted two sliding dove-tails, adjusted in grooves made in the crofs branches of the beam. The dove-tails having a motion every way, by turning about the long branch, go backwards and forwards along the crofs; so that when the beam has gone half-way about, one of these will have moved the whole length of one of the branches; and when the beam has got quite round, the same dove-tail has got back the whole length of the branch. Understand the name of the other dove-tail.

Note, the distance between the two sliding dove-tails is the distance between the two foci of the ellipse; so that by changing that distance, the ellipse will be rounder or flender. Under the ends of the branches of the crofs are placed four flet points to keep its fall.

The use of this compass is easy; by turning round the long branch, the ink, pencil, or other point, will draw the ellipse required. Its figure shews both its use and construction.

COMPASSES, German, whose legs are a little bent outwards towards the top; so that, when shut, only the points meet.

COMPASSES, Hair, so contrived within file, as to take an extent to a hair's breadth. The outward appearance of the hair compasses is like that of a common pair of compasses; the peculiarity consists in one of the legs A, being attached to the brass by a spring B (Fig. 6), whose action throws the leg inwards, and is counteracted by a small screw D; by turning which the leg can be moved small distances, and let to the greatest nicety, without moving the joint.

Fig. 7, represents a pair of pocket compasses, the legs, a, b, of which are hollow, and contain, the one a pen, c, and the other a port crayon, at, at the opposite end of each point, f and g.

COMPASSES, Lapidary's, a piece of wood in form of the shaft of a plane, clinet a-top, as far as half its length; wherein they measure the angles, &c. of the precious stones, as they cut them. In the clinet is a little brass rule, fastened there, at one end, by a pin; but so that it may be moved in the manner of the bevel; with this kind of square they take the angles of the stones, laying them on the shaft as they cut them.

COMPASSES, Proportional, are those whole joint lines between the points terminating each leg; they are either simple or compound. In the former sort the centre is fixed, so that one pair of these serves only for one proportion.

COMPASSES, Compound proportional, consist of two branches (see Fig. 8,) each pointed at either end with steel: the length of the branches is cut through, for a cursor to slide up and down; in the middle of which cursor is a screw, serving to join the branches, and to fix them at any point required.

On the one leg are divisions, serving to divide lines into any number of equal parts, for reducing of figures, &c. On the other are numbers, for inscribing any regular polygon in a circle proposed.

The use of the first is easy: Suppose v, gr., a right line required to be divided into three equal parts; push the cursor till the screw be just on the figure 3; where fixing it, take the length of the given line between the two longest parts of the legs; the distance between the two shortests will be one third of the given line. In the same manner may the line be divided into any other number of parts.

For the use of the line of polygons: Suppose, v, gr., a pentagon required to be inscribed in a circle; push the cursor till the middle of the screw be against 5, the number of sides in a pentagon; between the shortest part of the legs take the femidiameter of the circle: the legs thus opened, the distance between the points of the longest parts will be the side of the pentagon to be inscribed in the circle. And thus for a figure of any other number of sides.

Fig. 9, is a pair of proportional compasses; the bras part of the two legs A, B, have longitudinal openings in them, for the pin, round which they move as a centre, to slide in, and can be fixed at any place by a screw e, so that the distance from the centre to the points e, d, shall be twice, three times, or in any other aliquot part of the distance to the points e, f, and of course the openings at each end will be in the same proportion.

Fig. 10, represents a method of adapting a quick and smooth motion to a pair of the compasses; a is a brass bar, with an oblong opening cut in it, to receive a screw, b, fastened to one leg of the compasses; the other end of the bar, d, is cut into a screw, with a fine thread, and has a nut, f, on it, turning in a collar jointed to the other leg of the compasses. When the screw, b, is loose, the compasses can be set to any opening; but when it is fast, they can only
be moved by turning the nut. The screw, \( t \), is put into a hole in one of the legs of the compasses, so that it can easily be removed, and inserted into a hole made in the moveable centre, to give it a slow motion if required.

**Compasses, Proportional, with the Sector lines.** The structure of these is so like that of the common proportional compasses, only a little nicer, that it needs no particular description. See sect. 1.

The lines on the first face are the line of lines, marked lines: it is divided into 100 equal parts, every tenth numbered: and the line of chords, which goes to 60°, is marked chords.

On the other face are a line of lines to 90°, and a line of tangents to 45°. On the other side are the tangents from 45° to 71° 34′; on the other, secants from 0° to 70° 30′.

*For the use of these compasses:* 1. To divide a line into any number of equal parts, less than 100: divide 100 by the number of parts required; flip the cursor till the line on the sliding dovetail be against the quotient on the line of lines; then the whole line being taken between the points of the compasses, will remote from the centre, the aperture of the other will show the division required. 2. A right line given, supposed to be divided into 100 parts, to take any number of these parts; flip the line on the sliding dovetail to the number of parts required; the whole line being taken between the points farthest from the centre, the aperture of the other two will include the number of divisions required. 5. The radius being given, to find the chord of any arc under 60°; if the line on the sliding dovetail to the degrees required on the line of chords; the radius being taken between the points farthest from the centre of the cursor, the aperture of the other line will be the chord required, provided the number of degrees be greater than 29; if it be less, the aperture taken from the radius will leave the chord required. 4. If the chord of an arch under 60° be given, and the radius required, flip the line on the dovetail to the degrees given on the line of chords; the given chord being taken between the two points next the cursor, the aperture of the other will be the radius required. 5. The radius being given, to find the sine of any number of degrees. Slip the line on the dovetail to the degree on the line of lines whose sine is required; the radius taken between the points farthest from the cursor, the aperture of the other will give the sine of the angle required. But if the sine sought be less than 30°, the difference of the sines of the opposite points will be the sine required. 6. The radius being given, to find the tangent of any number of degrees under 71°: if the tangent required be under 29° 50′, then flip the line on the dovetail to the degree proposed on the tangent line; the radius taken between the points farthest from the cursor, the aperture of the other will be the tangent of the degrees required: if the tangent required be above 29° 50′, but under 45°, the line on the cursor must be flipped to the degrees given on the tangent line; then the radius being taken between the points farthest from the cursor, the aperture of the other will be the tangent. If the tangent required be greater than 45°, but less than 56° 20′, flip the notch on the tangent side of the turned cheek to the degree 0 on the tangent line on the side of the compasses; the radius taken between the points farthest from the cursor; the difference between the aperture of the other, and these, added together, will be the tangent required. Thus, for the tangents of other degrees under 71. After the like manner may the secant of any number of degrees under 71 be found.

Mr. Heath, a mathematical instrument-maker in London, constructed a pair of proportional compasses in 1746, with a curious and useful contrivance for preventing the shorter legs from changing their position, when these compasses were used. It consisted of a small beam soldered to a screw, and running parallel to the leg of the compasses, nearly of the length of the groove; in this beam a flat was made, which admitted of a sliding nut, the other end of which fell into a hole in the bottom of the screw, belonging to the great nut of the compasses. The screw-pin of the beam passed through an adjuster, by means of which the mark on the slider might be brought exactly to any division. But the proportional compasses have been much out of use since the invention of the sector, which see.

**Compasses, Spring, or Dividers, are made of hardened steel, the head arched; which, by its spring, opens the compass; the opening being directed by a circular screw, fastened to one leg, and let through the other, worked with a nut.**

**Compasses, Triangular.** See Compasses of three legs, and Triangular.

**Compasses, Trisecating, the invention of M. Tarragon, for the trisection of angles, geometrically.**

The instrument consists of two central rules, and an arch of a circle of 120 degrees, immovable, with its radius; the radius is fastened with one of the central rules, like the two legs of a sector, that the central rule may be carried through all the points of the circumference of the arch. The radius and rule must be as thin as possible; and the rule fastened to the radius hammered cold, to acquire an elasticity; the breadth of the other central rule must be triple the breadth of the radius. In this rule there is a groove, with a dovetail, to be fastened on it, for its motion; in the centre of each rule must likewise be a hole. See the Journ. des Scavans, Sept. 1688.

**Compasses, Turn-up, a late contrivance to save the trouble of changing the points; the body is like the common compasses; towards the bottom of the legs, without fibre, are added two other points, besides the usual ones; the one carrying a drawing pen-point, the other a port-crayon; both joined so as to turn round, and so be in the way of use, or out of it, as occasion requires.**

The points of small compasses are tempered by a lamp and blow-pipe, heating them red-hot; when cold, they are hard: the larger are tempered by a charcoal fire and a blow-pipe, heating them to a cherry colour, then plunging them in water.

See M. Bion's Construction and Uses of Mathematical Instruments, by Stone; and Robertson's Treatise on the same subject.

**COMPASSEMENT de feux,** in Military Language, a manner of fixing the distances between the chambers of mines, and dipping of the fuse-threads, so as to communicate the fire to them at one and the same instant of time.

**COMPASSING,** in Naval Architecture, a term used to denote such pieces of timber as are incrusted into the figure of an arch.

**COMPASSING the king's death, in Law.** See Treason.

**COMPASSION,** in Ethics, a mixed passion, compounded of love and sorrow, and excited by the sight or recital of distress: or, as Dr. Hartley concretely defines it, it is the uneasiness which a man feels at the misery of another. Accordingly he traces it to several affections, both in children and adults, upon which it seems to be grounded; and he observes, that persons, whose nerves are easily irritated, and those who have experienced great trials and afflictions, are in general, more disposed to compassion than others; and that we are most apt to pity in those distresses and calamities which
which we either have felt already, or apprehended ourselves in danger of feeling hereafter. A compassionate temper, says this writer, being great matter of praise to those who are ended with it, and the actions which flow from it being a duty incumbent on all, men are led to praise these actions, and to incite upon themselves the motives of compasion, by attending to difkets, actually present, or defended in history, real or fictitious.

Hobbes makes this a merely selfish passion, and defines it, as being for our selves; Hutcheson refutes it into instinct; but Dr. Butler much more properly considers compasion as an original, distinct, particular affection in human nature.

According to Dr. Cogun, in his "Treatise on the Passion", compasion is that infinity of affection, which is excited either by the actual distress of its object, or by some impending calamity which appears inevitable. It is, says this writer, a benevolent arrow at their suffering or approaching misery. The etymology of the word expresses this idea with strict propriety, as it signifies "founding with the object." Compasion is always connected with a disposition to relieve, and will always prompt to vigorous exertion, wherever there is a possibility of success; unless some important considerations should render the undertaking improper or unjust. It has no necessary connection with the character of its objects; their difkets being a sufficient excitement. From the great extent and univerality of this affection, it may be justly considered as a generic name, comprehending several other affections which have a more specific application, as mercy, commiseration, pity, &c. Dr. Reid remarks, that it seems to be a holy religion alone that is able to check the tear of compasion. We are told, he says, that in Portugal and Spain, a man condemned to be burned as an obstinate heretic, meets with no compasion, even from the multitude; observing, that they are taught to look upon him as the enemy of God, and doomed to hell fire. But should not this very circumstance, he adds, move compasion? Surely it would, if they were not taught that, in this case, it is a crime to show compasion, or even to feel it. COMPATIBLE, something that may suit, or confide with another. See INCOMPATIBLE.

COMPENDIUM, an abstract, epitome, or reduction of a large matter into a little compass. See ABSTRACT and EPITOME.

COMPENSATION, an action whereby anything is admitted as an equivalent to another.

Compensation, in the Civil Law, is a kind of right, whereby a debtor pur sued by his creditor, for the payment of a debt, demands that the debt may be compensated with what is owing him by the creditor. Compensation is equivalent to payment, and answers to that which is called Serifer in common law.

Compensation-Balance, in Horology, is the balance of a chronometer, so ingeniously contrived, that two opposite actions counteract each other's natural effects at all times upon it, and equalize its momentum under all the changes of temperature experienced in different climates and seasons. The opposition of two natural effects, produced by an artificial arrangement of the acting parts, is very properly called the compensation, which has been effect ed in various ways. The most simple compensation that has been produced in a machine for measuring time, is that which depends upon the variable fluidity of the oil applied to the pivot holes of the balance arbor, and of the other arbors of a watch; oil, it is well known, however good, is more fluid in hot weather than in cold, and therefore diminishes the friction at the pivots more in summer than in winter, the consequence of which variation in the friction of a watch with the ordinary crown-wheel escapement, would have its rate accelerated in the former season, and retarded in the latter, by this simple cause, if there were no compensating property in the structure of some part of the mechanism; this property naturally exists in the balance and balance-spring, both which are subject to have their dimensions enlarged by heat, and contracted by cold; and these changes alternately occasion retardations and accelerations in the rate of going; but in such a way, that when the watch is dispersed to have its rate accelerated by the more fluid state of the oil, it is also dispersed to have the same retarded by the contemporary enlargement of the balance and balance-spring; hence the quantity that one of those dispositions prevails over the other in any watch, when regulated to mean time at a mean temperature, constitutes its liability to vary its rate of going in different months of the year. Berthoud, who attempted to proportion the thickness of his pivots to the oil with a given balance, so as to produce an approximation towards a good compensation, has called this the natural compensation, which is a very proper appellation, as it exists in a certain degree in all chronometers and watches that have oil applied to them. This natural compensation, however, is found to be a very imperfect one, and unfortunately interferes with the effects produced by the better compensations, which, in opposition to this, may be called the artificial compensations. To banish the interference of the variable effects produced by oil, is one of the difficulties, and indeed now the principal one, that opposes the efforts of the chronometer-maker, to make the action of his mechanism permanent, uniform by the most fluid state of the oil, which is also nearly agreeable to the order of time in which they were invented.

Compensations at the Spring.

1. Harrison's Compensation Curb.—We have said, under our article CHRONOMETER, that Mr. James Harrison of Barton, in Lincolnshire, was the first person who applied a self-compensating piece of mechanism to the balance of a watch, which contrivance, according to his provincial dialect, he called a curb, and which we have taken the liberty to name a curb. Fig. 1. of Plate XXVIII. of Horology, represents the balance, balance-spring, small cock, and curb, as they would be seen by an eye placed directly over the back of the pillar-plate, when the large cock is taken off, that bears the verge-pivot; AA is the plate on which the mechanism is placed; B the balance of a uniform metal; C the spiral spring of regulation; DE the thermometrical curb, so contrived as to lengthen the effective length of the spring in the different degrees of temperature, without manual adjustment; G a double cock to which the curb DE is attached; and F the small cock, or pin, to which the exterior end of the spring is pinned. The thermometrical curb, DE, is composed of two long slender slips, one of brats and the other of steel, pinned

Vol. IX.
pinned together in different places, and is attached to the smallest half g of the double cock G, so that it may be brought nearer to G, or removed farther from it, as pleasure, before e is fixed to G, in order to place it at the requisite point between a and b of the spiral; the double cock is revolved in the figure as though it were fixed by a cork and freely pin to the plate B, but in the original time-keeper, it was adjustable between two parallel pieces, that allowed it to approach the fluid T, or recede from it, for the purpose of ascertaining particularly the height length of the curb, for effecting the requisite compensation: the side of the curb next to D was steel, and the side next to E brass, and the effect produced by changes of temperature was that: when the time-keeper was exposed to heat, the balance, and balance spring, had their dimensions altered, so that the momentum of the balance was increased, supposing its arc of vibration unaltered, and the force of the spring diminished, or at least would have been considerably diminished by its elongation, if the curb had not been applied; and the natural consequence would have been for the piece to retort; but the same heat, which naturally produces these changes in the balance and balance spring, produces such a change in the shape of the curb, as counteracts these natural effects; in the cafe of heat, the brass part, E, of the curb becomes more lengthened than the steel part D, by reason of its greater expansion, and a consequence is, that the original side of the piece D E, becomes convex on the brass side E, and concave on the steel side D; that is, the remote or free end of the curb, considered as an index, moves from a towards b, and as this end carries two pins between which the straight end of the spring passes, these pins, and not the steel, form the limit of length at all times of the regulating spring, which consequently is curved as to its effective length, under all the variety of elongations, that it experiences from different degrees of heat; so that it may be said to be always both lengthening and shortening in nearly the same proportion: on the contrary, when the piece is exposed to cold, or to speak more scientifically, is exposed to a low temperature, the steel side D, becomes convex, and the brass side E, concave from its greater contraction, and the free end of the curb moves from b towards a, thereby mechanically lengthening the spring, as it naturally contracts, in a degree sufficient to check the velocity which the balance would acquire from its diminished dimensions. Thus, whether it is summer or winter, in hot or in cold climates, the compensation of the curb is calculated to counterbalance the natural effects of changes of temperature on the dimensions of the balance, and of its regulating spring.

It has been ascertained, that the elasticity of the balance-spring is affected by changes of temperature; but we conceive it to be its force, or that power which depends on its length that is naturally altered, and not, at least in any sensible degree, that property which depends upon its temper. This contrivance, we have said, in another place, laid the foundation of modern chronometry, though it was afterwards found to be a better application of the compound bar, that the balance itself should bear it, in order that the dimensions of the balance and of the compensation pieces might be affected in a contemporary manner by the variation of atmospheric temperature, so that the artificial changes going on in the balance itself might compensate the changes naturally produced in it and in the spring, instead of the artificial changes in the spring being made to compensate the natural changes in its dimensions, and in those of the balance.

We have before said, that this mechanism was invented and used so long ago as the year 1726, and that it is incapable of the usual adjustment for rate, except at the fixed fluid, from which the fastening pin must necessarily be taken, to admit of the spring's being lengthened or shortened.

**Compensation by F. Berthoud.**

In the year 1752, which was about seven years before the Board of Longitude published the principles of Harrison's Time-keeper, Mr. F. Berthoud, the famous clock and watch-maker of Paris, contrived and introduced, into No. 1, of his marine clocks, a compensation curb, acting on the spiral spring of the balance in a manner similar to the action of Harrison's curb, except that the backward and forward motion of his *pince spiral*, or curb, was produced by the difference of two direct expansions according to the disposition of the grid-iron pendulum, which Harrison had previously invented, (for the description of which see the section, "Alodynamical clock, by Mr. Reid of Edinburgh," under the article Clock.) The mechanism by Berthoud, is represented in fig. 2. of Plate XVIII, the eye being, as before supposed, to be directly over the pillar plate of the frame; the circle AA denotes the plate just mentioned; B B, the grid-iron frame, attached to the end-plate, and composed of alternate bars of steel and brass, joined together by end-pieces like the compensation-pendulum alluded to, which therefore need not be again minutely described; the pair of brass bars in the middle of the frame, or grid-iron, are those which act by protruding more or less in different degrees of heat against the tail-piece D, of the double cork DE, movable on an arm with pivots borne by the plate and cock G, or by G made as a double cock; H is the principal cock, in which the balance pivot runs in the triangular hole, made by three friction-rollers, not shown in the figure; the *pince spiral* b, and arm a are fast to an arm which is pivoted into the cock H, and a small cork under it, which is attached to it; this arm is parallel to the balance verge, and is so contiguous to it, as to be in one of the eccentric points, from which the spiral of the spring which it holds is geometrically described; that is, at half the distance from the verge, that the two nearest spirals are from each other; on each of these two levers, a and b, is a sliding piece of metal; that on a for the lever E to roll against, and that on b to have a fit for receiving the thread of the spiral spring; they are both fixed by piercing holes to their respective levers, when adjusted to their proper places thereon, but b is prolonged to d, which is attached to the graduated L piece by the screw e, and this L piece has a pointer, used as an index for the graduations on the bridge I, that lies across the grid-iron frame, when attached to the plate AA. K is a spring, pressing against a tail-piece of the lever e to keep it always in contact with the lever E; G is the spiral regulating spring, as in an ordinary watch, and F an adjustable fluid, for the exterior end of the spring, with an oblong perforation for the pressing screw; the interior end of the spring being fast to a collet on the verge, which is adjustable by friction. The mechanical action is thus produced; the difference of the expansibilities of the steel and brass rods of the grid-iron frame becomes sensible at the pin D, in the tail-piece of the bent lever DE, movable in a point of bridge G, between those two letters; the part E, being longer from the centre of motion than the part D, which is acted on, moves faster and carries before it the lever a, and together with it the *pince spiral* b, and L piece with the screw e; and it is obvious, that, as the sliding piece, borne by lever a, limits its effective length from its place of contact with lever F, the relative lengths of these two levers may be varied at pleasure by adjustment, till the effect produced...
The Application of Harrison's Curb to a common Watch.

After Berthoud had made the alterations, which we have just described, in Harrison's curb, he turned his mind towards simplifying it so as to become useful in a common watch; the manner in which he succeeded in doing this is shown in fig. 4 of our present plate, where it will appear by inspection how the action takes place, particularly as we have placed the same letters of reference to the same parts, as in fig. 3; the difference of the two contrivances consists chiefly in the fluid, F, being here fixed half to the circular plate of the frame, in the curb-lever being bent and having its centre of motion on a separate small bridge, H, and in the opposing spring, K, being attached to the face of the plate itself; otherwise the adjustment for temperature is performed as in fig. 3, and is equally capable of taking in the extreme limits of temperature. (For another disposition somewhat similar to the present one, see Berthoud's "Supplement au Traité des Horloges Marins." Plate III. fig. 8.)

Compensation by Mr. Alexander Cumming.

Mr. Cumming published his book on "The Elements of Clock and Watch-work," in the year 1766, in which he has given an ingenious though complex method of compensating the effects of heat and cold on the balance and balance-spring, different from the foregoing ones, and depending on the difference of the direct expansions of two separate and different metals, added, like Berthoud's, by the introduction of adjustable levers; whether the invention preceded or followed Berthoud's gridiron frame and lever, is a consideration which does not, perhaps, affect either of their two claims to originality, as Harrison's curb was most probably heard of, if not previously known, by both the mechanisms in question; nor does it appear that either of the two complicate methods here spoken of has been copied by others in practice. Fig. 1. of Plate XXX. of Horology, represents a view of Cumming's mechanism of compensation, without the balance, as viewed by the eye placed directly above it, when fixed to the back of the pillar-plate of the frame. The outermost circular rim, A A , is of steel, and has eleven small rollers revolving on as many pins or studs inserted into the plane of the rim, and the interior rim, B B B , which rides against the rollers, is of brass, but is not an entire circle; one end of this interior, or brass, rim, is screwed fast to the plane of the steel rim, by means of a spirally grooved extremity, placed upon the plane of the steel rim, as shown in the figure; in this situation it is clear that the excess of the brass rim's expansibility will make its opposite ends approach each other in a high temperature, and recede in a low one, while the friction-rollers will prevent jerks; hence any object opposed to the free end of the brass rim will be pushed forwards by it, as the temperature is raised, which effect affords the means of alternately lengthening and shortening the spiral spring of the balance in the following manner; the free end of the brass rim presses against the end, a, of a lever moveable on a stud about the middle of it, and the oblong slit made in the opposite end of the same lever receives a pin inserted into the contiguous end of a second lever, b, moveable about its remote end round a socket concentric with the balance-vertex, or nearly so; the lever, b, which may be called the curb-lever, has two pins in underneath, not seen in the drawing, between which the outermost thread of the spiral spring passes; hence it is plain, from an inspection of the figure, that when the end, a, of the flat lever is pushed forwards, its opposite end draws towards the pin of the curb-lever, and with it the curb, so as to shorten the effective length of the
the spring in this case; and on the contrary, when the brafs
rim shortens by a low temperature, the contrary effect takes
place: for the end, d, of the flite lever follows the free end
of the said rim as it retires in contracting, in confequence of
a spring, not seen, impelling it into contact with this end at
tall times; the ratio of the two actuating ends of the two levers
from their respective centres of motion is adjusted by the
horizontal axis, g, squared at the end to receive a key; for as the
interior end of this axis is formed into a flite which paffes
into a tapped hole in a square nut on which is the centre of
motion of the flite lever; the said square nut is made to flide
in an oblong hole of the plate below the lever; and thus the
different parts of the flite may be made, successively, to
impel the pin of the curb-lever, as the compensation may be
found on trial to require. The balance, of course, is
placed above this mechanism, and vibrates free from it. We
observe that in the original drawing given by Cunnings,
(fig. of his Plate XIV.) the spiral is made to turn the wrong
way about, so that the effect of heat will be to elongate the
spring, which contradiction would double the natural effect
of variations of temperature instead of compensating them,
as the contrivance is intended to do, and would do, if rightly
conducted; but we see no reason to doubt this being as
effectual and permanent as any of the foregoing modes of
producing a compensation, when the spiral is bent the right
way round, as we have placed it.

Berthoud's Compensation by a Brafs Arch.

Another method of producing a compensation, different
from any of the preceding ones, in its mode of application,
comes next under our consideration, as another production
of the French clock and watch maker, whose name we have
had frequent occasion to mention with respect.

Fig. 5, of Plate XXVIII. exhibits the plan of all the
effential parts of this contrivance, in an intelligible manner;
A, as usual, is the principal cock over the pillar plate; B,
the balance of the metal; C, the spiral spring; D, an
arch of brafs with its ends refitting in two flapping notches
filed into the steel bar, E, which is fixed by a screw, near E,
in the middle, to the plate, so that it may be at liberty to
yield both ways to the action of increased or diminished
temperature on its total length; F, is, as before, the flit
to hold the exterior end of the spring, while the interior
one is left to a collet on the balance-verse; G, is a flite lever,
with a pin in its short end, g, and its long end pointed
as an index, to reach to the dividers, H, made on the
plane of the plate, which bears the mechanism; the effect
is thus produced; the brafs arch, D, is more elongated than
the straight steel bar, E, with the less increase of heat;
this arch carries a small screw, the head of which is just op-
posite the pin, g, already mentioned, between which screw
and pin the outermost coil of the spiral spring paffes; now
if the screw and pin were made to approach till they both
should touch the spring at opposite fides, they would be-
come in place of a curb, and there limit the length of the
spring that comes into action; on the contrary, if they were
made to move from each other as the spring tended up to the
flit, F, placed on the plate, they would be too narrow; but
when they are placed at such an intermediate distance
from each other that the screw limits the opening of the
spiral, and the pin its closing, before the part of the spring
near the flit is moved by the motion of the balance, then
the natural effective length of the spring is contrived, and
the pin and screw together become a species of curb, that
limits the effective length of the spring from an indif-
fini-ted point, lying somewhere between the flit and the
said pin and screw; which indifferen-tiate point will always
be nearer to the flit the more the pin and screw are removed
from each other, and vice versa; hence it is easy to see,
that moving the index, G, forwards or backwards, on the
graduated portion of a circle, H, will bring the pin, g,
next to, or remove it farther from, the screw head, than a
mean distance, and will thence affect the rate depending
on the effective length of the spiral spring, with a given ba-
ance, maintaining power, and eafement; but it is the
same thing if the index be suffered to remain, and the screw
be brought nearer to the pin; for the one limits the right
hand and the other the left hand excursion of the balance;
this is the precise operation of the contrivance; the superior
elongation of the brafs arch over the feel bar shortens the
radius of curvature of the arch, and makes the screw-head
approach the spring, more or less, according to the change
of temperature, to which the acting parts are exposed.
The law by which the approach is effected is somewhat dif-
ferent, however, from that by which an expansion-rim is
guided, with one of its ends at liberty; and the manner also
in which the effective length of the spring is limited, allows
a long scale of lengths, in a corresponding fhort scale of
differences between the screw head and pin; the latter
of which laws is evidently disadvantageous to the nicety of the
adjournment for temperature; besides, when the brafs arch
and the feel bar are found on trial not to be in their due propor-
tions to each other, the remedy cannot be applied with-
out varying the original proportions, by lengthening or
shortening the verfed line, as the cafe may be, which altera-
tion will require the mechanism to be displaced.

Improvement on the left Compensation.

Berthoud, having discovered the inconvenience and ob-
jections to the last described compensation curb, proposes
another in his " Haloire du Temps," tom. ii. p. 101 and 102,
thus: A, fig. 6, Plate XXVIII., is the principal cock,
mounted as usual on the pillar plate behind; B is again the
balance of one metal; C, the usual spiral spring; D, b, a
rack moveable on a focket concentric with the balance verge,
with some additional apparatus carried by it; E is a second
cock; and F a third, bearing the pin, or sliding flit, with its
frame and securing spring as in fig. 3 of the fame plate
already described; G is a pinion with an arbor squared at
the projecting end, to receive a key, which pinion has its
teeth formed fuitable to impel the teeth of the rack D d;
a and b are two coin pound bars of brafs and steel, lattice-
ted together with hard focder, inferted at d into a bearing piece,
and kept fay by a prifing screw e, urging them together
with the loofe piece, d, interposed, and kept parallel by a
clamping piece f; the rack has a circular perforated groove,
which allows it to pass backwards and forward by the ac-
tion of the pinion, while the heads of the two fcrews, f and g,
confine it to the fame plane on the back of the plate; and
fally, the compound bars, a and b, have each a pin at their
free extremities, which contain between them the left coil of
the spiral spring, the action of which is limited precisely
in the manner described in our last compensation mecha-
nism; here, however, the law of limitation in the effective
length of the spring is different; the latter, as we have seen,
depends on the quantum of play between the pins, whereas,
in the former, there was no play at all, and the curb itself
was the limit; seeing the effective length of the spring di-
minishes as the pins approach each other, the exterior la-
ments of the compound bars, a and b, must necessarily be
brafs, and the interior ones fteel, to shorten the spring in
high temperatures, and the contrary; when the effect pro-
duced is too great, the clamping piece, f, is carried outwards
towards the pins, in order to shorten the bars, which have
their lengths measured from this clamp; but when the ef-
feet produced is too little, the said clamp must be brought
inwards towards $d$ to lengthen the bars; so that the scale
of adjustments here runs along the length of the two paral-
lel compound bars, as it relates to the variations of tem-
perature; while the adjustment for a mean rate is made by the
index $b$, which showed the quantum on the contiguous por-
tion of a divided circle. Still, we think, that while a small
variation in the play, between the curving pins, produces a
large variation in the effective length of the spring; this
contrivance can have no pretensions to rank in utility with
some of the more recent inventions, that place the compen-
sating parts on the balance itself.

Compensation by Breguet.

A compensation similar in effect to the two foregoing
ones by Berthoud, but more simple than the latter, is the
which Breguet of Paris has applied with success to his
common watches; this compensation is shown in fig. 7 of Plate
XXVIII. where the bounding circles denote the back plate of
the frame; $A$ the principal cock; $B$ the balance of one
metal; $C$ the common spiral spring; $D$ the a three
armed piece, called by the French a rateau, to which is
attached the mechanism of compensation thus: the curv-
ilinear fork, $a$, is composed of two metals: each prong con-
fined to a slip of steel and a slip of brass, so attached together,
that the fork is the exterior, and the brasses the interior part in
each; the end $a$ is screwed to the lever $D$, and the end $b$
loose, consequently at liberty to approach or recede from
the spiral spring, as the changes of temperature affect the
fork; the interior end, $a$, of the fork bears a pin near the
letter $b$, not seen by reason of the lever $D$, which lies over
it, and a second pin similar to the other is carried by the
lever $D$, between the two largest coils of the spiral; these
two pins limit the effective length of the spring exactly in
the way that the two preceding compensating contrivances
have been explained to do, for which reason we do not re-
peat what we have already said on this part of the subject;
the alternate inward and outward motions of the pin, $b$, re-
gulate the distance between the two pins, on which the play
depends, and consequently the length of the spring also, as
it has regard to the action; the prong $a$ has a tendency to
become slanting by heat, in consequence of the concave
part being brass, but the prong, $b$, has a tendency to be-
come still more convex in consequence of the brasses being the
convex part; the joint effect of which alterations of shape
and position will be, that, as the balance and its spring be-
come enlarged, the space between the curving pins will be-
come diminished, and the contrary. The watch is regu-
lated for mean time by the index part $d$ of the three-armed
rateau, and the third arm, $e$, contains a pin about the middle
of the spiral spring, which we conceive to be the banking
pin, though no mention is made of it in the original de-
scription. "Histoire de la Meure du Temps, by Berthoud."

Compensation by Mr. James Scott.

In May of the year 1805, Mr. James Scott, of Graffton Street,
Dublin, published an account in Mr. Nicholson's Journal, (vol.
XI. p. 19—21, 8vo. series) of a compensation curb which acts in a manner somewhat analogous to that which we have
described as the invention of Cumming; but it is evident
he had not previously seen the one alluded to, nor yet Ber-
thoud's, otherwise he would not have laid in his letter to
Mr. Nicholson, that "artsists have not been able to invent a
compensation curb adjustable to the exact expansion re-
quired." The contrivance now before us is ingenious, and
we presume might be applied to an ordinary watch with con-
"Compensation.

Compensations
Compensation.

Compensation on the Balance.—Thermometer of Peter le Roy.

We have said under our article Chronometer, that Harrison was the first person who suggested the idea of the balance carrying its own compensation, and Peter le Roy was the first who in 1766 succeeded in such a construction; in our notice of this invention, however, there is a typographical omission which we beg leave to correct here before we proceed to our description; it is said under the article just referred to, that the compensation was effected by means of two thermometers, one of mercury and the other of alcohol, attached to, and borne by the balance itself; instead of one or each bearing mercury, and the other end alcohol, &c., as will now be more clearly understood.

Figs. 1 and 2 of Plate XIX. of Horology, exhibit so much of the balance of Peter le Roy as is necessary for explaining its construction; A Δ, in fig. 1, is a portion of the arm or verge to which the balance B is attached by screws; C is a small ring attached to the inferior part of the verge which holds the two screws of regulation for mean time, and which also clamps the horizontal parts of the two glass thermometrical bent tubes, D and Ε, placed diametrically opposite to each other, one of which is seen in a detached plate in fig. 2; these tubes are also held fast by two other clamps, to the middle of the verge, as may be seen in fig. 1; the superior end of the straight vertical part of each tube is open to admit the pressure of the atmosphere on the mercury, which is now seen standing at the same level in both the upper portions of each thermometer, after the inferior or horizontal connecting part is filled; but the bulbs and parts above the tubes Δ D and Ε, are filled at a mean temperature with alcohol, respectively resting on the columns of mercury:

when the balance and balance-pring are enlarged by heat, the alcohol has also its bulk increased, and descends below the letters D and Ε, for instance, in very high temperatures as low as the horizontal connecting part, in which case the mercury pressed upon it descends under the alcohol, but ascends in the same proportion at the other end, till it reaches nearly the open superior end of the vertical straight part of the tubes respectively; the mercury which was before in a column parallel to the verge, but at a distance from it, is now also parallel but contiguous, and as it is a ponderous fluid, the momentum of the balance is considerably diminished by the approach of the mercury to the centre of motion, which change of position of the mercury constitutes the compensation required to balance the effect of an enlargement of the balance itself, and of an elongation of its regulating spring taken jointly: in a low temperature the contrary change takes place in the situation of the mercury, for as the bulk of the alcohol contracts and retires round the acute angular part into the bulb, the exterior vertical branch becomes filled by the mercury. Peter le Roy, we have before said, was disposed to prefer this balance to the balances he made entirely of metal, but the fragility of the bent tubes, and the liability of the fluids to be agitated, if not to be mixed, sometimes constituted objections to its portability, that prevented its being copied by other chronometer makers. The adjustment for the extremes of temperature must have been made by varying the quantity of mercury in a given tube; and probably tubes of various dimensions were tried successively before the exact effect was produced, both at the extremes, and at all the intermediate degrees of temperature. The balance being heavy, was furnished by a thread above the superior end, A, and the slender cylindrical part, underneath the same A, rotated in a triangular hole, made by three surrounding friction rollers, not shown in our figure; lastly, two regulating springs, wound in contrary directions, were placed under the ring, C, near the lower pivot of the verge, which springs are purposely left out, that the reader may not have to view more parts than are necessary for explaining the compensation balance itself.

Compound metallic Balance of P. le Roy.

Peter le Roy, however, was not content with trying his thermometrical tubes, only to effect a compensation on the balance; but he so far adopted Harrison’s idea on the requisite construction of a balance, carrying its own compensation in motion, that he tried moreover his compound bars of steel and brasses, not, indeed, as curbs, applied to the springs according to Harrison’s method, but as rings to the balance itself; fig. 2 of Plate XXIX. shows a balance of this contrivance, where A is the diametrical bar fixed to the verge, and BB and CC two separate semicircular portions of the compound rim, which were each composed of laminae of steel and brasses respectively riveted together in different places, in such a way that the brasses were the exterior or convex ones, and the steel pieces the interior or convex ones; the loads are not given in the drawing, but the inventor says “Memoire sur la meilleure manière, &c.” that his contrivance made a considerable portion of the circumference to approach the centre of the balance in a high temperature; so that either it must have had loads on the ends of the semicircular parts of the rim, or otherwise these parts themselves must have been thick, which would prevent their due obedience to the variations of temperature. Fig. 4 is a kind of register contrived to examine the law by which the flexure of a compound bar was guided, as compared with a mercurial thermometer, thus: A is the croffes and rim of a balance of one metal, steel, we will suppose, and the compound plate B, were set at the end of the plane of the rim, has its end, C, at liberty to obey the changes of temperature; near b is a small cock into which a roller, bearing the index C, is pivoted above, against which roller the free end, b, of the compound bar, B, acts, whilst the interior end of the index points at the divisions made on the portion of a circle, D, near the centre of the balance: the experiments that were made with this instrument, according to P. le Roy’s account, showed that the rim of the index, in circumstances, corresponded very well with the rim of a mercurial thermometer, in all the different parts of the scale; and if this was found to be really the case, we cannot help thinking it extraordinary that the contriver of the compound metallic balance, which has flexibility and portability to recommend it, did not prefer it, in actual practice, to the mercurial balance, which was liable to the objections we have stated.

Arnold’s Balance.

Some pains have been taken to prove that Mr. Arnold, senior, did not invent his compensation balances himself, but borrowed them from Peter le Roy; we confess that we have not met with any conclusive argument in favour of such a supposition, but, on the contrary, have ascertained under our article Chronometer, that, “a variety of different shapes were given by Arnold to his balances, and actually tried in practice, before he adopted the one in present use, some of which balances are yet in existence;” and we have it now in our power to say further, that many of the balances here alluded to are yet in use, as ourselves have witnessed very lately; which balances have been proved to be excellent regulators, and some of which have public testimonies in their favour. We propose therefore now to describe them in succession, or at least such of them as have fallen in our way.
No. 1. In his preface to his printed certificates, Mr. Arnold, senior, says, that his first attempt to improve clocks and watches commenced in the year 1704; but we find it was not till the year 1715 that he turned his mind seriously to the construction of chronometers; the first compensation balance that he actually brought into use, was the one represented in fig. 5 of Plate XXIX, which was taken from one of the original balances while in our possession. The rim is 2.4 inches in diameter, and is, together with the three radial arms, of slender brass; the compensation bar is of brass and steel coiled round the balance verge, at a little distance from the mechanism which lies between it and the plane of the balance; the exterior part of this compound spiral bar is brass, and the interior part steel; a b is a piece of steel moveable round a tube surrounding the balance verge, and having a longitudinal aperture or slit, each way from the centre to nearly each extremity, a and b respectively; the end, a, is turned up a little, and has the exterior end of the compound spiral bar of compensation attached to it, so as to partake of its motion under all the changes of temperature; c d and e d are two bracket pieces of metal carrying each a pin under them, that exactly fit the longitudinal slit of the piece, a b; consequently these bracket pieces also partake of the motion produced by the compound spiral bar; the ends, c and e, of the bracket pieces are attached to h balance rums at the points, e and c, by the flat leaf metal springs, c c and e e, respectively; to the ends d d, of the load brackets are attached the long pins, d f and d f, which pass through the small leafy bridges on the rim, and carry the fettoral loads of temperature, f and f; the action produced on this mechanism by the changes of temperature may be thus explained: when the temperature is elevated, the exterior end of the compensation spiral bar, moves in a direction from a towards c, and carries with it the end, a, of the cross-piece, a b, at the same time the opposite end of this piece moves from b towards e which is contiguous to it; the opposite motions of the ends, a and b, of the cross-piece carry the two brackets in such direction that the loads of temperature, f and f, are both made to approach the balance, so as to effect its movement when in motion; which is the effect required in the above-named temperature; on the contrary, when the temperature is diminished, the motion of the load brackets is only objectionable; in this case, the ends d and d move towards d and d respectively, and the loads of temperature are thrown outwards, to increase the momentum of the moving balance. The quantity of effect is regulated by enlarging or diminishing the loads, f and f, of temperature, as compared with the fettors, c and c, or weights of adjustment for mean time; or otherwise, by screwing them into a new situation, cut or in, as the case may be; the springs, e e and e e, do not interfere with the inward and outward motions of the loads of temperature, but only confine the brackets to the plane of their action, and limit the direction of their motion. This compensation-balance was applied to ten or twelve different chronometers, between the years 1775 and 1778, but we have not been able to ascertain its comparative merit; its principle is simple, in that there is but one compound bar, to move two loads of temperature, but its mechanism is complex, which was probably the principal reason why it came into disuse.

No. 2. The next balance, which Mr. Arnold contrived, was that which is represented in fig. 6, of Plate XXIX, in which the mechanism is much more simple than in its predecessor; the rim and diametrical bar, by which it is attached to the verge-collet, are both steel, the parallel bars, a b and a b, are composed of brass and steel respectively, the brass being here interior and the steel exterior, and are inserted into pivot holes made in the rim of the balance; in some of the chronometers, the end, b, was fast to the balance, and the end, a, of the same bar loose, while the end, a, of the other bar was fast, and the end, b, of the same was loose, but in other chronometers both the ends of each bar were formed into pivots with flounders, and were inserted loosely by bending the bars about the middle; the cross pieces, c and e, which carry the loads of temperature, are of steel, and the rim itself is so notched as to admit of the loads being contiguous, that they may meet with very little resistance from the air, when in motion; the mode of action is obvious from a view of the figure, and from what has been previously said of a straight compound bar, being liable to become convex on the brass side by an elevated temperature, and the reverse in an opposite temperature; the bars, a b and a b, becoming convex, with increased heat, towards the centre of the balance, draw the loads, d and d, nearer to the rim, and when the balance is straight at a mean temperature, and, on the contrary, as the heat diminishes, the same parallel bars become convex on the sides next the rim, and carry the loads from the balance; and these alternations of motion, keeping pace with the changes made in the dimension of the balance, and of the balance-spring, constitute the compensation for the effects of temperature: the exact quantity of effect is adjusted as before, by altering the magnitude of the loads, d and d, as compared with the weights of the adjustment-screws, c and c, for mean time; or otherwise have their relative positions altered in regard to their distances from the centre. About twenty of these balances were made and applied as regulators, all of which performed their office, we are told, very well; the famous gold chronometer, No. 36, tried for 18 months by Dr. Markelyne, at the Royal Observatory, while worn in the pocket, under the different degrees of temperature, agitations of the body, and changes of position, had, and still has, one of these balances; and its rate, which has been published, established its credit to so high a pitch, that it was sold for 1000 l. or guineas, notwithstanding the detent of its escapement, after the fashion adopted by the French, is fixed to an arbor revolving on pivots. The balances of the present construction were made from the year 1779 to the year 1783, on the years 1775 and 1776, no objections were heard against them, for they were the play they necessarily had to allow for the difference in the temperature, which we think might have been scarcely perceptible when the pivots were well made and fitted tight into their holes.

No. 3. The object of the motion at the pivot holes in the later balance, (No. 2.) was attempted to be remedied by the construction exhibited in fig. 7, of the same plate, where the expansion pieces are of brass and steel, arranged in the form of a long S, which form was afterwards adopted by Emery, the Swiss watch-maker, who settled in London, and who has been the reputed inventor of this arrangement; the two halves of the S are joined at the middle, and the brasses, as before, are interior throughout; the rim and diametrical bar of steel, in the balance we examined, which was 1.2 inches only in diameter, by reason of its having been used in a pocket-chronometer; the exterior end, a, of the S is attached to one of the shortened crooks of the balance, and the interior end of the same bears the long pins, c and c, which carry the loads of compensation d and d; the long pins, c and c, do not pass through the rim, but are held to their proper positions by the two fettors, e e and e e, as in No. 1, or fig. 5; as before, the relative weights of the loads of compensation, d and d, and f f, the loads of adjustment for mean time, constitute the limit of effect to be produced by the expansion bars, sup
fopple their distances from the centre fixed; but if the
loads remain unaltered, the effect to be produced may be
adjusted by varying the distances of the screws respectively
as they regard the centre of the balance. Of these balances
about forty were made and applied to use between the
years 1779 and 1782, and have been found to perform
well.

No. 4. The length of the S pieces in the last balance
having been found difficult to execute of uniform thickness
and shape, by reason of their great length, the construc-
tion represented by fig. 8, was substituted, which is very nearly
similar to its predecessor, and indeed differs from it only as
the bends are united by an interposed piece of solid metal,
thereby dividing what was before one half of the S, into
two parallel compound bars; in all other respects, the
description just given of No. 3, together with the letters of
reference, will equally apply to our present balance; which
circumstance renders a further detail superfluous.

Of these balances not more than six or eight were con-
structed, by reason of the more simple form, which is now
in general use, having been adopted in 1782, when a patent
was taken out for it. The specification, however, contains
the drawings of Nos. 2 and 3 (figs. 6 and 7), as well as of
the common balance, which we have fully described under
our article Chronometer, to which the reader is respectfully
referred, and which was known to the workmen by the
name of the Z balance, by way of distinction from the S
balance. Besides the above-described constructions of the
compensation balance, Arnold, we are assured, contrived va-
rious others which never came into use, one of which had
the expansion pieces parallel to the verge of the balance, and
borne by it; and others had platinum in the expansion pieces,
instead of itself; but we conceive it to be unnecessary to
pursue the subject of his inventions further, than merely to
observe, that so regular a succession of different balances
actually made and used, where so many were constructed,
and where each was evidently meant to be an improvement
on the last preceding, may be taken, if not as a positive, at
least as a presumptive proof, that the imputation of plagia-
rum, unless otherwise fairly made out against him, is in
contradiction to the facts we have here adduced; which are
all facts open to still further investigation.

For the description of the compensation balance as made
by the Brockbanks and Earnshaw, the reader is directed to
the recent article Chronometer, where this part of our
present article has been anticipated. The description of
Earnshaw's balance and deception, however, which we have
quoted as the production of this chronometer maker, it may
be proper to note, was not his, but the production of Mr.
Firminger, the late assistant of Dr. Massey on at the Royal
Observatory, as we have been assured by the author himself,
since the publication of the pamphlet in which it appeared
obviously as Mr. Earnshaw's own account. And now that
we are on the subject of Mr. Earnshaw's balance and de-
ception, we beg leave to add further here, an acknow-
ledgment of our misinformation respecting the patent, which
we were credibly informed, and said, was never taken out;
but which we now find, on more minute examination, was
actually taken out and registered. How far his pretensions
to originality of invention are warranted by his construction,
is not the object of our present enquiry.

A Compensation balance by F. Berthoud.

Berthoud informs us, "Hilt. de la Mefure, &c." p. 104
of his memoirs, that he had proposed a means of compensation by
the balance itself, so long ago as in the year 1754; but that
it was not until 1787 that he effect ed his purpose. The
reader is led to suppose, that he was not indebted to P. le
Roy, or any other maker, for the contrivance, but that it
was the result of his own inventive genius; and that the
contrivance was his own is rendered somewhat probable
from this consideration, that in his "Traité des Horologes
Marines," two balls only were proposed to be used with
two compound bars; but after a calculation of the effect to
be produced, contained in page 195 of the Supplement, four
balls were found to be necessary with as many compensating
bars. The proposed arrangement is shewn in fig. 9 of
plate XXIX, and is certainly original; A, A, A, and B
are their radial bars of metal attached to the verge collet of
the balance by two screws, as seen in the figure; the flender
bars, a, a, a, and a, attached respectively to the exterior
ends of the four radial bars by screws and fixing pieces, are
four compound bars of steel and brass, the exterior lamelle
being of brass; and each of those compound bars has at its
free end a lint formed into a screw, upon each of which a
ball, B, with a long socket, is fixed towards or from the
verge, to adjust the momentum to the maintaining power,
and regulating spring, and also to effect the equilibrium,
when the machine is brought to time. From what we have
repeatedly said of the fixture of a compound bar, it is easy
to see, that the brasses portions being exterior, will cause
the balls to approach the centre of motion in hot weather, and
the reverse in cold; which effect constitutes the compensa-
tion. The author acknowledges that the exact effect to be
produced depends on the relative length and thickness of
each compound bar, and that many trials are necessary to
come at the due proportion; consequently, the want of an
adjustment for temperature, after the balance is tried, is in
this contrivance a fundamental objection to its general
adoption; otherwise we see no reason to doubt its accuracy
of performance.

This balance was used in No. 8 of Berthoud's marine
pieces.

Another Compensation balance by F. Berthoud.

The compensation balance which we have just described
being found liable to objection, the same author contrived
and used, in his No. 63, a different arrangement of the
compensation bars, which he again reduced to two, and
introduced two additional screws for adjustment of mean time,
placed at right angles to the former; the contrivance is
shown in perspective in fig. 10 of Plate XXIX., where all
the essential parts may be viewed at once; A A is the bal-
ance, made light and of the best brass, having four cylinders;
B and D are the compensation bars fixed to the rim of the
balance at one end, and bearing the screws or weights of
temperature, C and D, at the other respective; and D
and D are the screws or weights of adjustment for mean
time, borne by two of the opposite cylinders, as shewn di-
rectly in the figure. The balance as usual is attached to
the verge collet by a couple of small screws; the exterior
lamelle of the compound bars, B and D, are of brass,
and the interior ones of steel, so that a high temperature
brings them towards the centre of motion, as the balance it-
self balances, and as its spring elongates and becomes weaker.

The adjustment for temperature may be made in two ways:
either by altering the relative sizes of the screws of tem-
perature and screws of mean time; or otherwise, which is
more readily done, by screwing one pair in and the other
out, so as to produce a similar effect without taking either
of the pairs entirely out; it is hardly necessary to explain
that, in all the constructions, when the momentum of the
balance confits more of the moving weights of temperature,
than of the moving weights of mean time, the effect of the
compensation
Compensation bars will be the greater in the same proportion, and the contrary; but, however, the quantity of flexure of the compound bars in the present balance remains unaltered, and consequently the velocity of inward and outward motion is not capable of adjustment in any other way, than by altering the ratio of their length to their thickness respectively, which may be called an alteration rather than an adjustment.

Compensation balance by Jaffet Emery.

We have said, under our article Chronometer, that Emery's balance is one of the varieties previously constructed by the senior Arnold, (see his No. 3.) and the reader will now judge for himself how far our allusion was founded in fact. We take our drawing from Berthoud's figure of Emery's balance, which Saracen took over into France, and which was much admired for the accuracy and permanency of its regulation. Fig. 11 of Plate XXIX., presents the plane of Emery's balance to the eye placed over it; A A is the balance made with four croffes, the rim of which is brass; B B is a steel flat ring screwed to two of the croffes; C and D are the two compensation bars, each bent twice over into the shape of a long narrow S; D and E are the weights for mean time, formed into adjusting screws to fuit the female frets of the protuberances made on the plane of the balance; the screws, E and D, are the adjustable weights for temperature, but are tapped only at the parts nearest their heads; the points being fast to the exterior ends of the compound bars, and the intermediate pins being without threads and moving freely in the two lockets respectively fixed to the rims, or rather formed out of them in the solid; the S pieces have the brass laminate as usual on the exterior sides, so that at the middle of the S of each compound bar, the position begins to be reversed, in order that the condition may be fulfilled; the interior end of each compound bar presses against the circumference of the fleec ring B B, which we have said is fast to two of the croffes; consequently, whenever a change takes place in the temperature of the parts, the whole motion takes place at the foot of the screw of temperature, at each opposite side of the balance. The small interior circle F is the upper end of the cylindrical spring of temperature, together with the pin that holds one end of it, and the part that forms the banking, which have nothing to do with the compensation. In this balance, as in Berthoud's latter one, the adjustment for temperature must necessarily be made, by altering the rotation of the moments of the weights of mean time, and of the screws of temperature.

Mr. W. Hardy's Compensation-balance.

Among the most recent improvements in chronometry, may justly be reckoned the new compensation-balance of Mr. W. Hardy of Clerkenwell, communicated to the Society of Arts in the Adelphi, in March 1855, and renumerated with thirty guineas. The balance in common use, that brings the weights of temperature alternately towards and from the verge, by simple fixure of the compound rings, is objectionable, in the opinion of Mr. Hardy and others, on account of these considerations: 1st, The two metals of the compound pieces of the rim, when united by fusion of the bars, are liable to partial separations, which affect the permanency of the adjustment for temperature; adly, The variation of the centripetal force of the weights of temperature in large and small area of vibration overpower the elaticity of the expansion pieces, and affect the momentum of the balance, as adjusted for mean area of vibration; the weights being thrown from the centre more in the long arcs than in the short ones; and, zndly, The adjustments for rate and temperature, however carefully made, will affect the equilibrium of the balance, and the rate of the machine placed in different positions, without subsequent rectifications; to remove these objections, Mr. Hardy has availed himself of the direct expansion of two different metals, where their difference of expansion produces a mechanical action on the loads of temperature, such as is suitable for general introduction in practice.

Fig. 3. of Plate XXX. of Horology, exhibits a lateral view of the balance before us, and fig. 4. the balance inverted; A A is the balance bar or verge of the ordinary construction; B B is a fleec diametrical bar, borne by the collet of the verge, 1.6 in. long, 0.234 broad, and 0.031 thick; this fleec bar is made uniformly except at the two extremities, which are made narrow, and in each of which a notch is cut in the inferior surface, so far, that the remaining thin metal constitutes a fitting above each notch; between these springs, which we have said form a part of each end of the diametrical bar of the balance, are attached two fleec at right angles, so as to be parallel to the verge when the small springs are not acted on by any force; the upper parts of the fleec, in the original drawing, are formed into fers with threads adapted to the tapped holes of the two balls C, C, which they support, and which are weights of adjustment for temperature, but in our more recent drawing, the weights slide and are fixed by side fers; D, I, are two similar fers for rate which screw respectively into the inferior or thicker parts of the fleec, so as to be capable of increasing or diminishing the effective momentum of the balance according to circumstances; and E, E, are fers of adjustment for equilibrium; each end of the fleec diametrical bar has, moreover, a fluid or shoulder, pointing downwards under the item just described, which fluid cannot be seen in the figure in a separate plate; underneath the fleec bar, and exactly parallel to it and to each other, are placed two bars of brass, shorter but broader than the fleec bar; the length of each is 1.47", the breadth 0.078, and the thickness 0.032, like that of the fleec; each of the two brass bars has one of its ends secured to one of the fluids described, and profiling with its opposite end against the other, but in such a way, that their positions are reverted with respect to the fixing of the ends; the fixed end of the one being contiguous to the free end of the other reciprocally; a second view is given of these bars in fig. 4., where they are represented in an inverted plate. The action of the mechanism it is not difficult to understand, though the author has rendered his account somewhat confused by his mention of short levers, which the reader does not see in the figure. When the balance is exposed to heat, the fleec bar elongates a little both ways from the verge in the centre, but the two brass bars separately elongate more, and consequently each detached end, having liberty to move a quantity equal to the difference of the two expansions, pushes against the fluid or shoulder that is contiguous, and forces it outwards; the slender fers parts, above the notches of the fleec bars, now yield to the forces impressed respectively on the fluids, and the parts of the two fers which yield may be considered as centres of motion of a pair of levers; the distance from the yielding point of each spring to the point urged by the detached end of its brass bar, may be called the length of the short end of each lever, and the distance from the said point of each spring to the centre of the load carried by the nearest item, may be taken as the length of the long end of the lever, which two ends suppose as 1 to 20 respectively; then if the difference
of the expansions of the steel and one of the brass bars be called 1 outwards, the quantity of inward motion in the same denomination will be 20; consequently, the same heat which compresses the steel bar, and carries the bars from the centre of motion, will, at the same time, by the excess of expansibility of the brass bars, bring the same bars inwards towards the same centre, and the two contrary actions may be adjusted, by moving the loads up or down their proper limit, till the opposite effects exactly balance one another; for as those inbalances that have been mentioned of the shock ends of the levers are variable in length, or very nearly so, varying the longer end on a, viz., the difference of the arc, from the middle parts of the bars, considered as centres of motion, will alter the ratio, which may be done in the requisite proportion, till the compensation is found in the tentative adjustments to be perfect. When once the exact compensation is effected, it is evident, that the law by which it is preferred is uniform and constant, as that according to which the gridiron pendulum is constructed, which experience has proved to be permanently useful in practice. When the balance has its momentum properly adjusted for rate, with a given maintaining power, escape, and balance-spring, and when the balance is put into an exact state of equilibrium, the items being at all times either exactly parallel to the verge, or, if inclined a little by the extremes of temperature, alike inclined, it is self-evident, that, under these restrictions, the adjustment of the loads up or down for temperature will not destroy the adjustments of rate, and of equilibrium for the positions, previously made, provided the two loads be of equal weight, and placed in similar positions on their respective items; and even if one happen to be a little higher on the item than the other, no sensible bad effect will be produced thereby, which circumstance is one of the greatest recommendations of the present balance. The effects produced by variations of temperature, are said to be produced not by jerks, but regularly, notwithstanding the united structure of the parts is sufficiently firm; and, lastly, the construction is so simple, that a common workman may succeed in making and putting together the constituent parts of this balance without difficulty.

Compensation on the Balance and also at the Spring.

Double Compensation by Berthoud.—F. Berthoud having experienced much inconvenience, and lost much time in making the adjustments of his balances for rate, temperature, and position, at length determined to avail himself of the curb, as a supplemental aid, in addition to the compensation carried by the balance itself; the union of the two modes of effecting the due compensation, is represented in fig. 3 of Plate XXX. of Horology, in such a way that all the acting parts may be seen and understood: A is the balance-rod or brass, and bears four croffes, besides two projecting bars, B, B; these bars carry each a compound or compensation bar, C, of the usual construction, the free ends of which are perforated and attached to the crofles or loads of temperature, D and D, or, more properly speaking, to the sliding sockets on those loads screw in and out, in making the adjustment; E and E are the crofles or loads of adjustment for mean time: F is the cock, and G a small cock, bearing a jewel mounted on it, to take the pivot of the balance. The action of the compensation bars, C and C, needs no explanation, after what we have said about the effect of such pieces borne by other balances: I, is the compensation bar of the curb for the spiral spring, shown in the figure, and acts on the bent steel bar, K, which holds the cutting pins, and which has its centre of motion

under the cock, at a short distance from the balance-verse: the quantity of action of I on K is regulated by the holding piece, a, sliding in a dove-tailed groove, between the parallel bars, b and b, screwed to the piece N, which piece, N, is movable round a pin under it, near the part, a, in such a way as to admit of a little circular motion, together with the compound bar, I, to regulate for mean time without altering the length of I; and a flow motion may be given to the piece, N, by the graduated piece, M, which is movable on the pivots of its arbor, in the plate and small cock, L, with the tooth, or rounded part, lies in a converging part of the end of N, and imparts it almost imperceptibly as the end, M, moves; the graduations of the piece, M, are seen through a hole made in the interior case of the watch; and the adjustment for rate may be made there without trouble, and without altering the previous adjustments of the balance itself; but then, if there is an isochronal point in the acting length of the spiral spring, the adjustment made by means of the curb will correct for isochronism, which will become sensible as the arc of vibration varies in use; otherwise the adjustment for temperature might be completed by varying the length of the compound-bars, I, after this adjustment has been nearly effected on the balance itself, and after the balance has been brought into a state of equilibrium for the positions; but whether the effect produced by the joint agency of two causes, will be uniform in all degrees of temperature, has not been fabled by the author.

Compensation for the Spring's want of Isochronism.

That property of a balance’s regulating spring, which makes the balance perform all its vibrations, long, short, and intermediate, precisely in the same time, is called its isochronal or isochronous property, from the two Greek words, 

iso, equal, and chronos, time: it has been ascertained that there is a certain proportion between the length and thickness of the spring, of whatever shape; this doctrine has been maintained by Dr. Hooke and Peter le Roy separately, and has been subcribed to by Arnold the senior, Berthoud, and others, though Perminow of Cambrewey says there are different points in the same spring equally isochronal; now allowing that there is only one point in the length of every spring that determines its isochronism, and that consequently all other lengths of the uniform spring regulate the balance uniformly, only while the arc of vibration remains unchanged, to determine the isochronal effective length of such spring would be to render all compensations, for want of isochronism, unnecessary, and this point may in most springs be ascertained by repeated trials with long and short arcs successively, and by marking down the respective results; for it is found from experiments, that, if shortening the regulating spring makes the long arcs of vibration be performed in less time than the short ones, and vice versa, the spring under trial is capable of having its total length reduced gradually till the isochronal length is determined, but, generally speaking, not otherwise. Another method of managing the spring, which may be said to be effecting a species of compensation for want of isochronism, in the total length of an uniform spring, is tapering it from the outer to the inner end, till, with a given length, the long and short arcs are performed in equal times; this method was strongly recommended by Cumming in his Essay towards the improvement of watch-work, and after him, Earnshaw has laid much stress on this particular, so much indeed, that he considers his skill in the adjustment of
of the ifochronism, by a tapering spring, as constituting one of his chief claims to public encouragement; nay, he professes to manage the business so nicely, that he can make such a slight deviation from perfect ifochronism as will compensate the Hillary also, in the intensity of his springs in use!

The first notice that we have of a regular compensation, for want of perfect ifochronism in a regulating spring, is Harrison's, when he proposed to introduce the cycloidal-pin which we have already confided we do not understand, from the want of shading in the drawing of it, as attached to his compensation curb, in the publication by the Board of Longitude; we may, however, state, that Harrison, not knowing, probably, that there is naturally an ifochronal length in most uniform springs, concluded, that the long arcs are naturally performed in less time than the short ones, reasoning from the circumstance of one of his pieces having been observed to go faster in a horizontal position, than in a vertical one, though the arc of vibration was shorter in the latter than in the former position; he therefore applied his cycloidal-pin, as Mudge did after him, as may be seen in the drawing of his escapement, in such a way that the short vibrations were accelerated by its push more than the long ones, that were not so long acted on by auxiliary means; but the fact is, the use of such a contrivance would necessarily have an effect just opposite to the intended one, if the balance-spring happened to be pinned to the stud at the contrary side of the ifochronal point; that is, if the long vibrations were slower than the short ones, the cycloidal contrivance would make the difference still more feltible.

Berthoud's Compensation for want of Ifochronism.

Berthoud has given an ingenious method of compensating the want of ifochronism in a balance-spring in his "Supplement au Traité des Horloges Marins," which contrivance he calls an ifochronal compensator. (Compensateur Isochron.) The contrivance is represented in fig. 6, of Plate XXX, where A represents the balance with three radii; B an eccentric collet of polished steel, placed on the balance-verse, and pressing against the large roller C, which is carried by and pivoted into a small frame at the end of the flender spring D, attached to the cock, E, on the plate of the watch frame, whenever the long vibrations are found by trial to be performed in a longer time than the short ones, the position of B and C are respectively as in the drawing, at the time when the balance-spring is quickest; for then the pressure of the eccentric piece B, against the roller urged by the spring, is greater in the smaller arcs than in the long ones; but when the long arcs are performed in the least time, the position of B must be at h, and then C will be found by the force of its spring at e, where it is evident, that the pressure will be less in the short arcs than in the long ones comparatively; and the quantity of eccentricity of B must depend on the greatest difference of the two extreme vibrations. The principal reason why Berthoud adopted this ifochronal compensator in five clocks, and in his portable watch for the longitude, was, that whenever the cock was dismounted the ifochronism of his spring, however well adjusted, was generally found to be deranged when re-mounted. The eccentric collet was of course capable of being put to any given eccentricity as well as into any given position for accelerating long or short arcs at pleasure. The English watch-makers have not, that we know of, ever used this contrivance, but depend on their own patience and skill, in ascertaining the best length and most desirable shape of their regulating springs for fulfilling their own purpose.

Mr. W. Hardy's Compensation for want of Iochronism.

Mr. W. Hardy published a short account of a new method of making the balance of a chronometer perform its long and short vibration, in the same time, in Mr. Nichol-son's Journal for September, of the year 1826, (Supple-ment vol. iv. 8vo.) Series which recent, we propose, to copy with some slight verbal deviations, that are more adapted to our figures, as drawn in perspective. The spring a b, fig. 8 of Plate XXX, is screwed to the inferior side of the cock A, fig. 7, and lies over the upper part of the regulating spring, proceeding in a right line to the axis of the balance B, and having a bend to clear the verge, from which it passes on to the end of the spring which it holds. This straight spring is made of such a small strength, that it comes into action before the regulating spring. The other piece c, fig. 8, is attached to the cock, in a line with the flender one, but on the opposite face of the cock; the part of the piece, c, which is bent down, is divided into two parts, and admits the part, B, of the flender spring, to pass and play between its prongs at each side of the prongs is a lateral screw, presenting its point to the spring, in such a way, that the play between the prongs, or rather between the points of the two equidistant screws, may be limited according to circumstances, provided they are not farther asunder than the quantity of the escapement angle. The other end of the cylindrical regulating spring, as usual, is attached to a piece of metal carried by the verge of the balance. The effect produced by the compensating spring, a b, is thus, when the balance is first moved from its place of rest, the flender spring, a b, moves first, till it meets with the point of one of the two serows of the fork, then the cylindrical spring begins to be acted on, as in the chronometers in general; this motion of the stud, at the end of the flender spring, retards the motion of the balance, which begins to be accelerated only, when the stud is at rest; consequently the contrivance before us supposes that the short arcs are in general performed in less time than the long ones; and require on that account, to be checked in their velocity at starting; and the quantity of play in the fork limits the quantity of retardation; but as we have seen the long arcs may be, and often are, performed in less time than the short ones, with springs not adjusted for ifochronism; we conceive, therefore, that, like Harrison's cycloidal pin, which owed its origin to a contrary supposition, the application of the invention we are describing may happen to be productive of an effect, just opposite to that which it is meant to produce; for it can be used as a compensation for want of ifochronism, only in the particular case, when the short arcs of vibration are performed in less time than the long ones, which we have seen is just the opposite application of that adopted by Harrison, and founded, as we have said, on an opposite supposition; whereas the fact is, that sometimes one of the two contrivances may prove to be necessary, and sometimes the other, with a limited length of spring, accordingly as the long, or the short arcs of vibration, may turn out on trial to be performed in the less time; and the trial necessary for ascertaining, whether the spring is too long or too short, will afford the means of ascertaining very nearly, if not quite, the exact ifochronal length, such as shall require no compensation at all; to attain which object, though with some additional trouble, we are disposed to think the preferable practice.
COMPENSATION-Pendulum, is a superior kind of pendulum in which the natural effects of two actions are so opposed to each other, as to counteract or compensate each other’s influence on the motion of the going pendulum. We have already described the grid-iron pendulum invented by J. Harrison, and also Troughton’s new arrangement of the metallic bars, under our article Clock, to which we must here refer; and for the other various constructions of a compensation-pendulum the reader is referred to the word Pendulum, where he will find the subject treated at considerable length.

COMPETORIUM, in the Civil Law, denotes a judicial inquest made by delegates, or commissioners, to find out, and relate the truth of a cause.

COMPETENCE, or COMPETENCY, in Law, the authority, or right of a judge, for taking cognizance of any matter. See Jurisdiction.

COMPETENCY Militaire, Fr. military jurisdiction. In France, the officer of the troops took cognizance of, and pronounced the right of directing the process or proceedings in regard to every thing that concerned military affairs and offences, unless the proceedings were punishable by the provost marshal, and to judge of all crimes and offences committed by an officer against an officer, or by a soldier against a feldar against a civil individual had no concern or interest in it. And if the civil judges were obliged to caufe military persons to be arrested, the commands could demand them, and in case of refusal complain to the sovereign through the minister.

COMPETENT Witness. See Witness.

COMPETENCES, in Church History, an appellation given to the catechumens, when being sufficiently instructed in the Christian religion they required baptism.

COMPÉYRE, in Geography, a town of France, in the department of Aveyron, and district of Millau; one league N. of Millau.

COMPÉHDA, a town of Arabia Felix on the Red Sea, S.E. of Mecca, garrisoned by the Turks.

COMPIONO, a town of Italy, in the duchy of Parma; 12 miles from Ponsremoli.

COMPILATA, Ital. Compilis, Fr. The last prayer or hymn sung in full chorus, at the end of the service of the Roman church.

COMPiegNE (in Latin, Compudium), a handsome town of France, the chief place of a district in the department of Oise, situated on that river at the distance of two kilometres from the confluence of the Oise with the Aisne and 70 kilometres from Paris. N. lat. 49° 25', E. long. 3° 12'. A very extensive forest stretches from this town to the department of the North and that of the Lys. Before the revolution of 1789 the kings of France resided occasionally at the palace of Compiegne to take the diversion of hunting. This palace was built by Charles the Bald, repaired by several of his successors, and reconstructed on a grand scale in 1755 by Louis XV. There is also a beautiful bridge over the Oise which formerly was adorned with the arms of France elegantly carved in stone by Coustou: but this fine monument was mutilated in 1793 by a revolutionary stone-cutter, who put up a cap in its place. Compiegne has a sub-prefept, two courts of justice, and 63,599 inhabitants. The district contains a population of 88,045 individuals, distributed in 165 communes. Its principal trade is in wood, corn, and wool. Its wine is much esteemed. There are but a few manufactures of wove caps and stockings.

COMPITALIA, or COMBITILIA, feasts held among the ancients in honour of the Lares.

The word comes from compitiurn, a crowd-toay; because the feast was held in the meeting of several roads.

The compitalia are more ancient than the building of Rome. Diodorus Siculus, and Pliny, indeed, say that they were instituted by Servius Tullius; but this only signifies, that they were then introduced into Rome.

Notwithstanding what Di in relates, that the compitalia were celebrated a little after the Saturnalia, and that the Roman calendar fixes them on the twelfth of January, it appears that they had not fixed any day at least not till the time of Varro, as is observed by Cæs.ambon.

The feast being then movable, the day whereon it was to be observed, was proclaimed every year. It was ordinarily held on the fourth of the nones of February, i.e. on the second of that month. Macrobius observes that they were held not only in honour of the lares, but also of mania, madness.

The priests who officiated at them were slaves and liberti; and the sacrifices were few. They were re-established, after a long neglect, by Tarrquin the Proud, on occasion of an answer of the oracle, "That they should sacrifice heads for heads," i.e. that for the health and prosperity of each family, children were to be sacrificed: but, Brutus, after expelling the king, in lieu of those barbarous victims, substituted the heads of garlic and poppy; thus satisfying the oracle, which had enjoined capita, beides, at an earl rate.

During the celebration of this feast, each family placed at the door of their house, the statue of the goddess Mania; they also hung up at their doors figures of wool, representing men and women; accompanying them with supplications that the Lares and Mania would be contented with these figures, and spare the people of the house.

As for slaves, in lieu of the figures of men, they offered balls or flaxs of wool. Servius Tullius ordered, that the slaves who affiliated at the compitalia, should be free during the whole time of the feast. Augustus ordered the flaves of the Lares, placed in the crofs ways, to be adorned with flowers twice a year.

COMPLACENCY, in Pathology and Ethics, denotes full and continued satisfaction, connected with a considerable degree of approbation. It has intrinsic value, or some species of worth for its object. Some mental excellencies, or advantages accruing from them; some sentiment, dispositions, and sentiments, approved by others or others with whom we are immediately connected, which, upon close examination, we deem deserving of esteem or applause. Complacency may be enjoyed as the reward of our own conduct, or of the purity and benevolence of our motives; and it may also relate to the approved conduct, sentiments, attainments, and dispositions of others, for whom we are deeply concerned. The satisfaction produced by complacency indicates, that we have, in some respect or other, a personal interest in the object of it; and the approbation implied in it conveys the idea of some kind of excellency. In strict propriety of language, complacency is alone applicable to that species of good which originates from some mental or moral excellency; where there is an indication of property, ingenuity, wisdom, address, or dignity, in sentiment, design, execution, or of rectitude and benevolence in the motive, this affection will profess different degrees of strength, according to the various kinds and degrees of excellency discernible in the existing cause; and high complacency is the most grateful of all the affections. It poises an elevation and a favor peculiar to itself. It is a permanent satisfaction, enjoying the full approbation of reason; and consequently it suffers no alloy from the struggle of contending passions, or opposite desires. When it is in-
spired by our own conduct, it is accompanied by self-approbation, or the testimony of an applauding conscience, enlivened perhaps by the voice of gratitude, and enriched by the eftect of the worthy. If it proceed from the conduct of others, it augments the pleasures of affection, friendship, and gratitude. This affection, however, has its counterpart; and an erroneous opinion of ourselves may change the nature of this sublime affection, and render it the parent of vice and folly. Thus false conceptions of our own talents, acquirements, and conduct, may inspire pride, vanity, haughtiness, and arrogance. Cogan on the Passions, p. 71.

COMPLAINANT, in Law, a plaintiff, or one who prefers a complaint against another, to be relieved by justice or equity.

COMPLEMENT, in a general sense, denotes what is wanting, or necessary to complete some certain quantity or thing.

COMPLEMENT, Arithmetical. See Arithmetical.

COMPLEMENT, in Astronomy, is used for the distance of a star from the zenith; or the arch comprehended between the place of a star above the horizon, and the zenith. It is the same as the complement of the altitude, or co-altitude; or zenith distance.

COMPLEMENT of the course, in Navigation, is the number of points the course wants of 90 degrees, or eight points; viz., of a quarter of the compass.

COMPLEMENTS of the curtain, in Fortification, are those parts of the side of the interior polygon, which form the demi-gorges of the two bastions adjoining the curtain.

COMPLEMENT of the line of defence. See Line of defence.

COMPLEMENT, in Geometry, is what remains of a quadrant of a circle, or of ninety degrees, after any certain arch has been retracted from it. Thus, if an arch or angle be 30 degrees, we say its complement is 60 degrees, since 60 + 30 = 90.

The line of the complement of an arch is called the con- fuse of a tangent, the co-tangent, &c.

We sometimes also say the complement of an angle; meaning so much as it wants of a right angle, or of 90 degrees.

COMPLEMENT, in Heraldry, a term used to signify the full moon, for example, azure, the moon in her complement, and argent the crescent.

COMPLEMENTS of a parallelogram, are the two lesser parallel sides, made by drawing two right lines parallel to each side of a parallelogram, through a given point in the diagonal.

Such are the parallelograms C and M (Plate III. Geometry, fig. 50.) It is demonstrated, that in every parallelogram, the complements C and M are equal: for \( Z + C + \theta = R + M + \tau \); as making up on each side the great triangles, made equal by the diagonal; of which, \( Z = R \), and \( \theta = \tau \) (because the diagonal makes them so); wherefore the remaining parallelogram \( C = M \).

COMPLEMENT of life, in the Doctrine of Life Annuities, denotes the difference, according to M. De Moivre's hypothesis, between the age of any given life, and 86 years; thus, at the age of 50 the complement is 36—at the age of 37 it is 40—at the age of 50 it is 36, and so on. In this hypothesis the probabilities of life through every period of existence, are supposed to decrease in an arithmetical progression, so that out of 86 persons just born, one is supposed to die every year, till at the end of 86 years, which is considered as the utmost limit of humane life, the last survivor becomes extinct. M. De Moivre, who formed this hypothesis with the view of facilitating the computations of life-annuities, derived it from Dr. Halley's "Table of Observations," at Breslaw, which being the only table of the kind at that time, and making the decrements in the middle stages of life nearly equal, so far supported the truth of the hypothesis, and induced M. De Moivre in adopting it. But in the earlier and later periods of life the decrements are so irregular as by no means to accord with this hypothesis; and since subsequent tables, more accurately formed, and deduced from more extensive observations, have been published by Dr. Price, Metfis, Wargentin, Supmilch, and other writers on the subject; and the values also of single and joint lives for all ages have been computed from them; this hypothesis is rendered unecessary, even in cases where it is most correct; in other cases, which involve two or three lives in the quotion, especially if those lives be very young or very old, it gives solutions so inaccurate as to be altogether unfit for use.

By supposing an uniform decrement in the probabilities of life from infancy to extreme old age, the number of years which a person has an equal chance of surviving is made to be the same with the expectation which M. De Moivre by his hypothesis finds to be equal to half the complement of life; that is, if the age be four, the expectation will be \( \frac{86}{2} = 43 \); if the age be 82, the expectation will be \( \frac{86}{2} = 53 \), while the chance that a child aged 4 survives 41 years is \( \frac{2}{3} \), and the chance that a person aged 82 survives 2 years is \( \frac{2}{3} \). Now since each of these fractions is \( \frac{2}{3} \), it follows, agreeable to what has been observed above, that the one has an equal chance of living 41, and the other of living 2 years, or such a number as shall be expressed by their respective expectations. But by the Breslaw table the expectations of those lives are severally 40\(\frac{2}{3}\) and 31\(\frac{3}{4}\) years, while the chance of the younger living 40\(\frac{2}{3}\) years is 0.641, and the chance of the elder living 31\(\frac{3}{4}\) years is 0.53: that is, in the first instance, the chance is less, and in the second greater, than an even one, that the person lives such a number of years as shall be equal to his expectation. This is true in all other tables deduced from real observations, and proves that even in the simplest case the hypothesis is incorrect.

Mr. Thomas Simpson, instead of supposing the complement to be the difference between 86 and the age of the given life, assumed this complement to be equal to twice the expectation when computed from a table of the real probabilities of life, and by this means believed the inaccuracies of those rules which depended entirely on M. De Moivre's hypothesis. But had this excellent mathematician been poissied of the present tables of observation, there is no doubt but that he would have adopted a more genuine method of solution. As far as relates to the computation of the probabilities of survivorship between any given number of lives, M. De Moivre's hypothesis in many cases appears to give approximations which are sufficiently near the truth; but as the mere determination of such probabilities is of no use in computing the values of contingent reversions, inasmuch as the discount of money must be blended in each separate year with the chance of survivorship in that year, the investigation of them is a matter of no consequence, and therefore the hypothesis of an equal decrement, which often leads to great errors in the doctrine of life annuities, may be wholly laid aside without injury or inconvenience in any case. (See Phil. Transactons, vol. 75.)

COMPLEMENT of a Chord, in Music, the note or notes wanting in any chord, to complete its harmony.

COMPLEMENT of an Interval, is the minute quantity it wants in particular temperaments.

COMPLEMENT, is the difference or remainder between an octave or eighth, and any given interval, called also the inversion of that interval, (see Inversion); thus, a
fifth is the complement or inversion of a fourth, and a fourth
of a fifth; a minor third is the complement or inversion of
a major fifth, and vice versa. See Third, Fourth, Fifth.

COMPLETE, in French complet, in Military Language, a
regiment, troop, or company is said to be complete when it
has its full complement of officers, non-commissioned officer,
and privates, separately to the regulations for the time being.

COMPLEMENTS, in Botany, a complete flower, for-
mixed with both calyx and corolla: incomplectus being used
when the latter is deficient, and inchoate when the former.

COMPLEX, a term ordinarily used as synonymous with
compound; though, strictly speaking, there is some differ-
ence between them.

COMPLEX object. See Object.

Complex opposition. See Opposition.

Complex term, or idea, is a term or idea compounded of
several simple or incomplete ones.

Thus, in the proposition, A just God cannot leave crimes
unpunished, the subject of this proposition, viz. a just God,
is a complex term, or stands for a complex idea, composed of
two simple, or incomplete ones, viz. God and just. Mr.
Locke observes, that though the mind be perfectly passive
in the formation of simple ideas, yet it exerts several
actions of its own about them, when once formed: and
that by this means it is, that they become the materials and
foundations out of which all our knowledge is framed.

These acts are chiefly three, viz. 1. The combining of
several simple ideas into one compound one: and thus it is
that all complex ideas are made.

2. The bringing two ideas, whether simple or complex,
together; setting them by each other, and viewing them,
without uniting them into one; by which it gets its ideas of
relation.

3. The separating several ideas from all other ideas that
accompany them in their real existence: and thus all its
general ideas are formed.

As simple ideas are observed to exist in several combina-
tions united together; so the mind may consider them as
united, not only as they are really united in external objects,
but as itself has joined them: ideas thus made up of several
simple ones put together, we call complex; as man, beauty,
army, gratitude, &c.

Complex ideas, however compounded and decompounded,
though their number be infinite, and their variety endless,
may be all reduced under these three heads, viz. modes, sub-
stances, and relations: which see under their proper heads,
Mode, Substance, and Relation. Complex ideas are
often considered as simple and distinct beings, though made
up of several simple ideas; as body, spirit, &c. See Com-
position of ideas.

Complex proposition, in Logic, is that in which the sub-
ject, or predicate, or both, are made up of complex terms:
and if the term added to the subject be essential or necessary
to it, then it is called explicative; otherwise it is determina-
tive, the adjoined term limiting the subject to a particular
part of its extension. Some logical writers ascribe the
complexion of a proposition, in some cases, to the copula,
as in modal propositions: but this rather pertains to the
predicate. See Compound and Modal Proposition.

Complex figure, is that in which the middle term is
not connected with the whole subject, or the whole predi-
cate in two distinct propositions, but is intermingled and
compared with them by parts: e.g. The sun is a fenfeles-
se being, the Persians worshipped the sun, therefore the
Persians worshipped a fenfeless being.

COMPLEXI PART, in Anatomy, a name given by Rio-

lanus, and others, to a muscle called by Albins Iliacer
cervicis, and by some the complexus.

COMPLEXIO, COMPLEXUS, in Metaphysics, the union,
or coalition of several things different from each other;
either really, or only in our conception. See Complex.

Complexus, in Logic, is a compound word applied to the second
operation of the mind, viz. the judgment; considered as
it affirms or denies anything; such affirmation, &c. necess-
arily importing a combination of several things.

Complexus is sometimes also used by logicians in the sense
of dilemma.

Complexio, in Rhets, &c. is a figure including a re-
petition, and a conversation at the same time; the sentence
both beginning, and ending, with the same word.

Thus Tully: "Quis legem tulit?" Rutius. "Quis ma-
jorem partem populis fuisse privavit?" Rutius. "Quis
cominitis probavit?" Rutius.

COMPLEXION, in Physic, is used for the temperature,
habit, or natural disposition of the body.

Some philosophers distinguish four general and prin-
cipal complexions in man, viz. the sanguine complexion, which,
according to them, answers to the air; having the quali-
ities thereof, as being hot and moist. It takes its name
from sanguis; because the blood is there supposed to be pre-
dominant.

The phlegmatic complexion takes its name from the phlegm,
or phlegm, in which it abounds; and corresponds to water;
being cold and moist.

The bilious, or choleric complexion, takes its name from the
bile, or cholera: it is supposed of the nature of fire, hot and
dry.

Lastly, the melancholic complexion partakes of the nature
of earth, being cold and dry; but this sort of reasoning is
now not much regarded.

Under this article we may introduce a subject that has
occasions much dispute, and considerable difference of
opinion among physiologists. It relates to the variety
of complexion or of colour that has subsisted amongst the
inhabitants of different nations. Some persons, disapprov-
ing the several hypotheses that have been suggested for
explaining this phenomenon, have been led to conceive
that there is a specific difference in the human race, and that
the variations of colour are owing to their not having sprung
from one common original. But this hypothesis contradicts
the most ancient and authentic history extant, which repre-
sents Adam and Eve as the progenitors of all mankind;
and it is also liable to various other objections which we
shall take occasion distinctly to specify in the course of this
work. Dr. Hunter, who has published a thesis on this sub-
ject, has investigated it with particular attention; and he
gives it as his decided opinion, that there is no specific
difference among mankind. In order to guard against the
confusion which has arisen from the use of the term "spe-
cies," he begins with defining it, and he comprehends un-
der the same species all those animals which produce issue
capable of propagating others resembling the original
flock, from which they sprung. According to this sense of
the term, he considers the whole human race as belong-
ing to the same species. But, as in the vegetable creation,
one species of plants includes several varieties depending
upon climate, soil, culture, and similar circumstances that
are incidental, the case is the same with respect to the
human race; the varieties that occur pertain to the same
species, and are produced by the operation of natural causes.
Of the different colours that subsist among mankind, he
enumerates the following, viz.
In tracing the causes of these differences of colour, he sets out with observing that its fect is unquestionably in the skin; that it is confined to the cuticule, consisting of the epidermis and reticulum; and that it chiefly occupies the latter of these. The cuticule, he observes, is much thicker and harder in black than in white people; the reticulum in the latter being a thin mus, is the former a thick mem brane.

The cut of colour in whites he conceives to be transparent, and either totally deprived of vessels or furnished with a very few; the yellow colour appearing in the human cuticule when the cause of the diffuse is removed, which is not the case with a skin in the cuticule from gun-powder, or similar causes. He then mentions three causes, which contribute to destroy the pelliculity of the cuticule, to give it a brown colour, and to thicken it; i.e. access of air, nailes, and the heat of the sun: the effect of these is illustrated by examples; but he apprehends the last to be the most powerful. Admitting such influence of these causes, he supposes it to be sufficient to account for all the diversities of colour, which are observable among mankind. He proceeds to observe, that all the inhabitants of the torrid zone incline more or less to a black colour; and the difference that is perceivable among them may be owing, not to mere heat, but to the other causes also; and if we consider that even in the torrid zone there is a considerable difference of temperature, the existence of a white nation in this climate would not destroy the argument. He is far from opinion, that the existence of a black colour, and of considerable varieties from white, is the nor the innate and collect parts of Europe, may be very easily explained, by ad verting to the manner of life of the inhabitants, who of course are either exposed to the inclemency of the air, or to the constant mists of smoky houses. If, to this reasoning, it should be objected, that infants are subject to these differences even when they are born, and previously to the influence of the causes above mentioned, Dr. Hunter replies, that many peculiarities acquired by parents are transmitted to their posterity; in proof of which, he refers to hereditary defects, which will continue to infect families for many generations. Thus, a parent exposed to causes that destroy the natural whiteness of his complexion, will beget swarthy children; and the same causes continuing to operate upon the son, the blackness will be increased. In this manner, all the different shades may have been at first induced, and afterwards continued. To this objection, however, it might be anwered, that the fact is not admissible; as it is now generally allowed, that the children of the blackest negroes are born white.

Mr. Clarkton, in a dissertation introduced in his "Effay on the Commerce and Slavery of the Human Species," has considered and well illustrated the subject of complexion. In the investigation of this subject, the first question that occurs relates to the precise tint of the colour. As the old anatomists commonly divided the skin into two parts or lamina, viz. the cuticule and cutis or true skin, they must have supposed, that as the latter is the fame in all the varieties of mankind, however different their external hue, the fact of colour must have existed in the cuticule or upper surface. Malpighi, however, discovered that the skin is divided into three lamina; viz. the cuticule, the true skin, and a kind of coagulated substance situated between both, which he denominated the "rete mucosum." Accordingly, this discovery served to ascertain the point in question; for it afterwards appeared, that the cuticule, separated from the other lamina, was semi-transparent; and that the cuticule of the blackest negro was of the same transparency and colour with that of the purest white; and as the true skins of both were invariably the same, the rete mucosum must be the fact of colour. That this is the fact has been also determined by a variety of anatomical experiments and physiological observations. The causes, therefore, that operate in producing difference of colour, must affect it by acting on the rete mucosum, which, from the numberless perforations of the cuticule, is no less accessible than the cuticule itself. These causes are probably those various qualities of things which, combined with the influence of the sun, contribute to form what is called "climate." Moreover, it is a further confirmation of this hypothesis, that the mucous substance before-mentioned is subject to variation, according to the difference of climates from the equator to the poles. Thus, the inhabitants of many kingdoms and islands of Asia are found to have their rete mucosum black; those of Africa, situated near the line, are of the same colour; those of the maritime parts of the same continent, are of a dusky brown, nearly approaching to it; and the colour becomes lighter or darker, in proportion as the distance from the equator is either greater or less. The Europeans are the fairest inhabitants of the world; those situated in the most southern regions of Europe, have in their rete mucosum a tinge of the dark hue of their African neighbours. Admitting these facts, we are led to conclude, that climate has a very considerable influence in occasioning a difference of colour. It has, however, been objected to this reasoning, that people of the same climate, geographically considered, or under the same parallel, are not exactly of the same colour. But to this objection it has been replied, that climate, physically considered, depends upon a variety of accidental circumstances. See Climate.
COMPLEXION.

of the same parallel are not exactly of the same hue, yet they differ only by certain tints of the same colour; and, therefore, if climate has really an influence on the mucous substance of the body, we must expect to find not only a gradation of colour in the inhabitants from the equator to the poles, but also different shades of the same colour in the inhabitants of the same parallel. We might also add another argument of great weight, viz., that when the black inhabitants of Africa are transplanted to colder, or the white inhabitants of Europe to hotter climates, their children, born there respectively, are of a different colour from themselves, that is, lighter in the first, and darker in the second case. To this purpose the able Raynal observes, that the children, which the Africans procreate in America, are not so black as their parents were; and that after each generation, the difference becomes more palpable. It is possible, he adds, that after a numerous succession of generations, the men come from Africa would not be distinguished from those of the country into which they have been transplanted. If we admit the fact above stated, that climate has an influence on the mucous substance, we may reasonably imagine that this variation of the colour of children from that of their parents must take place; for being born white, and not being subject to the influence of causes equally powerful in colder climates, with those to which their parents were subject in the hotter climates from which they were removed, it must follow that the same effect cannot be produced.

On the other hand, we may here allege an important fact, stated by Dr. Mitchell (Phil. Trans. N. 470. § 4.), "The Spaniards," he says, "who have inhabited America, under the torrid zone for any time, are become as dark-coloured as our native Indians of Virginia, of which I myself have been a witness; and were they not to intermarry with Europeans, but lead the same rude and barbarous lives with the Indians, it is very probable that, in a process of many generations, they would become as dark in complexion." Another writer, describing the European settlements on the African coast, observes, that "there are several other small Portuguese settlements, and one of some note at Mitomba, a river in Sierra Leone; the people here called 'Portugueze' are principally born from a mixture of the first Portuguese discoverers with the natives, and now become, in their complexion and woolly quality of their hair, perfect negroes, retaining, however, a smattering of the Portuguese language." Another circumstance might also be mentioned by way of corroborating the argument before us; and this, that the members of the same family, separated from each other, and migrating into different countries, have not only changed their family complexion, but have assumed as many different colours as the different regions of the globe in which they have settled. The Jews furnish a remarkable instance to this purpose. These people, though scattered over the face of the earth, preserve themselves a distinct people, and never intermarry with any out of their own body, so as to have any mixture of blood in their veins, by which they should differ from each other; and yet it is an undoubted fact, that the English Jew is white, the Portuguese swarthy, the Armenian olive, and the Arabian copper-coloured; and there appear to be as many different species of Jews as countries in which they reside. It appears further from the testimony of the most ancient historians, that the darkest black complexion has actually changed in a succession of years into the purest white. Herodotus informs us, that the Colchii were black and that they had cropped hair. These people were a detachment of the Ethiopian army under Scylax, who followed him in his expedition, and settled in that part of the world where Colchian is said to have been situated. Their descendants probably remained in the same country. If this be the case, they must have totally changed their complexion; or the black inhabitants of Colchis must have acquired the hue of the fair Circassian. If indeed they migrated in any one direction from Colchis and to any distance within 1200 miles of Colchis, still they must have changed their colour; for if they had gone in an eastern or western direction, their colour must have been the same as that of the Circassians; if to the north, whiter; and to the south, of a copper colour. Within the above alligned distance of Colchis, there are no black people.

Professor Zimmermann of Brunswick, in his work entitled "The Geographical History of Man," has satisfactorily proved, that the complexion of the human species uniformly corresponds to the degree of heat or cold to which they are habitually exposed. In establishing this position, he differentiates between climates, considered geographically and physically, and thus furnishes an answer to the erroneous reasoning of Lord Kames on this subject. At Senegal, and in places adjacent, the thermometer is often at 112 or 117 degrees in the shade; and here we find the inhabitants jet-black with woolly hair. The heat is equally great in Congo and Loango, and these countries are inhabited by negroes only; whereas in Morocco to the north of these regions, and at the Cape of Good Hope, to the south, the heat is not so intense, nor are the inhabitants of so deep a hue. Lord Kames asks, why are not the Abyssinians and the inhabitants of Zaara as dark a complexion as the Moors on the coast of Guinea? Zimmermann replies, that these countries are much cooler. The defect is not only further from the equator, but the winds blowing over the Atlantic mountains, which, like the Alps, are covered with snow, and the westerly wind coming from the sea, very much mitigate the heat. Nor is Abyssinia so warm, as other Monomotapa or Guinea. The N.E. winds from the side of Persia and Arabia are cooled by their passage over the Red Sea; the northern winds of Egypt lose much of their heat on the chain of mountains that is extended between the countries; the winds from the south and west are sea winds. Thus the only quarter from which they can derive efficaciously heat is from the west, as the air on this side passes over tracts of heated lands. For a similar reason negroes are not found either in Asia or South America, under the equator. These countries, as M. Zimmermann observes, being exposed, from their situation, to sea breezes and cooling winds from the continent. He also observes, in confirmation of this hypothesis, that the mountaineers in warm climates, as in Barbary and Ceylon, are much fairer than the inhabitants of the valleys; that the Saracens and Moors, who conquered the N.E. part of Africa in 1700, from being brown, are become like the negroes near the equator; that the Portuguese, who settled at Senegal in 1449, became blacks; and it is averted by Tudela the Jew, that his countrymen in Abyssinia acquired the dark complexion of the conquered nations.

Upon the whole it may be observed, that colour is a kind of habit of the body, which is gradually acquired, and after a succession of ages, fixed and rendered permanent. Thus, the vague countenance will be perpetual in the highest latitudes of the temperate zone, and, as we descend to the south, we shall find the swarthy, the olive, the tawny, and the black. The uniformity of the effect in the same climate, and on men in a similar state of society, proves the efficacy and the certainty of the cause. As mankind are for ever changing their habitations by conquest or commerce,
merce, we find that, in all climates, they cannot endure the change, but are so affiliated by time, that we cannot say with certainty, whose ancestor was the native of the clime, and whose progenitor was the invading foreigner. For a further illustration and confirmation of the general arguments comprehended in this article, we refer to an "Effay on the Causes of the Variety of Complexion and Figure in the Human Species" by Dr. Smith, professor of moral philosophy in the college of New Jersey. See Neogene.

COMPLEXUS MUSCULUS, in Anatomy, derives its name from the intermixture of tendon with its muscular fibres, which gives to its surface a confused appearance. It arises from the transverse processe of five, six, or seven of the upper dorsal vertebrae, by so many distinct slips; from the transverse processe of the last cervical vertebra; and from the oblique or articulating processe of the fifth, sixth, and seventh vertebrae of the neck. The fasciculi of fibres from these numerous points of origin meet together to form a broad, flat, and strong muscle, which is inserted into the hollow in front of the external transverse ridge of the bone. It sometimes receives a small flabby portion from the spinous processe of one or two of the upper dorsal vertebrae; and is generally connected in some degree with the longissimus dorsi facrolumbalis and transversalis coli. That portion of the muscle, which is towards the spines of the vertebrae, is divided into two flabby portions by an intermediate tendon, and is separable from the rest at its origin; this is described by Albinus, Soemmerring, and others, as a distinct muscle, by the name of biventer cervicis: we follow Cowper, Douglas, and Winslow, in considering this as a part of the complexus, since it is always connected to the rest of the muscle, for two or three inches before its inception.

The action of the complexus consists in carrying the head backwards upon the atlas; and in restoring it to the erect position, when it has been bent forwards. Its longest fibres will also have the same effect on the neck, viz. that of straightening and carrying it backwards.

COMPLINE, in Ecclesiastical Antiquity, denotes that evening, which completed the whole service of the day in religious houses, and began at nine of the clock at night.

COMPLUTENSIAN BIBLE. See Greek Bibles, and Polyglott. The Complutensian edition of the Bible, which the reader will find described and particularly noticed, under the articles to which we have referred, has been highly extolled by Mill and Goetz, and as much depreciated by Wetstein and Semler. Michaelis, in the second edition of his "Introduction," &c. endeavoured to ler it a middle course between the opposite opinions of Mill and Wetstein; though he believed, on the authority of the latter, that the editors, actuated by religious zeal, had materially altered the Greek text from the Vulgate. But Goetz, he says, in his "Defence of the Complutensian Bible," printed at Hamburgh, in 1761, has enabled him to form a proper judgment of that work; and he acknowledges, that he had too closely adhered to the opinion of Wetstein, after the perusal of the following publications by the same author, &c. "Complete Defence of the Complutensian Greek Text, with a Collection of the principal Differences between the Greek Text, and the Latin Text of that Edition," printed in 1766, and the "Continuation of the Defence of the Complutensian Greek Testament," &c. published in 1769. Michaelis, having since had access to the Complutensian bible in the university library of Gottinges, has particularly used it in the Greek version of Genesis, the Proverbs of Solomon, and the first book of the Maccabees; and in these books he has found its reading as pure, and as little altered from the Latin, as Goetz had described them. It has been questioned what were the MSS. from which this edition was prepared, and whether the editors had any besides those which were sent to them from Rome; the silence of the editors is no proof of the contrary, for they make no mention of the Codex Rhodensis, which had been presented to Cardinal Ximenes, though Stunica, in his controversy with Erasmus, frequently applies it to, as a MS. used in the Complutensian edition; and the Codex Jefferisonianus, which was used in the Septuagint, had been presented to him, by the senate of Venice. Moreover, as the New Testament was begun in 1503, it is wholly incredible that they should have had no other MSS. than those sent from Rome, because Leo X. who communicated these MSS. was not pope before the year 1513, and the subscription at the end of the Revelation bears date January 10, 1514. If, therefore, the MSS. were sent by Leo X., they must have arrived when at least three parts of the Greek Testament were already printed, and yet the editors, at least in the preface, mention no other MSS. One mode, says Marth, in his notes on Michaelis's translation, of solving this difficulty is, to suppose that MSS. were sent from Rome by Julius II. the predecessor of Leo X., and that the writer of the preface to the Complutensian Greek Testament, who knew that the latter was at that time pope, but, perhaps, was ignorant how long he had reigned, committed an anachronism in ascribing to Leo X. what had been done by Julius II. Or, perhaps, he knew that there was no MSS. in the Complutensian edition; and the Codex Rhodensis, had other MSS. of the Greek Testament, which had been procured by the cardinal. But whether they were ancient or modern, of great or little value, it is difficult to determine, as the editors have given no account of them. Wetstein thinks they were modern, because the readings of the Complutensian bible have a remarkable agreement with those of the MSS. written in the 14th, 15th, and 16th centuries; and this opinion is confirmed by the shape of the types, for they are such as we find in the most modern MSS.; and it is probable that the editors had their types cast in imitation of the MSS., which they employed on the occasion. Michaelis, however, in this account of the types, is not quite accurate; for of all the specimens of Greek hand-writing, which Montfaucon has given in his "Palaeographia Graeca," from the first introduction of the small letters down to the 15th century, none resemble the types of the Complutensian edition more than that which is found in MSS. of the 9th century. On the other hand, letters not very unlike the Complutenian are found in MSS. of the 11th, 12th, and even 13th centuries. Moreover, as no MS. written in such letters, as are used for the Complutensian edition, is without accents, and the editors appeal not to the MSS. which they actually used, but...
but to the poems of Callimachus, and the Sibylline prophecies, there is reason to suspect, that their MSS. had accents, and consequently were modern. Accents, however, if it be allowed that the Complutenian edition had them, though it has been generally said (not judiciously) that it is printed without them, afford no proof that a MS. is modern; for they are found in several very ancient MSS. written even with uncial letters, as the Vaticanus, Claromontanus, &c. and perhaps, says Mr. Martin, there are as many ancient MSS. with uncial letters, which have accents as those which have not.

With regard to the main question, whether the MSS. used by the Complutenian editors were ancient and valuable, Mr. Martin candidly acknowledges that he is too little acquainted with the Complutenian Bible to be able to form any judgment; and he therefore contents himself with observing, that Grebich accedes to the opinion of Wetstein and Semler, and says, in the preface to the second volume of his Greek Testament (p. 16): "Complutensia non habuerunt codices Graeci, nulli pauciores, recentiores, exiguis fere, sed hebraicum bonitatem fructus, prout." It has been suggested, that the Complutenian editors, in consequence of a too high opinion of the Vulgate, and a mistaken zeal for the Christian religion, have sometimes introduced into the Greek text readings of the Vulgate, which they did not find in the Greek MSS.

The Greek text of the disputed passage, 1 John, v. 7, in the Complutenian edition, seems to have been a mere translation of one of the editors; because the passage is found not in a single ancient, and in only two modern MSS. the Montfortianus and the Ravianus, the latter of which is only a copy of this edition; and in the former, the text is very different from that in the Complutenian edition. It cannot, therefore, as in the third edition of Erasmus, have been taken from this MS.: though, on the other hand, it is not impossible that they found it in some modern with others, as in the passage, as in the codex Montfortianus, had been already translated. The question can never be decided, because the MSS. which they used are either destroyed, or are at least unknown. For an account of the fate of these MSS. see the article ALCALA. Michaelis candidly explains the conduct of the Complutenian editors so as to remove the charge of dishonesty. They might believe, he says, that this passage was really genuine, and, on account of its supposed importance, take no notice of its alteration from the Greek MSS.; in the same manner as the verse has been inserted by later editors in Luther's version. Or, they might have made some remarks on it, which were afterwards erased by the censors of this edition; for, contrary to their usual custom, they have a marginal note on 1 John, v. 7., which is in itself unimportant, and almost implies that something originally preceded. If they have taken the passage from a modern MS., they have only acted like Erasmus, who has inserted it on the authority of a very modern MS. which he had never seen. In short, many of the best editors have been guided in this passage by a mistaken zeal for the Christian religion, and have acted on principles which they have never admitted in other places. It was the principal object of Goeze to support the authenticity of this passage, and as it occurs in the Complutenian Bible, he defended the antiquity and value of the Greek MS. from which he supposed that passage had been taken. On the other hand, Semler's object was to show the spuriousness of this passage, and at the same time to support the opinion of Wetstein, that the text of the Complutenian Greek Testament, in general, is of little value. The genuineness of this passage is now generally exploded by the most approved biblical critics.

The Complutenian edition is extremely scarce, because only 600 impression were taken off, and it is become too expensive for a private library. That which is now at Gottingen cost 400 florins, and the late Michelken gave an order to his commissari not as far as 1602; and the price of it, says Michaelis, will still increase, in proportion as its great excellence, especially in the Septuagint, shall be better known. Mill, Bengelus, and Wetstein, have collected this edition as a MS with great diligence; but their extracts are by no means complete. Goeze has also given extracts from it, in his "Complete Defence of the Complutenian edition," (p. 277), which, in the proper sense of the word, may be called critical, and which no future editor of the Greek Testament ought to leave unnoticed. Michaelis thinks, that a real service would be rendered to those who are engaged in sacred criticism, if a new edition both of the Greek and Latin Testament was published, that was an exact copy of the Complutenian. From the Greek text of the Complutenian edition were printed the following, viz.: seven at Antwerp in 1564, 1571, 1574, 1599, 1601, 1603; five Geneva editions in 1569, 1619, 1622, 1628, 1632; and, lastly, that of Mavortius, in 1753. These are all described in Le Long Bibl. Sacra, ed. Masch. P. i. p. 191-105. See POLYGLOT.

COMPLUTICA, a town of Spain in the Tarragonensis, placed by Ptolemy in the country of the Callaici, and thought to be the present village of Compludo, in Galicia. It is marked in the chart of M. d'Anville on the right of the Durus, to the south-west of Pallantia.

COMPLUTUM, a town of Spain, in the Tarragonensis, placed by Ptolemy in the country of the Carpetani, and marked in the chart of M. d'Anville in Hispania exterior, N. E. of Mantua; now Acula de Henares, which fe.

COMPOLI, in Geography, a town of Italy, in the kingdom of Naples, and province of Lavoro; 4 miles E. of Sora.

COMPONE, or Gologia, in Heraldry, is composed of two colours in equal divisions in a border, or any other ordinary; if it consists of two ranges it is called counter-compony, and if of three, it is then termed chequy, and is generally used in a border to denote illegitimacy.

COMPOS Minut. See NON-COMPOS.

COMPOSED Effusion. See BASTION.

COMPOSER OF MUSIC, a person who invents a melody, and cloaths it with harmony, according to the established rules of the art. Under the word composition we shall detail the qualifications requisite to support this character. Yet there are insufficient to form a complete composer, whose productions will be felt and admired whenever they are heard. All the science possible, without the inspirations of genius, is unable to command attention, and interest an audience, at all times, and in all places. They are only gifted men that possess such powers. What is meant here by genius, is not a whimsical and capricious imagination, that quots a flowery road to ramble in thicket, through briers and brambles; that render harmony piquant, loads it with discord; and instead of grace and elegance, is labouring to surprise by extraordinary modulation, and to divide the whele scale into half notes; true genius is that latent fire which inflames the composer, irresistibly forces him to write, and incessantly supplies him with new melodies, always agreeable, expressive, and natural, accompanied by a harmony pure, touching, and majestic, which embellishes melody, without overpowering it. "This was the guide," says the Citizen of Genoa, "that led Corelli, Vinci, Perez, Jomelli,
melli, and Durante, to the sanctuary of harmony; and Leo, Pergolesi, Hafl and Buranello, to that of good taste." We have to add to these, Handel, whose sublime works were never heard by Roufeau; the elder Stamitz, Piccini, Sacchini, Cimarosa, and Pacchioni, with Haydn and Mozart, who have gone somewhat further in vocal music, and many leaguers in instrumental.

The knowledge of harmony is doublets the foundation of composition. To fill the chords, prepare and refute dissonances, is the fundamental base; and know all the other little elementary rules, is necessary; but with the rules of harmony alone, we are not nearer being composers, than being orators by knowing the rules of grammar. Padre Martini says, that no one can be a good composer without singing in good taste, and playing well upon the organ. His rules are for a real magister di capella, an ecclesiastical composer; but for secular music he would have said it was necessary to sing and play well on the harpsichord or piano forte. In setting words for the stage, he ought to know what passages are difficult, and what easy to execute; what style suits the finger, and what the character he has to represent; he is to know the compass of voices and instruments, and their peculiar genius and powers; how to produce effects, and when to apply them; to feel the character of different measures; to know all the difficulties and pedantry of the art: imitations, fugues, canons, double counterpoint, and how to write for double, triple, and quadruple choirs. To these add the mysterious laws of modulation; and all this is no more than preparatory to composition. But he must inherently possess a fund of beautiful melodies, sublime harmony, and grand defects.

Besides correct harmony, correct expression, in lyric compositions, is required. The spirit of three several kinds of composition must be called up in writing for the church, the stage, and the chamber. In the first, solemnity and harmony must be invoked; in the second, a distinct style for each character, strongly marked by the poet; ingenious and spirited symphonies, picturesque accompagnements, a judicious mixture of instruments, and their peculiar powers, occasionally called forth; and for the third species of composition, pieces that require but few hands and few voices; free from all tremendous difficulties, in want of no wind instruments; and, unless catches and glises are in question, no provision need be made for more than one or two voices, and a quartet band.

La musica di camera, chamber music, requires care, grace, and elegance, more than force, energy, and feats of execution.

Among the various styles of composition for which an accomplished master should be prepared, is the military, in which wind instruments and drums are chiefly employed. To know the compass, scale, genius, and defects, of the trumpet, horn, clarinet, hautbois and balloon, both in the orchestra and the field, will require some study, counsel and experience.

Roufeau seems sometimes to regard musicians as mere instruments, incapable of reflection; and that it is the businets of philosophers to think for them; so imagine M. Guizard, and all speculative musicians; but in the following advice to a composer, Jean Jaques seems to require more meditation and reflection than the demon of composition, by which a man of genius is poscified, will allow; who, absorbed in his own ideas, or impelled by the ideas of others, flies to his pen or his instrument, without metaphysical reasoning, or analytical inquiry into the foundation of his art. But Roufeau sums up the article Composer (Compofer), in his Dictionary, with the following instruction. "In composing, the author has to consider the physical production of sound, and that its sole use is to delight the ear; or if he moves to invite imaginative music, he has to move the passions by moral effects. In the first instance, he has to select the most pleasing series of sounds, and agreeable harmony; but in the second, he ought to consider music with respect to its similarity with the inflections of the human voice in speech, and the possible conformity between the harmonic combinations of sound and imitable objects." This is all very fine and profound; but we apprehend, that the most happy effusions of genius have been generated without speculative and demiurgic abilities.

For the mechanical rules by which a composer is to steer, we shall refer our readers to the article Counterpoint; where, though its principal rules are dispersed through the work, we shall collect and form them into a Synopsis, and illustrate precepts by examples.

In this musical grammar, we shall perplex the student with no mathematical calculations, no ratios, harmonics, or speculations on the philosophy of sound; but adhere closely to practical knowledge of immediate use in the first stages of study. We shall not even attempt to give new melodies, or harumonal combinations; but endeavour to indicate the foundation on which the best models of composition have hitherto been built. See Counterpoint, Conords, Discords, Harmony, and Modulation.

COMPOSITE, or Composite, in Botany, the twenty-first natural order in the Philosophia Botanica of Linnaeus; and the forty-ninth in the Prelections, published after his death by Gleeke. The plants with compound flowers are kept distinct by most authors, with only a little difference as to the proper limits and most convenient divisions of the order. But Linnaeus does not employ the term, but with the perfectly natural, its essential character is not easily determined. A compound flower, from the obvious meaning of the term, implies the union of several flowers, or florets, as in this case they are usually called, by some common bnd. But this character is not peculiar to the composite plants, nor does it extend to all their genera. For cephalanths, dipacus, feshinis, &c. have several florets included in a common calyx, but belong to a different family; and seriphium, corymbium, and drupae, have only one flower in each calyx, and yet cannot be separated from those which are truly compound. Nor will the united anthers, which Linnaeus has taken for the distinguishing character of his artificial class syngeconia, exactly apply to this natural order; salsines, viola, impatiens, &c. have such anthers, but cannot properly be arranged with the composite.

In the Philosohia Botanica the order stands thus:

All these are retained in the Prelections, except gerbera, which has been abolished, and its tipples referred to ane. Several of them are also placed in different divisions.
The following is the arrangement in the synoptic table annexed to the Prælectiones. Those printed in Italics were added by Linnaeus himself; and those marked with asterisks are additions by Giseke.

are composed by the multiplication of the prime integers, 2, 3, and 5; all primes larger than these, or composite numbers into which such enter, are not musical numbers, but are irrational or rud in a musical sense. See Musical Numbers.

**Composite, or Roman Order, in Architecture.** This name is used to denote a kind of column whose capital is composed of the Ionic and Corinthian forms; the vase or tambour of the capital being that of the Corinthian order, and ornamented in the same manner, with two tiers of leaves, and with a similar abacus; but to these are added Ionic volutes which supply the place of the caulicoli and sactrefus, proper to the Corinthian capital. See the plates of capitals. In other respects, in the shaft base and entablature, there is no uniform and allegiance difference between the Composite and Corinthian, and we shall, in a subsequent portion of this article, examine what claims this composite has to be considered as a distinct order.

The principal remains of antiquity in which the composite capital is found, are the following; the arch of Titus, the arch of Septimius Severus, and the arch of the goldsmiths, the building commonly called the Temple of Bacchus, without the gate of St. Agnes at Rome, the baths of Diocletian, the Baptistery of Conflantine, which is ornamented with porphyry columns of the most exquisite workmanship, removed from some more ancient edifices; the arch at Verona, and the chapel or balister at Nimes.

This capital was therefore very popular among the Roman architects, but it does not by any means appear that they admitted a distinct composite order. A passage of Vitruvius will throw some light upon this point; this author, after describing the capitals of the Doric, Ionic, and Corinthian orders, proceeds to observe, that "there are also other kinds of capitals called by various names, which are distinguished on the same columns, and which have no proper symmetry or relation to any separate order of columns, but they are all derived and transferred from the Corinthian, Pulvinated (Ionic) or Doric orders, from whose symmetries they only differ in the little novelties of the sculptur." In fact, the remains of Roman antiquity furnish a vast variety of capitals, many of which are more remarkable and remote from the usual orders, as well as more beautiful than the composite capital, and yet no architect has ever thought of erecting any of these into a distinct order. The capitals of the Temple of Concord at Rome, a very entire and considerable remain, are composite, being a melange of the Ionic and Doric; but no one has claimed the honours of an order for this strange production.

The difference between the pretended Composite order and the Corinthian, exists merely in the capital; for neither in the remains of antiquity, nor in the works of modern artists, is there any decided, uniform, and characteristic difference in any other particular. But the capital, though an important member, is not of itself sufficient to form an order, otherwise we should reckon not five but hundreds; and a composition which has no appropriate proportions, no exclusive character, can only be regarded as a variety of that order with which it is perpetually liable to be confounded. The equivocal nature of this production has caused great embarrassment to the system-mongers of architecture; for while its later origin would lead them to place it last in their systems, and highest in their buildings, its heaviness of appearance, in comparison with the Corinthian order, seems to indicate a contrary arrangement. It is unnecessary, for the three Grecian orders supply all the expressions which architecture is capable of giving with distinctness. The Doric is strong, the Ionic elegant, and the Corinthian rich; while they admit all the modifications of these qualities that can be required; but as to the Composite, what is it but an exaggeration of the Corinthian, in which the attempt at superior richness has only produced a degree of heaviness.

It has been before observed, that the Romans affected no particular entablature to the composite capital. In the temple of Bacchus the cornice is entirely plain, with a swell friz. The arch of Septimius Severus has a cornice enriched with dentils extremely similar to the Ionic of the temple of Fortuna Virilis, and the theatre of Marcellus; while the cornices of the arch of Titus, and the arch at Verona have both dentils and modillions, and the whole profile of the entablature is precisely in the style of the generality of Corinthian examples. Among the moderns, Palladio has imitated the frontispiece of Nero in his cornice and architrave; but he has omitted its beautiful friz, and substituted a swelled one. Scamozzi's entablature being only one-fifth of the column, and much divided, has rather a trifling appearance, though the details are upon the whole well designed. Vignola's composite has nothing in it remarkable; the architrave differs but little from that of the frontispiece of Nero, and the cornice is nearly the same with that of his Ionic order. Serlio's entablature is extravagantly absurd, being taken from the fourth order of the colonnade, a composition well enough adapted for the termination of that gigantic edifice, but wholly disproportionate to a fingle order.

**Composite Stalk.** See Stalk. **COMPOSITIO MEASUREM, the title of an ancient ordinance for measures, not printed; it is mentioned in the statute of 23 Hen. VIII. cap. 4.**

**COMPOSITION, in a general sense, is the uniting or joining of several different things, so as to form one whole, called a compound.**

The schoolmen distinguish two kinds of composition; the one *initiative*, which is between things of the same nature, e.g. two or more drops of water: the other *essential*, when things of different kinds are joined, and thus constitute new things, or effences, different from any of the parts: and thus say they, from the matter and the form of wood, arises wood; while effence is very different from either of those ingredients taken separately.

**Composition of bodies, in Chemistry.** See Combination and Affinity.

**Composition, in Commerce, a contract between an insolvent debtor and his creditor; whereby the latter agree to accept a part of the debt, in compensation for the whole, and give a general acquittance accordingly.**

**Composition for Trees, in Gardening, a sufflation discovered, prepared, and applied by Mr. Forsyth, for the purpose of removing diseases, defects, and injuries in fruit and forest-trees. It is directed to be composed in the following manner, in his "Treatise on the Management of Trees."**

"Take one bushel of fresh cow-dung, half a bushel of lime-rubbish of old buildings (that from the ceilings of rooms is preferable), half a bushel of wood-ashes, and a sixteenth part of a bushel of pit or riversand; the three last articles are to be sifted fine before they are mixed; then work them well together with a spade, and afterwards with a wooden beater, until the stuff is very smooth, like fine platter used for the ceilings of rooms."

It is advised that the trees should be prepared for its application "by cutting away all the dead, decayed, and injured parts, down to the fresh found wood, leaving the surface of the wood very smooth, and rounding off the edges of the bark with a draw-knife, or other instrument, perfectly
COMPOSITION.

flection, which must be particularly attended to; then lay on the plaster about one eighth of an inch thick all over the part where the wood or bark has been so cut away, filling off the edges as thin as possible; then take a quantity of dry powder of wood ashes mixed with a sixth part of the same quantity of the ashes of burnt bones, put it into a tin box with holes in the top, and shake the powder on the surface of the plaster, till the whole is covered over with it, letting it remain for half an hour to absorb the moisture; then apply more powder, rubbing it on gently with the hand, and repeating the application of the powder till the whole plaster becomes a dry smooth surface."

And he adds the following directions.

"All trees cut down near the ground should have the surface made quite smooth, rounding it off in a small degree as before-mentioned; and the dry powder directed to be used afterwards, should have an equal quantity of powder of aloof mixed with it, in order the better to retilt the dripping of trees and heavy rains."

Such parts or portions of the composition as may be left for a future use "should be kept in a tub or other vessel, and urine of any kind poured on them, so as to cover the surface; otherwise the atmosphere will greatly hurt the efficiency of the application."

And "where lime-rubbish of old buildings cannot be easily got, take pounded chalk, or common lime, after having been draked a month at least."

It is further remarked by the author, that "as the growth of the tree will gradually affect the plaster, by raising up its edges next the bark, care should be taken, when that happens, to rub it over with the finger when occasion may require (which is best done when moistened by rain), that the plaster may be kept whole, to prevent the air and wet from penetrating into the wood."

But "as the best way of using the composition is found, by experience, to be in a liquid state," Mr. Forsyth advises that it should "be reduced to the coarseness of pretty thick paint, by mixing it up with a sufficient quantity of urine and soapsuds, and be laid on with a painter's brush. The powder of wood-ashes and burnt bones is to be applied as before directed, patting it down with the hand."

It is also further advised, that "when trees are become hollow, to scoop out all the rotten, hollow, and dead parts of the trunk to the solid wood, leaving the surface smooth; then to cover the hollow, and every part where the canker has been cut out, or bit in the wood; and as the edges grow, to keep care not to let the new wood come in contact with the dead, part of which it may be sometimes necessary to leave; but to cut out the old dead wood as the new advances, keeping a hollow between them, to allow the new wood room to extend itself, and thereby fill up the cavity, which it will do in time, so as to make it as it were a new tree."

And if the cavity be large, to cut away as much as at one operation as will be sufficient for three years. But in this to "be guided by the size of the wound, and other circumstances. When the new wood, advancing from both sides of the wound, has almost met, to cut off the bark from both the edges, that the solid wood may join, which, if properly managed, it will do, leaving only a flight seam in the bark. If the tree be very much decayed, not to cut away all the dead wood at once, which would weaken the tree too much, if a stand, but endear its being blown down by the wind. It will consequently be necessary to leave part of the dead wood at hle, to strengthen the tree, and to cut it out by degrees as the new wood is formed. If there be any canker, or gum oozing out, the infected parts must be pared off, or cut out with a proper instrument. When the timber is very much decayed and hollow, it will be necessary to open the ground and examine the roots."

Various interesting facts and observations on the advantage and utility of this composition in the removal of the disfigure of different sorts of trees, may be seen below, as taken from Mr. Forsyth's valuable "Treatise on the Culture and Management of Fruit and Forest Trees."

It is stated by Mr. Forsyth as being "the received opinion and common practice of most professional men, to prune or lop their trees, from the month of October, when the juices have been exhausted by the summer foliage, autumnal fruit, and general nourishment of the body of the tree, until the month of March, when the sap or juices, re-invigorated by nature during the winter's repose, begin to re-ascend and perform the annual function of clothing it with fresh foliage, blossoms, and fruit. The reason of this practice is, he says, that the sap being fallen at that season of the year, it has been considered as the most proper period to lop off all superfluous growths, and the efforts of nature to heal the wounds thus necessarily given (before the rising of the sap in the following spring), have been judged best for the safety and health of the tree. The danger of performing this service when the juices are in a more vigorous flow, as in the months of May, June, and July, has been dreaded, from a fear of its occasioning a waste of the nutritive juices, discharging themselves through the wound, to the impoverishment and injury, if not the ruin of the tree."

And it is added, that "the pruning of fruit-trees, and the lopping off large branches from forest-trees during the winter season, has also been frequently attended with great hurt and impediment to their health and vegetation; the wounds being exposed to all the rigours of an inclement season, and thereby contracting those diseases which contain the principles of decay. Hence it is, that such numbers of forest-trees are continually injured in their value for public uses, either by unskillful management, or perverted depredation, or by the violence of boisterous winds, when their limbs and branches being torn off, the trees are left in that unprotected state to imbibe the seeds of decay and rottenness, which will in time pervade their very heart, and render them unfit for any of those valuable purpoises for which nature, by their frame and texture, appears to have designed them. And it may also be observed, that where branches have been cut off from the body of the tree, even at the distance of two or more feet from the trunk, with a view to prevent injury to the timber, even that method has not been found effectual to save the tree from very material detriment; as the remaining limb of the branch so cut away, dying soon after, becomes a ready conduit for conveying pernicious moisture and disease to that part of the tree with which it is connected; and so on, in time, to the whole."

But he supposes "the practice of others in lopping their trees close to the trunk, and drilling the part smooth and even, has left objections than the former; nevertheless, even according to this method, the tree is liable to injury. The effort of nature to heal the wounds thus given, discovers itself by encircling the wound with a kind of callus or lip, which incrusting in size, and swelling out from the annual flow of the juices, forms a hollow or cavity of the central part, where the rain or snow is very apt to lodge; and penetrating between the bark and wood, dried cracked by a hard frost, or a warm sun, promotes that fermentation with the natural juices, which is the certain source of disease and decay." It is suggested that "young, healthful, and vigorous
Composition.

Gorous trees, when they have been injured by being wantonly cut through the bark, or from other causes, will sometimes recover themselves, and, to all outward appearance, be restored to their original soundness; but when cut into planks and boards, internal blemishes and faults are discovered in them, which appear to have been occasioned by the early injuries which the tree had received; the texture of the wood not uniting where the wound was originally given; though, from the youthful vigour of nature, the bark has closed, and an external cure has evidently performed on such trees.

The composition is a most efficacious remedy to prevent these evils with all their destruotive consequences, and to restore found timber where the symptoms of decay are already apparent, which being applied in the manner directed, "to the wound or injured part, will infallibly prevent the bleeding of trees, or the oozing of juices through the wounds of limbs or branches that have been cut off in the middle of summer, when they are in their highest vigour, and most rapid flow of vegetation; by which means, any wafeful discharge of the juices is prevented, and they are duly configned to their natural operations of giving nourishment, growth, and fertility, to their respective bodies. By employing this remedy, trees of all kinds, whether in gardens or orchards, in parks or forests, may, he says, with greater safety and advantage he pleased or lopped in the spring, or early in the summer, than in the winter season; as the composition, when properly applied, repels the flow of the juices through the wound, causes a more active vegetation, and affords nature more powerfully in healing the wound at the time the sap is in full vigour, than when it is on the decline, as in autumn and winter seasons."  

The writer considers it also necessary to remark, further, "that both forest and fruit-trees (particularly those which grow in the shade) are very liable to be affected with disorders proceeding from the growth of liverwort, and various kinds of moss, that adhere to the outer bark of the tree, and frequently gain a considerable thickness, that not only prevents the natural flow of the juices, but causes a stagnation in the circulation and brings on decay; which, after destroying the outer bark, penetrates by degrees deeper into the wood. Where this circumstance is observed, care should be taken to clear the whole bark of the tree from these growths; and where it is infected, to scrape or pare it away. When the body of the tree is thus cleansed from infection, the composition may be applied to the bark so cleansed, to close the pores of the wood, when the tree will soon acquire a fresh bark, and improved health and vegetation."  

The author is "confirmed in these opinions by the many experiments and various trials that he has made, to ascertain, by the most positive proofs, the properties of this composition, before he ventured to offer it to the public attention."  "Indeed, every year's experience has increased his conviction of its general utility, when properly applied to the purposes for which it is recommended."  In order to give a more complete illustration of its virtues, and to place the advantages arising from it in a stronger light, he states a few of the very numerous experiments that he has made on the forest trees in his majesty's gardens at Kensington, where the salutary effects of it are extremely evident.

It is remarked that "the first trials of its efficacy were made on some very large and ancient elms, many of which were in a very decayed state, having all their upper parts broken, by high winds, from their trunks, which were withal so hollow and decayed, that a small portion alone of the bark remained alive and sound. Of these trees he cut away at first a part only of the rotten fluff from the hollow of the tree, and then applied the plaster to the place where the operation had been performed, by way of an internal coat. In a short time, however, the efforts of nature, with a renovating flow of the juices, were clearly discernible in their formation of new wood, uniting with feeling as it were from the old, till it became a strong support to that part of the tree where the composition had been applied. He then cut away more of the rotten wood from the inside, applying the plaster in the same manner, with the same good effects, and continued to use the knife in proportion to the acquisition of new wood; so that from the tops of the decayed and naked trunks, items have, he says, actually grown of about thirty feet in height, in the course of five or seven years from the first application of the composition; an incontrovertible proof of its good effects in redefining decayed vegetation in such cases."

And he adds, that "many other elm trees, which, had received hurts from bruises and other causes, and where disease and decay were already evident, after cutting away all the infected part, and duly applying the plaster, were fo completely healed, that the outline of the wound is scarcely discernible on the bark, and the new wood is as perfectly united to the old, as if it had been originally formed with the tree."  

It is stated that "of oak trees also, which had received very considerable damage from various accidents, as blows, bruises, and cutting of deep letter; the robbing off of the bark by the ends of rollers, or wheels of carts, and mutilated branches, a perfect cure has been made, and found timber produced. The acidity, or corrosive quality of the juice of oak-trees, when obstructed in their circulation from any of the causes already mentioned, and fermenting with the wet and moisture imbibed by the wounds from the atmosphere, will bring on disease, and promote decay; for, notwithstanding the hard texture of the oak, when once the principles of decay begin to operate, the acrimonious juices feed the disease, and accelerate its progress, as much, perhaps, as in trees of a softer quality and texture, but when the diseased or injured part is entirely cut away to the fresh sound wood, and the composition properly laid on, as perfect a cure has been made as he has already related in the recovery of elm trees."  

The writer likewise further states, that "various experiments have also been made on other forest trees, as ash, limes, elms, and fycamores, that had received the several injuries to which they are exposed; as well as many of the refuluous kinds, such as the cedar of Lebanon, and others of the pine tribe: in all of which he has experienced a degree of success that exceeded his most sanguine expectations. And as he feels a strong impulse to render his experiments of the most extensive advantage to the community, and in particular to the proprietors of landed estates throughout the kingdom, he begs leave to recommend to their particular attention, that all forest trees, whether felled with a saw or an axe, may be cut near to the ground; at the same time carefully preserving the stump and roots from any further injury. The surface may then be made quite smooth, and the composition be spread over the whole, according to directions already given. But in these cases the composition should have an equal quantity of the powder of asafoetida mixed with the dry powder generally directed to be used; after it is laid on, in order to render the surface harder, and of course better able to refill the bad effects of the dropping of trees, of rain, frost, and snow; an addition which is by no means necessary in the usual application to the stumps of trees."  

He concludes that, "in consequence of this proc-
COMPOSITION.

cefs, the vigour of the roots will operate so powerfully in the course of the succeeding spring, that a considerable number of buds or branches will shoot forth round the stump, which, with proper care and attention, may be trained to many valuable purposes, either straight or crooked, for fence timber, or other uses; and, by retaining only so many of these shoots as are designed to grow for any particular intention, more than one half will be faced, in point of time, according to the proportions of common growth; for, if a young tree be planted in a fall equal in quality to the state of the old stump, the roots growing from the latter will, in eight or ten years, attain to a size which the single plant will hardly acquire in twice that period. There are also many useful purposes of husbandry, as hop-poles and other poles used on various occasions, for which a number of shoots may be trained from one stump, whose fertile juices will shortly rear a healthy and numerous offspring around it. Very particular attention, however, should, be paid to regulate the number, according to the size and vigour of the stump. It would certainly be proper to leave more of them at first than are intended to be retained for final use, in order to draw up the lap; if too few are left, they will be liable to burst, from the superabundant flow of the juices from the old stock; to prevent which inconvenience they should be cut away by degrees, always supposing the composition as they are cut, and leaving the fresh stem to produce the new tree, and, in time, cover the old stump, and leave nothing but a faint kind of cicatrix at the junction of the old and new part of the tree.'

He thinks it "needless for him to insist on the great advantages which land proprietors and farmers will derive from this method of managing their woods and coppice-grounds, wherever they may be. In many counties of England, coppice, or underwood is an article in very great demand for charcoal, common fuel, or the purposes of particular manufactures, as well as to furnish a variety of articles for husbandry and domestic conveniences." And its advantages in a national as well as ornamental point of view, are still more obvious. See CANKER.

Composition, in Grammar, denotes the joining of two words together: or prefixing a particle to another word, to augment, diminish, or change its signification. See Word, &c.

Composition, in Law, an agreement or contract made between the owner of lands and the parson or vicar, with the consent of the ordinary and the patron, that such lands shall for the future be discharged from payment of tithes, by reason of some land or other real recompense, given to the parson, in lieu and satisfaction thereof. Land may be exempted from the payment of tithes, where compositions have been made; and real compositions for tithes are to be made by the concurrent consent of the parson, patron, and ordinary. Real compositions are distinguished from personal contracts: for a composition called a personal contract is only an agreement between the parson and the patronizers, to pay so much instead of tithes: and though such agreement is confirmed by the ordinary, yet (if the parson be not a party) that does not make it a real composition, because he ought to be a party to the deed of composition. (Mari's Rep. 87.) This kind of composition was permitted by law, because it was supposed that the clergy would be no losers by such composition; since the convent of the ordinary, whose duty it is to take care of the church in general, and of the patron, whose interest it is to protect that particular church, were both made necessary to render the composition effectual; and hence have arisen all such compositions as exist at this day by force of common law. But, experience shewing that even this caution was ineffectual, and the possessions of the church being, by this and other means, every day diminished, the disabling statute 13 Eliz. c. 10, was made, which prevents, among other spiritual persons, all parsons and vicars from making any conveyances of the estates of their churches, other than for three lives or twenty-one years. So that now, by virtue of this statute, no real composition made since the 15th Eliz. is good for any longer term than three lives, or twenty-one years; though made by consent of the patron and ordinary; which has, indeed, effectually demolished this kind of traffic; such compositions being now rarely heard of, unless by authority of parliament. See MODUS.

Composition is sometimes used for "decifio litus." Accordingly compositions were anciently allowed for crimes and offences, even for murder. By this expiation it was proposed to restrain the violence of private revenge. The custom may be traced back to the ancient Germans (see Tacit. de Mor. German. c. 21.) and prevalent in other uncivilized nations. The nature of crimes and offences was estimated by the magistrate, and the sum due to the person offended was ascertained with a minute, and often a whimsical, accuracy. Rothmann, the legislator of the Lombards, who engaged about the middle of the 7th century, discovers his intention both in ascertaining the composition to be paid by the offender, and in increasing its value: it is, says he, that the entity may be extinguished, the perfection may cease, and peace may be restored. About the beginning of the 9th century, Charlemagne struck at the root of the evil, and enacted, "that when any person had been guilty of a crime, or had committed an outrage, he should immediately submit to the penance which the church imposed, and offer to pay the composition which the law preferred, and if the injured person or his kindred should refuse to accept of this, and presume to avenge themselves by force of arms, their lands and properties should be forfeited" Tavernier relates, that in Persia, a murderer is still delivered to the relations of the person whom he has slain, who put him to death with their own hands; and if they refuse a sum of money as a compensation, the sovereign cannot pardon the murderer. Montesq. Sp. of Laws, vol. ii. p. 382. Robertson's Hist. of Ch. V. vol. i. p. 334, &c.

Composition, in Logick, is a method of reasoning, wherein we proceed from a general self-evident truth, to other particular and singular ones.

The method of composition, called also synthesis, is just the reverse of that of resolution, or analysis.

Resolution is the method whereby we ordinarily search after truth; composition, that whereby a truth found, is discovered and demonstrated to others; resolution is the method of investigation; composition, of demonstration.

The method of composition is that used by Euclid, and other geometers; resolution, that used by algebraists and philosophers. The two methods differ, just as the methods of searching a genealogy; which are either by descending from the ancestors to the posterity, or by ascending from the posterity to their ancestors: each have this in common, that their progress is from a thing known, to another unknown.

The method of composition is best observed by the mathematicians: the rules which are, 1. To offer nothing but what is conchted in clear and express terms; and to that end, to begin with definition. 2. To build only on evident and clear principles; to that end, to proceed from axioms or maxims. 3. To prove demonstratively all the conclusions that are drawn hence; and to this purpose, to make use of no arguments or proofs, but definitions already laid down,
axioms already granted, and propositions already proved; which serve as principles to things that follow.

Composition of ideas is an operation of the mind, whereby it combines several of its simple ideas into complex ones.

Under the same operation may likewise be reckoned that of enlarging; whereby we put several ideas together of the same kind, as several units to make a dozen.

In this, as in others, brutes come far short of men; for though they take in and retain several combinations of simple ideas; as possibly, a dog does the shape, smell, and voice of his master; yet these are rather so many distinct marks whereby he knows him, than one complex idea, made out of those simple ones.

An ingenious writer has suggested the impropriety of the phrase "composition of ideas," adopted by Mr. Locke, alleging it is merely a contrivance of language, and that only the composition is in the terms; and that it is as improper to speak of a complex idea, as it would be to call a collection a complex star. He further addts, that they are not ideas, but merely terms, which are general and abstract. Whatever he says, the immortal author of the "Essays under Understanding" has justly concluded in his reasoning on this subject will hold equally true and clear, if we substitute the composition, &c. of terms, wherever he has supposed a composition, &c. of ideas. If upon first examination this should appear to be the case, we shall need no other argument against the composition of ideas: it being exactly similar to that unanswerable one which Mr. Locke himself declares to be sufficient against their being innate. For the supposition is unnecessary: every purpose for which the composition of ideas was imagined being more easily and naturally answered by the composition of terms; whilst at the same time it likewise clears up many difficulties, in which the supposed composition of ideas necessarily involves us. This writer further adds, that it is as easy a matter, upon Mr. Locke's own principles, and a physical consideration of the senses and the mind, to prove the impropriety of the composition of ideas. Locke's Diversions of Purley, pt. i. p. 37, &c.

Composition, in Mathematics, is the taking of a given number of quantities, out of as many equal rows of different quantities, one out of every row, and combining them together. Here no regard is had to their places; and it differs from combination, in which there is but one row of things.

1. "The number of compositions of $n$ things taken out of $n$ rows, each row consisting of $m$ things, is $m^n$, and the $\text{m}^\text{n}$ power of $m$.

Let there be any number of rows, such as $\{a, b, c, d, e\}$, where these things are $a, b, c, d, e$, as $m$ or $m'$.

Then the number of combinations of every 2 is had by joining each quantity in the second row to all the quantities in the first, which will make as many times $m$ as there are things in the second row, or $m$ times $m$, that is $m^2$, for all the two's. Again, taking in the third row, there will be as many times $m^2$, as there are things in the third row, that is, $m$ times $m^2$, or $m^3$, for the composition of three things.

After the same manner, if a fourth row was taken in, all the combinations of every fourth would be $m^4$, and so on: and, therefore, universally, when $n$ rows are taken in, the number of combinations will be $m^n$, which is the number of compositions. Hence it follows, 1. That the number of compositions of all the one's, two's, three's, &c. to $n$, is $\frac{m^n - 1}{m - 1}$. For

\[
\frac{m^1 - 1}{m - 1} = m + m^2 + m^3 + ... = m \frac{m^n - 1}{m - 1}.
\]

And $\frac{m^n - 1}{m - 1} = m^n + m^n + m^n + ... + m^n = m^n$. As will appear by division, or, in general, $m^n = \frac{m^n - 1}{m - 1}$.
COMPOSITION.

Ans. \(1 \cdot 2 \cdot 3 \times \frac{1}{2} \cdot 3 \cdot 4 \cdot 5 \cdot 6 = 6 \times 60 = 360.\)

E. G. 2. How many compositions are in the form \(a^3 b^3 c^3 ?\) Here \(c = 3, m = 5, t = 2, v = 2, w = 1.\) The index 2 is twice repeated.

\[
\text{Ans.} \quad 1 \cdot 2 \cdot 3 \times \frac{1}{2} \cdot 3 \cdot 4 \cdot 5 \cdot 6 = 3 \times 30 = 90.
\]

E. G. 3. To find the compositions in the form \(a^3 b^3 c^3 d^3 e^3 f^3\). Here \(n = 2, m = 6, t = 3, v = 3, w = 2.\) The index 3 is twice repeated; and the letters \(a, b, c, d, e, f\) thrice.

\[
\text{Ans.} \quad 1 \cdot 2 \cdot 3 \times \frac{1}{2} \cdot 3 \cdot 4 \cdot 5 \cdot 6 = 1 \times 20 = 20.
\]

E. G. 4. To find the number of compositions in the form \(a^3 b^3 c^3 d^3 e^3 f^3 g^3.\) Here \(n = 4, m = 10, t = 3, v = 3, w = 2.\) The index 3 is twice repeated, and also the index 2. The letters \(a, b, c, d, e, f, g\) are thrice repeated; and \(h, i\) thrice.

\[
\text{Ans.} \quad 1 \cdot 2 \cdot 3 \cdot 4 \times \frac{1}{2} \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10 = 6 \times 25000 = 150000.
\]

E. G. 5. How many compositions in the form \(a^3 b^3 c^3 d^3 e^3 f^3 g^3 h^3 i^3 j^3 k^3 l^3 m^3 n^3 o^3 p^3 q^3 r^3 s^3 t^3 u^3 v^3 w^3 x^3 y^3 z^3.\) Here \(n = 6, m = 14, t = 5, v = 3, w = 2.\) The index 3 is twice repeated, and the index 1 thrice: the letter \(a\) five times repeated; and \(b, c, d, e, f\) thrice.

\[
\text{Ans.} \quad 1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \times \frac{1}{2} \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10 \cdot 11 \cdot 12 \cdot 14 = 60 \times 201805060 = 12108905600.
\]

So prodigiously do the numbers increase in these operations. See Composition and Composite numbers.

Composition of motion, in Mechanics, is an amalgamation of several directions of motion, resulting from powers acting in different, though not opposite lines.

If a point move or flow according to one and the same direction, whether that motion be equable or not, yet it will still keep the same right line; the celerity alone being changed, i.e., increased or diminished, according to the forces with which it is impelled. If the directions be opposite, as one, e.g., directly downward, the other upward, &c. yet till the line of motion will be the same.

But if the compound motions be not according to the same line of direction, the compound motion will not be according to the line of direction of any of them, but in a different one from them all; and this either straight or crooked, according as the direction or celerities shall require.

If two compound motions be each of them equable, the line of the compound motion will be a straight line; and this, though the motions be neither at right angles one to another, nor equally swift, nor (each to itself) equable; provided that they be but similar; that is, both accelerated and retarded alike.

Thus, if the point \(a\) (Pl. XV. Mechanics, fig. 1.) be impelled equally with two forces; viz. upwards, towards \(b,\) and forwards, towards \(d;\) it is plain, that when it is gone forwards as far as \(a,\) it must of necessity be gone upwards as far as \(e;\) so that the motions both equable, it would always go on in the diagonal \(a e.\)

Nay, suppose the motions unequal as to celerity, fo, vo, gr. as that the body move twice as fast upwards as forwards, &c. yet still it must go on in the diagonal \(a e;\) because the triangles \(a e c, a e c, &c.\) and \(a e d\) will still be similar, being as the motions are; and it will have described the diagonal in the same time which it would have required to describe either of the sides singly.

But, if the motions be dissimilar, then the compound motion must be a curve.

And, if a body, as \(b\) (Fig. 2.) be impelled or drawn by three different forces, in the three different directions \(b, a, \text{and } b d.\) So that it yields to none of them, but continues in equilibrium: then will those three powers or forces be to one another, as three right lines drawn parallel to those lines, expressing the three different directions, and terminated by their mutual concourses.

Let \(b\) represent the force by which the body \(b\) is impelled from \(b\) to \(a;\) then will the same right line \(b e\) represent also the contrary equal force, by which it is impelled from \(b\) to \(e;\) and by what hath been said before, the force \(b e\) is resolvable into the two forces acting according to the two directions \(b d\) and \(b c,\) to which the other impelling from \(b\) to \(e,\) is as \(b e\) to \(b d,\) and \(b c\) or \(d e,\) respectively.

So likewise two forces, acting without the directions \(b d, b c,\) and being equivalent to the force acting without the direction \(b c,\) from \(b\) to \(e,\) will be to the force acting according to the direction \(b c,\) from \(b\) to \(e,\) as \(b d, b c,\) to \(b e;\) and therefore, the forces acting in the directions \(b d, b c,\) and equivalent to the force acting in the direction \(b e,\) are to the force acting in the direction \(b c,\) as \(b d, b c,\) or \(d e,\) to \(b e;\) that is, if a body be urged by three different equivalent powers in the directions \(b a, b d,\) and \(b c;\) these three forces shall be to one another as \(b e, b d,\) and \(d e,\) respectively.

This theorem, with its corollaries, Dr. Keill observes, is the foundation of all the new mechanics of M. Varignon: by help of which may the force of the muscles be computed, and most of the mechanic theorems in Borelli, De Motu Animalium, be immediately deduced. See Motion.

Composition of proportion.—If there be two ratios, wherein the antecedent of the first is to its consequent, as the antecedent of the other is to its consequent; then, by composition of proportion, as the sum of the antecedent and consequent of the first ratio, is to the antecedent, or the consequent, of the first; so is the sum of the antecedent and consequent of the second ratio, to the antecedent, or the consequent, of the second.

E. g. \(\frac{A}{B} : \frac{C}{D} = \frac{A + B}{C + D} = \frac{A}{C} + \frac{B}{D}\) or \((B) : C + D : C + (D)\). See Proportion.

Composition of ratios, in Arithmetic and Algebra, is performed by multiplying the quantities or exponents of two or more ratios together; the product is then said to be compounded of the ratios whose components were multiplied. Thus, if the quantities or exponents of the ratios \(b\) to \(c, c\) to \(d, d\) to \(e, f,\) be multiplied, we shall have \(\frac{a}{b} \times \frac{c}{d} \times \frac{e}{f} \times \frac{d}{c} \times \frac{e}{a} = \frac{a c e}{b d f} \times \frac{d}{c} \times \frac{e}{a} = \frac{a c e}{b d f}.\) And the ratio \(a e c\) to \(b d f,\) is then said to be compounded of the severals ratios \(a b, e, c; d, e, f, &c.\) Thus also the ratio of \(10\) to \(12\) is compounded of the ratio \(2\) to \(3,\) and of \(5\) to \(4;\) for \(\frac{3}{4} \times \frac{5}{2} = \frac{15}{8}.\) This operation is by force called addition of ratios. See Ratio.

Composition, in Music, implies harmony, music in different parts, according with each other; and by the mixture of concords and dissonances embellishing melody, and communicating at once, to a well organized ear, the double delight arising from the union of the two great conduits ingredients in music, MELODY and HARMONY. To be able to write down or dictate a melody or single part, does not exalt its author to the rank of composer; though many have assumed that title, who have not been possessed of science sufficient to make a base to a ballad or minuet.

As the term Composition implies the union of various ingredients we shall endeavour in the important article Counterpoint.
TERPOINT, from our own knowledge, and from the precepts and practice of the greatest masters of the art, to describe these ingredients, and point out their legitimate use. See Counterpoint, which is to nearly synonymous with Composition, that we know not how to separate them.

We take it for granted, before a musical student is inflamed with the ambition of becoming a composer, that he is perfectly acquainted with the elements of the art; that he has read, or at least heard, the principal productions of great masters; that he knows intervals, and their relation to the key note and distance from every other found of the scale. See Scale and Interval. That he knows the different measures or kinds of time in music, nor is acquainted with rhythm, nor where the accents of each bar should be placed. See Time, Accent, and Measure.

That he knows and feels the difference between concords and discord; is offended with false intonation, and instruments out of tune; feels something wrong in the regular succession of two sharp 3rd's or 6ths; two 5ths or two common chords rising or falling one degree; that he knows the compass and genius of the voice or instrument for which he writes. But we must not take much for granted, or, in order to save ourselves trouble, tease our readers with too many references to articles connected with composition, we shall therefore refer our readers to the article Counterpoint, (which we have laboured with great zeal) for the mechanical rules of composition; still reminding the young student, that the scale of eight notes ascending and descending, which represents the whole system in a major key, consists of 5 tones and 2 semitones; the 6th note being a recurrence of the same letter, and nearly the same sound, is included in the same key note or principal base.

Keys are denominated major or minor, sharp or flat, from the situation of the semitones. Let C represent all major keys, and A be the minor. In the major keys, the two semitones lie from the 3d to the 4th, and 7th to the 8th; and in minor keys, from the 2d to the 3d, and 5th to the 6th, ascending in the major, and to avoid accidental sharps, descending in the minor, thus:

Major key.
Ascending.

Minor key.
Descending.

A sharp or flat at the clef, or an accidental sharp or flat in the middle of a melody, changes the place of the fifth semitone; and two sharps or two flats change the place of both.

Of these eight notes, some are termed concords, and some discord. Of the concords, some are perfect, and cannot be changed by an accidental sharp or flat, without becoming discord. These are the 4th, 5th, and 8th, which furnish, when used in the lower part of the scale, a base to the regular ascent in the treble. See Scale, Fundamental Base, and Composer.

Composition, in Oratory, the order and coherence of the parts of a discourse.

As a part of general elevation, (which see) it regards the turn and harmony of the periods: and therefore to composition belong, both the artful joining of the words, whereof the style is formed, and whereby it is rendered soft and smooth, gentle and flowing, full and sonorous; or the contrary: and the order, which requires things first in nature and dignity, to be put before those of inferior consideration.

Composition consists of four parts; which rhetoricians call Period, Order, Juncture, and Number, which see respectively. Ward's Oratory, vol. i. p. 340.

Composition, in Painting, is that great and important requisite, the knowledge of which enables the artist to dispose all the various objects in his picture, as required by the subject, and furnished by the imagination or invention, in such a manner as to render them, individually and collectively, most conducive to the beauty, the effect, and the expression of the whole work. The objects furnished by the imagination or invention, may be considered as so many unmanufactured materials, which the science of composition teaches us to work up and display, as the peculiar circumstances of each case may require. Composition, in its general sense, may, therefore, be styled the ground-work of painting, upon which the superstructure, expression, design, chiaro-scuro, and colouring, in a greater or lesser degree depend; and the science of it opens a wide field for our consideration, as it supposes not only the knowledge of all the various combinations or contracts of lines and forms, which are calculated to produce agreeable or striking effects in general, but likewise, that judicious choice in their felection which may be most applicable to the distinguishing character and expression of each subject or work in particular. Composition, thus contemplated, is no longer confined to the artificial pyramid or the forced contrail, but embraces every possible diversity of arrangement and distribution, from the artless simplicity of Giotto and Masaccio, to the most studied and complex grouping of Buonarotti and Rubens.

In treating this subject we shall follow the same method which we pursued in our inquiries respecting chiaroscuro and colouring. We shall commence by taking a cursory view of the style of the first restorers of painting, then trace the principles and systems of composition at different periods introduced by their successors, and conclude by recommending such examples and such precepts, as we conceive may be most calculated to infuse the studetn's improvement.

The efforts of the early artists, Cimabue, Giotto, and their school, were entirely directed to one great point, the appropriate expression of the story to be represented; every kind of artifice was to them unknown, and their pictures may be compared to the simple unembellished dictum of the rude but faithful historian, or to the wild but uncouth strains of the untutored muse. These old painter, in their feretrical or reckless representations in the churches of Italy, seem to have considered the art in no other light than as a means by which to convey to the devotion of the people, and as they really believed the truth of those stories which they endeavoured to represent, (upon which perhaps a great deal depends), so they described every incident exactly as they supposed, or had been taught by tradition to believe, it had taken place. In their pictures of the Madonna, styled in the Roman church, the Mother of God, and in their attempts to give the image of that eternal being which man never saw, the effect was rendered more awful and impressive by the introduction of choirs of angels and saints, in regular order, disposed on each side and behind the throne; a more picturesque distribution of figures may be found, it is true, in the larger altar pictures of the more modern painters, Carlo Maratti, Luca Giordano, and others; but then

all
COMPOSITION.

solemnity and dignity are sacrificed. where the Virgin Mary, with the saints and angels, her attendants, were muddled together with a little decorum, as if a group of her children, at play in the street, had been the subject to be represented.

In all those pictures of the old painters, which may be more particularly styled devotional, we perceive an attempt to elevate the mind of the spectator to the contemplation of celestial enjoyments; in the pictures of the moderns, beginning from the death of the divine Raffaele, artifice is too apparent, and the subject seems too frequently to have been made subservient to the desire of the painter to display his own academic acquirements. Nature alone seems to have been the precepts of the old painters in composition, and hence that variety, and at the same time that simplicity in their works which we so much admire; but as they were extremely deficient in many necessary parts of the art, and particularly in the: three: drawing, perspective, and chiaro-obfure, it is not surprizing if, in the eyes of curious obfervers, their pictures have alone to be the merit of antiquity, and that interest which is necessarily attached to the early efforts of man in every branch of study.

Inflances, however, may be found, even in the works of the oldest painters, of compositions uniting at once propriety of expression, with beauty of disposition: amongst the numerous frescoes of Cimabue still remaining in the church of St. Francis, at Affi, there is in particular one, representing a dead Christ with the Marys and other figures, where, the subject naturally allowing of it, the artist has given such an agreeable form to the groups, by introducing around the recumbent figure of our Lord, the varied attitudes of figures kneeling and standing, as to leave little to be desired, have a greater perfection in the executive and mechanical parts of the art.

The works of Giotto, the scholar of Cimabue, may be studied with abundant advantage as to invention and composition. The church of Affi, above-mentioned, possesses an extensive series of the frescoes of this extraordinary child of nature, representing stories of the life and miracles of St. Francis; here the compositions, though ever subservient to the expression of their subjects, are in some instances so beautifully grouped, as to leave it almost doubtful whether, in this respect, they ever were surpassed even by the best artists of later periods. One of these represents the story of a nobleman of dissolute character, who having heard of the fame of St. Francis, invited him and his companion, another friar, one day to his table. The holy conversation of the saint had such influence on the nobleman, that he made to him a full and contrite confession of his sins, when, after receiving absolution, he instantly fell down and expired. Giotto has seized this moment. The women, relatives of the deceased, the attendants, all flocked, with varied expressions of grief, astonishment, and terror, to the corner of the picture where he lies an elderly man, (as it is necessary the connection between this group and the other) is represented imploring the interposition of St. Francis, who, rising from his seat, seems to pity their sorrow, at the same time that he endeavours to allay it by the consolatory assurance that the sins of their master are forgiven, and that his spirit is in peace. The friar alone, accustomed to behold miracles, fits unmoved.

In another of these frescoes, Giotto has represented the moment, when, after the death of St. Francis, his body was carried, in the way to the place of burial, to the convent of Sta. Clara. The bearers of the body, surrounded by a concourse of people, have relented the bier on the ground: Sta. Clara is taking a last look at the face of him who, in her youth, she so much loved, one of the suns is kissing the feet of the departed saint, a second bathes his hand with her tears, whilst others, with a gracefulness and tenderness of expression not to be surpassed, are advancing from the three doors of the church to pay their last duties to the object of their affection and veneration. The church itself, beautifully enriched with altars, gives the most agreeable termination to the group.

We shall mention one more of this series of pictures, which, though not in point of beauty equal to the two last-described, is applicable to our present purpose as it strongly exemplifies how much a proper disposition of the groups in a picture contributes to the expression of the subject. The story represented is a miracle which took place some time after the death of St. Francis. A woman from some cause or other died without making a full confession; she had, however, upon the whole been a good catholic, and especially devoted to St. Francis; she therefore made intercession for her, and when the priest with his attendants were upon the point of carrying the body to the grave, she, to the great astonishment of all present, sat up, called a confessor who was present by name, revealed to him her hidden sins, and then once more died and was buried. In the middle of the picture is represented the woman sitting up on her bed, in the act of confessing to a friar, who at once unites in his countenance the strongest expression of terror with the most earnest attention; some women, the friends of the deceased, and a child, form a group on the right; the priest and his attendants are on the left; both these groups are kept at a distance from the two principal figures, in the center, by which the heads of feet and a confessor, a leading point in the story, is more decidedly given, than could have been accomplished by any other manner of placing the figures. The intercession of St. Francis to our Saviour is represented in the sky; and a little below, the effect of that intercession is unequivocably described, by the introduction of a celestial agent, who is driving before him the infernal spirit, by which the woman is supposed to have been perplexed.

Amongst the principal scholars of Giotto we may enumerate, Taddeo Gaddi, and Puccio Capanna: of the former many admirable frescoes are still existing in the church and facade of Sta. Croce, and in the court of Sta. Maria Novella at Florence, and of the latter, great part of the roof or vault, besides two excellent compositions of the taking down from the cross and the burial of Christ, on the side wall of the lower church of St. Francis at Affi.

However, the school of painting founded by Cimabue and Giotto, continued with but little variation or advancement, till about 1430. when Masaccio distinguished himself by a correctness and perfection of imitation, hereto unknown. He began to throw a just notion of perspective, and first succeeded in foreshortening the feet of his figures, to as to give them the true appearance of standing on an horizontal plane: a difficulty never surmounted by his predecessors, whose figures, except when in profile, seemed generally, as if standing on tip-toe. He gave a great breadth of light and shadow to his groups, and was an excellent colourist; and the heads of his figures are so finely drawn, so full of nature, and finished with such a delicacy and at the same time such a mellowness of pencil, as to be scarcely surpassed by the finest portraits of Raffael, Titian, or Del Sarto. In all the executive parts of the art, Masaccio eminently excelled; but we cannot join in the opinion of those who consider him as having equally contributed to the advancement of composition: his aim was to make the most correct possible transcript of the model before him; hence
hence his frescoes, in the celebrated chapel at the Carmine, abound with admirable representations of his friends and contemporaries, portraits that seem almost alive, but they are not always alive to the spectator, nor do they express by their actions or gestures, those feelings which the act of which they are represented as spectators, should naturally awaken in them; in the miracle of the boy restored to life by St. Peter, and in the martyrology of the same saint, the surrounding figures seem no more affected than so many indifferent persons met together in the market place, to talk over the ordinary news of the day. However this work of Masaccio greatly contributed to hasten the great era of painting which followed, by exhibiting to contemporaries, portraits such as those of his friends and contemporaries, that we are now treating of. The great Raphael, indeed, that the contemplation of their manifold faults in this particular, may tend to deter the student from pursuing a similar line of conduct. The subject is here made sublunary to the rage of the painter for displaying his talents in portrait; these frescoes containing flaring reminiscences of almost every lord, lady, or literary character of distinction of his time; and as the figures are throughout dressed in the drapery of the time, so this work is valuable, as giving perhaps the best idea of the general character of Florence towards the end of the fifteenth century, of any in existence; and to this, that the whole is admirably executed; but the spectator may long dwell on the various beauties of this work ere he discovers that it is intended to represent the principal heroes of the New Testament.

The happy era was, however, fast approaching, when the profound Leonardo, the great Michelangelo, and the divine Raphael, were defined, not only to unite all the various excellencies of the old masters, but Likewise, by an unparalleled and happy exertion of comprehensive and elevated genius, at once to carry all those parts of the art, which must ennoble it, to a height of perfection beyond which the efforts of succeeding artists have never enabled them to reach; if indeed they have ever approached it in the four great points of invention, composition, expression, and design.

It was about the year 1503 that the Florentines formed the idea of decorating their great hall of council with productions of the pencil. Upon this occasion Leonardo da Vinci executed in a cartoon the alluring Group of Horsemen fighting for the Standard, so well known by the fine print of Edelhuck: a composition replete, but not crowded, and which exhibits the utmost energy of action, without extravagance, and the most striking and beautiful variety of contrast, without affectation; this was Raphael's model for the intricate groups in his "Battle of Constantine," and is the great prototype of all those battles and battles so daringly executed by the bold pencil of Rubens. That Da Vinci at the age of fifty should have so far surpassed the efforts of preceding painters is, however, less a matter of surprise than, that the youthful Buonsodt, who entered the lists with him, should, as agreed by contemporary writers, have borne away the palm.

The subject chosen by Michelangelo for his cartoon, related to the war between the Florentines and Pisans: the moment taken was an imaginary one, when some of the Florentine folders, who had been bawling in the Arno, are hastening out of the river upon the signal of attack, buckling on their armour, and rushing to the assistance of their countrymen, who had already commenced the combat in the distance. This subject naturally embraced a very great variety of character, action, and expression, and was certainly most happily calculated for displaying academic acquirements, and particularly that knowledge of the human figure which Michelangelo is universally allowed to have polished in a greater degree than any other artist of modern times, and which, amongst the Florentine painters, was considered as at least paramount to all the other parts of the art put together. It is perhaps to this last circumstance that we must attribute the very decided pre-eminent
COMPOSITION.

given to the "Cartoon of Pieta" (as it was called) over that of Lionardo, and which soon after occasioned his quitting his native city in disgust.

Considering these two celebrated works in every other respect, it would be a difficult task to determine to which belonged the preference. The figures in Da Vinci's group, it is true, were somewhat disfigured by the introduction of capricious ornaments on their armour; but, on the other hand, the Cartoon of Buonarotti wanted that breadth of chiaro-recto which that of his rival possessed. Each, however, in its way, is a masterpiece for invention, composition, design, and expression; and each, in its kind, perhaps still remains unrivalled. We refer the reader to a very animated description of the "Cartoon of Pieta" in the third Lecture delivered by Mr. Fufelli to the Students of the Royal Academy.

The subjects which Lionardo and Michelangelo had selected for the display of their talents, afforded in their nature the most ample scope for the intricacies of grouping, and the novel charms of contrast; but it was not sufficiently understood by many of the young artists, who sloped to study these works, that that which they so much admired, and which in reality powerfully contributed to expression in the Cartoons before them, might be inadmissible, or at best should be sparingly used, in subjects of a different character. This censure applies not to Fra Bartolomeo, Andrea del Sarto, and two or three others, rather contemporaries than followers of Michelangelo; but it is certain, that the indiscriminate introduction of contrasts, fore-shortenings, and naked figures, without regard to propriety or expression, soon became a predominant characteristic of the Florentine School.

In the subsequent productions of Michelangelo's pencil, we almost ever find the happiest concordance of style with subject, nor can he be accused of having at any time sacrificed the invention or expression of his picture, to an ostentations display of his powers in the executive parts of the art.

The general design of his sublimer works, the "Vault of the Sistine Chapel," and the "Last Judgment," will be the subject of our consideration, when we come to treat of invention and expression in painting; we shall, for the present, content ourselves with observing, that there is no part of them which affords not a valuable leçon in composition. The beautiful angels, attendant on the Creator of the sun and moon, give dignity to the subject at the same time that they enrich the composition. The angelic troop, supporting the figure of the Almighty, in the Creation of Man, by furnishing a number of small parts opposed to one large one, produces a delightful effect; whilst the broad dark mantle which surrounds the whole, at once simplifies, whilst it throws out the group; this rich group is again finely contrasted by the simple unembellished figure of Adam. In the compartment where Adam and Eve are represented eating the forbidden fruit, Michelangelo has laid himself open to the accusation of having been guilty of an anachronism, as he has introduced in the same picture their subsequent expulsion from Paradise; but, earth we commend his conduct, it will be well to consider whether the fault, if it is one, in the cafe before us, is not amply made amends for by the additional interest and the awful leçon it furnishes—here is at once the cause, and the effect; the transgression and the punishment. This group of the "Tranfiguration of Man" is particularly deserving of our notice, as it furnishes an example in composition different from any other in the chapel; the Eve is fitting in a beautiful posture on the ground, and nearly in front; she extends her left arm to receive the apple presented to her by the tempter, who is represented, like the Scylla of the ancients, under the form of a female terminating in a serpent; Adam is standing immediately behind the figure of Eve; he extends both his arms to pluck the fruit off the tree, and thus discover a back view of his figure from the loins upwards, thereby making a most beautiful contrast to the Eve, at the same time that it afflicts, by its union or connection with the serpent and the tree, in forming a sort of arch over the figure of Eve, which produces a most agreeable and novel effect. In that tremendous group of the "Offspring Israelites tormented by Serpents," the low point of light increases the terror of the scene, at the same time that, by causing the figures to be fore-shortened, it permits the introduction of a greater number of them, and of a larger size than could have been the case, had the horizontal line been suppos'd higher. The "Prophets" and "Sybils" might each in their turn furnish a leçon; but it would far exceed our limits to attempt to point out the various master pieces of composition with which the Sistine Chapel abounds. Each compartment or group contains some principle or excellence more or less distinguishing it from every other, and peculiarly adapted to the expression of the subject it represents.

The "Last Judgment" was executed many years after the Vault of the Sistine Chapel. With respect to the composition of this celebrated work, as a whole, there have been various opinions; some highly approving the uniform arrangement of the groups into distinct subdivisions, as contributing to that awful majesty required by the subject; whilst others have regretted the absence of that perspective, that depth, that sfondo, employed by so striking and picturesque an effect in the great works of Titian, Paolo Veronese, and Rubens. The matchless perfection of the distinct groups has however remained undisputed, and we can therefore with safety recommend the prints from them by Georgio Mannus, or those recently published by Mr. Netz, as fources from which the student will béat acquire the principles of grand composition, at the same time that he imbibes the antidote to poverty of style, and to every thing trivial or common-place.

We have before observed that the older painters considered a certain degree of uniformity of disposition as indispensable in these representations, which were more especially intended as objects of devotion or religious awe. Michelangelo, though in most other respects he departed from the system of his predecessors, seems to have considered this principle as sacred; accordingly, in his designs of Madonnas, Holy Families, and Pietas, we often find this uniformity; sometimes effected by the manner of placing the figures, and balancing equally, as it were, one side of the composition with the other; sometimes by the regularity of the architectural decoration. His "Christ with the Samaritan Woman at the Well" is an instance of this kind, to the "Flagellation at St. Pietro Montorio," and, more particularly so, his "Reparation of the Crucifixion," where the two angels in the clouds and the two figures of the Madonna and St. John, are introduced absolutely at measured distances on each side of the crouf.

Fra. Bartolommeo di San Marco has practised a similar uniformity of composition in his great altar pictures, and has not infrequently Raphael, although in many of his numerous small pictures of the Holy Family he seems to have aimed at the expression of domestic felicity or maternal endearment, rather than to elevate the mind to the contemplation of the mysteries of redemption by a sublime image of the Virgin Mother with the Infant God.
If the works of Michelangelo excel in sublime imagery, or in the personification of supernatural agency, those of Raphael, on the other hand, have ever been considered the most perfect models of that species of painting which is properly termed historical or dramatic. "We stand with awe," says Mr. Fuseli, "before M. Angelo, and tremble at the height to which he elevates us. We embrace Raphael, and follow him wherever he leads us." The works of Raphael never fail to exhibit the happy union of composition every way adapted to the expression of the subject, joined to an inexhaustible variety of well-arranged and beautifully contrived groups; and yet every part seems so naturally to grow out of the story, and comes home to our feelings, that the spectator is often almost tempted to exclaim, with the countryman when he saw Garrick, "Why should I have done it so myself?"

The productions of Raphael furnish nothing like a recipe for composition. He well knew there was none, and hence those forcible and distinct impressions which each of his pictures makes on the mind, and leaves indelible on the memory.

If Raphael can be said to have regulated his compositions by any particular rule or maxim, it was that of making each as unlike the other as possible, confident with propriety of expression. Thus, in the Cartoon of "Christ giving the keys to Peter," the apostles, all crowding together to be witnesses of the action, occupy the principal part of the picture, and form a group as it were in profile, the Saviour, although in the corner of the picture, being nevertheless rendered evidently the principal figure, by the inflamed situation given to him, as well as by the actions of the apostles, who all press forwards towards him, as to the centre of attraction. This Cartoon is finely contrived by that representing the death of Ananias, where the figures of the apostles form a group in the centre, and are all seen in front. The admirable description of this composition by Mr. Fuseli cannot but prove acceptable to the reader. "In the Cartoon of 'Ananias,' at the first glance, and even before we are made acquainted with the particulars of the subject, we become partakers of the scene. The disposition is almost theatrical, the fence is a spacious hall, the heart of the action is the centre, the wings affild, elucidate it with the ends. The apocryphal figure before us is evidently the victim of a supernatural power inspiring the apocryphal figure, who, on the raised platform, with threatening arm pronounced, and with the word enforced his doom. The terror occasioned by the sudden stroke, is best expressed by the features of youth and middle age on each side of the sufferer; it is insinuant, because its shock has not yet spread beyond them, and this is done not to interrupt the dignity due to the sacred scene, and to flamp the character of devout attention of the assembly; what preceded and what followed is equally implied in their occupation, and the figure of a matron, entering, and aborbed in counting money, whilst the approaches the fatal centre, and whom we may suppose to be Sapphira, the accomplice and the wife of Ananias, and the devoted partner of his fate. In this composition of near thirty figures, none can be pointed out as a figure of common place or mere convenience; they are linked to each other, and to the centre, by one chain; all act, and all have room to act, repose alternates with energy." The Cartoon of "Peter and John healing the cripple at the Beautiful Gate of the Temple," is again strikingly different from either of the others. Raphael having, by nobleness of which any but a sublime genius would have been incapable, intersected his composition by the columns of the portico. But though divided, it is true, into separate, and almost equal parts, neither the unity of action, nor the expression of the picture, is impaired, whilst the effect produced is at once novel and beautiful. In the Cartoon of "Paul preaching at Athens," the elevated situation, and energetic action of the Apostle, splendidly denote him the hero of the piece, whilst the attentive but astonished circle gathered round him, receive, as it were, light from him, their centre, and unequivocally declare him the resplendent organ of divine truth.

The Series of "Scripture Histories," painted by Raphael in the Loggia of the Vatican, and his other works, do not less evince the desire of obtaining, as far as consistent with propriety of expression, this diversity in his compositions; but an attentive examination of the prints from them, will better elucidate this point, and induce every thing relative to composition, than a volume of prolix and laboured description. In short, the works of Raphael display the most becoming union of natural with acquired talent, strength of conception, and inexhaustible invention, with propriety of disposition in the whole, and oddities in the component parts.

After the death of this great master in 1520, the art rapidly declined, nor has any one since him tried with equal success the dignified and instructive path of history-painting.

The great reputation of Raphael, however, even for some time after his death, checked the ascendency of mitred principles, at least in Rome, where the great works in the Hall of Constantine, and other rooms of the Vatican, were still continued by Giulio Romano and Raphael's other scholars, after their master's designs.

Of Polidoro da Caravaggio, one of the most eminent, it might be said that the soul of a Greek animated his pencil, to replete with Attic purity and grandeur of style are his numerous frescoes on the facades of the palaces of Rome, now however better known by their prints by Grottius, Cherubino, Alberti, and Bartoli.

It was not till after the noted sacked of Rome in 1527, when the arts and artsils were forced to seek an asylum in distant parts of Italy, that painting was doomed to suffer degradation; Polidoro flew to Mezina, Pierino del Vaga to Genoa, and Giulio Romano to Mantua, where, in the palace of the T., he explored the regions of poetry, gave new force to the instructive lessons of fable, and decked the playful charms of allegoric fiction; still however firm to the principles of his great instructor, nor ever forsaking the true end of his art, the expression of the subject, to a too oftentastened display of his prowess in the means.

We have before observed that Michelangelo's celebrated Cartoon of "Piaf," contributed not a little by its influence to determine the future character of the Florentine school. Blind to its more sublime excellencies, the vigour of its conception, the energy and variety of its parts, and its unity of action as a whole, the young students of Florence ignorantly imagined that a similar introduction of naked and shortened figures into their compositions, without any reference to the subject of their pictures, would at all times infuse them the appaance of the artificers of their own country, and the envy of those of neighbouring states; nor had Michelangelo the good nature or the good sense to point out their error.

An army of expert mannerists, for the most part joining to a miserable felicity of conception the most audacious rapidity of execution, but proud of polishing what they thought the true secret of the Grand Gyle, now felled forth; nor can it be a matter of surprize that the palaces, the churches, and the halls of Rome, Florence, and part of
of the other cities of lower Italy, were so soon degenerated
with the common-place productions of mediocrity, since
the unrelenting pencils of Giorgio Vasari and Federigo
Zuccaro alone, covered many square yards of wall or canvas
that had been effected by the honest diligence of perhaps
any ten of their predecessors.

The due expression of the subject of a picture was now
the last consideration. Provided two or three well drawn
academy figures, however unmeaning, occupied the
foreground on one side, and some women sporting with
their children, on the other, whilst the centre displayed a
pyramidal group, all was well; the employer was delight-
ded, and the painter applauded. Thus a stranger may
pass and repass through the Sala Regia in the Vatican with-
out being struck by, or discovering the meaning of one of
these frescoes which occupy its spacious walls, or without
being afterwards enabled to call to mind the familiar feature
distinguishing one from the other. This subversion of art,
this silly fuss, for what was erroneously considered pic-
tureque composition, for nearly a century afterwards degraded
the school of Rome and Florence; we shall therefore leave
them, and turn the reader’s attention to those of Lom-
bardy and Venice.

If the anatonic studies of the old Florentine artists had
rendered them almost exclusively the masters of correct
design, the painters of Lombardy could boast a more com-
plete insight into the doctrine of perspective, and were cer-
tainly the first who applied it with real effect in large
works.

Melozzo da Forli, in the middle of the fifteenth cen-
tury, in his fresco in the vault in the tribuna of the church of St.
Apolloni at Rome, first discovered what the Italians call the
knowledge of the Sotto in Suo, that is, the method of fore-
shortening figures, so as to give them the due appearance of
rotundity and projection when seen from below: and upon the
same principle, Andrea Mantegna, in several of his great
works, and particularly in a chapel at Padua, where theordained
compartments are entirely above the eye, adopted, with
equal boldness and effect an ideal point of light upon a line
with the eye of the spectator, that is beneath the very bot-
tom of the picture.

From sources like these, Antonio Allegri da Correggio,
the splendid meteor of the Lombard school, imbibed the
first principles of his art. With a spirit every way con-
formable to his name, he pictured the "Joyful Assumption
of the Madonna amidst Myriads of the Anceic Holt," in the
cupola of the duomo of Parma, and the "Assent of Chrift,"
in the church of S. Giovanni in the same city; works which he
justly styled the never-equalled models for that species of composition.
In the execution of theft,
and probably of his other chief works, he was however
greatly afflicted by his friend Antonio Begarelli, a celebrated
Moldese sculptor, who modelled for him in clay all the
figures, so that Correggio, by placing and grouping them
together as they were to be represented, was enabled to de-
linate, with the greatest correctness, ever fo forthshortening,
and at the same time to acquire a truth and boldness of
light and shade unattainable by any other means. And
here it may be well to observe, that the trouble of pre-
paring such models in the first instance, is amply repaid by
the great facility, or rather certainty, which it gives the
artist in the execution of his work. Moreover, the painter
having his modelled figures before him, and being enabled,
by varying the situation of his eye, to view them in every
direction, will frequently discover beautiful combinations
which he never dreamed of, at the same time that he is
rendered less liable to the error of too often repeating the
same view of a figure, or the same action, and is taught to
avoid a common-place mode of composition.

Primaticcio, a native of Bologna, in his commerce with
Giulio Romano, whom he assisted in his works at Mantua,
acquired an admirable talent for treating poetical subjects.
Master of perspective, and the Sotto in Suo, his beautiful
fictions on the ceilings, and other compartments, in the pa-
lace of Fontainebleau, alike charmed by the fire with which
they were conceived, the elegance of their composition, the
prodigious boldness and truth of their effect, and the easy
grace with which they were executed.

The grandeur and striking appearance of projection and
depth, for which the works of Primaticcio were to remark-
able, judging as well by their prints as by the writings of
those who witnessed them prior to their destruction, was in
a great measure occasioned by his having universally chosen
what is called in perspective a short point of distance; by
which mode of conduct the figures in his near-ground ap-
ppeared proportionally large, as those behind diminished in a
more rapidgraduation. This mode of conduct in Primatic-
cio is the more worthy of remark, as it is the reverse of
what we generally find adopted in the works of the great
Roman and Florentine painters, his predecessors. It be-
came, however, a favourite doctrine of the Venetian school,
particularly of Titoreto and Paolo Veronese, and was one of
the leading principles of the Caracci in the formation of
their style.

The composition of Giorgione, Titian, and the other
Venetian painters, is simple and dignified, suggested by the
subject alone, and of course liable to none of those objec-
tions which appertain to the works of their followers, Ti-to-
reto, Paolo Veronese, Palma, and a multitude of others,
who, like the Florentines, valued themselves Chiefly upon
the possession of only a part of the art, sacrificed to their
favourite dainties all the remainder. No longer expression,
but colouring and glitter of effect became their object, and
hence, with all their prodigious talents, they soon turned
the art into a splendid toy.

The works of these great masters (for great they were in
spite of all their faults) may nevertheless be studied with
benefit, even as to composition, as they at all times poise a
balance and variety of different parts, which rank them far
above the infidel and man-trèd performances of their contem-
poraries of Florence and Rome.

About the end of the 16th century, the Caracci of
Bologna attempted, by an union of the scattered excellences
of the various schools before mentioned, to establish a perfect
system of art: but though they indeed so far succeeded as
to form a little in which no particular fault seemed to pre-
dominate, still in no one point did they fully reach the pur-
poped objects of their emulation. Their works present
neither the dignified composition, the just and striking ex-
pression, the beautiful variety of character, which dis-
guishes the work of Raphael; the sublime conception, or
the learned and grand design of Domenichino; the grace and
enchancing effect of Correggios, nor the truth and richness of
Venetian colour; but from rather the result of a style
founded on the basis of a compromise between the eye and
the understanding, the mechanical and the ideal of the art,
in forming which compact, however, the former have been
evidently allowed the preponderance. This remark is, per-
haps, less applicable to the productions of Ludovico Ca-
acci; but with respect to the chief works of Annibale, and
particularly his Farnese Gallery, which cannot fail to hold our
affection to the critiques of Mr. Fuseli, and the severer but jvel
remarks of Mr. Webb.

Having said thus much, it cannot be expected that we
should
should hold forth the Caracci as models for imitation; there is nevertheless a breadth, a concordance of the various mechanical parts of the art, and an ease in their style which render it highly deserving our regard, and would have fully entitled the Caracci to a reputation even greater than that which they have so long enjoyed, had their prodigious powers been made the vehicle of more elevated conception.

With respect to the scholars of the Caracci, and other artists of reputation, who immediately succeeded this epoch, it is only to our present purpose to observe, that grace and beauty rather than grandeur or sublimity, seem to have been their objects, and that whatever eminence they sometimes attained in their Holy Families and devotional subjects, fitted the dignity of historical painting was evidently on the decline.

Niccolo Poullin alone seems to have considered the art as a language addressed to the mind through the organs of vision. Possessed of a refined and frutimizing mind, he at all times collected, and, with the greatest ingenuity, inferred in his pictures all those collateral circumstances, probable or possible, which his subject could furnish; and hence his works, more addressed to the imagination than the eye, at once invite and are sure to reward investigation. The greatest defect, however, of his compositions, seems to be that these explanatory or accessional groups generally appear too principal, and thereby not unfrequently counteract their object, by detracting the attention from the principal figure or group, destroying the unity of action, and weakening that expression which they were intended to augment. Were we to draw a comparison between Poullin and Raffaele, we should liken the former to the cool but subtile refoner, who by slow degrees brings us to grant his position; Raffaele to the heaven-taught genius who at once darts the ray of truth upon our minds.

The works of Poullin, though esteemed even in his lifetime, had little influence in correcting the corrupt and meretricious taste which was every day gaining ground in Italy. The proper end of the art had been long forgotten or habitually sacrificed, and that bane of painting, picturesque, or artificial composition, which, however varying in its mode, was ever the same in its effect, became every day more deeply rooted.

Poverty of conception, or rather no conception at all, common-place or unmeaning attitude, contrari to often repeated as entirely to lose its effect, and, above all, empty bubble, were now become the elements of what was still called historical composition: if to this we add a brilliant rapidity of execution, joined to gay colouring and tolerable light and shade, with occasionally a madonna's or an angel's head, rather pretty and seductive than devout, we have the sum total of the merits of the most eminent artists who succeeded this period, and the genuine characteristics of the admired Pietro da Cortona, the facile Luca Giordano, and the infidip Carlo Maratti.

It would swell this article beyond our preferred limits, without throwing much additional light on our subject, were we to attempt to trace the different changes of style which at various periods took place in the schools of painting of Germany, Flanders, Holland, or France. The succession of young students, who at all times considered a visit to Italy as an indispensable part of their education; naturally imbued in a greater or less degree the principles of taste to whom they had been taught to look up as models for their imitation: hence the style of the Florentine and Roman mannerists of the 16th century, unjustly denounced the followers of Michelangelo, was caricatured in the preposterous works of Martin Heemskerck, van Man.

Rubens, however, who, though long in Italy, became no wife infected by that poverty of style which then prevailed, broke the fetters of corrupt system, and refuted his countrymen from the effects of such base influence. His comprehensive genius, cultured by reading, enlightened by travel, and blest, above all, with that envied quality, a just appreciation of its own powers, could not but obtain its object, that object being once clearly defined and steadily pursued. What that object was, the decided character of his works sufficiently determines: it was unquestionably the union of magnificent and expressive composition, with the most splendid colouring and the greatest breadth of chiaro-fuoro; for, however enchantcd by the spells of colour, Rubens never forgot that painting is mute poetry, and its first great prerogative, the convert; which, through the medium of the eyes, it is permitted to hold with the understanding. It cannot, therefore, be said of Rubens, as of the Venetian painters we have cenured, that he sacrificed the ideal to the mechanical part of his art. With the exception of his smaller works, or such as he was sometimes necessitated to undertake, in compliance with the will of his employers, we generally find in his productions the most judicious application, the most happy combination of his powers:—Subjects allowing full scope to the exuberance of his invention, compositions furnishing an ample field for the magic blaze of his tints, and the broad expanse of his malleus.

It was the good fortune of Rubens that the burines of the most eminent engravers were employed under his own inspection, to make prints from all his chief works; and indeed so admirably is the character of the originals preferred in those of Bleeuwrt, Volterm, Pontius, and others, that when the pictures shall be no more, they alone will be sufficient to eternize the claims of this great master of the Flemish school. As an inventor and composer, the "Battle of the Amazons," the numerous "Huntings of Wild Beasts," the "Raising of the Crof," the "Michael combating the Devil and his Angels," and the two tremendous representations of the "Fall of the Wicked," are alone sufficient to place Rubens in the first rank; to lay nothing of his celebrated "Garden of Love," and the truly poetic allegories in the "Luxemburgh gallery."

Of Rembrant, the great head of the Dutch school, it has been justly remarked by Mr. Fuchs, that he was "a genius of the first class, in whatever relates not to form." We have in another place spoken of his chiaro fuoro, (see Clair Obfure,) and we can, with equal propriety, upon the present occasion, recommend the study of his works to all those who feel with us, that the telling of the story, and the appropriate expression of the subject are the true ends of composition; nor will we omit to add, that the works of many of the other Dutch painters, particularly Oskade and Dwwer, however the humble representations of low and vulgar nature be their object, abound in admirable examples of composition, and may be studied with advantage, even by such as make the more noble path of historical or epic painting the course of their pursuit.

In the retrospect we have taken of the styles of composition at different periods, adopted by the schools of Italy, it has been our care to point out to the student such examples as are best calculated by their influence to promote his advancement towards the legitimate end of our art; at the same time, that we have cautioned him against that corrupt but specious system of grouping, which, for dilution's sake, we have called picturesque.
The art of painting is a language addressed, through the medium of the eye, to the understanding; like that addressed to our minds through the ears, it must have some ideas, some truths to communicate; and the perfection of painting, as well as of writing, consists in conveying those truths to the mind in the most clear, the most forcible, and most beautiful manner. A judicious distribution of the arguments in a discourse is of importance, inasmuch as it gives additional force, and finds increased interest on the evidence contain'd; but in a picture this propriety of distribution is itself the argument and the evidence, and is therefore indispensable.

Those who are conversant with the first sketches and drawings of great masters, know that a few simple rude lines are frequently found sufficient to impress the mind with a decisive and immediate idea of the story meant to be represented, and that, in many cases, even the expressions as well as the actions of the chief figures seem evident, although no features of the countenances be delineated.

We may, therefore, safely affirm, that any rule, any mode of composition, except such as is dictated by the subject of a picture, is wrong, and that, were this doctrine sufficiently understood, we should not so frequently pass unversed by graphic representations, or remain ignorant of the subjects they were intended to express.

To attempt, therefore, to prescribe any general method of distribution would be to insult the understanding of our readers and to degrade the art. The painter, warmed by his subject, must form the ideal picture in his imagination, and then transfer it to the canvas: it is only as to the relative economy of the parts of the work that some hints may be suggested: these are the result of observation and experience, and bear the strictest analogy to the precepts we have inculcated respecting chiaroscuro and colouring, and, perhaps, to every other part of the art.

As there should be in a picture one principal mass of light, which, however connected with others, should still predominate: so one group or one figure should strike the eye with the same superiority over the secondary groups or figures of the composition; as in chiaroscuro there is no rule by which we are obliged to place the principal light in any one given part of the picture; so are we at liberty to give to the chief group or figure of the composition that situation which we judge most appropriate. As in chiaroscuro, inequality of parts, a subdivision of several main masses to one larger one, never fails to produce richness and beauty of effect; so in composition a similar richness and beauty are the result of an opposition of several small bodies or parts, to one large and simple; as we have before illustrated by the sublime group of the Almighty, supported by a multitude of angels, in the "Creation of Adam," by Michelangelo.

As by the addition of smaller masses of light, connected with the principal masses, that mass acquires at once greater breadth and influence; so the unity of action in a composition is in most cases powerfully augmented by a repetition of nearly the same action in two or three of the accessorius figures arranged together, one nevertheless being principal: this was the frequent custom of Raphael; it has its foundation in nature, where similar sentiments most frequently excite similar outward demonstrations, and never fails, if judiciously managed, to produce its effect.

Everything that has been said relative to contrast of chiaroscuro, or relieving dark or light masses immediately by their opposites, equally applies to composition, where strong contrasts of line, of back to front figures, &c. produce similarly striking and beautiful effects, and must to infuse those effects be used with similar discretion and parimony. The too frequent introduction of contrasts of lights and shadows or of colours, produces a spotty and confused effect; the inordinate use of contrasts in composition produces fancied confusion, and defeats their end. The moderate introduction of them in both cases gives a zest to the picture. It is like the border or other well-disposed ornament on a piece of drapery; but when indiscriminately used, the work refumbles the rich gothic medley of an embroidered petticoat, where the beautiful folds of the stuff are wholly obscured by tinsel and gewgaw.

Having observed thus much, we must refer the reader, who is desirous of obtaining a more complete insight into the subject of this inquiry, to the works of the great masters above-mentioned, or to the numerous prints which have been made from them, by the most eminent engravers of the last three centuries. One hour spent in the study of the Cartoons of Raffaèi, or the Last Judgment of Michelangelo, will perhaps teach more than could be inculcated by words in the contents of this volume.

What we have laid of historical composition may equally apply to landscape; each work should possess a decided character, distinguishing it from its neighbour, and calculated to incite a train of kindred reflections. This we sometimes find in the simple views of the Flemish and Dutch painters, who painted nature as they found her, and did not think it necessary that every picture should possess a given proportion of fore ground, middle ground, distance, and extreme distance; a winding road, a meandering stream, a water-mill, a church steeple, a hanging wood, and a mountain.

The works of the two Poufì, some of those of Salvator Rosa, Dominichino, and the Caracci, and the admirable etchings from the drawings of Titian, abound in the finest examples of sublime and characteristic landscape, and are indeed so perfect in their way, that they can never be sufficiently contemplated by the artist who would attain eminence in this delightful branch of art.

Plates illustrative of composition.

2. "The Cartoon of Pisa" (or according to Vafari, their chief group) by Michelangelo Buonarotti.

4. "Groups of the Last Judgment," by the same author in the same chapel.

5. "Paul preaching at Athens" from the Cartoon, by Raffaèl, at Hampton Court.

Composition, in Pharmacy, the art, or act, of mixing ingredients together into a medicine; so that they may aid each other's virtues, supply each other's defects, or correct any ill qualities thereof.

Composition, in Printing, ordinarily called composing, is the arranging of several types or letters in the composing-floor, in order to form a line; and of several lines ranged in order in the galley, to make a page; and of several of these to make a form.

The composing-floor is made of iron generally, sometimes brafs or wood; of greater or less length or depth, according to the page to be composed, or the compositor's fancy: it hath two lining pieces, to be fastened by means of a nut and screw, which are hinged forwards or backwards, at the pleasure of the compositor, and according to the space...
force which the lines, notes, &c. are to take up. See Plate Middelmay, Fig. 5.

The composing-flick ordinarily contains seven or eight lines of a middle-sized letter; when, when set, are taken out, by help of a thin slip of brass, termed a rule, and disposed in the galley; and others composed, till a page be formed. The page being composed, is tied up, and set by; and the rest of the pages of the sheet prepared in the same manner: when done, they are carried to the imposing or correcting-rome; there ranged in order, and disposed in a chafe, or iron-frame, fitted with wooden furniture; then, the quires being struck in, it is carried to the press to be printed.

Composition, in Sculpture, from Compouisions, Italian, the art of placing figures or other objects together, whether by entwining them in groups, or forming them into masses more nearly or diffily apportioned. The word bears the same meaning in the arts of design as in literature, from which it was most probably received, with many other terms, by the Italian artificers at the revival of learning. Although in its most simple sense it is only synthesis, or joining together; yet, in its extended application, it comprehends the production, order, and fitness of all the parts contained in the whole. The first elements, therefore, are invention and sentiment; the invention should be new and copious, affording an abundant choice of beautiful parts according to the subject, whether there be many figures or one only; the sentiment must be just and striking; according to the rule “feel yourself if you would make others feel!” this must pervade every part of the character of the figures; their action or passion expressed to the points of their fingers and toes as well as in the very folds of their drapery.

The order of composition contains the divine, heroic, and historic. The divine contains all sublime and terrific subjects of divinities, angels, departed souls, and infernal ministers. The heroic, according to the ancients, consists of those mortals, said to have one mortal and one immortal parent. The historic class contains the whole series of human life, in which however the most exalted persons and circumstances are always to be preferred.

The arrangement must be dramatic, representing an action; because sentiment only affects the countenance of the figure prior to action, and words cannot be expressed by mute figures; therefore the sentiments and passions must be demonstrated by the action, in which the figures partake. The principal person must have the most distinguished place, while the inferior person is the most distinguished; thus in “Prometheus chained.” Prometheus occupies the first interest and place, whilst Force, Strength, and Vulture are grandly inferior, although linked in the same group. If the hero or heroine of the subject be not entwined in the same group with other figures, he or she will be distinguished by a preferable situation to those in which the inferior persons are placed: this rule is observed in all the best pictures of the Herculaneum collection. In the antique baffe-relievos and painted vases, and in the best works of antiquity, we scarcely ever see more figures introduced than such as are sufficient to tell the story, and for this reason that the expression may be the stronger, being less divided.

Outline. The general outlines of a composition, whether it consist of one or more groups, should be agreeable to the eye, which is produced by a succession of curves of different segments alternately reversed; or, in other words, a succession of S. lines of different curvature and dimensions. These will be more gentle in tender and graceful subjects, such as the Triumphs of Hymen, Achilles, and Sea Divinities, the Judgment of Paris, &c. In the antique baffe-relievos, the curves become more violent with a mixture of angles in subjects of great exertion, such as the War of the Giants, the Battles of the Lapithes and Centaurs, the Athenians and Persians. See Stuart’s Athens, vol. ii. Museum Pium Clementinum. Baffe-relievos. In the fine antique groups, as the Laccoon, Niobe and her Daughter, Cupid and Psyche, and the Fauns and Nymphs, the lines are interwoven (chained) as it were linked into each other in whatever view they are seen.

Light and Shadow. Sculpture is not like painting, seen and forced on our perception, by the variety and brilliance of its colours. On the contrary, it has properly no colour at all; and its forms are underlaid by the effect of light and its privation, with the degrees of their medium called middle tint; these, in fact, produce the all of sculptural forms to the eye, because such a thing as outline really exists, and when we speak of it or use it, it is only to demonstrate form geometrically. Light and shadow will be continually varied in the varied forms of the human figure. If seen abroad in the open air, or illuminated from a sky-light within doors, the light will strike most powerfully on the head and breast, and gradually with less force on the lower part of the body and inferior limbs as they approach nearer to the earth. If the figure be recumbent, or in any horizontal position, those parts will have most light which are nearest to the luminary. If the figure be inverted, the bottoms of the feet will have the strongest lights, which will gradually diminish as they approach the head; and consequently all those parts which are shadowed, when the figure is upright, will be lightened in this position, and vice versa.

It must be remembered that, as the human figure partakes of globular forms, some one part will be lighter than the rest, and that light will be brightest in one point. It will be found that figures in sculpture are almost covered with middle tint, having a small portion of bright light nearest the luminary, with a very few dark and strong shadows which relieve particular projections. Baffe-relievos present the general effect of darkish figures on light back-grounds; in distribution of quantity, of both lines and form, that will be most agreeable which is inherent in the nature of things, which pervades all creation, and is more particularly evident in musical proportion of thirds, fifths, and fifths, with their subdivisions and relative quantities.

We must however observe, that the rules for composition, like all other rules laid down for liberal art, will only assist genius; they will never produce any thing without the vigorous exercise of mental powers and manual industry, in the fabulous investigation and diligent imitation of nature; all must be done by sympathy and beautiful representation; rules may be compared to the compass for raising a building. We must therefore remember that the beauties of nature are also various as they are endles; and from them only we can furnish ourselves with original materials for composition, by continually observing the expression of sentiment and passion in men, women, and children; the characters of their faces, the forms and action of their limbs, their draperies, and the manner in which the direction of the folds of the clothes or indicates the bodies or limbs, in the grouping of figures; the entwining of the limbs should be carefully observed, and the planes in which the different parts of the bodies and limbs are directed.

In the liberal arts, the sentiment of a composition applies to our sympathetic feelings, as the invention for prizes and delights by its novelty, and both together animate the mas as a body is animated by the soul; and as no composition would be complete or interesting without them, so when these vital principles are obtained, great care should be
be taken to confine their demonstrative forms within that department of art to which they belong, in order that the whole may be as pleasing as interesting, without deformity or absurdity. Thus, for example, all those positions which extend the human figure by violent action should in bas-reliefs be represented in the flattest view, in which all the lines of the body and limbs may be underfoot in the fullest and clearest manner, without legs or arms standing out horizontally from the back ground, like scaffold poles driven into a wall. Such extended members belong only to the class of entire sculpture, as ãtucs and groups. The lines and limbs in the composition must be more parallel to the back ground, as the alto-relievo or baso-relievo recedes from entire sculpture, until, in the flattest relief, the most complicated forms and groups are distinguished by little more projection than an outline gives.

COMPOSSIBLES, COMPOSISSLIA, in Logic, such things as are compatible, or capable of subfiling together.

COMPOST, in Agriculture, a term signifying that fort of manure which is formed by the mixture or combination of one or more different ingredients with dung or other similar material, so as to constitute an uniform mass or substance fit for the improvement of the soil.

Thse comports are usually made by mixing various substances with fable or yard dung; and hence, in some countries, are called mixes.

The most common materials for this purpose are turf pared from walk places, virgin earth, peat earth, lime, the scourings of brooks, ponds, and ditches, weeds, sea-land, rubbish of buildings, coal-ashes, &c. That dung alone, properly managed and applied, is a most valuable manure, is beyond all doubt, but it is certainly not equally useful in all soils and situations. It is much better calculated for active than inactive soils. On lime-dune, chalk, &c., it meets with abundance of active materials; but upon clays, deep loams, &c., it operates best in conjunction with lime or some other stimulating substance. When dung is intended for a compost, no attempts should be made to add a large quantity of lime, earth, &c., till it is properly fermented, every addition of this checking the fermentation. The lime, earth, &c., should be added after the fermentation is finished, and the whole then carefully mixed, and laid up together. In a few days a second fermentation will come on; and if the mixture has been properly turned over and properly incorporated, it will be fit for use in a month or six weeks. Some judgment and attention will be requisite, with regard to the quantity of lime and other active principles employed; for, if the quantity be small, their action upon the rich substances in the dung will be partial and imperfect; and if too great, a considerable loss may be sustained by their over action. If the quantity of earth also be too great as to press the dung too hard, the air will be excluded, and the second fermentation be impeded or prevented. It is certainly a right method to lay a good coat of earth as a foundation for the dunghill, into which the moisture of the dung may sink down; and it is no bad way to make a heap of such substances as can be readily obtained, apart from the dung, and to throw the moisture of the dunghill, and the urine of cattle over it frequently.

The composts employed by the farmer are formed in various ways. In some places where there is a head or foot ridge, too high to admit the water being readily discharged from the field, they plough it, then fill it full of lime, dung, or both, and, after frequent ploughings, spread it upon the field. After the lime by these means is fully intermixed, the earth may be gathered into a heap with the spade, and mixed with dung; or the whole operation may be performed with the spade, which is still better.

It is remarked by Mr. Young, that "the farmer may have great advantage from composts; which, when they contain of proper materials, and are skilfully mixed, he may safely depend upon. Where a variety of materials can be had, they may, he says, be laid as follows: first clay or strong earth, next soap ashes, dung, loamy earth, lime, turner's bark, green vegetables before they run to feed, earth, or as many of these as can be got; also fat chalk, fen-weeds, fen-land, and several others; which may be so mixed, as not only to raise a general fermentation throughout the whole compost; but likewise to suit the nature of the land on which it is intended to be laid. The common way is to lay the several materials in layers, one over the other, till a large heap is raised; and it is advised by some authors, and the practice of many farmers, is, to make these layers from six inches to a foot in thickness: but this he has found by experience is wrong. For the fermentation raised in the compost is not strong enough to penetrate these thick layers, especially those of clay, or strong earth; for after the red have sufficiently fermented, and the compost is turned, these layers ride alms; as whole as when first laid, and must be broken by hand, to mix them with the rest of the compost; whence arise two inconveniences, one an extraordinary expense, and the other that twice or thrice turning is sometimes necessary to diffuse these large pieces; and as a new fermentation is excited every time the compost is turned, the strength of the manure is greatly wasted before it is laid upon the land, where it is then incapable of raising any considerable fermentation, which is, he thinks, one of the principal ues of manure."

It has been suggested, that the best way of making compost is not in thick layers; but after the ground is marked out for the compost, to lay the several materials, after being well broken, in heaps round the space marked out for the compost heap; and to place a man between each two heaps, to throw the manure spreading upon that space. In this manner, the compost heap will soon be raised to the intended height, and the several sorts of manure being thus well mixed, the whole will soon begin to ferment, and will incorporate as fully in two months, as the same manures, placed in layers in the usual way, will in four or five. The owner, therefore, in making such composts, should not prepare them too long before they are laid upon the land; otherwise they will be much wasted, and their bulk evaporated and destroyed. And "composts prepared in this manner need not be turned, or at most not above twice. If the fermentation is observed to abate too soon, holes should be made with a pole from the top almost to the bottom of the heap, upon which throw urine, or the returning of a dunghill, which will fill the holes, force through the whole substance of compost, and soon complete the fermentation." It is added, that "such a compost, by duly proportioning the ingredients, may be made to suit any sort of land, and is excellent for meadow or pasture grounds. A way to improve these, is to cut them live or fix inches deep with the five-cuttered cutting plough, or fascinator, which cuts the surface in chips four or five inches asunder, but does not raise or turn them. This cutting of the roots of the grass, and the manure laid on at the same time, linking into these incisions made by the coulter, cause an improvement in the quality of the herbage, and also make such grass grounds produce much more than they did before. But here it is to be noted, that cutting the ground first, and then laying on the manure,
ure, makes a greater improvement than manuring by, and then cutting; and both are superior to manuring and not cutting; all which have been proved by experiments. The cutting-plough is used with success upon clay grounds, loams, and gravel; but in very strong grounds, the cutters are apt to be thrown out of their work by clods; and therefore, it is not proper to use the cutting-plough where clods abound to any great degree"

It is added, that "in such composts, where it is intended to use a large proportion of earth, that lies at a considerable distance from the limekiln, to have the double carriage of it to and from the compost heap, the dung and other materials may be carried to a head land of the field to be manured, and be there mixed into a compost."

It is contended that "the bell situation for a compost, is upon level ground; or if made upon a deficient, a trench should be cut on the lower side to receive the running of the heap, which is some of the bell part of it, and is old from time to time be thrown up again, which will quicken the fermentation."

It is supposed that "the richest composts may be made in the farm-yard, which should be made deepening all round from the sides to the middle in form of a hollow ditch or bafon. When the yard is made in this form, little of the urine or liquid part of the manure can run off or be walked. When the dung is carried from the stables, cow-houses, &c. into the farm-yard, it should not be thrown carelessly in heaps, each fort by itself, but carried in carts or wheelbarrows, and laid regularly, and spread all over the yard. Upon this should be spread a thin layer of earth, mud, the flowerings of ditches and ponds, green vegetables before they run to seed, and other such materials as are most suitable to the nature of the land, to be manured with them. The rafts and cribs out of which the cattle are foddered, should be frequently moved over the yard, that the offal straw and hay may be equally differed, and trod in by the cattle. This method of spreading the dung and other materials being continued, the whole will be incorporated with the urine of the cattle, and make an extraordinary rich compost."

It is supposed that the only inconvenience of this kind of compost, is its being filled with the feeds of weeds, from the earth mixed with the hay, straw, and dung of the cattle. It is, therefore, a manure bell suited to grass-grounds, and to such arable lands as are to be hewed, as turnips, cabbages, carrots, potatoes, beans, &c. as these weeds will in a great measure be destroyed by good hoeing, or a proper attention to the after culture of the crops. And the earth or mud gathered from the bottom of ditches is excellent for composts. It is usually the lightest part of the soil, carried thither by water, and frequently contains a large proportion of vegetable matter. To this may be added, the cleanings of yards, especially where they are laid with lime. One of the bell materials for composts is peat-earth: this fills up the pores of a sandy or gravelly soil, without diminishing its friabillity. Even when applied by itself to such soil, peat increases its fertility. In a hard clay soil, it should be fermented with lime or dung, or both, and frequently turned, to make it mix properly. Without this precaution it dries, hardens, and cannot be afterwards properly mixed and incorporated with the soil. With regard to the making of composts, if only one fort of manure be used, it is only necessary to put the manure and earth into alternate layers, in a long ridge, and top it so that the rain may not wash through it. When both lime and dung are used, a layer of earth should be interposed between every two beds of lime and dung; for lime, if mixed with dung in the full stage of its putrefaction, corrodes and dissipates its effluvia. After the first fermentation of the dung is completed, the whole should be turned, to mix the ingredients; and this operation should be repeated until the mass shall be sufficiently pulverized; which is done by cutting the compost with a spade in perpendicular stiles. All the weeds should be collected from the neighbouring fields, before they run to seed, and mixed with the compost. The weeds also that grow upon it should be buried down in it. Such kinds of composts may be used for any crop, and when sufficiently pulverized, are excellent for a top dressing to pastures; the parts being gradually crumbled down, and beaten into the soil by the feet of cattle, or washed in by rains. Some are of opinion, that no advantage results from mixing dung with earth; a bottom of earth, however, must always be useful to retain the moisture that flows from the dung. Quicklime mixed with the dung is useful, by keeping the manure in a proper state, and preventing the putrefaction from proceeding to too great a length. It has been observed, that making compost dunghills is a general practice in Norfolk. The principal source of them is the flowerings of ditches, which are found there to be fragularly fertile. It is not the sediment of water from the inclosures, but it contains entirely of dead weeds, leaves of the hedge, and the mouldering of the bank and files of the ditch. The most barren sub-lfratum, exposed a few years in the face of a ditch bank, is frequently changed into a rich black mould. Perhaps the sea air, acting upon a loose porous foil, may afford in producing this change. Other flowerings of manure are useful, the backs of ditches, the borders of fences in general, the sides of lanes, the nooks of yards, and which, in many places, are covered to remain the nursery of weeds. These are turned up into ridges, to root the roots of the grasses and weeds, and to receive the menstruation of the air; which done, they are carted in due feation to the dunghill, to be well incorporated with that subliration. It is stated as a good and economical mode of raising a large quantity of compost manure, to bed the farm-yard about two feet deep with earth, and on this cleanse the flables, cow-houses, hog-huts, &c. and to move the cribs in which loose cattle are fed, with straw about it. This bed of earth will retain the urine, so that, when the whole is mixed together, it will all be nearly of equal goodness, and admirably adapted to gravelly and loofe foils in general, through which the essence of dung always escapes, as well, as in one season; and a top dressing of loofe, pigeons' dung, &c. would last but one crop, and very rotten pure dung would be little better. Having the drains from the flables, cow-hinds, and other offices, made so as to discharge themselves into places where these different sorts of earthy materials are depolitated, might be a cheap and expedients method of procuring good compost-manure. And another good method of raising compost dunghills is by making them into clamps. Make a layer of hedge earth from a grubbed border, two feet deep, and about twelve feet square, in the beginning of November; the quantity of earth will be about twenty-six loads of six tons or bushels each; on this clean all the yards and heds. The yard not being bedded with earth, should be well littered, to soak up the urine, and to be made into dung by the hogs and loose cattle; this may be cleared once or twice a week, and the heds once a week, and piled regularly on the foundation of earth, until the heap is about seven feet high; and when one clamp is thus filled up, another foundation of earth may be laid adjoining to it. In order to enrich the compost, the flowings of the wheaf should be prevented from running off, and thrown upon occasionally on it. By thus pluming the compost in clamps, it will be in very good order for arable land early in the spring; which will not be the case if it be left to be trodden flat over the
the whole yard, and every particle washed by the rain. Fermentation goes on much quicker in this method; and it would be better still if the heap were made under a roof, to keep off all water but what is thrown up. Another advantage of this method is, that any part of the compost may be used, by taking a division of the hill that has been the longest finished, and is consequent in the most suitable state for application. See Duo.

It is found that all sorts of animal substances, mixed with earth, litter, or any vegetable material, make a rich compost. Sawdust, mixed with the blood and oil of a slaughter-house, and incorporated till the whole becomes a mouldy mass, is a rich compost. Two loads of it, with three loads of earth, will be sufficient for an acre of wheat or spring corn. Being a kind of top dressing, it should be put on at the time of sowing, and harrowed in with the grain. This kind of manure is best adapted to lands of an open texture. Tough clays require lime, and plenty of dung, to break the cohesion of their parts. As this compost takes up little room, it is very convenient for the use of such farmers as are obliged to bring manures from a distance: it is also extremely rich, and will probably continue longer in the land than yard or stable dung. All animal substances being of the same nature, the refuse of whale-fish, after the oil is boiled out, will make a rich compost with fresh dung, which will reduce the blubber speedily into a putrid flake, or with earth and dung. Having marked out the length and breadth of your intended dung-hill, make a layer of earth, such as moor earth, or that of ant-hills, about a foot in thickness; over this put a layer of yard or stable dung of the same thickness, then a layer of blubber, and over that another layer of dung. Repeat the operation till the heap be raised about six feet, then give it a thick covering of earth, and coat the heap with sods. In about a month, turn the whole in the usual manner; and when turned, coat with earth as before; to confine the putrid flake. In a month or two, the heap will be considerably fallen, when it should have a second turning. This operation must be repeated at proper intervals, till the whole becomes an uniform putrid mass. In general, this compost should not be used till it is a year old. The heap must be guarded from dogs, swine, &c. This compost may with great advantage be applied to all purposes where good rotten dung is required. It is excellent for cabbages and for meadow ground. One hoghead of whale refuse will make eight loads of dung: and must be of great importance to such farmers as lie at a distance from manure, but within reach of those places where train oil is prepared. The practice of throwing this kind of offal into the sea was highly wrong and inconsiderate. And it is obvious, that the refuse of all sorts of fish, and fish itself, when in haws too great for consummation in the way of food, may advantageously be made into a compost in the way above described. These are local advantages; and are mentioned principally with a view to put farmers upon searching diligently for such substances as are within their reach, that are capable of assisting the sheepfold and common dung-hill, upon which in many places they rely wholly, however inadequate to their wants; abundance of good manure properly managed, being the life and soul of husbandry. Where there is a deficiency of materials for making good composts, proper for the soil in many cases, a mixture of different soils may answer the purpose. Thus, where clay predominates, the addition of sand, where it is happily within reach, is often sufficient to ensure fertility: and where sand prevails, the addition of clay or chalk will answer the same purpose. Gravel enriches peat-moss; and that in return improves gravel. The farmer should, therefore, search everywhere above ground and below, for such substances as may improve his several soils, by being properly mixed with them.

In considering the nature of manures, and the methods of applying them to lands, under different circumstances, further directions will be given in regard to the making and applying of composts. See Manure.

COMPOSTELLA, or St. Jago de Compostella, in Geography, a city of Spain, and capital of the province of Galicia, with an archbishop's see and an university, situated in a peninsula formed by the rivers Tambre and Ulla. N lat. 42° 34'. W. long. 7° 17'. It has a great number of nunneries and monasteries, and contains about 3000 houses. The public squares, the churches, and particularly the cathedral, are magnificent. The Spanish military order of St. Jago derives its origin from this place, where the body of St. James is reputed to be buried, which circumstance likewise is to draw a vast concourse of pilgrims from most parts of Christendom in former times.

The number of pilgrims who went thither from England in 1428, amounted to 916 persons: in 1433 the number was 5201 in 1434, 2460, and in 1445, 2100. It was the practice for the crown to grant licences to matters of ships for carrying out a limited number of these votaries of superstition, who took with them considerable sums of money, not only for their necessary expenses, but for offerings and other charges incurred by this pilgrimage. See St. Jago.

Compostella Nueva, or New Compostella, a rich town of North America, in Old Mexico, or New Spain, in the province of Xalio, built by Nuño de Guzmán in 1531, near the South sea; 400 miles N.W. of Mexico. The soil is barren and the air infurbrious; but it has several mines of silver at St. Pequeno, in its neighbourhood. N lat. 24° 10'. W. long. 115° 13'.

COMPOND, the result or effect of a composition of different things; or that which arises from them.

Strictly speaking, every new compound does not produce a new compound; but only that from which a new essence arises. Thus, when one drop of water is added to another, there does not arise a new physical compound; the essence being the same now as before the union.

Compound differs from complex, and flanks opposed to simplex, which see respectively.

COMPOND, in Botany, applied to leaves, expresses their being compound of more than one piece, or leaflet, connected by a common footstalk, which is either simple or branched. Folium decompostum is applied to a leaf more than once compound, and supri-decompostum to any greater degree of such conformation. See Leaf.

A compound flower is limited by Linnæus to that particular kind of aggregate flower, (see Aggregate) whose florets are sessile on a common receptacle, within a common calyx, and furnished with anthers united into a tube. These are the exclusive characters of the great natural clafs fyngeta, the 19th in the Linnæan System, the last order of that clafs, menaginis, consisting of simple flowers, being now, by general consent, put a class. Compound flowers consist either of uniform perfect florets, each furnished with filaments and pistils, and all ripening perfect seed; or of such florets in the disk, with female, or even neutral, ones in the radius; or, finally, of male florets in the disk and female florets in the radius. Their partial corollas are either tubular and five-leaf, or ligulate, drop-shaped. Their manner of becoming double is for the tubular and perfect florets of the radius to become ligulate and female only, or even neutral, which change is often extended to all the florets, even to the centre, in which case no seed is formed. Sometimes the ligulate florets become not only abortive, but tubular,
tubular, or quilled. The prevailing colour of compound flowers is yellow, especially their disk. The ligulate radius is often white, red, or blue, with a yellow disk, but if the radius be yellow, the disk is never of any other colour, except what arises from the anthers or ligular.

Compound Port. Forms, Puffils, Fractions, Fracture, Glund, Harmony. See the substantives.

Compound interest, called also interest upon interest, is that which is reckoned not only upon the principal, but upon the interest itself forborn; which hereby becomes a sort of secondary principal. See Interest.

Compound Larceny. See Larceny.

Compound Machine, Machinery. See the substantives.

Compound motion, that motion which is effected by several conspiring powers.

Powers are said to confpire, if the direction of the one be not directly opposite to that of the other; as when the radius of a circle is conceived to revolve about a centre; and at the same time a point to move straight along it.

All curvilinear motion is compound.

It is a popular theorem, in Mechanics, that in an uniform compound motion, the velocity produced by the conspiring powers, is to that of either of the powers separately, as the diagonal of a parallelogram, according to the direction of whose sides they act separately, to either of the sides. See Composition of motion.

Compound numbers. See Composite.

Compound proportion, in Mechanics, that which consists of several weights constantly keeping the same distance, both from each other, and from the centre about which they oscillate. See Pendulum.

Compound proposition. See Proposition.

Compound quantities, in Algebra, are such as are connected together by the signs $+$ and $-$: thus, $a + b - c$, and $bb - b$ are compound quantities.

Compound ratio is that which the product of the antecedents of two or more ratios has to the product of their consequents. Thus $6 \cdot 72$ is a ratio compounded of $2$ to $6$, and $3$ to $12$. See Proportion and Composition of ratios.

Compound Sounds, Sord, Tofe, Ulcer, Words. See the substantives.

Compound flops on an organ, are such wherein each finger-key acts upon two, three, four, or even five pipes of different pitches, and causeth them all to sound together, whenever a key in this flop is put down. The most common of these are the Cornet, the Sesquialter, and the Mixture, or Furniture flops. (See these articles:) the use of these compound flops with others which are not tuned to the actual note which they represent, or that on the diapason flop, but to the XIIth or XVIth thereof (See Twelfth, Tiers, and Largo, Stop,) is to introduce an inconceivable number of actual discords into the common chord, even during full performances, as any person may, at leisure, satisfy himself by writing down the several notes produced by a chord formed of the flops above-mentioned, combined with the diapason and other unisonant flops, or by putting down all the keys on a piano-forte at the same time, to which a chord on these flops succurs. No problem in the science of harmonics is more difficult of solution, than to account for the ear's receiving pleasure from such a confused and dissonant afflembly of sounds: and it can only perhaps be accounted for by supposing, that the concordant notes being so many more in number in these kinds of chords, overpower and drown the dissonants to such a degree, that the ear is able by a sort of mental exertion to pass over and not attend to the latter, any more than to the rattling of the keys of a badly constructed harpsichord, or the noise of carriages in the street adjoining a concert-room, &c.

COMPOUNDED IDEA, in Logic, notes several ideas of a different kind, which are usually considered as distinct single beings, whether these united ideas be simple or complex. See Collective idea.

COMPOUNDING Felony, in Law. See Theft, Bote.

COMPOUNDING of informations upon penal statutes, is an offence of an equivalent nature to CHAMPION in criminal cases; and, besides, it is an additional misdemeanour against public justice, by contributing to make the laws odious to the people. At once therefore to discourage malicious informers, and to provide that offences, when once discovered, shall be duly prosecuted, it is enacted by statute 3 Eliz. c. 5, that if any person, informing under pretence of any penal law, makes any composition without leave of the court, or takes any money or promise from the defendant to excuse him, (which demonstrates his intent in commencing the prosecution to be merely to serve his own ends, and not for the public good,) he shall forfeit 10/s., shall stand two hours on the pillory, and shall be for ever disabled to sue on any popular or penal statute.

COMPREHENSION, in English Church History, denotes a scheme propounded by Dr. Orlando Bridgman in 1667-8, for relaxing the terms of conformity in behalf of protestant dissenters, and admitting them into the communion of the church. A bill for this purpose was drawn up by lord chief baron Hale, but disallowed. A project to the same purpose was proposed and argued in parliament soon after the restoration, in 1661; but the royalists and zealous churchmen formed a majority, and the endeavours of those who wished to avail themselves of the king's declaration to this effect, proved ineffectual. The attempt was renewed by Tillootson and Sibbling in 1674, and the terms were settled to the satisfaction of the non-conformists, but the bishops refused their assent. This scheme was likewise revived again immediately after the Revolution; the king and queen expressed their desire of an union: however the design failed after two attempts; and the act of Toleration was obtained. Birch's Life of Tillotson, p. 49, 167, &c.

COMPREHENSION, in Metaphysics, is that act of the mind, whereby it apprehends, or knows, any object presented to it, on all the sides, wherein it is capable of being apprehended, or known.

To comprehend a thing, is defined by the schoolmen, comprehendo; totum & totaliter cognovisse. See Apprehension.

COMPREHENSION, in Rhetoric, a trope, or figure, whereby the name of a whole is put for a part, or that of a part for a whole; or a definite number of any thing for an indefinite.

COMPREIGNAC, in Geography, a town of France, in the department of the Upper Vienne, and district of Bellac; 10 miles N. of Limoges.

COMPRESS, in Surgery, from the Latin word comprimere, to press together, is a bolster of linen cloth folded several times, and employed on various occasions.

Compresses are formed sometimes of lint or surgeon's tow, but more commonly of half-worn linen without seam or selvage. The fize, thickness, and form of them, must be regulated by the part to which they are applied, or the object which the surgeon has in view.

When they are intended to cover other dressings to a wound, &c, they must be always larger than the subjacent plasters, and must lie upon the part in an equal and even manner,
manière, so as to retain the dressings deadly on the affected part.

Compresses are divided into simple and graduated. A
simple compress consists of linen or flannel folded from two
to eight times; and are made quadrangular, triangular, or
with pieces cut off a square at the corners, so as to give the
compress a crucial form, &c. A graduated compress con-
ists in a number of simple ones laid one above the other,
and sometimes sewed together in the shape of a pyramid;
these latter are used for compressing a bleeding artery, or
they are applied to the bottom of a fistulous sore, or to the
siders of a deep fleshly wound, or upon ganglions, and some
other tumours, in order to disperse them.

Compresses are employed to fill up inequalities, or hollow
parts of the body; they are also used to guard wounds under
the contact of irritating substanances, and sometimes
merely to receive the purulent discharge. They are fre-
cently moistened with different medicated fluids, and are
applied either warm or cold according to the surgeon's
intention.

Compresses are sometimes of considerable length, and of
little breadth, especially when employed to the extremities
of the body in a circular form, after the manner of common
bandages. (See BANDAGE.) The latter kind of bandage is
named by the French longuette. The methodical applica-
tion of such compresses has effected a cure in some aneu-
rism: they are also found particularly useful in fistulours
and deep sore, where matter is apt to collect and require
counter openings. From the various natures of compresses,
writers have named them extensile, uniting, diverfive, &c.

Tourinquet, trifles, and some other surgical instruments,
are only particular kinds of compresses. (See ANEURISM,
and HERNIA.) Compression is now and then made very
advantageously by means of the finger only, and will often
stop a violent bleeding in parts where no surgical apparatus
can be employed. Thus the root of the nose is comprized
with the fingers, in order to stop violent bleeding, and the
crown of the teeth in order to relieve the tooth-ache; and
in order to make polypi suppurate, platulate, or fall-off,
their roots are comprized between the fingers. A great
number of the bandages that are used, produce their ef-
teys merely by the support which they give to the parts.

The diversity of cafes in which a skilful surgeon will em-
ploy compression with advantage, cannot here be detailed;
but in addition to what has already been said, we may add
that by this means alone; drophical swellings may frequently
be dissipat; and of this, Mr. John Bell records a striking
example in his "Principles of Surgery," 4to. vol. i. p. 128,
where he treats of bandages in general. By the way, we
may mention, that Mr. John Bell has here given some ex-
cellent general observations; but (as in other parts of his
writings) he affects to have read in authors what one
elle can find; and in the influence before us, he pretends to
have read the treatises of Soranus, Galenus, and Dioscorid,
in which," he says, "I find nothing but what has fallen
into deferred neglect;" whereas these authors have not
written any treatises upon bandages that have descended
to the present generation! Well might this author ask the
question, "Why should we go back to the ancients in this
pitiful manner?"

Compressed Fossilis, this term is applied by naturalists to
various extraneous substances found in the earth, which
seem to have suffered a flattening or change of shape, from
the weight of the superincumbent strata; this is not un-
common with fossil shells, of large size compared with their
thicknes, as echini, &c., and should be particularly noted
in describing the circumstances of any stratum, where such
compressed fossilis appear.

The mountains of Quediack and Portfallet in Norway,
contain an argillaceous pudding-stone, the silicious pebbles
of which have been thought by some to be compressed, becau-
s these in the lower part of the stratum are progresively thin-
er than those above (Kirwan's Geo. Exp. 3.); but this
probably was their original shape. The small black chert
pebbles, which form uniform layers in the lower part of the
London clay stratum, are all of them somewhat flat, but
certainly not by compression, we think.

Bituminized wood, or the resemblance of trunks of trees
in wood-coal, is often found flattened, as at Todi, and near
Aquap-Sparis in Umbria, at Thun in Switzerland, in Ice-land, &c. Silicious petrifications have frequently some-
what the appearance of compressed wood, and have been so de-
nominated: but a careful examination of several specimens,
in which the transverse section presented two equal seg-
ments of circles joined together by their chords, instead of a dilat-
ed ellipse, which would probably be the form of round
wood when compressed, has induced us to think that these,
and probably many extraneous fossilis said to be comprized,
may originally not have been round.

Peat-fossilis of the present race, such as the trees found
in the sea at Sutton in Lincolnshire, and in other places,
have without doubt been flattened, by the weight of peat
and earth lying upon them, when in a soft and decaying
state.

COMPRESSION, from the Latin compressio, is the act
of pressing, or squeezing matter together, so as to force
its parts nearer to one another, and enable the whole to oc-
cupy a smaller space; or the effect produced by that cause.
Compression and condensation denote the production of
the same effect; that is, the reduction of a certain quantity
of matter into a smaller space; with this difference, howev-
er, that when the effect is produced by the application of
any external force, as by the pressure of a superincumbent
fluid, or by means of mechanical engines, it is more propo-
denomination compression; but when the effect is produced
by some internal action, as by the escape of caloric in cooling,
it is then called Condensation, which see.

Compression takes place in various natural processes,
and it is also practiced by art for various mechanical and eca-
onomical purposes. The inquiries which may be made con-
erning it, are, 1st, the principal cafes in which compression
is produced in nature; 2dly, the mechanical methods which
are used for compressing bodies in manufactories and in civil
economy; and 3dly, the principal effects which result there-
from. Of the natural compressions, those which arise from
the weights of superincumbent folids are sufficiently obvious,
and they will, besides, be particularly examined under the
articles Gravity, and Mechanics; but those which are
occasioned by fluids, being much less evident, are seldom
sufficiently understood even by those who are concerned
with them.

Water and air are the two fluids with which mankind is
naturally and unavoidably concerned; and the presurres
of those fluids differ materially from each other. The pre-
sure of water is proportionate to its perpendicular height and
not to its quantity, and that pressure is exerted in every di-
rection; for influence, let two vessels of the same height, but
of different sizes, as a small pipe and a large reeyer, be
filled with water to the same height; then if you measure
a square inch in the bottom of the small pipe, and a square
inch in the bottom of the reeyer, the pressure upon those
two different square inches is the same; though the refer-

may
may contain twenty or thirty thousand times more water than the pipe. Also, if you take a square inch on the side of the vessel close to the bottom, the lateral pressure upon it will be equal to the pressure on the square inch of the bottom; excepting indeed a trifling difference which arises from the perpendicular height of the water above the latter, which barely exceeds the perpendicular height of the water above the former.

But though water presses upon every body that is immersed in it in proportion to its perpendicular height, and tends to force the parts of those bodies closer to each other, provided that those bodies have not pores large enough to admit the water; yet water is not itself susceptible of compression, and, though a very slight, and scarcely perceptible degree; hence at different depths, water is nearly, if not exactly, of the same density.

The air of the atmosphere, as well as the other aerial fluids, is highly elastic, in consequence of which it only presses upon all bodies that are immersed in it; but, by pressing upon itself, its own density is rendered different at different altitudes. The bulk of a given quantity of air has been found to decrease in the direct ratio of the force with which it is compressed; hence it has been demonstrated, that if the altitudes above the surface of the earth be taken in arithmetical progression, the densities of those altitudes will be in geometrical progression decreasing. If a very long tube, closed at one end be filled with water, and then be inverted in a basin of water, that fluid will remain suspended in it to the height of about 33 feet, that weight of water being counterpoised by the pressure of the atmosphere; (see the articles Atmosphere, Pneumatics, and Hydrostatics.) Therefore, since a man on the surface of the earth is pressed by the weight of the atmosphere, if he places himself at 33 feet below the surface of the water, he will be pressed by twice the above-mentioned weight of the atmosphere; if he places himself at 66 feet below the surface of the water, he will sustain a pressure equal to three atmospheres, and so on.

If the above-mentioned experiment be tried with a tube filled with and inverted in a cup of quicksilver, instead of water, it will be found that the quicksilver will remain suspended in it to the height of about 30 inches, the specific gravity of quicksilver being much greater than that of water. As the pressure of the atmosphere counterpoises a perpendicular pillar of quicksilver about 30 inches high, or more accurately speaking, between 28 and 31 inches; for it varies between those limits (see Barometer); the weight of such a pillar, let its base be what it may, shows the pressure of the atmosphere upon a surface equal to that base. A pillar of quicksilver, whose base is an inch square, and whose altitude is a mean between 28 and 31 inches, weighs 144 pounds, avoidoposite; therefore, at a mean, the pressure of the atmosphere upon every square inch of the surface of the earth, is equal to 144 pounds; and by the rule of proportion, or by simple multiplication, we may determine the weight of the atmosphere upon any other given surface. Thus the pressure of the atmosphere on a square foot, (which is equal to 144 square inches) is 2268 pounds. The pressure on the body of a middle-sized man, whose surface is equal to about 12 square feet, is 27216 pounds; and the pressure on the surface of the whole earth is equal to about 11043085440000000000 pounds. For further explanation of the mechanical properties of fluids in general, see the articles referred to above, and likewise the article Elasticity.

The artificial methods of compressing substances, either solid or fluid, as employed in the arts, and for economical purposes, are very numerous; different compressing instru-

Vol. IX.
Mr. Canton was of opinion that the above-mentioned diminution of bulk under the receiver of the condensing engine, is not to be attributed to any air contained in the water, or any of the other fluids; because when Mr. Saffuré performed the experiment with water which had been boiled to inhibit more than an usual quantity of air, the compression did not appear to be greater. Yet it may be observed, that considering the flight degree of compression which water is capable of, and the difficulty of depriving water entirely of air, one might be induced to doubt whether that compression is not to be attributed to the air. See Canton's account of those experiments in the 52d and 53d vol. of the Philosophical Transactions.

With respect to the effects produced by compression, it is in the first place to be remarked, that certain bodies, when prefl'd, suffer a derangement of form; but as soon as the pressure is removed, they recover their former shape. Those bodies are said to be elastic, and they are distinguished into perfectly elastic, when they recover their former bulk and shape entirely, as the caife with common air, and imperfectly elastic, when they recover their former shape only in part; which is the caife with for the greatest number of bodies.

When the bulk of a body is reduced by compression, the specific gravity of that body is proportionately increased; thus the specific gravity of fine gold, that has been fused only, is 19,253; but the specific gravity of the same, after having been hammered, is 19,562. The specific gravity of pure silver, that has only been fused, is 10,471; that of the same hammered, 12,514. The specific gravity of copper, simply fused, is 7,738; that of the same hammered, is 8,978, and so forth.

Whenever the bulk of a body, and especially of a metallic one, is diminished in bulk by hammering, flattening between rollers, or by any other sort of compression, its hardness or rigidity is increased at the same time; thus soft brass, or silver, or copper, by hammering, or prefling, is rendered hard and elastic. By the application of a degree of heat, somewhat lower than incandescence, that hardness or elasticity of the metal is removed, and at the same time its specific gravity becomes equal to what it was before the hammering. This process is called annealing or softening.

The other remarkable effects of pressure may be reduced to three; namely, a modification of the action of the same degree of heat on bodies, an extirpation of heat, and an extirpation of light. When heat is applied to any body, the effects differ according as the application takes place under different atmospheric preflures. On the tops of mountains, where the prefluence of the atmosphere is considerably less than it is on the level of the sea (in confluence of which the quicksilver does not stand so high in the barometer as it does in the latter), water boils at a lower temperature; and so do other fluids. At the level of the sea, water boils at about the temperature of 212° of Fahrenheit's thermometer; but Mr. Saffuré found on Mont Blanc, which is reckoned the highest mountain of any in Europe; where the barometer stood at 17.05 English inches, that the heat of boiling was 165°.

From the experiments of Sir George Stubbkirk, and of Mr. De Lin, the following table of the heats of water boiling under different preflures of the atmosphere, which are indicated by the altitudes of the mercury in the barometer, was calculated by Mr. Kirwan.

Mr. Watt observed, that in a very good vacuum water boils, or produces copious vapours, even when its heat is not greater than 55°. On the other hand, when water is caused to boil under a great prefluence, a much greater degree of heat must be applied: thus, in Papin's digester (being a strong vessel in which a quantity of water is confined) the water may be rendered nearly red hot; and in that state the dissolving property of water is increased prodigiously. In Ireland a natural discharge of hot water comes out of a deep pit, and when this water falls upon the surface of the earth, it deposits a white powdery fusculent subfance, which, it is supposed, the water was enabled to dissolve by the volcanic heat, that acted upon it under a great degree of compression.

Dr. Hutton, like some other geologists, has ascribed the formation of the various minerals chiefly to the action of subterraneous fires; but he thought that that action was modified by the compression of the superincumbent strata of the earth, which rendered it capable of producing such effects as could not be equally imitated on the surface of the earth; for it seemed to him, that under a great degree of compression, volatility would expose to a high degree of heat such substances as generally fly off in our fires, on the slightest application of heat. Hence, by their chemical relations peculiar combinations might arise; such as are dug from the bowels of the earth. What Dr. Hutton supposed, was in a great measure verified by Sir James Hall, bart., who, by his numerous and well imagined experiments, has shown a variety of remarkable effects, on different substances, by the action of heat modified by compression; but his interesting experiments will be described amongst the effects of heat.

The other two remarkable effects of compression on bodies, are an extirpation of heat and an extirpation of light. These effects having been observed with all those bodies which may be subjected to decisive experiments; it may be presumed from analogy, that the same effects take place in various degrees, with all bodies which are susceptible of compression, but not with those which are not compressible; and, in fact, liquids which are only compressible in the slightest degree imaginable, cannot be heated by agitation, which is friction amongst their particles; and there is no friction without compression. As heat is evolved from a body when compressed, so when the bulk of a body is enlarged, heat is absorbed; in confluence of which the surrounding bodies are cooled; and this absorption of heat seems to be directly proportioned to the enlargement of bulk. The following instances will illustrate the nature of these remarkable effects. The blacksmith, by about twenty strokes of the hammer upon a piece of iron bar not thicker than a man's little finger, can render one extremity of it red-hot, visible in the day light. But it is to be remarked, that the same extremity of the iron bar cannot be rendered red-hot.
red-hot a second time, unless it be previously softened in the fire. The condenfation of common air, quickly performed, produces a considerable degree of heat; so much so, that cotton has been set on fire, and so has heated charcoal, by compressing the air quickly upon it. An ingenious mecha-
nics in Paris is said to have kindled tinder in tubes, or compressing pumps, of about a quarter of an inch in di-
diameter, and six inches in length, by a single blow of the pillow. Steam, also, by mechanical compression, may be made to yield its latent heat. A mixture of oxygen and hydrogen gases, if quickly compressed, takes fire and ex-
plodes with great force. The discharge of an air-gun is at-
tended with a faint flash of light, visible in a darkened room; and the sudden compression of the air in a tube, to the end of which a strong glass is fitted for the purpose of manifesting what passes within, is likewise attended with light.

In explanation of these phenomena, it is supposed, that independent of the specific caloric, peculiar to every body, a quantity of it is lodged in the pores of each body, and that this may be extricated by compression, in the same manner as water is squeezed out of a sponge. But a far-
ther examination of facts will throw more light upon the subject.

It is well known, that friction amongst solids generates heat, which often occasions actual inflammation and com-
bustion. Thus the axles of wheels of carriages, and other machines, are sometimes set on fire by the violence of the friction; thus, in a turning lathe, the pieces of work are heated to a great degree; thus, the violent collifion of a steel against a flint, renders the abraded particles of the former perfectly red-hot. Count Rumford, willing to in-
vestigate the origin of the heat produced by means of fric-
tion, instituted an interefling series of experiments in the workshops of the military arsenal at Munich, where cannons are bored; in which cases a degree of heat far exceeding that of boiling water, is produced. After having examined the temperature of the metallic shavings, their quantity, capac-
ity for containing caloric, &c., and finding reasons sufficient to account for the production of that remarkable quantity of heat which was manifefted in the course of the boring, he began to consider which way that heat might be derived, whether from the contiguous metal or from the air, and in order to determine the matter by means of actual experi-
ment, he contrived a suitable apparatus, the principal part of which was intended to turn a piece of metal in a box full of water, whilst a blunt borer acted forcibly against it, so as to produce a considerable degree of friction, without abrating from the piece of metal more than an inconsider-
able quantity of it in a feally powdery flate. With this ap-
paratus, in which both the piece of metal and the borer were plunged in water of the temperature of the atmos-
phere, no heat could be derived from the air. The ma-
chine which turned the piece of metal being put in motion, the water in the box, &c., began to be heated soon after, and in 2½ hours time, from the commencement of the operation, the water actually boiled. The result of this experiment showed, that the heat, which had caused the water to boil, was not derived from the air, and from computation it appeared, that the abraded metallic powders could not furnish it in confequence of the change of their capacity. "Is it possible," quoth Rumford, "that the heat could have been supplied by means of the iron bar, to the end of which the blunt borer was fixed? or by the small neck of gun-metal by which the hollow cylinder was united to the cannon?" "These suppositions appear more improbable even than either of those before-mentioned; for heat was con-
tinually going off, or out of the machinery, by both these
passages, during the whole time the experiment lasted. And in reasoning on this subject, we must not forget to con-
consider that most remarkable circumstance, that the source of the heat generated by friction, in these experiments, ap-
purred evidently to be inexhaustible. It is hardly necessary to add, that any thing which any inflated body, or system of bodies, can continue to furnish without limitation, cannot possibly be a material substance; and it appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of any thing, capable of being excited and communicated in the manner the heat was excited and communicated in these experiments, except in motion." Phil. Tran. for the year 1798.

It seems strange that so distinguished a philofopher as Count Rumford should be induced to admit the immaterial-
ity of heat from the refult of the above-mentioned exper-
iment, without advertifing to the compreflion which the metal muff have received from the action of the borer.

Having mentioned the principal effects which arise from compreflion, amongst which the extrication of heat has been reckoned the moft interefling; we might now State feveral in-
stances of the contrary effect, namely, of the abforption of heat attending the enlargement of bulk which takes place in feveral bodies after the removal of the caufe which occasioned their compreflion. With refpect to this, how-
ever, we need not be very profic in this place. The hy-
draulic engine at Scheffmuth furnifhes a ftrong inftance of the latter effect. That engine operates by cauing a fall of water to comprefs air in a strong vefsel, the re-action of which forces other water to rife in another pipe Tor certain purpofes. Now, in confequence of the great height of the fupercintendent column of water, the air in the air-vefvel of this machine, is very much comprefled, and it is faid that if the flop cock of this vefvel is opened, the air, in ruth-
ing out of it and expafsing itself, absorbs fo much heat, and, of course, cools the adjacent bodies fo much, as to pro-
duce a copious deposition of moisture from the atmos-
phere, and the actual formation of ice upon the flop cock. The cold produced by the evaporation of water, and es-
cially by that of fpirituous liquors, might be likewise ad-
duced as inftances of the above-mentioned property.

But the farther investigation of these latter phenomena belongs to other branches of natural philofophy, which will be ex-
plained in other places.

The term compreflion, in astronomy and geography, has often been used to denote that diminution of the curvature of the surface of the earth, which has been observed about the poles, as if the earth had been comprefled at the poles by some external forces, which caused it to lose its perfect sphericall form, and to assume nearly that of an oblate spheroid; it being, however, well known that the spheroi-
dal figure arifes from the centripetal force of the parts dif-
tant from the poles, which is likewise the cafe with the other planets. The precise quantity of deviation of the polar regions from the earth from the sphericall form, or the difference between the equatorial and polar diameters, has been variously flated by different astronomers. Sir Iaff Newton, following the defity of the earth to be uniform, has assigned $\frac{1}{2}$ for the difference of the above-mentioned two diameters. Duchess, taking a mean of all the dif-
f erent measurements, found the difference of the two dia-
meters equal to $\frac{1}{2}$ or $\frac{1}{4}$ of the earth's diameter. From other measurements and calcula-
tions made by other able mathematicians, this dif-
ference has been reckoned equal to $\frac{1}{2}$ or $\frac{1}{4}$ of the earth's diameter by De la Lande; to $\frac{1}{4}$ or $\frac{1}{4}$ by De la Place; to $\frac{1}{4}$ by Sejour; to $\frac{1}{4}$ by a late anonymous writer. These latter results agree pretty well with the lengths of the pendulums, which have been
been found to vibrate seconds in different latitudes; so that upon the whole, or a fraction not much differing from this, seems to be the nearest to the true difference of diameters; and the disagreement between the different measurements probably arises from the imperfection of instruments, from the partial attraction of mountains, and from the unequal density of the earth. See professor Playfair's paper on the figure of the earth, in the Transactions of the R. Society of Edinburgh, vol. v. p. 1.

Compression, in Surgery, not only signifies the act of compression, but denotes a class of dilataions produced by the pressure of an extraneous body; and, in some cases, a compression will cause the most serious consequences. For example, compression of the brain, arising from a fracture of the cranium, and a portion of the brain in a depressed state, may occasion inflammation, concussion, and destruction of that part of the brain to which the mechanical effect is applied; which will be more or less, attended by comatose symptoms, and privation of sense or voluntary motion. In such cases, the surgeon endeavors to remove the cause, by elevating the edge of the bone, or extricating it entirely, either with or without trepanning, as the circumstances may indicate. (See Trepanning and Trephining.)

When the symptoms of a compressed brain are evidently marked, no time ought to be lost in setting about an examination of the state of the cranium, wherever appearances point out, or even lead us to conjecture, in what part a fracture may be situated. For this purpose an incision is to be made upon the spot through the integuments to the surface of the bone, which must be sufficiently exposed to admit of a free examination. Some authors have recommended a crucial incision; others, one in form of the letter T; while many advise a considerable part of the integuments to be entirely removed. But as it is more agreeable to the present mode of practice to have as much of the skull as possible, a simple incision is generally preferred, unless the fracture runs in different directions, and then the incision must vary accordingly. It will frequently happen, that a considerable part of the integuments must be separated from the skull, in order to obtain a distinct view of the full extent of the fracture; but no part of the integuments is to be entirely removed. When blood-vessels of any considerable size are divided, either before or at the time of the examination, they ought to be allowed to bleed freely, as in no case whatever is the least of blood attended with more advantage than the present. When, however, it appears that the patient has lost a sufficient quantity, the veins ought to be secured.

After the integuments have been divided, if the skull be found to be fractured and depressed, the nature of the case is rendered evident; but even where there is no external appearance of fracture, tumour, discoloration, or other injury; if the patient continue to labour under symptoms of a compressed brain, if the pia mater has been separated from the bone, and especially if the bone has lost its natural appearance, and has acquired a pale white or dusky yellow tinge, the trepan ought to be applied without hesitation, at the place where these appearances mark the principal seat of the injury. Again, although no mark, either of fracture or of any osseous underneath, should appear on the outer table of the bone, yet there is a possibility that the inner table may be fractured and depressed. This indeed is not a common occurrence, but it happens perhaps more frequently than surgeons have been aware of; and where it does happen, the injury done to the brain is as great, and attended with as much danger, as where the whole thick youths of the bone is beaten in. The application of the trepan is therefore usually deemed a necessary measure.

But if after the application of the trepan, it happens that no mark of injury appears either on the outer or inner table in that part, or in the dura mater below it, and that the symptoms of a compressed brain still continue, a fracture in some other part is to be suspected; or that kind of fracture termed by practitioners counter-fracture, where the skull is fractured and sometimes depressed on the opposite side to, or at a distance from, the part where the injury was received. This is not in most cases a frequent occurrence, and has even been doubted by some; but different instances of it have, beyond all question, been found. If therefore the operation of the trepan has been performed, and no fracture is discovered, no extravasation appears on the surface of the brain; and if blood-letting and other means usually employed do not remove the symptoms of compression, the operator is to search for a fracture on some other part. The whole head should again be examined with much accuracy; and, by probing deliberately but firmly over every part of it, if the smallest degree of sensibility remains, the patient will show signs of pain, either by moans or by raising his hands, when pressure is made over the fractured part. In this way, fractures have been frequently detected, which might otherwise have been concealed.

Having here considered every thing preparatory to the operation of the trepan, we shall point out the means best adapted for the removal or elevation of a depressed portion of the bone, by the use of that instrument, under the article Trepan. After the operation, the patient should be placed in as easy a position, in bed, as possible, with his head and shoulders elevated a little more than vertical. If the operation be attended with fevers, he will begin from the signs of increasing sensibility and the original head symptoms will gradually disappear. In this state, he ought to be kept as quiet as possible; proper laxatives being occasionally administered, and such as may be kept of a nauseating nature. His food ought to be simple and easy of digestion, and his drink of the most dihtent kind. If he complain of the wound being unseasy, an emollient poultice should be immediately applied, and renewed three or four times in the twenty four hours. By taste means there will commonly be a free suppuration from the whole surface of the fore.

Every time the wound is dressed, the purulent matter ought to be wiped off from it with a fine warm sponge; and if any degree of floechnesis takes place on the dura mater or parts adjacent, it will then be completely separated. Granulations will begin to form, which will continue to increase till the whole area to a level with the surface of the cranium. The edges of the fore are now to be dressed with some milde cerate, and the rest of it covered with fine lint, kept gently pressed on it by a night-cap properly secured. In this way the cure will go on favourably; luxury of granulations will commonly be prevented; the parts will cicatrize kindly; and as all the skin has been preferred in making the first incision, the cicatrix will be but little observed.

But things do not always proceed in this favourable manner. Sometimes, in a few hours after the operation, the patient is seized with a kind of relightfulness, tending his arms, and endeavouring to move limb by limb, while the symptoms of a compressed brain remain nearly the same as before. In this case, especially if the pulse be quick and strong, the patient ought to be bled freely, as there will be reason to suspect some tendency to inflammation in the brain. Sometimes, though the trepan has been properly applied, the symptoms are not relieved, on account of extravasated fluids collected internally under the dura mater, or between the pia mater and brain, or in the cavity of the ventricles. The danger in these cases will be in proportion to the depth of
the collection. Particular attention, therefore, ought always to be paid, to the state of the dura mater after the perforation has been made. If blood be collected below the dura mater, this membrane will be found teuche, dark eburned, caotic, and even livid; in which case, an opening becomes absolutely necessary to discharge the extravasated fluid. Gentle scratches are to be made with a scalpel, till a probe or directory can be introduced; upon which the membrane is to be sufficiently divided in a longitudinal, or sometimes even in a crucial, direction, till an outlet to the fluid be given.

After the dura mater has been cut in this manner, there is a possibility of the brain protruding at the opening; but the danger from this is not equal to that arising from excited fluids compressing the brain. A troublesome appearance also now and then follows the operation of the trepan; namely, the excreta which are pressed out, and which is a piece of gravel, called fangi (ice fungus), formerly supposed to grow immediately from the surface of the brain, but which, in general, originate from the surface of the dura mater or edge of the bone granulating too luxuriantly. After the wound is cured, only a small crater will remain, and, in general, the parts will be nearly as firm as at first, but when much of the integuments have been separated or destroyed, as they are never re-generated, the wound will be left covered only by a thin cuticle, with some small quantity of cellular substance. When this is the case, the patient usually wears a piece of silver, copper, or tin, properly fitted and lined with flannel, to protect it from the cold and other external injuries.

This is the method now commonly practiced in cases of compression; but it frequently happens, that instead of compression, such a degree of concussion takes place that no assistance from the trepan can be attended with any advantage; for the effects of concussion (see Concussion) are totally different from those of compression, and therefore to be removed in a different manner. In Part III. of his Surgical and Physiological Essays, Mr. Abernethy says, the degree of pressure which the brain can sustain without great injury to the system, probably may vary according to the disposition of that organ to be affected by it, the quality of its application, and the direction in which it is made; and although it must be very difficult to obtain any practical knowledge on this subject, yet there is great reason to believe that the brain can bear more pressure without injury to it than was formerly supposed. The fullness of the cerebrospinal cavities may be a source of great inconvenience. Various means have been used to prevent the excreta from effusing out of the body, and from causing much inconvenience. Where a compressing cause does not, in the least instance, occasion bad effects, if inflammation of the brain ensues, it seems then to act injuriously; which probably arises from the increased susceptibility of the brain. We can rarely judge of the effects of pressure when any part of the cranium is beaten in by a blow; for in that case the shock generally occasions inflammation. Internal hemorrhages, perhaps, afford us the best criterion whereby to determine the effects of pressure on the brain. A case (the seventh) which Mr. Abernethy relates, sufficiently illustrates this remark, for it appears that a considerable hemorrhage must have taken place before it deprived the patient of his faculties; since he walked home, undisturbed himself, and went to bed, after the trunk of the middle artery of the dura mater had been ruptured. In cases of apoplexy, also, the hemorrhage is generally very large, before it produces those consequences which destroy life.

Compress of the brain will sometimes arise from the luxuriant growth of a part of the inner table of the skull, or a small projecting piece of bone, which may have advanced superficially; and it has now and then been discovered that epileptic fits arise from this cause. In apoplexy, the common cause of a compression of the brain is blood or serum. When persons have a palsy of the lower extremities from incrustation of the spine, the paralysis arises from compression made on some part of the spinal marrow by a dislocation of the vertebrae; and nothing can relieve a patient effusively in this case, unless the pressure be removed by extending the spinal column mechanically. (See Curvature of the Spine.)

A dangerous compression may be produced in different parts of the body, by the existence of tumours, by dislocation of the joints, or by fractures, &c. See Tumour, Dislocation, and Fracture.

COMPRESSOR NARIS, or Narium, in Medicine, is a muscle of the nose, described also under the name of constrictor nasi. It arises from the root of the ala nasi, where its fibres are strongly connected with the diaphragm labii superioris et alae nasi, and are also mixed with those of the depressor alae nasi. It proceeds to the dorsum of the nose, and spreads its fibres between the ala and the osseous nasi; they are partly joined with the fibres of the opposite muscle, and partly connected with those of the frontal portion of the fronto-occipitalis. By drawing down the movable part of the ala nasi, and bringing it to the septum, it closes the aperture of the nostrils; in this case the dura-mater alae nasi must concur with it, in order to render the inferior part of the ala fixed. If this latter muscle did not act at the same time, the compressor naris will elevate the lower part of the ala, and thereby expand the naris. Cooper calls it elevator alae nasi: Santorini and Winblad, transversalis nasi.

COMPRESSOR PRESTATA. It seems doubtful whether this should be considered as a distinct muscle, or only as a portion of the levator ani. It arises from the under surface of the arch of the pubis, and is lost between the profunda and rectum. It will therefore have the power of elevating or compressing the former part.

COMPRINT, a surreptitious printing of one bookseller's copy by another person, for gain; which was contrary to common-law and now is under certain limitations, restrained by statute. See Literary Property.

COMPRISE NIENT. See NIENT.

COMPROMISE, a treaty or contract, whereby two contending parties establish one or more arbitrators, to judge of and terminate their differences in an amicable way.

The regular way of appointing a compromise is by a writing, expressing the names of the arbitrators, the power of choosing an umpire, or super-arbitrator, in case of need, a time limited for the arbitration, and a penalty on the party who does not abide by the decision.

By the civil law, a slave cannot make a compromise without the leave of his master, nor can a pupil without the authority of his guardian, or a wife without that of her husband. So a slave, a deaf or dumb man, a minor, and the person who is a party in the cause, are incapable of being chosen arbitrators in a compromise.

The occasions on which a compromise is not allowed of, are restitutions, marriage-causes, criminal affairs, questions of title; and, generally, any thing wherein the public interest is more concerned than that of private persons.

In our law, a compromise is not of so much extent. Well defines it the faculty, or power of pronouncing sentence between persons at controversy, given to arbitrators by the mutual private consent of the parties, without public authority.

Matters
Matters compromised are also matters of law referred, or made an end of. See Arbitration and Arbitration.

Compromise is also used in beneficiary matters; where it signifies an act, whereby those who have the right of election, transfer it to one or more persons, to elect a person capable of the office or dignity.

COMP, in Geography, a small town of France, in the department of the Var, and chief place of a canton in the district of Draguignan; ten miles N. of Draguignan. It contains 3,190 and the canton 2,949 inhabitants. The territory includes 525 kilometres and 0 communes.

COMP, in Geography, a towns of Italy, in Samium, towards the south-east, upon the Appius. At the siege of this city was killed Mico, so well known by Cicero's oration on occasion of his murder of Catilina. See CAMPEA.

COMPATRIOT, a river of Thrace, mentioned by Herodotus, which ran from north to south, and discharged itself into the lake Biflonis, near Abdera.

COMPEL, Lewis, in Biography, a native of Dordrecht, and of the order of Jesuits, went to China in the character of missionary in the year 1635. Upon his return he published "Memoirs of the present State of China," &c., in two vols. As an historian he has been accused of a too great partiality for the charafter and manners of the Chinese, and of attributing to them earlier advances in civilization and improvement than he was warranted by real facts. His work was proscribed, and condemned to the ban, as the most means of refuting his opinions. He died at his native place in the year 1739. Nov. 15, Diet. Hist.

COMPTRE, Nicholas, a French monk, a native of Paris, is known as the author or editor of different works which have been met with a favourable reception. Among others, he published "The remarkable Travels of Peter della Valle, a Roman Gentleman, translated from the Italian, in 4 vols. 4to."—"A new and interesting History of the Kingdoms of Torquay and Laos, in 4 to." translated from the Italian of Father Manni in 1666. In the year preceding this, he published the third volume of his Lewis Coulom's "History of the Jews." He died at Paris in 1689.

COMPTERING, or COUNTING-HOUSE, an office in the king's household, under the direction of the lord steward. As called, because the accounts for all expenses of the king's household are there taken daily by the lord steward, comptroller, cofferer, master of the household, the clerks of the green-cloth, and the clerks comptrollers. They also there provide for the household, and make payments, and orders, for all the good government thereof.

In the compting-house is the board of green-cloth.

COMPTON, Henry, in Biography, an eminent English bishop, was the youngest son of Spencer, the second earl of Northampton. He was born in the year 1632, and, though deprived of his father by death at a very early age, was initiated with great care in the rudiments of learning, after which he was entered at Queen's college, Oxford, where he prosecuted his studies with much diligence, till the year 1632. From the university he went to the continent, with a view of perfecting himself in the modern languages, and of acquiring an accurate knowledge of foreign establishments, ecclesiastical and civil. On his return, he accepted under Charles II. a canon's commission in the king's horse guards, which he soon resigned and devoted himself to the service of the church. He was immediately admitted to the degree of master of arts in the university of Cambridge, and afterwards obtained the grant of the next vacant canonry of Christchurch, Oxford. In 1666, he was admitted canon-commoner of that college, and shortly after was in possession of the rectory of Cottenham in Cambridgeshire. He was in the following year made master of St. Crofie's hospital near Wisbech, and in 1669 installed canon of Christ church. Without further delay he took the degrees first of bachelor of divinity, and then of doctor of divinity. In 1674 he was nominated to the bishopric of Oxford, where he remained but a single year, when he was appointed dean of the royal chapel, and translated to the see of London. For these valuable and highly important preferments, Dr. Compton was indebted as well to his own excellent character as to his family connections. Soon after he had been made bishop of London, he was sworn in of his majesty's privy council, and undertook the supervision of the religious education of the princesse Mary and Anne. To the conscientious discharge of his duty as a preceptor may be justly ascribed the zealous attachment of his pupils, afterwards sovereigns of England, to the Protestant religion, as by law established. This worthy prelate endeavored to devise methods of reckoning the differences to his own church; his intentions were unquestionably good, but some of the means which he used to effect his purpose could not be justified on the principles of protestantism. Under the pretense of guarding the church from heresy, he obtained a royal mandate to prohibit certain discussions on the doctrine of the Trinity; he nevertheless showed himself a decided friend to the Protestant reformation, and encouraged his clergy to defend it with Christian zeal, when the principles of popery, or a more blameable indifference to all religion, were encouraged by the profligate court of Charles II. His conduct in this respect, which cannot be too highly applauded, rendered him obnoxious to the king and to his brother, who soon after ascended the throne as James II. The name of the excellent prelate was immediately after this event struck out of the list of the privy council, after which he was deprived of his office as dean of the royal chapel. For refusing to become an instrument of ecclesiastical tyranny among his own clergy, and to sanction various unconstitutional measures of the king, he was, in 1686, suspended from his episcopal office. In 1688 the dread of a revolution in favour of the prince of Orange, induced the king to attempt regaining the affection of Dr. Compton, and that of the other clergy, who had been lately treated, by restoring them to their office. It was, however, too late to effect a reconciliation, and the bishop shortly after took a decided part in favour of the new order of things. He joined in conducting the princess Anne of Denmark from London to Nottingham; in after time he was made a Lord. He died, and in waiting on the prince of Orange at the head of his clergy, to thank him for his interference in preserving the laws and liberties of the nation; and in the house of peers he voted for the prince and princess of Orange in the room of the abdicated king. Immediately after this event he was determined on, he was restored to the office of privy counsellor, and to that of dean of the royal chapel; he had also the honour of performing the ceremony at the coronation of King William and Queen Mary, instead of archbishop Sancroft, who refused to take the oaths to the new government. In the year 1689 he was appointed one of the commissioners for reviewing the liturgy, and president of the convocation, in which certain proposed amendments were to be discussed. In this situation he at first joined the moderate party, who were for compromising differences by adjusting the liturgy to their minds, but afterwards he united himself with those members who avowed and obtained the discontinuance of the convocation faction. Dr. Compton was appointed, as bishop of London, a commissioner of trade and plantations, and in this capacity he declined and sent over
over to the colonies in America, such clergymen as he thought best adapted, by their talents and zeal, to promote the interests of the Church of England. In the year 1765, he attended the king, at his own expense, to the congress at the Hague, where the grand alliance against France was concluded. From this period he united himself more closely with the Tory party, in consequence of which his influence at the court of king William was greatly diminished, if not wholly terminated; but in the reign of queen Anne, he recovered his former power and interest. Dr. Compton was in the commission for promoting the union of Scotland with England; he was assiduous in obtaining the act for augmenting small livings, by a grant of the first fruits and tithes; and he maintained a friendly correspondence with the foreign Protestant churches, and the university of Geneva, with a view of impressing them with favourable sentiments towards the Church of England, and of obtaining their disapprobation of those who should dissent from its discipline. He died at Fulham in the year 1713, in the eighty-first year of his age. For some time before his decease he is represented to have been much in the power of others, and to have followed their will rather than the dictates of his own mind. Through the whole of a long life he was exemplary in his moral conduct, and displayed the manners of a gentleman. He was a warm friend, a generous patron, and truly charitable to the wants of those about him. As a bishop he maintained the interests of the church, and was attentive to the conduct and advancement of his clergy, but as a preacher he was extremely dull and inanimate. His character as a literary man was respectable, though his works are not numerous nor of the first rank in merit. He published a translation from the Italian of "The Life of Donna Olympia Maldachini, who governed the church during the time of Innocent X." "The Jesuits' Intrigues with private Instruction of that Society to their Emulations," translated from the French. "A Treatise of the Holy Communion," and letters to the clergy at different periods, which were reprinted in 1766, under the title of "Episcoplia, or Letters of the Right Reverend Father in God, Henry Lord Bishop of London, to the Clergy, &c." He also published "A Letter on Non-reliance," which may be seen in memoirs of Mr. John Kettlewell. Dug. Brit. Todd's Continuation of Rapin, vol. vi. &c.

COMPTON, Little, in Geography, a town of the United States of America, in Rhode island.

COMPTONIA, in Botany, (so named by Dr. Salander, in honour of the right reverend Henry Compton, lord bishop of London, who cultivated many exotics at Fulham.) L'Herit. Strup. Nov. Schreb. 1764. Wild. 1644. Gart. tab. 50. 57. 6. (Liquidambar aphnifoillum; Lian. Sp. Pl. Myrica, Linn. Hort. Cliff. Gale marina. Petr. Mus. 753. Myrti brabantissimi americanis; Philk. ann. 250. tab. 100. fig. 6, 7.) Species near three feet high, shrubby, slender, hairy, branched. Leaves from three to four inches long, half an inch broad, alternately situated, almost to the midrib, resembling those of spleenwort, dark green, hairy underneath, sitting close to the flanks. Male catkins lateral, erect. Nut offensive, turgidly lenticular, naked, smooth, shining. Obsoletely broad, of a bay colour. A native of New York, Pennsylvania, Virginia, and Carolina; cultivated by the botanists of London in 1714; flowering from March to May. Balf. was well acquainted with it in Carolina, and observed, that the branches generally died at the end of the third year, the new wood then succeeding to the old, as in the rubis; it was also seldom found in fruit, though it flowered abundantly.

COMPTROL, or Controle, is properly, a double vellaller, kept of the officers of the officers or commissioners in the revenue, army, &c. in order to receive the true state thereof, and to certify the truth, and the due keeping of the acts subject to that enregistrement. See RECENT.

COMPTROLLER, an officer established to comptrol, or over-see public accounts, and to certify, on occasion, whether things have been comptrolled and examined, or not. Thus, we have a comptroller of the king's boydall, or of the accounts of the board of green-clath; comptroller-general of the customs; comptroller of the navy; comptroller of the mint; comptroller of the exchequer; comptrollers of the accounts of the army; of the chamber, &c. See CLERK.

COMPTROLLER of the Artillery, is the person who inspects the artillery-mutters, makes out the pay lists, takes the accounts of stores and the remainder of them, and is accountable to the office of ordnance.

COMPTROLLER is also the name of an officer, who superintends, examines, and inspects the accounts of the army at large.

COMPTROLLER of the hanaper, is an officer in chancery, attending the lord chancellor daily in term and fealt time. This officer is to take all things sealed from the clerk of the hanaper, inclosed in bags of leather, and to note the just number and effect thereof; to enter them in a book, with all the duties belonging to the king and other officers for the same, and to charge the clerk of the hanaper with them. See CLERK AND HANAPER.

COMPTROLLERS OF THE PELLS are officers of the exchequers, whereof there are two, viz. two chamberlains clerks, who keep a comptrol of the roll of receipts, and going out; originally they took notes of other officers' accounts, in order to discover if they did amiss.

COMPTROLLER of the pipe, an officer of the exchequer, who writes out summonses twice a year, to levy the farms and debts of the pipe. See EXCHEQUER AND PIPE.

He was anciently called duplex ingressor.

COMPTROLLER'S BAY, in Geography, a bay of the Pacific ocean in the N.W. part of America, situated to the north of Cape Sucking, and of an island, stretching S. E. and N.W. about 3 leagues, and lying on the N.W. side of the N. E. end of Kaye's island. N. lat. 60° 6'. W. long. about 21° 30'.

COMPULSION, and inevitable Necessity, in Law, constitute a species of defect of will, and they denote such constraint upon the will, by such a man is urged to do that which his judgment disapproves; and which, it is to be presumed, his will (if left to itself) would reject. As punishments
punishments are only intended for the abuse of that free will, which God has given to man, it is highly just and equitable that a man should be rewarded for those acts, which are done through unavoidable force and compulsion. Of this nature is the obligation of civil subjection, whereby the inferior is constrained by the superior to act in a manner contrary to what his own reason and inclination would suggest; as when a legislator establishes iniquity by a law, and commands the subject to do an act contrary to religion or found morality. How far the excuse will be admitted in foro conscientiae, or whether the inferior in this case is not bound to obey the divine rather than the human law is a question, which admits of no doubt. Nevertheless, obedience to existing laws is unquestionably a sufficient extenuation of civil guilt before the municipal tribunal. The sheriff, who burnt Latimer and Ridley, in the bigotted days of queen Mary, was not liable to punishment from Elizabeth, for executing an order for the destruction of two of her subjects. But in civil cases, the principal cause whereof the inferior is answerable as a delinquent, is the exigency of the municipal community: the inferior, for example, may be liable for injuries to his property, which are done by a superior, even when the superior does it by the superior's authority, or under the compulsion of the public interest or command of the sovereign. And, therefore, if a woman commit adultery, or other civil offences against the laws of society, by the command of her husband; or even in his company, which the law construes a cohabitation; she is not guilty of any crime; being considered as acting by compulsion, and not of her own will. (1 Hal. P. C. 45.) This doctrine is at least a thousand years old in this kingdom, being found among the laws of king Ina the West-Saxon.(cap. 57.) This rule, however, with regard to crimes, admits of an exception in crimes that are mortal in law, and prohibited by the laws of nature, as murder and the like. Also in treason, no plea of coverture shall excuse the wife. In inferior misdemeanors there is likewise an exception; for a wife may be indicted and hath in the pillory with her husband, for keeping a brothel. And in all cases where the wife is offends alone, without the company or coautory of her husband, she is responsible for her offence, as much as any malefe. Another species of compulsion or necessity is what our law calls adffictio per mationem; which is, a third force of necessity, distinguished from the actual compulsion of external force or fear, is, when a man has his choice of two evils, yet the worse, and being under a necessity of choosing one, he chute the lesse punished of the two. Of this sort is that necessity, whereby a man by the commandment of the law is bound to enrich another for any capital offence, or to dismiss a riot, and resistance is made to his authority; it is in this case justifiable and even necessary to bat, to wound, or perhaps to kill the offender, rather than permit the murderer to escape, or the riot to continue. (1 Hal. P. C. 53.) There is another case of necessity, which has occasioned much speculation among the writers upon general law; viz. whether a man in extreme want of food or clothing may justify himself, to relieve his present necessities. Grotius and Puffendorf, and many other of the foreign jurists, maintain the affirmative; alleging that it is just cases the community of goods by a kind of tacit concession of society is revived. Some of our own lawyers have held the same opinion (See Buxton, c. 10. Mitr. c. 4. § 16). Though it seems to be an unwarranted doctrine, borrowed from the notions of some civilists; as at least, it is now antiquated; the law of England admitting no such except at present. (1 Hal. P. C. 54.) However, the founders of our constitution have thought it better to vest in the crown the power of performing particular objects of compulsion than to constance and establish the example of a general acknowludging law. (Blackft. Com. vol. iv.)

COMPULSOR, formed of the verb compellere, to oblige, percurrin, an officer under the Roman emperor, dispatched from court into the provinces, to compel the payment of taxes, &c. not paid within the time preferred.

Thus were charged with so many exactions, under colour of their office, that Honorius called them by a law in 412.

The laws of the Visigoths mention military compellors; who were officers among the Goths, whose business was to oblige the tardy folders to go into the fight, or to run an attack, &c.

Caflian mentions a kind of monastic compellors, whose business was to declare the hours of canonical office, and to take care the monks went to church at the fixed hours.

COMPULTERIA, in Ancient Geography, a town of Italy, in Campania. It is described to former times to have been the residence of the Roman emperors. Thus is it founded by Honorius but Fabius restored it by the sword.

COMPUNCTION, formed from commiseration, of puerors, to pray, in Theology, an inward grief in the mind for having offended God.

The Romans own their confession insignificant, unless attended with compunction, or pricking of heart. See Confession.

Among spirituists, compunction bears a more extensive significance; and implies not only a grief for having offended God, but also a pious feeling of grief, sorrow, and diftisfaction, on other motives. Thus, the miseries of life, the danger of being lost in the world, the blindness of the wicked, &c. are to pious people motives of compunction.

COMPARATOR, in Law, one that by oath justify, or declare, another's innocence. They were introduced as evidence in the jurisprudence of the middle ages, and their number varied according to the importance of the subject in dispute, or the nature of the crime with which a person was charged. In some cases these comparators were multiplied to the number of three hundred. (Barnes, Nicol. ed Vitkins, p. 11.) But the usual number was eleven. It has, indeed, been held by later authorities, that fewer than eleven comparators will answer the purpose; but Sir Edward Coke is positive that there must be this number; and his opinion is founded both on better authority and on better reason, for as wager of law is equivalent to a verdict in the defendant's favour, it ought to be established by the same or equal testimony, namely, by the oath of twelve men. Thus Glanvill expresses it (ib. c. 9.) "labora duodecima manu"; and in 9 Hen. III. when a defendant in an action of debt waged his law, it was adjudged by the court "quod defendentis duodecima manu." Thus too, in an author of the age of Edward I., we read, "aujudicatitur reus et legitum etem duodecima manu." And the ancient treatise, entitled, "Diversio de causa," expressly confines Sir Edward Coke's opinion.

This device, which was adopted for rendering the pur-
ties of blood connected him. Whoever then was bold enough to violate the laws, was safe of devoted adherents, willing to act and eager to screen him in whatever manner he required. The formality of calling compurgators proved an apparent, not a real security, against falsehood and perjury; and the sentences of courts, while they continued to refer every point in question to the oath of the defendant, became so flagrantly iniquitous as to excite universal indignation against this method of prevention. See Oath and Wager of Law.

COMPUTATION, the manner of accounting and estimating time, weights, measures, and money. The word is sometimes also used among mathematicians in the like sense as Calculation.

COMPUTATION of a planet's motion. See Planet.

COMPUTATION is particularly used in Law in respect of the true account, or computation of time, so understood, as that neither party do wrong to the other, nor the determination of time be left at large, or be taken otherwise than according to the judgment and intention of law.

A deed, dated May 11, to hold from the day of delivery, shall be construed to begin on the 15th day of May.

If indentures of demife be ingrossed, bearing date May 11, 1760, to have and to hold the land in S. for three years from henceforth; and the indentures be delivered the 4th of June following; in this case, from henceforth shall be computed from the day of the delivery, and not from the date. And if the indentures be delivered at four of the clock in the afternoon, the said 4th of June, the lease shall stand the third day of June in the third year; the law, in such computation, rejecting all fractions or divisions of the day, on account of that uncertainty which is the mother of contention. In writings, ordered by the flat. 27 Hen. VIII. to be inrolled within fix months, if such writings have date, the fix months shall be accounted from the date, and not from the delivery: if they want date, it shall be accounted from the delivery. Coke, lib. 5.

If a deed be shewn to a court at Windinfield, it shall remain in court (by judgment of law) all the term in which it is shewn: for all the term is but as one day in law. Coke, ibid.—If a church be void, and the patron does not present within fix months, the bishop of the diocese may collate his chaplain; but these fix months shall be computed according to 28 days of the month; and not according to the calendar.

COMPUTATION of Miles, after the English manner, allows 5280 feet, or 1760 yards to each mile; and the same shall be reckoned, not by straight lines, as a bird or arrow may fly, but according to the nicest and most usual way. Cro. Eliz. 212.

COMPUTO, a writ thus called from its effect, which is to compel a bailiff, chamberlain, or receiver, to yield his accounts. It is founded on the statute of W. & M. 2. c. 12.

COMPTA, in Ancient Geography, a town of Italy, in the territory of the Hirpini, towards the frontiers of Lucania. Hannibal, after the battle of Cannae, was invited into the country of the Hirpini by Statius, who promised to surrender to him the town of Compta. The modern name is CONS or CONZA. See also COMPZA.

COMRADE is a common appellation for a fellow-soldier in the same regiment, troop, or company.

COMSHE, in Geography. See COMSHE.

CONAT .VENDAINT, a country situated in the south of France, formerly belonging to the pope, by whom it was ceded, together with its chief city Avignon, to the French government, soon after the revolution of 1789. It now forms part of the department of Vaucluse.

COMTE, Count. The titles of comte, of duke, of vicar, of centurion, or burgun before the time of Charles the Bald, were not hereditary in families. These offices alleviated the finances and justice in the provinces: they were, at the same time, magistrates and military characters; they convoked the bail and arriere-bail. They assembled and conducted the troops to the general rendezvous. And when they judged a cause they had their shield on.

CONTE du Palais. See MAJORROME.

COMUM, in Ancient Geography, a town of Gallia Transpadana, situated towards the north, on the southern bank of the lake Larius. It was founded by the Gauls, became a Roman colony, and was enlarged by Scipio. Julius Cesar established Greeks in it, and then called it the new Comum, but upon their departure it lost this epitaph. It was a municipal town. Pliny founded in it schools and a public library. See COMUM.

COMUS, in Mythology, the god of jollity or festivity. There is great reason to believe, he was the Chamos of the Moabites; Bala-Phorig, Bala-Poor, Priapus, and Bacchus. He is represented under the appearance of a young man, with an inflated red countenance, his head inclined, and crowned with flowers; his air drowsy; leaning on a huntsman's spear in his left hand, and holding an inverted torch in his right. His statue was placed at the chamber doors of new married persons; his pedestal crowned with flowers.

CON, Ital. a proposition, placed before many musical terms; as Con arie, with the bow, after a piu riconato, which fee. Con fordini, with the fordini or mute. Con affetto, tenderly. Con furore, furiously. Con effenzione, differently, as to rapidity. Con violini, with violins, &c.

CONADIPSAS, in Ancient Geography, an ancient town of Scythia, on the other side of Imaus.

CONAFADOS, an episcopal town of Arabia, under the metropolis of Boitra.

CONAJOHARY, in Geography, a pilt town of America, on the south side of Mohawk river, in the state of New York, 36 miles above Schenectady, and 313 from Philadelphia.

CONAME, in Botany, the name given by Aublet to a genus formed by him for a shrub found in Cyenche, which has since been considered as a phyllanthus. He gives it the following character. Male and female flowers on different plants. Calyx fix-cleft. Cor. none. Stam. numerous. Pfl. Germ diatated; style bifid; stigma villous. Peric. Caps. fix-celled.

CONANA, in Ancient Geography, an episcopal town of Asia, in Pamphylia.

CONANICUT, in Geography, an island near the coast of America, a little to the east of Rhode Island. N. lat. 41° 25'. W. long. 71° 20'.

CONANT, John, in Biography, was born at Yeatenton, Devon, in the year 1608. He was entered at Exeter college, Oxford, in 1626, where he acquired great reputation for his diligence and for his talents as an able disputant. As a classical scholar he was remarkable for the purity of his Latin style, and for his intimate and extensive acquaintance with the Greek language. He was also well versed in the several oriental tongues. In 1652, he was chosen fellow of Exeter college, where his fame, as a tutor, procured him pupils from many very respectable families. He m.
commencement of the civil wars obliged him to retire from
the university, and he officiated for some time at the living
of Lymington, where he was plundered of his property,
and imprisoned. As soon as he was liberated he went to
London, and became domestic chaplain to Lord Chasno.
While he continued in his lordship's house at Hanfield in
Middlesex, he preached a gratuitous lecture at Uxbridge
on a week day to numerous audiences. On the 7th of June
1694, he was unanimously chosen rector of Exeter college,
without any solicitation on his own part. Shortly after
this he was in danger of being driven out of all public em-
ployment, by the parliament's requiring his subscription to
the "engagement," by which a promise was to be given to
be true and faithful to the commonwealth of England,
without a houfe of lords. This he at first declined; having
however a fortnight given him to reconsider the matter, he
submitted; but under a declaration, subfribed at the same
time with the "engagement," which rendered that instrument
almost nugatory. He now entered upon his office as rector
with increased zeal, and discharged the several duties incum-
benent upon him, with the utmost diligence and fidelity.
In December 1674, he was appointed divinity-professor of
the university of Oxford, and in three years afterwards he
was raised to the dignity of vice-chancellor of that univer-
sity, which he retained till August 5, 1675. While he held
this high office, he was very instrumental in procuring Mr.
Selden's valuable collection of books for the public library;
he distinguished himself by the correction of abusés, and by
the regulation of the public exercises in such a manner, as
proved highly beneficial to the interests of solid learning.
By some of his biographers, Mr. Conant has been applauded
for the share which he took in defeating a project for erect-
ing an university in the county of Durham. Praise on this
account to us seems very ill bestowed, because the intended
object was worthy of a great nation, whose places of public
instruction cannot be regarded as sufficiently numerous, to
supercede the necessity of others in distant parts of the
kingdom. Upon the restoration of Charles II. Dr. Co-
rant, in his official capacity, came to London, attended by
the proctors, and others, and being introduced to the king
he made a Latin speech on the occasion, and prefented his
majesty with a book of verses written by the members of
the university. He was appointed, in March 1661, a commis-
fioner with others to review the book of common prayer,
and he siflled at the Savoy conference. After this, upon
the passing of the act of uniformity, he was debarred of his
preferments, because he refused to conform. During eight
years he lived in retirement, when, upon fervent deliberation
on the nature and lawfulnefs of conformity, he resolved
to comply, and submitted to a re-ordination by Reynolds, bi-
shop of Norwich, whose daughter he had married nearly
twenty years before. Preferments were now immediately
offered to his choice; and he accepted of the vicarage of
All-Saints, Northampton, in which town he had for sever-
al years resided, in the highest estimation of the most re-
spectable inhabitants. In Sept. 1673, his church and the
greater part of the parish were destroyed by fire; but his
own house escaped. In the succeeding year the bishop of
Norwich offered him the archdeaconry, with this high com-
pliment, "I do not expect thanks from you, but shall be
very thankful to you, if you will accept of it." He con-
ced to this handiome requirt, and discharged the office
worthily, as long as his health would allow. In December
1681, he was initiated a prebendary in the church of Wor-
caster, at the request of the earl of Radnor, who asked for
it of the king, saying he came to beg preferment for a very
delivering person, who never sought any thing for himself.
He had long laboured under a weakness of body, which
terminated in total blindness in the year 1686. This heavy
calamity, and the weight and infirmities of old age, he
bore with exemplary resignation to the divine will till his
death, which happened March 12, 1693. He was interred
in his own parish church of All-Saints in Northampton,
where a handsome monument was erected to his memory.
Dr. Conant was a man of solid and extensive learning, but
his great diffidence led him to conceal his acquirements. We
have five volumes of his sermons, of which one was dedicated
by himself to the inhabitants of Northampton, the others
were published after his death, by Dr. John Williams,
 Afterwards bishop of Chichester, and Mr. Coates principal

CONARIUM, in Anatomy, a term which has been ap-
p lied to the small gland of the brain, in consequence of its
conical figure. See Brain.

CONATUS, endeavour, a term frequently used by phi-
losophers and mathematical writers; nearly equivalent to
nuit. Conatus seems to be the same, with respect to motion,
that a point is with respect to a line; at half the two
have this in common, that as the point is the extreme of
the line, or the term from which it commences; so is the begin-
ning of all motion called the conatus. And, that as in
mathematical demonstrations, the extension of the point is con-
ceived as if it were nothing at all; so, in the conatus of
motion, there is no regard to the time wherein, or the length
which, it advances. See Laws of Nature.

Hence, some define conatus to be a quantity of motion
not capable of being expressed by any time or length.
Accordingly, all motion tends precisely the same way wherein
the moveable is acted on, or determined by the same moving
power. See Motion.

CONAWANGO, in Geography, a northern branch of
Allegany river, in Pennsylvania, which rises from Cha-
nguee lake.

CONCA, CAY. SEBASTIANO, in Biography, an historical
painter of considerable reputation in the 18th century. He
was born at Gaeta in the year 1676, and became the disciple
of F. Solemene, the most celebrated master of the school of
Naples at that period. At the age of forty, Conca estab-
lished himself at Rome, and spent five whole years in
drawing from the faithful productions of ancient and modern
art, in the vain hope of uniting to the graceful facility he
had acquired from his master, a greater purity and correct-
ness of design. But it was too late; bred a manufact, he
had infensibly imbibed those maxims which were to decide
his future character; and at length he had the good felic
ity to adopt the advice of the sculptor Le Gros, by purity-
ing the track which had originally been pointed out to him.
He soon became an able machinist (pietre di macchina), in
a style not very unlike that of Cortona. He united to facili-
ty of invention, and rapidity of pencil, a gay and fa-
cinating distribution of colour; but his flesh has generally too
green a hue in the shadows. Amongst his large works at
Rome, the "Assumption," at the church of St. Martino, and
the "Prophet Jonas," at St. Giovanni Laterano, are of
the best. Many of his other productions are at Loretto,
Ancona, and other towns of the ecclesiastical state, besides
an infinity of cabinet pictures dispersed throughout all parts
of Europe. This artist died in 1764. He had a brother,
Giovanni Conca, who assisted him in the execution of many
of his large works, and is said to have been an excellent
copyist. Lanzi, Storia Pictorica.

CONCA, in Geography, a town of the island of Corfus;
12 miles N. of Porto Vecchio.—A T, a market town in a
small lake in the Campagna di Roma, in Italy.—All, a
small
small river of Italy, which has its source in the duchy of Urbino, and flows into the gulf of Venice.

Concam. See Concave.

Concave Bay, in the channel, on the coast of the department of Hilly and Vilaine in France, is a fine bay, in which the English effected a landing in June 1758, and whence they proceeded to the port of St. Malo, where they burned about 100 vessels of different kinds.

Concamerated, among Builders, an appellation given to such roofs as are arched in the vaults.

Concameration, was an arched room in our ancient churches, between the east end of the church and the high altar; so formed, that in processions they might surround it.

Concan, or Cockun, in Geography, a tract of country on the western coast of Hindoostan, situated between Bombay and Goa, and separated from the rest of the continent by a ridge of high mountains called the Gauis. When the Moguls seized on Hindoostan, they found this coast infested with pirates, and fitted out a fleet to protect their vessels. The Maharratns, finding their pirates interrupted, armed against the Moguls, ravaged their possessions, and fitted out a fleet to protect their pirates. Conagy Angria, who by his courage had acquired the supreme command, was appointed governor of Severndroog, one of the fortresses on the coast, where he formed an independent state, and in a little time extended his dominions for the space of 40 leagues along the coast, and six leagues wide towards the mountains. His successors assumed the name of Angria, and made peace with the Maharratns on paying an annual tribute. They continued to make depredations on the coast, and seize all vessels that passed that way till the year 1776, when their fleet was destroyed, and the strong fort of Ghairah, in which the chief refiined, was taken by admiral Wotton and colonel Chive. The country now belongs to the Maharratns. The principal towns are Choul, Fort Victoria, Dehri, Severndroog, Ghairah, Tamans, and Sunderdoo.

Concana, in Anciant Geography, a town of Spain, towards the north-east of Lucus Aferum, and to the south of Salis, near the sea. Horace says, that the inhabitants of this city took pleasure in drinking the blood of horses: and although a change took place in the manners of the people in Spain under the dominion of the Romans, Silius Italicus, who wrote under Trajan, gives an account of them similar to that of Horace.

Concangium, a Roman station, under the government of the honourable the duke of Britain, not mentioned in the itinerary, but recorded in the Notitia Imperii, and generally believed to have been situated at Watercrook, near Kendal, where are visible remains of a Roman station, and where Roman antiquities have been found.

Concarneau, or Conquerneau, in Geography, a small, but neat sea-port town of France, in the department of Finisterre, and chief place of a canton in the district of Quimper, 43 miles S.E. of Brest. The place contains 2,520, and the canton 6,320 inhabitants; the territory includes 12,7 kilometres, and 4 communes. Its principal and almost only trade, is in pickards, of which the average annual shipment is 600 barrels. The price of a barrel varies from 150 to 200 livres. N. lat. 47° 55'. E. long. 3° 45'.

Concatenation, in Philography, a connection of things, in manner of a chain.

The concatenation of second causes is an effect of Providence. See Cause.

Concave is applied to the inner surface of a hollow body; particularly if it be circular.

Concave is particularly understood of mirrors and lenses; concave lenses are either concave on both sides, called concavo-convex; or concave on one side, and plane on the other, called plano-convex; or concave on one side, and convex on the other, called concavo-convex, or concavo-concave, as the one or the other surface is a portion of a left sphere.

The property of all concave lenses is, that the rays of light, in passing through them, are deflected, or made to recede from one another; as in convex lenses they are refracted towards each other; and that the more, as the concavity and convexity pertain to lens circles.

Hence, parallel rays, as those from the sun, by passing through a concave lens, become diverging; diverging rays are made to converge the more, and converging rays are either made to converge less, or become parallel, or go out diverging.

Hence, objects viewed through concave lenses appear diminished; and the more so, as they are portions of left spheres; and this in oblique, as well as in direct rays. See Lens.

Concave mirrors have the contrary effect to lenses: they reflect the rays which fall upon them, so as to make them approach more to, or recede from, each other than before, according to the situation of the object; and that the more as the concavity is greater, or the spheres whereof they are segments, less.

Hence, concave mirrors magnify objects presented to them; and that in a greater proportion, as they are portions of greater spheres. See Mirrors.

Hence, also, concave mirrors have the effect of burning objects, when placed in their focus. See Burning-Glass.

Concavity. An arch of a curve has its concavity turned one way, when the right lines that join any two of its points are all on the same side of the arch.

Archimedes, intending to include such lines as have rectilinear parts, in his definition, says, a line has its concavity turned one way, when the right lines that join any two of its points are either all upon one side of it, or while some fall upon the line itself, none fall upon the opposite side. Archim. de Sphær. and Cyl. Def. 2. Mac Laurin's Fluxions, art. 180.

When two lines, having their concavity turned the same way, have the same terms, and the one includes the other, or has its concavity towards it, the perimeter of that which includes, is greater than the perimeter of that which is included. Archim. ib. ax. 2.

Concealers, in Law, such as find out concealed lands, i.e. lands kept privy from the king, by common persons, having nothing to shew for their title, or edate therein.

They are thus called per apathes, a concealas; as monas is a movenda, &c. Lord Coke calls them turbidum bonum genus.

Concealment of Laughter's death. See Bastard.

Concealment of Treason. See Misprision.

Concelho de Angliaens, in Geography, a town of Portugal, in the province of Traes-Montes; 8 miles W.N.W. of Miranda.

Concelho de Jate, a town of Portugal, in the province of Traes-Montes, 10 miles W.S.W. of Miranda.

Concellana, a town of Naples, in the province of Bafiluzza; 5 miles S. of Accenza.

Concentage, a town of Spain, in the province of Valencia; 25 miles N. of Alicante.
CONCENTRATION, in general, denotes the retiring, or withdrawing of a thing inwards, towards the centre, or middle.

External cold is said to concentrate the heat within bodies: after meals, the natural warmth retires, and as it were concentrates to promote the digestion. This is also said by Dr. Grew for the highest degree of mixture, viz. that wherein two or more atoms or particles touch, by a reception, and intrusion of the one within the other. See MIXT.ION.

This he takes to be the case of all fixed bodies without taste or smell; their constitution being so firm, that till the particles be detached from each other by some extraordinary means, they cannot affect thosefenet.

CONCENTRATION, in Chemistry, the act of increasing the strength of fluids, which are rendered stronger by abstracting a portion of the mere menstruum. This is generally effected by evaporation, where the menstruum is driven off at a lower heat than is required to drive off the substance with which it is united. Thus, dilute sulphuric acid may be considered as a mixture of the real acid with water, and by applying a certain heat, the water may be evaporized, leaving the acid behind in a state of concentration. When concentrated as much as possible, its specific gravity is about twice as great as that of water, but it can rarely be obtained denser than 1.85. When concentrated to 2,000 it contains a considerable portion of water, as has been proved by combining it with barites or potash, in which case water remains behind, and does not enter into the combination. Again, vinegar consists of an acid and water, and brandy of alcohol and water, and in proportion as the acid and alcohol are freed from the water, they are said to be more or less concentrated. This may be performed, 1. Either by simple distillation, in which case the acid or spirit comes over first, leaving the water behind; or 2. By exposure the vinegar or brandy to severe frost, when the water will be frozen, and the acid or alcohol will be found in a state of concentration in the middle of the ice; the greater the cold, the higher the state of concentration; M. Lowitz has found, that the acid, however concentrated, congeals at -22°. Sulphuric acid, on the other hand, exposed to a much less severe cold, crystallizes, and to effect this, it must not be greatly concentrated. 3. Another mode of concentrating the acetic acid, is by distilling acetate of copper, reduced to powder, in a retort: at first there comes over a liquid nearly colourless, and almost inodorous, and afterwards a highly concentrated acid tinged with green; but being distilled a second time in a moderate heat, it is colourless, transparent, exceedingly pungent and concentrated. 4. The most perfect method of obtaining this acid in a concentrated state, was discovered by M. Lowitz of Petersburg; it is thus: distil a mixture of three parts of acetate of potash, and four parts of sulphuric acid, till the acetic acid has come over into the receiver. To separate it from the sulphuric acid, with which it is slightly contaminated, it must be distilled over a portion of acetate of barytes. By the experiments of Adet, Darraque, and others, on concentrating the acetic and acetic acids, it is ascertained that they differ only in concentration, each containing precisely the same proportion of oxygen. Concentrated acetic acid is capable of an accession of oxygen, and in that state it is called oxygenated acetic acid. Sulphuric and nitric acids, whether diluted or concentrated, are still the same sulphuric and nitric acids; but sulphuric, and phosphorus, or nitric and nitrous acids, whatever be the state of concentration, have different properties, and are of course specifically different acids. Elem. de Chymie. Thompson's Chemistry, Gren's Principles.

CONCENTRATION in Distillery. Dr. Shaw, in his "Essays on the Distillery," is for introducing a method of concentrating the fermentable parts of vegetables from which their spirits are to be drawn by distillation; which, if it can be brought to be practised in the large way, will prove of very great use to the British distillery, as it will greatly shorten the distiller's business, which, at present, including the brewing, fermenting, &c. is much too long. He proposes only to evaporate carefully the water, or other tinctures or decoctions of vegetables made for the distilling of their spirits, to the confidence of treacle: in this form they might be sold to the distiller, who might keep them by him as long as he pleased, and occasionally use them, by the easy method of reducing them into water, by mixing warm water with them.

CONCENTRIC, in Geometry and Astronomy, something that has the same common centre with another. The word is principally used in speaking of round bodies and figures, viz. circular, elliptical ones, &c. but may be likewise used for polygons, drawn parallel to each other, upon the same centre.

Concentric flats opposite to eccentric.

To find the area of the space included between the circumferences of two concentric circles; see AXIOMS.

Nonius's method of graduating instruments, confuted in describing with the same quadrant 45 concentric arches, dividing the outermost into 90 equal parts, the next into 89, &c. See NONIUS.

CONCENTRICITY of the Strata, in Natural History. The idea has very generally prevailed among geologists and mineralogical writers, that the several layers of matter or strata, which compose the surface of the earth we inhabit, were originally formed or deposited in uniform and level beds, or concentric to the centre or mass of the earth. Among these Mr. Whitehill, in his "Enquiry into the Original State and Formation of the Earth," 1st edit. p. 192, says, the strata "obtained an uniform concentric arrangement, surrounding the centre of the earth, as so many shells may be supposed to surround an egg." And nearly similar have been the opinions of a large portion of writers on this subject. Mr. Kirwan, "Geological Essays," p. 22, supposes, that the crystallization of strata from the chaotic or polynematic fluid, in some cases, began at the surface, as we see happen to some faults and to lime water under evaporation, and that thus extensive strata might have been formed and sunk to the bottom, moliy in an horizontal position, but often from accidental ruptures during their fall, in an oblique or nearly vertical position. Dr. Townson, "Philosophy of Mineralogy," p. 68, says, "we must not suppose that the strata regularly surrounded the globe like the concentric circles of an onion; they are rather like the scales of a billy; rather squamiform than tunicata. Though, in general, they are of great extent when not broken and joint, they are known to have a natural termination." In the "Philosophical Transactions," No. 391, Mr. John Stacey gives a figure for explaining a supposition of his on this subject, viz. that the strata were originally formed while in a soft state, as so many wedges, each pointing to and terminating in the axis of the earth; and that by the diurnal revolution of the earth from west to east, these became bent into spirals, each lapping round each other, for some distance, and then ending, in succession.

Whimsical as this last idea must have appeared, when it was first published, now more than 80 years ago, we are
CONCEPTION.

somewhat surprized that it had not the effect of occasioning subsequent geological observers to notice, more particularly, the endings of the Straits, and the remarkable prevalence of their dip towards the south-east, compared with those in any other direction; especially when practical miners must have to often mentioned the dip "towards the 10 o'clock line," as being the most common. Under the articles Coal, and Colliery, the writer of this has endeavored to show that the strata of the British islands end in succussion in proceeding from the south-western part of England towards the north-west; the general dip being towards the south-east or nearly so, except in immensely dilated parts of the country, as the wealds of Suffolk, Kent, and Surrey, the peak of Derbyshire and Staffordshire, &c. of which some further and curious particulars will be given under the articles Denudation, Elevation, and Endings of the strata.

From all which, it is expected that it will be made evidently to appear, that the strata were not originally concentric with the earth's centre, but that the same formed planes or zones, inclined eastward in a small angle with the horizon, which were of amazing extent, and were perfectly regular in their position, before they experienced the rude and almost inconceivable violence, which broke and tore the earth in pieces, and left it in its present form.

CONCEPTACULUM, in Botany, was originally applied by Linnaeus to that kind of feed-vehicle which he afterwards termed folliculus, and which consists of one valve only, burthing longitudinally, as in the natural order of afclepidae. Garttner uses the term conceptaculum in a general and lax sense for a feed-vehicle, nor is it at present technically applied to any particular kind of fruit.

CONCEPTION, in Geography, otherwise called Perez, a city of Chili, in South America, and capital of a juridiction or bishopric, suffragan of the archbishop of Lima, and having a chapter, consisting of a bishop, dean, archdeacon, and two prebendaries. The ancient city stood at the mouth of the river St. Pierre, E. of Talcahuana, on the S.W. shore of a beautiful bay, and on a small declivity, having a little river running through it, in S. lat. 36° 43' 15", and in longitude from the meridian of Teneriff, according to Father Feuillete, 30° 18' 30". The houses were built with mud or burnt bricks, and covered with tiles; the churches, and also the Franciscan, Augustine, and Dominican convents, as well as those belonging to the fathers of mercy, were small and mean, but the college of the Jesuits was constructed in a superior style of architecture. This city was first founded by captain Pedro de Valdivia in the year 1550; but the powerful revolt of the Indians of Arauco and Tucapel, obliged its inhabitants to remove to Santiago. Pedro de Valdivia, its founder, was killed in this contest, and his successor in the command shared the same fate. The inhabitants, however, petitioned the audience of Lima for leave to return to their original city; they were again either slain or dispersed by the Indians; but those that survived were afterwards restored to their former position, and they for some time continued to enjoy with apparent security. In 1693 a more general consideration was formed against the city, by which it was almost wholly destroyed; but receiving fresh succours, it was again repaired. Subject, however, to dreadful earthquakes, and confitting of buildings ill adapted for permanent duration; it was totally destroyed by an earthquake in 1751 and nothing but its ruins are now visible on the spot where it once stood. After the destruction of this town, which, during the earthquake, was swallowed up rather by the sea than by the land, the inhabitants dispersed and encamped in the environs. In 1763, they selected another spot, situated about a quarter of a league from the river Biobio, and three leagues from the ancient town of Conception, and the village of Talcahuana. On this spot they erected a new town, to which the bishopric, the cathedral, and the religious houses were transferred.

The houses consist only of one story, that they may be able more effectually to resist the shock of earthquakes, which occur in those parts almost every year. This town occupies a large extent of ground. The inhabitants are about 10,000; and here is the residence of the bishop and a colonel of horse, who is the military governor of the town. The bishopric is nominally bounded on the north by that of Santiago, the capital of Chili, where the governor-general resides, and on the east by the Cordilleras, and extending on the south as far as the straits of Magellan. But its true limit is the river Biobio, about a quarter of a league from the town. M. de la Perouse says of this part of Chili, that it is the most fertile spot in the world. Corn, he says, produces sixty-fold, and the vine is equally abundant; the fields are covered with innumerable flock, which, without requiring any care, multiply beyond all calculation. The only care necessary is to keep separate the different property of individuals; and oxen, horses, mules, and sheep herd together in the same pastures. A large ox is commonly worth eight dollars, a sheep ½ of a dollar; but there are no purchasers, so that the inhabitants kill every year a great quantity of cattle, the skins and tallow of which are sent to Lima. They also cure some provisions for the consumption of the small coasting vessels which navigate the south seas. The climate is remarkably healthy, and M. Peroue found several in this town that had completed 100 years; but notwithstanding all these advantages, the colony is not now thriving, which he attributes principally to the prohibitory regulations that extend through every part of Chili. This kingdom, he says, of which the productions, increased to their maximum, would supply all Europe; whose wool would be sufficient for the manufacture of France and England, and whose herds, converted into felt provision, would produce a vast revenue; has no commerce. Four or five small vessels bring every year from Lima tobacco, sugar, and some articles of European manufacture, which the miserable inhabitants receive after having been charged with heavy customs at Cadiz, at Lima, and, finally, at their arrival at Chili; in exchange for which they give their tallow, hides, some deals, and their wheat, which, however, bears so low a price, that the cultivator has no inducement to extend his tillage. Unfortunately, says Pérouse, for this country, it produces a small quantity of gold; the annual amount of which in the district of Conception is estimated at about 200,000 pistoles. The administration of justice is very defective. To these several circumstances it is owing that the land remains uncultivated, that commerce is in a low state, that the habitants are almost destitute of furniture, and that the only workmen in the town are foreigners. The dregs of the women confids of a plated petticoat, d'overing half the leg, formed of gold and silver fluff, which, being reserved for extraordinary occasions, is transferred, like jewels, from grand-mother to grand-daughter, striped stockings of red, blue, and white, and very short shoes, but such ornaments are only within the reach of a few; the rest having carelessly clothes to cover their nakedness. The idleness, together with the credulity and superstition of the inhabitants, has filled this kingdom with convents, both for men and women. The common people are a mongrel race, much addicted to theft, and the women are very coy of access. Nevertheless, those of a superior class, or the
true Spaniards, are extremely polite, and hospitable. The inhabitants, and even the women, excel in horsemanship; they are very dextrous in managing the lance and noose; and they rarely miss their aim, though at full speed, with the noose, which they throw 40 or 50 yards, and thus halter the object of their diversion or revenge. The noose is made of thongs of cow-hides, which they twine with oil, till it is rendered supple and, stiff. As to holding, it is fast, a wild bull which would break a halter of hemp of double thickness.

Conception, the bay of, is one of the most commodious that can be found in any part of the world. The length from Terra-firma, N. and S. is nearly 3½ leagues, and its breadth from E. to W. about 3 leagues, which is contracted by the island of Quiriquina, forming two entrances; of these, that on the east side is the safest, being two miles broad, and accordingly frequented by most ships. The west entrance is between the island and Talcaguna point, and is near half a league in breadth. In the principal entrance of this bay is 30 fathom water, which depth afterwards decreases to 11 and 12, till within about a mile of the shore, opposite to the entrance. The western entrance, though the numerous rocks and breakers in it make it appear very dangerous, has a channel with water sufficient for the largest ship, the depth being at first 30 fathoms, and never less than eleven. Within the bay are three roads or harbours, where ships anchor; for though the bottom be every where clear, it is only in one of these three places that ships can ride in safety, being no where else sheltered from the wind. The first, called Puerto Toro, lies close and well, with the north point of Quiriquina, contiguous to the coast of Terra-firma. The anchoring place is about half a league distant from the land; in about 12 fathom water. But this road is used only when the ships come in during the night; it being difficult to reach either of the other two before day-light, as several tacks must be made for that purpose. In this bay the principal port is that of Talcaguna. It is properly an elbow, and bears S.S.W. from the south point of Quiriquina. This is much the most frequented, ships in general anchoring here, as it has not only better ground than any other part of the bay, but is most sheltered from the north winds. Whereas at Curillo Verde, a little green mountain, situated near the city, they lie exposed not only to these winds, but also to the south winds; the land which should intercept them being low. Besides, the bottom is of a loose mud, so that the anchors in a hard gale of wind generally come home; and consequently the ships are in great danger of being stranded on the coast. From these inconveniences it may be concluded, that the only ships which anchor here are such as happen to be in these parts in the midst of summer, for which reason this road is most convenient, as it is nearest to the city. Although the tide rises in this bay five feet three inches, the water is smooth, and there is scarcely any current. It is high water here at the full and change of the moon, at 45 minutes past one. The bay is open only to the north winds, which never blow but in the winter, that is, from the end of May to October. Two rivers empty themselves into this bay; one of which passing through the city of Conception bears its name; the other is called St. Pedro. The first is the watering place for ships anchoring at Curillo Verde; whereas those at Talcaguna supply themselves from streams that flow from the adjacent eminences; they easily take on board a sufficient quantity of wood, of which there is plenty, and also of all other necessaries. Ships, before they enter the bay of Conception, endeavour to make the island of Santa Maria, and then coast along it keeping at the same time a good look out for a reef of rocks which stretches out almost three leagues from the north-west point; thence they continue their course, keeping at a little distance from the main, there being no rocks besides those that are above the water. After weathering the rocks on the island of Santa Maria, they fly directly for Talcaguna point, at the distance of about half a league; from which sea-ward is a rock called Quibra Olas, which should be carefully avoided, as it is surrounded with shoals. After being abreast of this rock, they steer for the north point of Quiriquina; off which two rocks swarming with sea-wolves; but as there is a sufficient depth of water all round them, there is no other danger in sailing near them besides that which is visible. After passing them, the course is continued as near as possible to the island of Quiriquina, care being taken to avoid some other rocks lying along the shore. In making several tacks to get into Conception-bay, the island of Quiriquina must be avoided on the east and south sides, as there is a shoal on the south extending to a considerable distance from the shore. At a third part of the distance between the road at Talcaguna, and the point of the same name, is another shoal, running about half a league towards the eait, in the middle of which is a ridge of rocks. To avoid this shoal, it is best at entering the bay with a land wind, to steer directly for the middle of a spot of red earth on a mountain of middling height, situated at the bottom of the bay, continuing this course till the ship has passed the shoal; and then to steer directly for the houses at Talcaguna, till within about half a mile from the shore, which is the usual anchoring place in 5 or 6 fathom water. The same care is also necessary to avoid another reef of rocks, lying between the Morro and the coast of Talcaguna.

Conception, or Conception de los Pampas, a town of South America, in Paraguay, on the S. side of the river Paraguay. S. lat. 30° 30'. W. long. 57° 11'.

Conception, La, a sea-port town of America, in the province of Veragua, on the Spanish main, with a harbour, formed by the river Veragua; 50 miles W. of Panama. N. lat. 3° 57'. W. long. 83° 51'.

Conception, a river of America, on the illusmus of Darien, which runs into the Spanish main. N. lat. 9° 4'. W. long. 78° 15'.

Conception Bay, a large bay on the east coast of Newfoundland island, whose entrance is between Cape St. Francois on the southward, and Flamborough head on the northward. It runs a great way into the land in a southerly direction, having numerous bays on the W. side, in which are two settlements, Carbonee and Havre de Grace. Settlements were made here in 1610, by about 40 planters, under Governor John Guy, to whom king James had granted a patent of incorporation. N. lat. 47° 40'. W. long. 52° 40'.

Conception de Salazar, or of Salayo, a small town of North America, in the province of Mexico, in Mexico. It was built by the Spaniards, as well as the nations of St. Michael and St. Philip, to secure the road from Mexico to the silver mines of Zacatea. N. lat. 10°. W. long. 83° 5'. They have also given this name to several bowards of America, to a sea-port of California, &c. &c.

Conception de la Vega, a town of Hayti, in what was formerly the Spanish part of Haiti, or St. Domingo. It gave the title of duke to the family of Columbus, the immortal discoverer of America.

Conception, in Grammar. See Syllepsis.
CONCEPTION.

Conception, in Logic and Metaphysics, the simple apprehension or perception which we have of any thing, without proceeding to affirm or deny any thing about it.

The schoolmen usually make two kinds of conception; the one formal, the other objective.

The first is defined to be the immediate and actual representation of any thing proposed to the mind: on which footing, it should be the same thing to the understanding, that a word or voice is to the ear; whence some also call it verba mentis.

The second is the thing itself represented by a formal conception. But others explode the notion of an objective conception, as being, in reality, no conception at all; excepting where the mind contemplates its own acts, &c.

Formal or proper conceptions, are subdivided into universal, where several things are indefinitely represented as under some common ratio, or in the same degree of perfection; analogous, where several things are represented as under some proportional likeness; and equivocal, where they are represented immediately as such, without regard to any common ratio or likeness.

Dr. Reid, in his "Inquiry into the Human Mind, on the Principles of Common Sense," and also in his "Essay on the Intellectual Powers of Man," (Eff. iv.), substitutes the word conception instead of the simple apprehension of the schools, and employs it in the same extensive signification. He also uses it, in common with some other writers, as synonymous with Imagination, which see. To this purpose, he says, that "conceiving, imagining, apprehending, understanding, and having a notion of a thing, are common words to express that operation of the understanding, which the logicians call "Simple Apprehension," which is defined by them to be the bare conception of a thing without any judgment or belief about it. However, although conception may be exercised without any degree of belief, even the smallest belief cannot take place without conception; for he who believes must have some conception of the object of his belief. Dr. Reid, without attempting a definition of this operation of the mind, explains some of its properties, states different theories concerning it, and points out some mistakes of philosophers in their account of it. In every operation of the mind, says this writer, and in every thing which we call thought, there must be conception. Our senses cannot give us the belief of any object, nor can we remember or reason, nor exert any of our active powers, without this mental operation; but in bare conception, there can, he thinks, be neither truth nor falsehood, because it neither affirms nor denies. In this respect, conception differs from opinion; as an opinion, though ever so wavering, or ever so modelly expressed, must be either true or false; whereas a bare conception, which expresses no opinion or judgment, can be neither; to this purpose, Mr. Locke observes very justly, if we sublimate conceptions for ideas, that our ideas, being nothing but bare appearances, or perceptions, in our minds, cannot properly and simply in themselves be said to be true or false, no more than a simple name of any thing can be said to be true or false. Mr. Locke, following the example of Des Cartes, Gassendi, and other Cartesian, has given the name of perception to the bare conception of things; and he has been followed in this respect by bishop Berkeley, Mr. Hume, and many late philosophers, when they are diffusing the subject of ideas. They have been probably led into this impropriety, says Dr. Reid, by the common doctrine concerning ideas, which teaches us, that conception, perception by the senses, and memory, are only different ways of perceiving ideas in our own minds; and if that doctrine be well founded, he thinks that it will be very difficult to find any specific distinction between conception and perception. He adds, there is reason to distrust any philosophical theory, when it leads men to corrupt language, and to confound, under one name, operations of the mind, which common sense and common language teach them to distinguish. This author further observes, when he is tracing the analogies that subsist between the operations of body and those of the mind in the plastic arts, and particularly in painting, that nothing more readily gives the conception of a thing than the seeing of an image of it; and hence, by a figure common in language, conception is called an image of the thing conceived. Nevertheless, the image in the mind is not the object of conception, nor is it any effect produced by conception as a cause, but it is conception itself. In this mode of illustrating conception, Dr. Reid differs from many other philosophers, who have generally maintained, that in conception there is a real image in the mind, which is its immediate object, and distinct from the act of conceiving it. This author proceeds to trace the analogy that subsists, not only between conceiving and painting in general, but between the different kinds of our conceptions, and the different marks of the painter. As this art illustrates fancy-pictures, or copies from the painting of others, or paints from the life, that is, from real objects of art or nature which he has seen, our conceptions, in Dr. Reid's opinion, admit of a very similar division. Some conceptions may be called fancy-pictures, being commonly called creatures of fancy or of imagination, which are not the copies of any original that exist, but are originals themselves. There are other conceptions, which may be called copies, because they have no original or archetype, to which they refer, and with which they are believed to agree; and we call them true or false conceptions, as they agree or disagree with the standard to which they are referred. These are of two kinds, viz. such as are analogous to pictures taken from the life, or such as we have of individual things that really exist; and such as are analogous to the copies which the painter makes from pictures done before, which are the conceptions we have of what the ancients called universals, or of things which belong or may belong to many individuals. These universals are always expressed by general words; and all the words of language, proper names excepted, are general words, or the signs of general conceptions, or of some circumstances relating to them. Such general conceptions are formed for the purpose of language and reasoning.

Having thus stated the three different kinds of our conceptions, and illustrated them at large, our author proceeds to describe their different properties. Accordingly he observes, that our conception of things may be strong and lively, or it may be faint and languid in all degrees. In this connection it is said, that imagination, when it is distinguished from conception, seems to signify one species of conception, viz., the conception of visible objects. Again, our conceptions of things may be clear, distinct, and ready; or they may be obscure, indistinct, and wavering. Moreover, when we barely conceive any object, the ingredients of that conception must either be things with which we were before acquainted by some other original power of the mind, or they must be parts or attributes of such things. Thus, a man cannot conceive colours, if he never saw, or felt them, if he never heard. If man has not a conception, he could not conceive what is meant by moral obligation, or by right and wrong in conduct. Nevertheless, we are uncon-
The powers of sensation, of *perception* of memory, and of conviction, are all employed solely about objects that do exist or have existed; but *conception* is often employed about objects that neither do, nor did, nor will exist. To prevent impudence in this matter, we ought to distinguish between that act or operation of the mind, which we call conceiving an object, and the object which we conceive. When we conceive any thing, there is a real act or operation of the mind; of this we are conscious, and can have no doubt of its existence; but every such act must have an object: for he that conceives must conceive something. For the different theories of conception stated by Dr. Reid, with his observations upon them, we must refer to the article *Idea.* This author eloses his account of the faculty of conception with an enumeration of what he conceives to be the errors into which writers have fallen in their discussion of the operations of the mind. In all judgment and in all reasoning, he says, conception is included. We cannot judge of a proposition, nor reason about it, unless we conceive or apprehend it; and therefore those are mistaken who do distinguish between conception, judgment, and reasoning, as to imply, that a conception, or even a syllogism, may not be simply apprehended. Dr. Reid further observes, that the division, commonly made by logicians, of simple apprehension into sensation, imagination, and pure intellect, seems to be, in several respects, very improper. Sensation, and the perception of external objects by the senses, are, in his opinion, very different operations of the mind; and, though commonly confounded by nature, they ought to be distinguished by philosophers. Neither sensation, nor the perception of external objects, is simple apprehension; because both, as he thinks, include judgment and belief, which are excluded from simple apprehension. Moreover, those who distinguish imagination from pure intellect, by referring to the imagination an image in the brain, and to pure intellect an image in the intellect, ground their distinction upon an hypothesis; since we have no evidence, as he apprehends, that there are images either in the brain, or in the intellect. See *Imagination.* Dr. Reid further observes, that it is a mistake to represent simple apprehension as the first operation of the mind; and, that, as a composition or combination of simple apprehensions, which mistake probably has arisen from supposing that sensation and the perception of objects by the senses, are nothing but simple apprehension. Although these are very probably the first operations of the mind, they are not simple apprehensions. See *Perception.* Instead of saying, that the more complex operations of the mind are formed by compounding simple apprehensions, we ought rather to say, that simple apprehensions are obtained by analyzing more complex operations. In this connection, Dr. Reid observes, that a similar mistake pervades the whole of Mr. Locke's *Essay.* It is this, that our simplest ideas or conceptions are got immediately by the senses, or by conception; and the complex afterwards formed by compound- ing them. He notices also another mistake concerning conception, which is, that our conception of things is a tell of their possibility; so that, what we can distinctly conceive, we may conclude to be possible; and of what is impossible, we can have no conception. This opinion has been held by philosophers for more than 100 years, without contradiction or dissent, as Dr. Reid believes; and he considers it as a necessary consequence of the received doctrine of idealism; since it is evident, that there can be no distinct image, either in the mind, or any where else, of that which is impossible. Our author has investigated this opinion, and urged a variety of objections against it. Whatever, he says, is declared to be possible or impossible is expressed by a proposition; and every proposition, of which you understand the meaning distinctly, is possible. Further, every proposition, that is necessarily true, stands opposed to a contradictory proposition that is impossible; and he that conceives one, conceives both; thus, a man who believes that two and three necessarily make five, must believe it to be impossible that two and three should not make five. Again, mathematicians, have, in many cases, proved some things to be possible, and others to be impossible; which, without demonstration, would not have been believed; "yet I have never found," says Dr. Reid, "that any mathematician has attempted to prove a thing to be possible, because it can be conceived, or impossible, because it cannot be conceived." Moreover, mathematicians often require us to conceive things that are impossible, in order to prove them to be false; and this is the case in all their demonstrations, "ad absurdum." For other particulars connected with the subject of this article, and a fuller view of Dr. Reid's illustration and reasoning, we must refer to his *Essay* above cited.

A late excellent writer, to whom those who wish to understand the philosophy of the human mind are under great obligation, though they may not admit all his principles and reasoning, has particularly considered the power of conception. By conception professor Dugald Stewart (see his "Elements of the Philosophy of the Human Mind," ch. iii,) means, that power of the mind which enables it to form a notion of an absent object of perception, or of a sensation which it has formerly felt. Although this is not exclusively the proper meaning of the word, yet he thinks that the faculty now defined deserves to be distinguished by an appropriated name. Conception is often confounded with other powers; memory recognizes the features of an absent or deceased friend, and every act of this faculty includes an idea of the past; whereas conception implies no idea of time whatever. Thus considered, the word conception corresponds to what was called by the schoolmen *simple apprehension;* with this difference only, that they included, under this name, our apprehension of general propositions; whereas the professor wishes to limit the application of the word *conception* to our sensations, and the objects of our perceptions. By thus restricting the application of the term, more than Dr. Reid has done, our ideas become more distinct; and for such a restriction the authority of philosophers in an analogous case may be justly pleaded. In ordinary language, we apply the same word *perception* to the knowledge which we have by our senses of external objects, and to our knowledge of speculative truth; and yet an author would be justly censoed, who should treat of these two operations of the mind under the same article of perception. "Thus," says the professor, "there is as wide difference between the conception of a truth, and the conception of an absent object of sense, as between the perception of a tree, and the perception of a mathematical theorem." For this reason, he has confined conception to that faculty, whose province it is to enable us to form a notion of our past sensations, or of the objects of sense which we have formerly perceived. The bullies of conception, thus defined, is to present us with an exact transcript of what we have felt or perceived. The first remarkable fact which strikes us with regard to conception is, that we can conceive the objects of our senses much more easily than those of others. Thus, we can conceive an absent visible object much more easily than a particular found, a particular taste, or a particular pain, which we have formerly felt. This peculiarity seems to arise from
this circumstance, that when we think of a found, or of a
name, the object of our conception is one single detached
notion, whereas every visible object is complex, and the
conception which we form of it as a whole, is aided by the
association of ideas, which connects the different parts to-
gether, and presents them to the mind in their proper arrange-
ment; whilst the various relations which these parts bear to
one another in point of situation equally contribute to
strengthen the associations. This power of conceiving visible
objects may be much improved by habit. These observa-
tions, together with others adduced by our author, are
applicable to conception as distinguished from imagination,
though the two powers are very nearly allied, and often so
blended, that it is difficult to say to which of the two some
particular operations or the mind are to be referred. Among
logicians, it is a common, and almost an universal doctrine,
that conception (or imagination, often used as synonymous
with it) is attended with no belief of the existence of its
object. To this purpose, Dr. Reid says, "perception is
attended with a belief of the present existence of its object;
memory with a belief of its past existence; but imagination
is attended with no belief at all; and was therefore called
by the schoolmen operpfius simpies." Professor Stewart
controversly the truth of this principle, and alleges several
circumstances in justification of his doubts concerning it.
If it were a specific distinction between perception and
imagination, that the former is always attended with belief,
and the latter with none; then, the more lively our imagination
were of any object, and the more completely that object
occupied the attention, the less should we be apt to be
lieve its existence; for it is reasonable to think, that when
any of our powers is employed separately from the rest, and
there is nothing to withdraw the attention from it, the laws
which regulate its operation will be most obvious to our
observation, and will be most completely discriminated from
those which are characteristic of the other powers of the
mind. So very different however is the fact, that it is
matter of common remark, that when the imagination is
very lively, we are apt to ascribe to its objects a real exis-
tence, as in the case of dreaming or madness; and we may
divide, in the case of those who, in spite of their own general
belief of the absurdity of the vulgar stories of apparitions,
dare not trust themselves alone with their own imaginations
in the dark. That imagination is in these instances attended
with belief, we have all the evidence that the nature of the
thing admits of; for we feel and act in the same manner as
we should do, if we believed that the objects of our attention
were real; which is the only proof that Metaphysicians pro-
duce, or can produce, of the belief which accompanies
perception. The author acknowledges, however, that in
most cases it is true that imagination is attended with no
belief, if by belief we mean a permanent conviction which
influences our conduct. But if the word be used in the
strict logical sense, he inclines to think, that the exercise
both of conception and imagination is always accompanied
with a belief that their objects exist. From a variety of ob-
servations, which we cannot rate within the limits of this
article, the ingenious professor infers, that when the concep-
tions of the mind are rendered steady and permanent, by
being strongly associated with any sensible impression, they
command our belief no less than our actual perceptions; and,
therefore, if it were possible for us with our eyes shut to keep
up for a length of time the conception of any sensible object,
we should, as long as this effort continued, believe that the
object was present to our senses. See Nominalists, Real-
ists, and Universals.

Conception, in Physiology, denotes the changes which
take place in the internal organs of generation of the female
sex, connected with the development and growth of the em-
bryo. See Generation.

Conception, in Animals, is said to be occasioned by
something emitted by the male, in the set of sperm, app-
proaching and uniting with the rudiments of an animule
contained in the female. To explain in what manner this is
effected, and to shew

"How the dim speck of entity began
To expand its recent form and stretch to man,

Garth,

has been the object of anxious inquiry from the earliest ages.
But though much learning has been expended on the sub-
ject, and several ingenious theories contrived, to explain the
mystery (see Generation), yet very little of real knowledge
has been obtained.

In this place, without deciding whether the male sperm
contains the animule, or only a phytic aura, giving life to
something engendered in the female, it will be sufficient to
observe, that the first effect of impregnation, or conception,
will be found in one of the ovaries, or female testicles, as
they are called (see Ovary), and not in the uterus, as was
generally believed. That the ovaries are necessary to conception, has been
long known, as is evident by the practice of foaming (that is,
taking out the ovaries of) cows and other animals, to
prevent their breeding. The late Mr. John Hunter took one of
the ovaries out of a cow (Ob. on the Animal Econ. 4to.),
and found the left off breeding two years sooner, and pro-
duced fewer pigs at each litter, than another cow, kept with
her, that was perfect. The perfect cow continued breeding
five years, and produced 162 pigs; the half-bated f.w.
continued to be fruitful only four years, and brought only
80 pigs: whence he concluded, that there is a certain limited
number of eggs in each of the female ovaries, and when they
are exhausted, the animal is no longer fit for conception.

Anatomists, in the course of their examination of the bod-
ies of females, have found hair, teeth, and other organised
parts in the ovaries; and ovary, containing fustules, have been
found in the Fallopian tubes. (See Fallopian tubes, also
Poetus extra uterin.)

On carefully examining into the contexture of the ovar-
ies, they are found to consist of clusters of vessels, like bunches
of grapes, which are supposed to be ova or eggs.
Whose one of the vessels, or eggs as they are called, be-
come ripe, it enlarges, and puts on a yellowish hue, and it
at this time it should be impregnated by the male sperm,
it bursts the thin membrane that confines it to the ovarium,
enters the ambrated end of the Fallopian tube, and thence
defends into the uterus.

The rent in the ovarium, through which the ovum had
palled, forms a cicatrice, which is called, from its colour,
corpus lateum. (See Corpus lateum.) On dissecting the
ovaria, there are always found, as many of these corpora
lutea, as the woman, the subject of the dissection, had borne
children.

While impregnation, or conception, is taking place in the
ovarium, and the fertilized ovum is descending through
the Fallopian tube, a process is going on in the uterus, to
prepare it for its reception. The vessels of the uterus, which
were before so extremely minute, as not to be visible, begin
to be conspicuous; the whole organ is enlarged, and a secre-
tion of a mucous takes place, and lines its internal surface.
This mucus soon puts on the appearance of a rough and
haggy membrane, defined to become the medium of con-
nection between the ovum and the uterus. The late Dr.
William
William Hunter called this membrane the decidua, because it is called off at the birth of the fetus. He was surprised to have first discovered it: but Needham, who published his "Observations de formato Foetu," in 1667, gives a clear description of it and of its office, but acknowledges that his account is taken from brutes; he never having had an opportunity of opening the body of a woman who had died undelivered. There are three membranes, he says, lining the uterus of viviparous animals when pregnant: "extima profusissima fibrosa eft, nulla vera, aut arteria vivilli donata." p. 170: it serves as a sheath, he says, to the other membranes.

Thomas Harvey describes it as still more distinctly. Before any vellige of the conception can be seen, he says, "mutur quaedam filamina tanguam anearanm tele, et uti fimo superiore cornu angulo ducentur: que famul juncta membranam ac mucilaginam tunica, live manticae vacuam ferment." Exercit. lexigraphus nova.

The ovum being received into the uterus, in a little time, pushes out small fibers, or vesicles, principally, perhaps, from that part by which it had been connected to its calyx in the ovarium, in a manner not dissimilar to that by which an acorn is joined to its cup, or a hazel nut to its outer green shell. These vesicles, piercing the decidua, which affords a support to them, infiltrate themselves into the pores of the uterus, and absorb the moisture from it, for the support and increase of the ovum, as the young fibres, or slender radicles of plants and trees, absorb their nourishment from the earth. Although the uterus is intended by nature, and is thus prepared for the reception of the ovum, yet if it happens to be detained in the Fallopian tube, or to fall into the cavity of the abdomen, it there puts forth its radicles, and attaches itself to the part it happens to fall upon, or be in contact with, and the inclosed fetus is nourished and comes to maturity nearly in the same manner, as if it had been received in its proper matrix. (See Poetus extra uterine, also Poetus, Nourishment of, in Utero.)

On examining the ovum, after its descent into the uterus, it appears to contain a clear glutinous fluid, like the white of an egg; in a little time, a concretion, like a small maggot, is seen in the centre of the fluid, which is the primordium of the embryo. Very minute blood-vesicles are now visible, branching upon a part of the chorion, heretofore to become placenta; the little galba, or maggot, being attached to it by slender threads, scarce a line in length, the future limbs umbilicalis. At one extremity of the cone three vehicles are seen, the rudiments of the eyes and brain; and beyond them, a crimson moving point, the gymnium sallis, or heart. Soon after, fine white flakes are perceived, variously circumvolved, the intellines. The result of the vescera are now faintly delineated; then the integuments covering and confining the vescera; then the extremities, or limbs, begin to sprout, at first short stumps, without hands or feet, which at length emerging, complete the transformation. The whole fetus is said to be completely formed, by the end of the fourth week from the time of conception. See Harvey, De Generat. Anim.: and his predecessor, under whom he studied at Padua, Fabricius ab Aquapendente. For the further development and growth of the fetus, see Embryo, and also Poetus.

Conception, Symptoms of, in Women. As soon as a woman hath conceived, a train of symptoms commence, which announce some considerable alteration has taken place. "Muiter ubi concipit," Hippocrates says, "alter in horreto, et inacxit, ad dentibus fluidet, et articulos reliquae unque corpus, convulso praebent, et uterum torpor." A woman, as soon as she has conceived, swells, and then becomes hot, her teeth chatter, and she suffers a light convulsive motion of her whole body. And in another place. "Perianatem mulierem, si alter non cognoscas, occult tracteri, et caviores sunt, et candidum umbilicorum albidum naturam non habet, sed lividum existim." Op. Om. cura Vard. Linden, t. ii. p. 245. In pregnancy the eyes become hollow, the whites of them lose their clearness, and become thick and muddy. If towards the end of the term of uterine gestation, he adds, the eyes become hollow, and the face and the whole body are affected with edema, if the tips of the ears and of the nose are white; and the lips livid, the child will be found to be dished or dead. Andreas Laurentius, who was physician to Henry IV. of France, recited the following circumstances, as indicative of a woman having conceived. "Ness mulierem concepisse eklammas," he says, "if in feminam concussum totum corpus leviter cohorruerit, aut titulatu quodam uterum contrahi persecipt; si exceptum cum voluptate semen non excitert; si uteri os internum exquisitum connivat; si mentura succinat purgatio; si lenis doloris fetus circa umbilicum et hypogastrum obrect; si mammis obscurate, extubenter, perdoleat; si sensis appetitum languecat; si oyssia lactatur, et su- bindae morae afficiatur; denique si in culdis falsixium." We know a woman to have conceived, if immediately after copulation she is affected with dizziness; if the fermen, received with pleasure, is not suffered to escape; if the mouth of the womb is found to be completely closed; if a slight faint of pain is perceived about the navel; if the ceases to menstruate, and the breasts become large, hard, and painful, if the appetite for venery abates; if she has frequent and sudden changes from mirth to sadness; and, lastly, if she has a loathing to her usual food, and a desire for things before indifferent, or to which she had an aversion. These observations are in general full, and may serve to shew the accuracy with which the ancients noticed the minute circumstances; but they are for the greater part such as we can make little use of in practice; as we should neither be permitted to inquire whether a superior degree of pleasure was felt at the moment of coition, or whether the fermen was retained, or to examine whether the os uteri was completely closed. Wearing, therefore, theses minutiae, it will be sufficient to describe the most usual symptoms attendant on conception and pregnancy, in the order they occur, and to make some observations on each of them, with the view of shewing the causes from which they are derived, and the means by which they may be mitigated, or appeased, when they are so violent as to endanger abortion, or are likely to occasion any permanent evil to the constitution.

The first symptom by which women judge themselves to have conceived, is an intermission of the regular discharge of the menes. This is so general, that women who have been accustomed to be regular, always date their conception from the time they first miss their courses, as they are popularly called; and in this judgment, they are almost constantly right, unless fever, or some other cause has intervened, to which the interruption of them may be attributed.

Nausea and vomiting are also pretty constant attendants on pregnancy. These are most troublesome in the morning, and often commence before the period for menstruation arrives. They have been supposed to be occasioned by the subdurance of the uterus into the pelvis, dragging part of the bowels with it. But as they come on before the uterus has obtained sufficient bulk to disturb the bowels by its weight, they are with more propriety ascribed to sympathy, between
CONCEPTION.

between the stomach and the uterus. Nausea and vomiting, unless uncommonly violent, are rather to be esteemed falutary than dangerous, and it has been observed, that women, attacked with these symptoms, are less liable to miscarriage, than those who are free from them. Blood has even been known to be thrown up from the stomach, from the violence of the vomiting, without any subsequent ill consequence. When, however, the vomiting is extremely violent, and obstinate, if there are also fumes of phlethora, or general fulness of the vesicles, two or three small bleedings have often proved falutary. In the mean while the body should be kept open, by administering gentle emetics, which the collective state of the bowels, incident also to pregnancy, renders particularly necessary. Infusion of fennel, with soluble tartar, or the bitter purging salt; kiesene diaphyr, rubarb, magnesia, or calfort oil, may be conveniently used, or emollient and opening glysters, administered advantageously for this purpose. In the relaxed state of the bowels, to which some delicate women are inclined, the confecio alkernes, or aromatica, given in weak cinnamon water, with three or four drops of the tincture of opium, twice or thrice a day, or from a quarter of a grain to a grain of opium may be given advantageously every night at bed time; where these have failed, the diarrhoea has been removed, by giving occasionally, in addition to the above, small doses of ipecacuanha; or, lastly, by change of air, all other methods having proved unsuccessful.

The disposition to vomiting usually ceases between the fourth and fifth month, or soon after the woman has quickened, (see Quickening.) The uterus now rising above the brim of the pelvis, and entering into the cavity of the abdomen, is less pressed upon by the neighbouring parts, and has more room for dilatation; perhaps also having been long used to the irritation, occasioned by the increase of the ovum, it is less sensibly affected by it. In some constitutions, however, the sickness and vomiting continue to harass the women through the whole course of pregnancy; yet even in these cases, although the vomiting is so incessant, that the whole of what is taken into the stomach seems to be ejected that way, yet such women have ordinarily as favourable labours, produce as healthy children, and recover from child-birth as speedily and completely as those who pass through their pregnancy with only the usual sickness.

Subsidence, or falling in of the abdomen, so as to be less prominent than usual, is considered as another of the early symptoms of pregnancy.

Dans une vntre plat
Un enfant il y a,
as the old French proverb has it. This has been said to be occasioned by the descent of the uterus into the pelvis, drawing with it a portion of the bowels, but with little propriety. The real cause seems to be emptiness of the bowels: Women not only vomiting up the greater part of the food they take in, during the first live or six weeks of their pregnancy, but being usually during that time so troubled with nausea, as to have little inclination to take fullness.

The aureola, or circle round the nipple, which in virgins is of a beautiful pink colour, becomes darker, it is said, after conception. It is certain, the aureola is darker in women who have had children, than in those who were never pregnant, and in some women who have borne many children, it becomes of a dark chocolate colour, but as that colour continues after child-birth, no indication can be taken thence, whether the woman is actually pregnant, unless perhaps with the first child.

Enlargement, hardness, and tenderness of the breasts, with pains darting through them, and a discharge of a thin pale milk, or whey, are commonly attendant on a pregnant state. This alteration in the state of the breasts usually takes place in the third or fourth month after conception, sometimes earlier, and is indicative of the preparation making in them for the secretion of milk, the future nourishment for the child. If from this plump and firm state, the breasts subside, and become bolder and flaccid, unless a violent diarrhoea may have superinduced to occasion it, the fetus may be expected to be weak, sickly, or dead.

Cardialgia, or heart-burn, is a frequent and troublesome attendant on pregnancy. (See Cardialgia.) This has obtained its name cardialgia, from its being supposed to be an affection of the cardia, or upper orifice of the stomach. A sense of burning, or of intense heat, melts the patient, which demands almost incessant drinking to appease it. As the uterus enlarges, it thwarts the intestines higher into the abdomen, hence the liver, and other viscera, are disturbed and straightened, and thence probably a more plentiful secretion of bile, which flowing into the stomach, is thought to occasion this uneasy sensation, which is observed to be more troublesome in a recumbent, than in an upright posture. Pills with spap and rubarb, Columbo root, magnesia, and other tafeless powders, are found to be the most useful medicines in this complaint. Milk and water, pyrnon and other chalybeate waters, barks and tonics are also serviceable; but it sometimes resists every medicine, and only subsides after the food is digested, and the stomach is nearly emptied. This points to the only preventive, abstinence. Women subject to this complaint should content themselves with the lightest diet, and that taken in small quantities. In the mean while, the rubarb, spap, and Columbo, should be perfused in to help digestion, and to cleanse and empty the bowels.

Cramp, attacking the legs, thighs, or belly, is also a frequent attendant on the pregnant state. This is probably occasioned by the pressure of the head, or other part of the fetus on the iliac or neighbouring nerves, and consequently becomes more troublesome the farther the woman advances in her pregnancy. An unnaturally irritable state of the nervous system seems to be the pre-disposing cause of this complaint. Hence, persons in the higher ranks of life, whose constitutions are dibilitated by sitting up late at nights, by large companies, luxuriant diet, &c. are most frequently tormented by it. A more simple diet, early hours, exercise in the open air, keeping the bowels empty, bark, and other bitter and tonic medicines, promise relief, both in preventing and curing this troublesome complaint.

Of the symptoms here enumerated, many are equivocal, as happening indifferently in the pregnant, or in the unm-pregnated state; and none of them are singly of sufficient validity, to enable us to form a decisive opinion from them; but from the conjunction of severa of them, a pretty certain conjecture may be formed. If a woman accustomed to be regular, soon after marriage ceases to be so, and about the same time is affected with nausea and vomiting, there would be little hazard in pronouncing such a person to be pregnant. But where the symptoms are equivocal, it is always best to defer giving a decisive opinion, until the commencement of the sixth month, when from the motion of the fetus, and the increased bulk of the abdomen, we may be enabled to determine with certainty.

About this time, a new train of symptoms succeeds, principally dependent on mechanical causes. The volume of the uterus, daily enlarging, presses on, and flattens the urinary bladder, and diminishes its capacity. Hence a more fre-
CONEPTION.

quent necessity for making water. The uterus, at the same
time, pressing on the rectum, occasions the alvine faces to be
discharged with difficulty; hence colicomenes, and the re-
turn of the blood by the iliac and hemorrhoidal veins being
prevented, by the same cause, the piles; hence, also, e-
strumental swellings of the legs, thighs, and labia pu-
dendi.

The labia pudendi, swelling almost entirely of cellular
membranes, are sometimes so enormously dilated as to pre-
vent the person from walking, and occasion considerable
pain. Sacrificing the labia, or making two or three pu-
tures with a lancet, the parts being afterwards fomented
with warm water, sometimes succeeds in reducing these
swellings. Bleeding and moderate purges are also neces-
sary. However formidable the appearance of the labia,
when thus enlarged, may, in these cases, uncommonly ex-
pedite. In these phlegmopathic habits, the fibres seem
to have lost their tone or power of resisting, and to
give way to the slightest impulse, so that the child is fre-
quently expelled by the most trifling effort. The haemor-
rhoids, or piles, are not so tractable, but frequently elude
every attempt to cure them, until after delivery, when they
usually soon subside.

Varices, or enlargement of veins of the legs and
thighs, being dependent on the same cause, the pressure
of the uterus, preventing the return of the blood from the
lower extremities, can only be palliated, until after the
birth of the child, when they gradually vanish. It will be
right, while waiting for this event, to moderate the dilata-
tion of the veins, and prevent their burbling, by keeping in
a recurrent posture, and by wearing bandages around the
parts. The piles may be relieved by taking a fcrmt spoon
full of cream of tartrate every day, and by anointing them
with a preparation, consisting of galls of Aleppo reduced
to an impalpable powder, and mixed to the consistence of an
ointment with cold drawn linseed oil, or green tea, macerated
in boiling water, may be applied as a poultice.

An idea prevails among women, that it is necessary they
should take a greater quantity of nourishment during the
pregnant state, than at other times, as they are then to furnish
nourishment to an additional being; and they frequently, at
the exhoratation of their friends, take in a greater quantity
of food than they have any inclination for, lest they should
deprove the child of its necessary nourishment. But as no
more of the food they swallow can be of use for that pur-
pose, than what is properly digested, and as all the symp-
toms thaw the defluded state of the stomach, it is evident
that by loading that organ unceessarily, all the complaints
incident to the pregnant state will be aggravated and increa-
sed. The greater part of the bile being digested by vo-
miting, during pregnancy, a sufficiency does not remain to
complete the digestion of the food to which it greatly con-
tributes. Hence the chyle, admitted in too crude a state into
the intestines, by its limbus, excites after every meal a kind of
hectic, by which the body is emaciated, the face is con-
tracted, or shrunk, and the eyes, as Hippocrates observed,
become furred and hollow. In this state, therefore, an in-
creased quantity of food, by increasing the labour of diges-
tion, adds to the mischief. A moderate diet, with a due
quantity of vegetables, and of ripe fruit, with country air,
when it can be obtained, are the best remedies, and are to
be recommended in every case during pregnancy.

It has been observed, that the effusion of the menes is
one of the earlier signs of pregnancy; but some women
continue to have a discharge of blood from the pudenda,
recurring at longer or shorter intervals, for the first four,
five, or six months of their pregnancy; but the return of
these discharges is rarely regular, recurring at the end of the
second, third, or fourth week, and sometimes at the end of
longer intervals. The quantity also varies, being some-
times more sparry, at others more profuse than the menes
usually are. These discharges happen whenever any portion
of the placenta, or membranes, is detached from the uterus,
and generally terminate in abortion, or the premature birth of
the fetus; or if the woman carries her birth to the end of the
ninth month, the child is usually weak, sickly, or dead.

"St. pregnant," Hippocrates says, in the place last quoted,
"purges, purges given them from twenty to forty days, and
the child will have a fine, white, and healthy countenance.
A slender diet, with occasional small bleedings, and mild purges are the best pre-
ventives, in these cases.

Pica, or an irregular or depraved appetite, exciting
women to long for, or intensely desire, some particular kind
of food, is sometimes an attendant on pregnancy. (See Pica.
This formerly, from an improper indulgence of the ap-
etites and fancies of pregnant women, was a very trouble-
some, and sometimes a formidable affection; as not only the
health and life of the mother, but the perfection of the fetus,
were supposed to depend on gratifying these longings.
If a child happened to be born with some mark or blemish
on its body, the memory of the female relatives or friends
was raked, to recollect some f desire of the woman that had
been disappointed, to which the accident was attributed.
Sometimes, however, these marks were supposed to have
been occasioned by the sudden fright of some object, which
it was thought to resemble.

This idea of the power of the imagination of the mother,
in making or disfiguring the fetus, is so ancient that we can
trace its origin. We read in Genesis, that Jacob
placed peeled rods before the eyes when in company with
the rams, and it came to pass, that when the ewes looked
at the rods, that the lambs they yeancan, were party-col-
oured, and streaked. And Heidou, the most ancient of the
Greek poets, says, Ne que reddi e funere, libers
operam det, ne imaginatio rei trilis, in proles tranfaret,
safque permetat." Let no one returning from a funeral,
embrace his wife, lest the melancholy he had contrived,
should make an impression on the fetus. Dr. Daniel
Turner, who was an intire convert to the opinion, has made
a large collection of histories of monstrous births, all oc-
casioned, he says, by the disappointed longings of their
mothers, or by their being frightened by the sight of some
hideous or monstrous objects. See his Treatise, De Morbis
cutaneis. lib. xiii. Turner's book was answered by Dr.
Blondel, in a masterly and satisfactory manner. The op-
inion is now wearing away very fast, and bids fair in a little
time to be totally obliterated. See IMAGINATION.

When the appetite, during pregnancy, is inordinate or
depraved, requiring improper food, it may be remedied
by taking small doles of ipecacuanha, of rhubarb and mag-
nezia, of Columbo, and other bitter and tonic medicines.

CONEPTION, immaculate, of the Holy Virgin, is a feast
established in honour of the Holy Virgin; particularly with
regard to her having been conceived and born immaculate:
i.e. without original sin; held in the Roman church on the
8th of December.

The Latin church, says Gibson, (Hist. of the Decline
and Fall of the Roman Empire, vol. i. p. 265,) has not
disdained to borrow from the Koran the immaculate con-
ception of the virgin-mother. It is darkly hinted in the
Koran (c. 3. p. 39.) and more clearly explained by the
tradition of the Sonnites. (Sale's Note, and Maracci, ton.
i. p. 112.) In the 12th century, the immaculate concep-
tion
tion was condemned by St. Bernard as a presumptuous novelty. However Allatius, in his Prolegomena on Damascenus, endeavored to prove this to be founded on several churches in the East, as early as the eighth century. It was first established about the year 1135, though it is not known, with any degree of certainty, by what authority it was, introduced, nor in what place it was first celebrated; about 1140 certain churches in France began to observe it; but it had been observed in England, in consequence of the zeal of archbishop Anselm, before this period.

The church of Lyons in France was one of the first that adopted this new festival, but the canons of Lyons were severely confounded by St. Bernard for the innovation, and he vigorously opposed the immaculate conception of the Virgin, because it supplanted her being honoured with a privilege which belonged to Christ alone. Thus commenced a controversy, which occasioned two parties in the Christian church that contended with each other for several centuries.

This has been a great subject of controversy between the Scotists and Thomists; the former maintaining, and the latter impugning it.

The Dominicans espoused the party of St. Thomas, and held out a long time in defence of the Virgin's being conceived in original sin. When this controversy was renewed at Paris in 1384, by John de Montefono, a native of Aragon, a Dominican friar and professed of divinity, who publicly asserted that all who believed the immaculate conception were enemies of the true faith, the college of divines, and the whole university of Paris, condemned this, and some other tenets of Montefono. Upon this the Dominicans, together with their champion Montefono, appealed from the sentence of the university to pope Clement VII, at Avignon, (the name assumed by cardinal Robert of Geneva, on his election during the pontificate of Urban VI.) and raised an outcry, that St. Thomas himself was condemned by the judgment passed upon their brother. But, before the pope could decide the affair, the accused friar fled from the court of Avignon, went over to the party of Urban VI, who refuted at Rome, and thus, during his absence, was excommunicated. Whether or not the pope approved the sentence of the university of Paris is not ascertained. The Dominicans, however, deny that he did, and affirm, that Montefono was condemned merely on account of his flight; though there are many others who assert, that his opinion was also condemned. And as the Dominicans would not acknowledge the sentence of the university to be valid, they were expelled in the year 1389, and were not restored to their ancient honours in that learned body till the year 1404. The council of Trent, held in the decree of original sin, declares it not to be the intention of the council to include the Virgin under it; her conception it calls immaculate; and appoints the constitutions of Sixtus IV. to be observed with regard to it.

This controversy between the Dominicans and Franciscans was revived in the seventeenth century; and a festival was appointed by Clement XI. in 1708, to be celebrated throughout the Romish church; however, the Dominicans peremptorily deny the obligation of this law, and in maintaining their ancient doctrine.

In the three Spanish military orders of St. James of the Sword, Calatrava, and Alcantara, the knights take a vow, at their admission, to defend the immaculate conception. This resolution was first taken in 1562.

Peter d'Alva and Albarga have published forty-eight huge volumes in folio, on the mysteries of the conception.

Conception, Order of, in Germany, was instituted in 1618, by Charles de Gonzague of Cleves, duke of Nivernois and Rethelbois, and was confirmed by pope Urban VIII. in 1624. The badge of this order was a golden cross of eight points enamelled blue; in the centre a medalion rayonated gold, therein the image of the Virgin standing on a crescent, holding in her arms our Saviour, and round her head 12 stars all enamelled proper; the reverse was enamelled as the front, and on the medalion St. Michael, the whole of the star environed with the cordon of St. Francis, tie at the bottom: this badge was worn round the neck pendent to a sky blue ribbon.

Conception, religious of the order of. See Treatises.

Conceptionists, in Logic and Metaphysics, a denomination given to a party of nominalists, who took a middle road between the two sects of nominalists and realists, into which the scholastic philosophers were divided from the beginning of the twelfth century. That universality, which the realists hold to be in things themselves, and the nominalists in name only, the conceptionists hold to be neither in things nor in names only, but in our conceptions, whence they derived their appellation; but being exposed to the batteries of both the opposite parties, they made no great figure. It is not an easy matter, says professor Dugald Stewart (Elements of the Philosophy of the Human Mind, p. 193), to ascertain precisely the meaning of the conceptionists on the point in question, their language on the subject being involved and inaccurate; but the professor thinks that, upon the whole, it amounted to the two following propositions: first, that we have no reason to believe the existence of any essences, or universal ideas, corresponding to general terms; and, secondly, that the mind has the power of reasoning concerning genera, or classes of individuals, without the mediation of language. In denying the existence of universals, the conceptionists agreed with the nominalists. To what then, can we suppose, says the professor, that they differed from them, but about the necessity of language, as an instrument of thought, in carrying on our general speculations? Mr. Locke is referred by Dr. Reid (Essays on the Intellectual Powers of Man, p. 473) to the class of conceptionists. He does not maintain, that there are things which are universal; but that we have general or universal ideas which we form by abstraction; and this power of forming abstract and general ideas, he conceives, to be that which makes the chief distinction in point of understanding between men and brutes.

If Mr. Locke, says professor Stewart (ubi supra), had any decided opinion on the point in dispute, it did not differ materially from what is stated in the general propositions, which we have already cited. The apparent inconsistencies which occur in that part of his Essay in which the question is discussed, have led subsequent authors to represent his sentiments in different lights; but as these inconsistencies plainly shew, that he was satisfied neither with the system of the realists, nor with that of the nominalists, they seem to demonstrate that he leaned to the intermediate hypothesis already mentioned, notwithstanding the inaccurate and paradoxical manner in which he has expressed it. Dr. Reid's opinion seems to the professor to coincide nearly with that of the conceptionists; or, at least, to coincide with the two propositions, which are supposed to contain a summary of their doctrine. The absurdity of the ancient opinion concerning universals, as maintained both by Plato and Aristotle, he has expelled by the clearest and most decisive arguments; and by his own very original and important speculations concerning the ideal theory, he has, in the ingenious
ingenious professor's opinion, completely destroyed that natural prejudice from which the whole system of universal ideas gradually took rise. If, even in the case of individuals, we have no reason to believe the existence of any object of thought in the mind, distinct from the mind itself, we are at once relieved from all the difficulties in which philosophers have involved themselves, by attempting to explain, in consonance with that ancient hypothesis, the process of the mind in its general speculations. On the other hand, it is no less clear from Dr. Reid's criticisms on Berkeley and Hume, that his opinion does not coincide with that of the nominalists; and that the power with which the mind polishes of reasoning, concerning classes of objects, appears to him to imply some faculty, of which no notice is taken in the systems of these philosophers. However, he has no where positively asserted, that language is not an essential instrument of thought in our general reasonings. At the same time, as he has not affirmed the contrary, and as he has declared himself dissatisfied with the doctrines of Berkeley and Hume, his readers are naturally led to conclude, that this is his real opinion on the subject. His silence on this point is the more to be regretted, as it is the only point about which there can be any reasonable controversy among those who allow his refutation of the ideal hypothesis to be satisfactory. In consequence of that refutation, the whole dispute between the realists and the conceptuists falls at once to the ground; but the dispute between the conceptuists and the nominalists (which involve the great question concerning the use of signs in general speculation) remains on the same footing as before. See CONCEPTION.

CONCERT, an assembly of musicians, or a band of musical performers assembled for the entertainment of musical lovers. Concert Spirituel, Fr. A concert of sacred music, originally established at Paris in 1725, by permission of the abbot of the manager of the opera; which permission was purchased by the brother of the celebrated Philidor, to perform concerts in Lent, on the days the theatres were closed, at the price of 1000 livres a year, for three years, on condition that no French music or selections from the opera should be performed at these concerts. This first gave birth to the use of foreign music and foreign musicians in France. The license was renewed from time to time, but always at an advanced price, till it amounted, in 1749, to 9500 livres a year. In 1734, the two celebrated Bezzi's, from Turin, performed at the concert spirituel, one on the hautbois and the other on the bassoon, with more applause than any foreign musicians had ever before received in France. The celebrated Mondonville had the direction of this concert for several years, and composed expressly for its use motets for a single voice, accompanied by a rapid and difficult harpsichord leffon. It was at the concert spirituel, which, like our oratorios, takes place when no dramatic performances are allowed, that Giornovichi, La Motte, Vietti, the Agujari, Madame Mara, the Tod, Savoi, and David, were first heard in France; and afforded the inhabitants of Paris an opportunity of comparing the music and performance of foreign musicians with their own.

In 1749, during Lent, Gemignani had a concert of sacred music at Drury-lane theatre, the vocal pieces were all Italian to Latin words. Gemignani himself led the band on this occasion, and played one of his own solo's. This performance, in imitation of the French, was called Concerto Spirituale.

In Italy and Spain, academia, Ital. implies a concert. In France, Académie Royale de Musique was the title given at Paris to the establishment of the opera under Luilli by Louis XIV. in 1672, which it retained till the revolution. Roufseau, the foremost French musician and French musicians, translated both so much in his famous letter on French music, that he was burnt in effigy at the Opera-House door. And in the article Académie Royale de Musique, in the Encyclopédie, and Dictionnaire de Musique, he has given great offence by a pun; when after barely mentioning this academy, he only adds—\[I shall say nothing further concerning this celebrated establishment, except that all the academies in the world, this is that which has made the most noise;\] (le plus de bruit).
CONCERT-PITCH.

that on which the teenu-cliff is placed, being also the ledger-
line above the base flaff or the same below the-
treble staff of music, is now generally made the-
key-note, in finding the notes of the octave, whether diatonic
or tempered, we shall adopt each of the formulas, to the
finding of the pulses made by this note in ten fecon's of
time, to be determined by a hlop-watch, a second pendulum
clock, or a simple pendulum, used for the express purpose
of determining periods of 10th each. (See Pendulum.)
The first method was suggested by Pierre Mercier. It
consists in a wire or catgut string, of about 15 to 17 feet
length, over two fixed bridges at its extremities, and after
this, dividing the distance between the bridges accurately
into eight equal parts, then fixing another bridge at one of
those divisions from the end, taking care that the new
bridges, which should have a tolerably sharp edge or top,
does not strain the string, or force it out of its straight line.
The tuning-fork, pipe, or string C, upon the instrument
whole pitch is to be determined, is now to be compared
with the found of the 8th part of the string, and if its
double octave below nearly agrees therewith, the tension of
the whole string is to be altered, as in tuning a stringed
instrument, either tightening or slackening it, until the 8th
part is in exact unison with the double octave below the
note C, without any beats or undulations: if the found of
the 4th of the string should be found on trial to give a clear
musical note, and yet differ very materially from the double
octave below C, it may be necessary to assume a greater or
lesser length between the extreme bridges, and to deter-
mine anew the place of the bridge for the 8th part thereof;
and after the 4th part has been nicely adjusted to the double
octave below the note C, as above, it will be proper again
to compare the measure of the 8th part of the string with
its whole length, to see that the points of bearing on the
bridges are accurately adjusted to these proportions. Now
remove carefully the middle bridge, and cause the whole
string to vibrate, which it will be found to do so slowly,
as not to cause an audible sound, [if any found is heard, it
will be one of the Harmonics of that note, see that article,
and Trumpet], but so that its number of vibrations in 10th
can be found and counted, especially if a echo will be held
so near to the middle part of the string, that it may touch
it at each extremity of its vibration; 32 times the number
of these vibrations will give the number of pulses or com-
plete vibrations made by C in 10th, and may be called
its pitch.
The second method is that which Dr. Robison used,
wherein a machine, consisting of a combination of wheel-
work, could be so regulated by the motion of a fly, that
any given number of the teeth of a wheel should pass and
strike a quill projecting against them, during the space of
10th. In using such a machine as this, the velocity of the
last wheel should be so regulated, that the sound produced
by the impacts of the quill against the teeth, should be in
exact unison with the note C; when the known number of
teeth which strike the quill in the given time, will deter-
mine the pitch.
The third method is by the same learned and ingenious
gentleman, who contrived an apparatus, regulated in the
manner already described, which opened and shut the passage
to an even current of air, produced by a pair of bellows, such
as are used in organs, any required number of times in 10th;
this singular apparatus was found to give a clear musical
found, which regulated to an union with C, gave the exact
pitch thereof, by the number of alternate openings and
shuttings of the cock in 10th.
The fourth method is founded on the following propor-
tion, by the author herein mentioned, viz. "An open organ,
pipe, when sounding its fundamental note, undulates with
one node in its middle, and its undulations are analogous
in respect of their mechanism, with the vibrations of a wire
of the same length, and the same weight, with the column of
air in the pipe, and stretched by a weight equal to that of a
column of the same air, reaching to the top of a homoge-
ous atmosphere, or equal to the weight of a column of
mercury, as high as that in the barometer." (See Pipes.
Theory of the Sound of Trumpet, &c.) Whence this
simple practical rule, when the barometer stands at about
30 inches, and the thermometer at about 53°, viz., divide
the number 256620 by the length in inches and tenths,
of an open cylindrical pipe which founds C, and the quotient
will be the number of pulses or complete vibrations made
thereby in 10th.
The fifth method consists in suspending a known weight
(equal to W grains) at one end of a wire, such as is used for
the lowest notes of a piano-forte, the other end of which is
lapped round a thumb-peg, such as is used for tuning a viola,
screwed tightly into the mainfins, near to an instrument
whose pitch is to be determined; then by turning the peg,
lengthen or shorten the vibrating part of the wire, until
when struck it founds exactly a double octave below C;
measure exactly the length of the vibrating part of the string,
between its contact with the peg and the loop which lat-
tains the weight; call this L inches. After this, cut off
exactly L inches of this same wire and weigh it, call its
weight V grains; then will the number of complete vibra-
tions or pulses made by C in 10th be found by the following
theorem; viz. \[\frac{154463 \times W}{L \times W}\] See our article Cords.
The sixth method is by Dr. Robison, and is as follows.
Let a violin-guitar, or any such instrument, be fixed up
against a wall with the finger-board downwards, and in such
a manner that a violin-string, tained by a weight, may rest
on the bridge, but hang free of the lower end of the finger-
board. Let another string be tained by one of the tuning-
pins, till it be in exact union with C, then hang weights on
the other string, till upon drawing the bow across both
strings at a small distance below the bridge, they are found
to be in exact unison, taking care that the pressure of the
bow on the strings is moderate, as not to affect the tension
of the string fired tuned. Then, having noted carefully
the weight appended to the first string, add one-fortieth part
thereof to the same. Now draw the bow carefully again
across the strings as before, and an audible beating will be
heard between the sounds of the two strings; count the
number of these beats during 10th, and 81 times this will be
the number of complete vibrations, or pulses, made by C
in 10th.
The seventh method, as well as the base, depends on tun-
ing a major comma; for which several rules are given under
the article Comma. From the octave below C tune upwards
three successive perfect fifths upon a single flaps of an organ,
C G, D G, and D A; and thence tune downwards the per-
fected major fifth, A C; which last C will be a major comma
above the first C, and will be carefully counted when founded
therewith; count these beats during 10th, and 81 times this will
be the number of complete vibrations, or pulses of C
in 10th. See Dr. Smith's Harmonics, p. 195.
The eighth method (Harmonics, p. 197) consists in tuning
a major
a major fifth, C A, above C, not perfect, but such that it may beat sharp B times in 128; from thence tune downwards three times.

Every perfect fifth, A D, D G, and C G; which last note will be an imperfect octave below C, the beats of which octave are to be counted during 128, carefully distinguishing whether it beats sharp or flat, and calling the number, if sharp, S, and if flat, F; then will 81S + 16B, or 16B - 81F, according as the case may be, express the number of complete vibrations, or pulses of C in 100.

It is not in our power to give so satisfactory an account of what is the present concert or opera-pitch in this country, as we could have wished; but we hope that experiments will hereafter be multiplied, for fixing it very exactly (at a mean flat of the barometer and thermometer), and after such determination, that the exact number of pulses or complete vibrations from one extreme of the vibrations of a string until its return to the same point, will be reported to by instrument makers and tuners, for regulating the pitch of their forks, pipes, and instruments.

The vibrations, mentioned in M. Euler’s experiment, (after our fifth method, under our article Choixs) were semi-vibrations, or those made, while a point in a musical string, went from and returned to the axis, or line of rest, between the two points of fulgention, and not complete vibrations, or those made while the string went from and returned to the place of its greatest deviation from the axis: therefore \( \frac{392}{2} \) or 196, was the number of complete vibrations per 1", made by the A, a minor third below our C; whence this made \( \frac{6}{5} \times 196 \times 10 = 2351 \) complete vibrations in 100.

Dr. Robert Smith (Harmonies, p. 210 and 271), calculated about the middle of the last century, that the tenor clef C note, upon the organ in Trinity college, Cambridge, made 2322 complete vibrations in 1", or 2322 in 100, which, he says, was above half a mean tone lower than the London opera-pitch at that time, and which therefore probably gave about 2452 or 2470 pulses in 100. The above experiment of Dr. Smith’s was made, after Trinity college organ had been deprived a whole tone in its pitch, by making the keys each to act on two pipes lower in the scale than they originally did, by which it was reduced (Harmonies, p. 208, and 218) to the Roman pitch, or that to which the pitch-pipes, made about the year 1720, were generally tuned. Dr. Thomas Young, in his lectures at the Royal Institution (Syllabus, p. 97), states our C to make 256 vibrations in 1", apparently only, for the purpose of agreeing with an imaginary C eight octaves below, which is to make but 1 vibration in 1", but which imaginary C, according to the recent determinations of concert-pitch, which we are about to mention, ought to make but the \( \frac{3}{8} \) part of a vibration in 1", the 8th octave above which will be moved at the rate of 2400 puls in 10 seconds.

The late Dr. Robison applied our second, third, and sixth methods, for determining the complete vibrations made by C, and states them all to agree extremely near with 240 in 1", or 2400 in 100. Many other experiments are upon record, but generally some other note than C was selected for the experiment, the exact interval between which and C we are ignorant of, owing to the temperament of the inferior instrument; this is the case with Dr. Smith’s determinations (by the fifth and others of the methods above, Harmonies, p. 102, &c.) of the vibrations made by D 5/4 of a, upon the organ above-mentioned.

We were lately present at an experiment by Mr. John Isaac Hawkins, at his house in Great Titchfield-street, where he manufactures the finger keyed clav and double-bells, mentioned under our article CLAVILDE, (see FINGER-KEYED VIOL) according to our fifth method above: two pieces of hard wood, about an inch thick, were forced down to the floor in his room, at about 22 feet distance, and were pierced for the two string-peg of a harpsichord wire; several thin pieces of wood with a sharp edge at top, and rilled a very small height more above the floor, than the fixed pieces of wood, were provided as moveable bridges. A brass wire, called No. 15, by the piano-forte makers, and the largest size which they use in grand piano-fortes, which was found to be .023 inch diameter, was lapped on the pins, and stretched by turning one of them. From a point marked 0 on the floor, 8 or 10 inches from one of the fixed pieces of wood, the several distances .75 inches, .75, .70, .65, and .625 inches were carefully measured and marked under the string; a bridge was then placed under the string, at the point 0; another at .75, and another at .70, and one of the tuning pegs was turned until the short portion of the string, .65 to .75, was in perfect union with Mr. H’s small, or mouth tuning-fork, C; which is a very considerable improvement upon the large tuning forks which were to be fixed upon a table, (see Tuning-Fork.) the bridge at .75 inches was then successively moved to .70 and .65 inches, in order to compare the octave and double octave below with the fork, and which on trial appeared to be accurately in tune. This middle bridge was then removed, and the counting of the visible vibrations of the whole string, .65 to .75, or five octaves below C, was conducted as follows. Mr. H. kneeling down on one knee, placed a seconds watch before him, and held a quill with one hand slightly against the string, about two feet from the bridge, to see it to be struck by the wire at each vibration; this was for afflicting the ear, in counting the vibrations, by means of the audible strokes thus produced on the quill: for some time. Mr. H. continued attentively to notice the vibrations, and to beat down with his toe at every fourth vibration, as a performer on the violin, &c. does in playing in common time; this was purged, until such a regular rate of beating was obtained by the toe that the experiment was not interrupted by a new twitch or impulse given to the vibrating string by an aficionado; the counting then commenced, and was continued during 60 seconds, in the first of which 111 beats of the toe were made, and in a repetition of the experiment, after examining the time of the 8 1/2 part of the string, 113 beats were counted; the mean of these, or 112 per minute, gave 112 \( \times \frac{4}{3} = 6 \) = 74 vibrations for the whole string in 10 seconds, and consequently C, five octaves above, gave 475 \( \times 32 = 2380 \) vibrations in 100, which agrees extremely near with Dr. Robison’s experiments above mentioned, in showing, that 2400 may be taken as the present concert pitch.

We have only to add, that an experiment and calculation some years ago by the fifth method above, gave us 2415 puls in 100 for a tuning-fork then in our possession, marked C, but whether the fame had been adjusted to the acknowledged concert-pitch, we are unable to say. The rate of the barometer and thermometer should always be noted, at the time of making experiments of this kind, if it is intended accurately to determine the pitch: and it may be well, instead of trusting to the ear alone, in determining the unison or octave of the fork and string, to count and equalize their beats with a third found, a little different from both of them, as recommended by Mr. Nicholson, Phil. Journ. 8vo. i. p. 320, for the making of correct tuning-forks.

Concert
CONCERT of Ancient Music. This excellent establishment was originally suggested by the late earl of Sandwich in 1776, in favour of such solid and valuable productions of old masters as an intemperate rage for novelty had too soon laid aside as superannuated, was supported with spirit and dignity, by the concurrent zeal and activity of other noblemen and gentlemen of the first rank, who united their lordship in the undertaking. till 1787, when it was honourably closed with the presence of their majesties, whose kind attendance ever since has given to this institution an elevation and splendour, which perhaps to establishments of this kind ever enjoyed before. Here the productions of some of the old masters, particularly those of Purrell and Handel, are performed by a select and powerful band, with such correctness and energy, as the authors themselves never had the happiness to hear.

Concert, To, in a Military Style, is not only to deliberate upon, but to arrange, form, and agree upon plans of co-operation, for the purposes of either offence or defence.

CONCERTANTE, Ital. from concertare, to concert, order, arrange. In the musical technica, it used to be equivalent to harmonizing, adding instrumental parts to the voice. But at present, the term concertante is used substantively, for a symphony or full piece dialogised. In which there are solo parts for the display of great talents on particular instruments. At the concerts of Bach and Abel, solo parts were frequently allotted in these compositions to Cramer, Fétcher, the younger Stamitz, Hindemith, Sheldon, Holmes, Tacit, and the elder Florio. Abel, on the viol da gamba, and Bach himself on the pianoforte. Bach's concertante in C, and Phyle's in E, were always heard with delight; not only from the merit of the composition, but exquisite manner in which they were performed, and the ingenuity of the written cadences, generally furnished by Fétcher.

CONCERTATO, a term in Music, implying the addition of instrumental parts to the vocal composition; as motto concertato, a motet or anthem, accompanied by instruments.

CONCERTO, synonymous with concerto, which long supplied its place. Concerto and sonata implied nearly the same things in the days of Doccaccio, as concerto and sonata since; but concertare and concertanti were at first applied to the union of instruments with voices, in motets and madrigals, by doubling the voice-parts. It was not till late in the seventeenth century, that instrumental pieces of many parts, began to be called concertos, and of few parts sonatas.

The earliest compositions which we found in Italy, for three or more instruments of the same species, were Ricercari and Fantasia. But of these none seem to have been printed, when the elder Doni published the second edition of his "Libreria," 1557, as all the instrumental music that appears in his catalogue of musical compositions, which had then been published in Italy, are "Intabulature da organi, et da liuto, d'Anton da Bologna, di Giulio da Modena, di Francesco di Milano, di Jacque Dues, piu di dieci volumi, & continue." About the beginning of the seventeenth century madrigals, which were almost the only compositions in parts for the chamber, then cultivated, seem to have been suddenly superseded in the favour of lovers of music by a passion for fantasies of three, four, five, and six parts, wholly composed for viol, and other instruments, without vocal assistance. And this passion seems to have arisen, from the calling in of these instruments to reinforce the voice parts, with which they played in union, in the performance of motets and madrigals, thence termed concertati. At length the instrumental performers discovered that both the poetry and singing of the times might be spared without any great loss or injury to musical effects; as the words, if good, were rendered unutterable by fugue, imitation, and multiplicity of parts; and the singing, being often coarse and out of tune, could be better supplied by their own performance. Thus vocal music not only lost its independence, but was almost totally depressed by society; as the ancient Battou, calling in the Saxons to stuff them in their conflicts with the Poets, were themselves subdued and forced from their positions, by too powerful auxiliaries. See Fancies and Base-Viols.

Simpson in his "Compendium," speaking of fancies, page 118, says: "In my opinion, no action is equal to the English in this way, as well for their excellence, as for their various and numerous consorts of 3, 4, 5, and 6 parts, made properly for instruments, of which fancies are the chief."

In the MS. "Memoirs of Music," by the hon. Roger North, who speaking of Jenkins, an eminent English composer, in the time of Charles I., says, that "of all his concerts, none flew with his name to it, so universally, as the small piece called his "Five Bell Confero." And this is only in three parts, so that the import of the term concert or concerto was not then settled.

Montague, who travelled through Italy and Germany in 1750, says that the mas in great churches was accompanied by organs and violins. But though the word concerto occurs so early as the year 1587, in the "Trattenimenti," and "Divertimenti" of Scipio Bargagli, it was only applied to short Fantasia and Ricercari. Saini concertati was often used when instruments were added to voices, in concerti ecclesiastici.

At the latter end of the 17th century most of Baffani's, Corelli's and Torelli's violin music was composed for the church. The first and third set of Corelli's sonatas, and his first eight concertos, we are certain were thus appropriated. Samei, Veracini, and Tartini, composed their own solo concertos, and performed them likewise in the several churches of Italy. And Pugnani used to accompany the "Messa Bolla," or Silent Mass, at the chapel royal in Turin, with his violin solo concertos.

Concertos merely instrumental, for secular use, seem to have had no existence before the time of Corelli. The honour of the invention has been assigned to Torelli, but from no good authority. Six concertos by Alessandro Scarlatti, manifestly, from the gravity of their style, composed for the church, were printed by Benjamin Cook, in New-Street, Covent-garden, about the year 1730. But at the beginning of the last century, besides the concertos of Corelli, Geminiani, and Handel, concertos by Albinoni, Alberti, Tassanini, and Vitaldi, were dispersed all over the kingdom, and heard with great delight at our country concerts, music-meetings, and clubs. These were chiefly on the model of Torelli and Corelli, but with melody of a lighter kind. They were all in seven or eight parts for two choirs; that is, with solo parts for the concertini, or solo instruments, and ripieno parts for the concerto grosso, or choirs of the whole band. But these were soon superseded by great performers on the violin, such as Locatelli, Tartini, Somis, Veracini, Nerli, and Giordani, who, in order to display their superior powers of execution, rendered them too difficult for general use. But these being brought into public favour by the admirable performance of their several authors, were followed by the concertos of Bartelemon, Cramer, La Motte, Lollis, Solomon, Viotti, Giovanni, and others, who, by some peculiar excellence in the knowledge of the finger-board, use of the bow,
bow, or accurate performance of double-flows, seem to have arrived at the acme of perfection in executing solo concerts.

Concerto Grossi, a grand concerto, or full piece.

Concerts, public. These were first established in London by Banister, master of King Charles II's new band of 24 violins. The first notice we find of these assembles is in the London Gazette, No. 742, for Dec. 20th, 1672, in which there is the following advertisement: "These are to give notice, that at Mr John Banister's house, now called the music-school, over against the George Taverner, in White Yriers, this present Monday, will be music performed by excellent masters, beginning precisely at four of the clock in the afternoon, and every afternoon for the future, precisely at the same hour."

There are other advertisements from Banister of the same kind, in 1674, 1676, and 1678. In that for Dec. 11th, 1676, his musical performance is said to be "At the academy in little Lincoln's-inn fields," where it was to begin "with the parley of instruments, composed by Mr. Banister, and performed by eminent masters."

In Mr. North's manuscript "Memoirs of Music," we have a more minute account of these performances. "Banister having procured a large room in White Yriers, near the Temple back-gate, and erected an elevated box or gallery for the musicians, whose modelly required curtains, the roof of the room was filled with tents and small tables, alcove, and fountains. One shrilling, which was the price of admission, entitled the audience to call for whatever they pleased. There was very good music, for Banister found means to procure the best hands in London, and some voices to fill them. And there wanted no variety, for Banister, besides playing on the violin, did wonders on the flageolet to a thorough base, and several other masters likewise played folos."

These were followed by other public concerts of a superior kind, at the Crown and Anchor, the Colly in Pater-noster row, the Swan and King's Arms, Cornhill, York Buildings, Hickford's Room, &c. &c.

Concessi, q. d. I have granted; a term much used in conveyances, &c. Its effect is to create a covenant in law, as debi (I have given) does a warranty. Co. Lit. 384. This word is of a general extent, and is laid to amount to a grant, feufofitment, leaf, and release, &c. 2 Saund. 96.

Concession, in Rhetoric, a figure whereby something is granted or allowed to the adversary, either to prevent being detained by unnecessary incidents, or to make some advantage of. "I will not contend with you the reality of the contract; what I plea for, is relief against the injustice of it." "True, she is fair; but ought he not to shew her acknowledgments to heaven for the favour, by making a virtuous use of her beauty?" See Epitrope.

Concessit, Sur, in Laws, a species of Finc. in which fee.

Gen. Ch. Male flower not known. Female. Cal. one-leaved, flabby, trigonous near the bottom, with three large glands at its base, terminated by five thick acute teeth, each of which has on the inner side of its base a gland prelling upon the germ. P8. Germ superior, triangular; style none; fihmas three, thick, concave, furrowed, incurved. Peric. Capsule globular, trigonous, with three furrows, three-celled, three-valved, each valve dividing into two. Seeds, one in each cell, roundish, enveloped in a white pulpy matter which has a sweet pleasant taste.

Sp. C. guianensis, a small tree. Trunk ten or twelve feet high, about a foot in diameter, with grey bark and white wood, much branched. Leaves alternate, at unequal distances from each other, oval-oblong, acuminate, toothed, green and smooth on their upper surface, crenate underneath. Stipules in pairs, small, cadous. Flowers feathery, alternate, in a terminal spike, common peduncle fleshy, trigonous. A native of Guiana, on the banks of rivers. When the bark is cut, or the leaves torn, a greenish juice flows from the wound.

Concez, in Geography, a town of France, in the department of the Corrèze, and district of Drive; 6 leagues N.W. of Drive.

Conch, in Mythology. See Triton.

Concha auris, in Anatomy, is the hollow hollow of the external ear, included between the tragus, antitragus, and antehelix, and having at its anterior part the commencement of the meatus auditorius externus. See Ear.

Concha, Nervos, in Anatomy, a liquid measure among the Athenians, which contained two minima, or half an ounce. As much oil as it was capable of holding, weighed five drams one scruple and twenty grains, according to Cor. Defin. Phisic. Lex. & Eticonom. Others think that the concha contained two minima, or five spoons, which, according to Jacobus Sylvius, are equivalent to five drams. According to Galen, in his works De Ponderibus & Mensuris, cap. ii, the concha magna contained the same quantity with the acetabulum, which in liquid measure was an ounce and a half, and in weight fifteen grains. The concha minor was in liquid measure half an ounce, and in weight five Grains.

Conch, in Conchology. See Conchology.

Concha, in Music, a trumpet among ancient instruments, or a trumpet-marine, such as Triton used.

—— Tritona vocat; conchæque sonār
1upirare jubes.

Ov. Met. i.

Concha anatrida. See Anatrida.

Concha anamphora, the name of a fossil shell-fish, found in great abundance, and in a great variety of species, but not known in any of them living, on the shores or in the seas of our own or other countries. In Gloucestershire, and some other of our counties, these are found as common as pebbles on the ploughed lands in other places. They are a sort of bivalve shell, the valves of which are of unequal extent, both of them convex, and the head or back of the longer valve crooked, and falling over the head of the other.

The great general division of this numerous class of bodies, is into those which are of a smooth surface, and those which are of a striated or rough one.

Others also of the same class, or of one very nearly allied to it, are found in many of our inland counties, some very long from the cardo, or hinge, to the margin; and others very short, and very long the contrary way. They are found indiscriminately in all sorts of lands, in earth, in stone, in sand, and among gravel. See Anaxa.

Concha fortis, a name given by some authors to the genus of shells, called by others the Murax.

Concha globosa, the name of a large genus of shells, called by authors the Dolium, and in French the tonne.

Conch'n Lapide, was the name by which some
writers distinguished the fossil shells found lodged in the Aran
ta of the earth, before the whims of certain authors re-
secting the vis plicata, vis formativa, &c., by which they
attempted to account for the formation of these organic
remains, had been entirely exploded, and the truth of their
being animal exuviae generally established.

**Concha margaritifera**, a name sometimes used for those
mytili which produce pearls. See **MUSCUL**.

**Concha margaritifera**, is the name by which some
writers have described a fossil shell, somewhat resembling
the recent shells of this genus, in the equality of their valves,
the appearance of their gutted and toothed hinges, &c.

**Concha maritum**, in **Anatomy**, is a term applied to the
turbinate bones of the nose. See **SKELETON**.

**Concha specicorum**, in **Natural History**, the sp. fere shell,
a name given by authors to a species of volua, from some odd
figures described on its surface, representing rough droughts
of terrible phantoms. It is an elegant shell, of a middle fize,
and is of a white ground, and the figures are reddish; these
form three large and broad bands, surrounding the shell at
the top and bottom, and in the middle; and between these there
are several series of small spots. It is a scarce shell, and
usually sells at a large price.

**Concha Veneris**, the name by which several species of
chasam are called. The shell is univalve, wreathed,
and has a small longitudinal and denteculated chink, or
aperture, in it. It is also called conch porcellana, from
its aperture in some measure resembling the mouth of a
hog; and concha etyrbea, from its being found in the Red
Sea, called etyrbeum. It is also called concha etyriana,
from Venus, who received the epithet etyriana, from Cy-
thera, a Greek island. That this fish was used by the
ancients as an aliment, we read in Seneca, Ep. 95. Mund-
ius affirms that they prove a stimulus to venery, and pro-
voke urine. Rondeletius informs us, that these shells are an
ingredient in the filula de bellis, for removing fluxes,
and curing ulcers in the uterus. But instead of the concha
veneris, the apothecaries generally use cockles. Excellent
dentifrices are prepared from this shell, which is also used
for curing ulcers in the canthus of the eye, and the filula
lacrimalis. It is remarkably drying, without exciting any
heat.

**Concharum Promontorium**, in **Ancient Geography**,
a promontory of Asia Minor, on the Thracian Bosphorus.
It is the fourth part of the Cenchrean gulf.

**Conches**, in **Geography**, a town of France, in the
department of Eure, and chief place of a canton in the district
of Evry, 18 miles S.E. from Evry, 59 S. from Rouen,
and 87 N.E. from Paris. The place contains
2,459, and the canton 13,520 inhabitants. The territory
includes 27,753 kilometres, and 33 communes.

**Conches**, a town of France, in the department of the
lower Pyrenees, and district of Pau; 6 leagues N.N.E.
of Pam.

**Conchites**, or **Conchitix**, in **Natural History**, a
name which has been indifferentely used by writers, in de-
scribing fossil bivalve shells of different kinds.

**Conchites marmis**, a name given by the ancients to a
species of marble dug near Megara, and remarkable for
containing a great number of sea-shells, and other marine
bodies imderfed in it.

**Conchium**, in **Botany**, from κυκλος, a bivalve shell,
in allusion to the form of the fruit. Smith. Tr. of Linn.
Malmaison, 110. (Hakea; Schrad. Sert. 27. Cavan. Je. v.
6. 24.) Muscule shrub. Cliffs and order, tetrandria mono-

Gen. Ch. Cal. none. Cor. of four petals, linear, cohere-
ing at their base, somewhat dilated and concave at the stam-
nit in, nearly equal. Stem. four filaments short, inserted to-
wars the summit of each petal; anthers lodged in the ca-
vity of each petal, erect, oblong, two-celled. Pfl. Ger-
men superior, small, ovate, oblique; style ascendine, re-
curved, cylindrical, thick, as long as the corolla; stigma
turbinate, pointed. Petal. Capula ovate, oblique, gibb-
ous and rough, pointed, of two hard, thick, woody
valves, and one small eccentric cell. See C conches, two,
 elliptical, flat on one side, convex on the other, filling the cavity of the
capula, each furnished with a black, membranous, transverse, oblong wing.

Eff. Ch. Calyx none. Petals four, bearing the stamens.
 **Silviasa turbinate, pointed. Capulae**, of one cell. **Seeds** two,
winged.

Sp. 1. C. gibbosa, Donn. Cant. 21. (Bankia gibbosa; 
Hakea gibbosa; Cavan. Le. 1. 534. H. pateceas; Schrad.
Sert. 27.) "Leaves cylindrical, slightly downy, rather
longer than the fruit. Corolla' mouth. **Capulae roundish-
ovate, gibbous, rough." Sm. MSS. Stem shrubby, branch-
ed, rigid, smooth. Young branches hairy. Leaves
numberous, evergreen, alternate, fesfle, spreading, cylindrical, near two
inches long, somewhat downy; especially when young, each
 tipped with a sharp spine. **Flowers** in small, axillary, hairy
whites. **Corolla** nearly or quite smooth. **Capulae**
solitary, the size of a walnut, black and rough, very gib-
bose underneath; the valves extremely thick, hard and
woody, each tipped with a short sharp point; cavity very
small, eccentric, uneven, of a mahogany colour. **Seeds** with
black wings like gauze or crane. A native of New South
Wales, near Port-Jackson. It is now frequent in the more
curious European green-houses, but is rather singular than
beautiful. 2. C. spheroidea. "Leaves cylindrical, as long
as the fruit, downy as well as the branches. **Capulae** orbi-
cular, depressed, smoothih." Sm. MSS. A smaller shrub
than the last. **Branches** clothed with dense woolly hairs.
**Leaves** about an inch long, very hairy. **Flowers** unknown
in Europe. **Capulae** of a rusty brown, the size of the leaf,
but much less rugged, and when viewed vertically, almost
orbicular, their points scarcely extending beyond the cir-
cumference. Sent from Port-Jackson with the preceding.
aison. (Hakea fibresa; Schrad. Sert. 27.) **Leaves** cylin-
drical, smooth, as long as the fruit. **Corolla** smoothish.
**Capulae roundish-ovate**, rugged, elongated at the point." Sm.
MSS. Like C. gibbosa, but in all its parts about half as
large. **Leaves** in every period of their growth quite
smooth. **Flower-flaps** and young branches silky. **Fruit**
more oblong than in the two preceding, but its lateral pro-
tuberances are more globose. A native of Port-Jackson,
not rare in our gardens. 4. C. longifolium. Donn. Cant. 21.
(Bankia teretifolia; Salib. Prod. 517.) "Leaves cylin-
drical, smooth, thrice as long as the fruit. **Corolla** cloth-
ed with silky hairs." Sm. MSS. **Leaves** three inches or
more in length, fleshy, as in all the foregoing, always
smooth, as well as the branches. **Corolla** clothed with white,
close, silky hairs. Perhaps only a variety of C. pugioni-
forme hereafter described, which cannot be determined to
the fruit of the present species be known. 5. C. compres.
a. "Leaves cylindrical, smooth, scarcely so long as the fruit.
**Capulae** ovate compressed, somewhat rugged." Sm. MSS.
The fruit of this is not more than an inch long, and ovate,
pertaining but little of the globular protuberant figure of the
preceding kinds. **Leaves** small and slender. 6. C. pugio-
forme. (Hakea pugioniformis; Cavan. Le. v. 6. 24. 1.

592
Properly and Culture. All the species are shrubby and perennial, chiefly raised from seeds brought in the capsules from their native country, and requiring with us only the usual shelter of a green-haue or conservatory. Those from King George's Sound are as yet strangers to our gardens. The others thrive in sandy peat earth, but require regular and rather copious supplies of water. They may be increased by cuttings. C. fallicn timens feeds in abundance when planted in the ground under glass, and ricks to the height of 12 or 15 feet.

CONCHOID, or CONCHILIS, in Geometry, a curve line which always approaches nearer a straight line to which it is inclined, but never meets it. It was invented by Nicomedes, and much used by the ancients, as we learn from Pappus, in the construction of folid problems.

It is described thus: to draw a right line B D (Plate, Analysis, fig. 2) and another AC, perpendicular to it in E; draw the number of right lines, as CM, CM, cutting B D in Q, make QM = QN = AE = EF: the curve wherein the points, M, M, are found, is the conchilis, or conchis prima, so called by Nicomedes. The other, wherein the points, N, N, are found, is the conchis secunda; the right line B D the rule, or directrix, the point C the pole, or centre of the conchoid. In reality, they are both parts of the same curve, having the same pole C, and four infinite legs, to which the line B D is a common asymptote. The inventor also contrived an instrnent, whereby the first conchoid may be described mechanically thus, in the rule A D (fig. 3.) is a channel or groove cut, so that a smooth nail, firmly fixed in the moveable rule C B, in the point F, may slide freely within it into the rule E G is fixed another nail in K, for the moveable rule C B to slide upon. If then the rule B C be so moved, that the nail P passes along the canal A D; the frlle, or point in C, will describe the first conchoid.

Now let A P = x (fig. 2); A E = a; P E = M R = a - x; wherefore, as x increases, a - x, or M R will decrease; and therefore the curve continually approaches nearer to the rule B D.

In the same manner it appears, that the right line N O multi continually decreases; and therefore that the second conchoid, also, multi continually approaches nearer the rule.

But so much as between each conchoid and the right line B D, there will be the right line Q M or Q N, equal to A E; neither of the conchoids can concur with the right line B D: consequently B D is an asymptote of each conchoid. See Asymptote.

If from any point, A, of the curve (fig. 4.), A H and F T P be drawn perpendicular to the rule, or directrix, H T, and A L parallel to it; and if the quadrant, FG K, be described interciting A L in G; we shall have P L \times L G = T I \times L A. For the triangles, A H B, T L G, are similar and equal, as the angles at H and L are right; and A B = T F = T G, and A H = T L; therefore B H = G L. Also the triangles, A H B, A L P, are similar. Whence A H : H B :: P L : A L; that is, T L : G L :: P L : A L; therefore, P L \times G L = T L \times A L.

Hence, the same thing being supposed, we shall have A G = B T, and G L = H B. For A L = H T, and G L = H B.
\[
\begin{align*}
= HB; \text{ therefore, by subtraction, we shall have } AC &= BT. \text{ This proposition is equally true in the inferior conchoid (fig. 5). In the inferior conchoid } g l = b b. \text{ Moreover, in the superior conchoid (fig. 4), if } PTF \text{ and } AH \text{ be perpendicular to the directrix } HT, \text{ and } AL \text{ parallel to it, } TL^2 = TF^2 - AH^2 : PL^2 : AL^2. \text{ For, by the preceding proposition, } TL = GL = PL = AL, \text{ and } TL' = GL' = PL' = AL'. \text{ But } GL' = GT^2 - TL^2 = TF^2 - AH^2 : PL^2 : AL'.
\end{align*}
\]

Hence, putting } FT = a, PT = b, \text{ axis } TH = x, \text{ ordinate } HA = y = \text{ the equation of the superior conchoid will be }
\[
\frac{b + y}{\sqrt{a^2 - y^2}} = y = AL, \text{ or, by reducing }
\]

\[
it, \text{ we shall have } b + y = y = \sqrt{a^2 - y^2} = x = AL, \text{ and, by reducing }
\]

\[
2b^2y + 2a^2x - y^2 = x, \text{ or } \sqrt{a^2 - y^2} = y = x, \text{ and } a^2b^2 + 2a^2y + a^2y^2 - b^2y^2 = b^2 = y^2 = y = x; \text{ whence, by transposition, we shall have } y^2 + 2b^2y + b^2 - a^2y^2 + x^2 - 2ab = a^2b^2. \text{ Thus also, in the inferior conchoid (fig. 5), if }
\]

\[
pt \text{ and } ab \text{ be perpendicular to the directrix } bt, \text{ and } al \text{ parallel to it; we shall have } tf = t = a^2b^2 : PL = a^2. \text{ For } tl = gl = PL = a^2; \text{ and } tl' = gl': PL = a^2: \text{ but } gb' = gb = a^2 - a^2b = t = a^2; \text{ therefore } tf = a^2 = a^2b = PL = a^2.
\]

Hence putting } tf = a, PL = b, \text{ axis } tb = x, \text{ ordinate } ha = y = \text{ the equation of the inferior conchoid will be }
\[
\frac{b - y}{\sqrt{a^2 - y^2}} = y = a. \text{ And, when reduced, } y = \frac{a}{x}, \text{ it may be from the equation of the other curve by merely }
\]

\[
2b^2 + 2a^2 - y^2 = x = a^2. \text{ Or, it may be from the equation of the other curve by merely }
\]

\[
\text{changing the sign of } y, \text{ which in this case is negative.} \]

\text{Of the whole conchoid, expressed by the two equations, or rather by one equation only, with different signs, there are three classes of species; as first, when } E < F \text{ is less than } E C, \text{ as in fig. 2; when } E F = E C \text{, as in fig. 6; and when } E F > E C, \text{ as in fig. 7, in which latter case the conchoid is called nodated. The same equation holds for this nodated conchoid, the whole difference being merely that } a \text{ is here greater than } b.
\]

\text{Sir Isaac Newton approves of the use of the conchoid for trisecting angles, or finding two mean proportionals, or for constructing other solid problems. To this purpose, he says, in the linear construction of equations towards the close of his "Universal Arithmetic:" "The ancients at first endeavoured in vain at the trisection of an angle, and the finding of two mean proportionals by a right line and a circle. Afterwards they began to consider several other lines, as the conchoid, the cissoid, and the conic sections, and by some of these to solve these problems." Again, "Either, therefore, the conchoid is not to be admitted at all into geometry, or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and there is the same reason for other curves; for which reason we approve of the trisecting of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have preferred to the invocations of all others in this case; because we ought either to exclude all lines, besides the circle and right line, out of geometry, or admit them according to the licency of their descriptions, in which case the conchoid yields to none, except the circle." Lastly, "that is arithmetically more simple which is determined by the more simple equations; but that is geometrically more simple which is determined by the more simple draw.
\]

\text{CON}

\text{CON}

\text{CHONOEY. "The study of shells, or telluric animals," it has been well observed by a plain, but ingenuous writer, "is a branch of natural history, though not greatly useful in human economy, yet perhaps by the infinite beauties of the subjects it treats of, is adapted to recreate the senses, and infallibly lead the amiable admirer into the contemplation of the glory of the Divinity, in their creation." Or, in the more harmonious periods of the poets, we would say,

"Each shell, each crawling insect holds a rank Important, in the plan of him who framed This scale of beings;" —Stillingfleet.

Shells appear to form a part of the creation not immediately subservient to the purposes of human life. This is granted; but they are a link in the great chain of nature; they constitute a department of rational inquiry worthy the rehearted of the man of science; and when we consider the amazing diversity of singular and beautiful objects they embrace, in full, we are persuaded, as cannot fail to arrest in a particular degree the regard of every common observer.

A late writer, whose talents we respect, affirms, in undisguised terms, that the pursuits of the conchologist are frivolous, and tend to no useful purpose. For the credit of the philosophical inquirer, in this pleasing department of natural knowledge, we could wish to see this opinion controverted. We shall not indeed endeavour to support the pretensions of conchology to a distinguished rank among the more beneficial pursuits of science, but we do not fear to prove it in a pre-eminent degree entitled to the attention of every contemplative mind. In the present enlightened period, it is not, we should conceive, incumbent to offer any argument in its behalf, because we are unable to prove its utility in the common acceptance of the term. We are not, for this reason alone, to esteem it frivolous; or, in a word, to declare that our ideas are entirely absorbed in the contemplation of interrelated views and the love of wealth, or that we are fudicious only to gratify our immediate wants. Our untaught ancestors cultivated the oak, we are told, that they might eat acorns, regardless of the importance of the parent timber; but we are not to imitate their example, and deem it trifling to cultivate any branch of natural science, that is unlikely to afford us some direct benefit; nor are we to be content with ascertaining what may be merely useful as food for ourselves, or fodder for our cattle. How unworthy would this be of the refined conceptions and dignity of intellectual men? But we are convinced that a more enlarged and liberal idea of this subject will be conceived on the rightest reflection by every intelligent mind; that the science of conchology will be hereafter more successfully pursued in this country than it has hitherto been, and that the observations we have to offer as we proceed, though less abstruse than the science may seem to demand, will to a certain extent facilitate this desirable object.

One clear and most important fact, the truth of which we would wish to impress on the mind of the reader, should be premised, that whatever opinion we may form on this sub-
CONCHOLOGY.

All tellaceous animals are composed of two parts; one of which, the animal itself, is soft and mol luscous; the other is the shell, or habitation, which is hard, of a flinty or calcareous nature, and either partially or entirely covers the animal. The animal is attached to the shell by means of ligaments or muscles.

It was long considered as a matter of dispute among naturalists, whether the arrangement of shells should be constituted from the animals or their habitation. No one can deny, that if we proceed on principles strictly scientific, we must regard them as a department of zoology, and should, on that account, dispose them according to the nature and structure of the animal. But the classification formed from the characters of the shells is universally followed, and we must confess too, is for many reasons preferable to any other. Neither is it, in the hands of the skilful conchologist, attended with so much indecision, as might be generally imagined.

In the first place among the vast variety of shells hitherto discovered, how small comparatively is the number of those, whose whole animal inhabitant is described or known. It is not of species only that we speak, but of whole natural families or genera, not a single species of which has been yet discovered with the animal appertaining, so little are we acquainted with the mol luscous orders, or animals inhabiting the shells. Of the shells we daily see in collections few are filled up alive, the far greater number are found on shores, dead or empty. Neither, if it were otherwise, are accurate descriptions of animals whose parts are not easily seen, or anatomical investigations, which are in many cases necessary, within the capacity of every one. Many of their parts, and their respective functions, are not to be ascertained, except by comparative analogy, and which in itself presents an insurmountable difficulty, or a field of critical inquiry to extensive and complicated that few, even with the ability to pursue it with success, could be prevailed upon to devote that attention to the subject which it requires.

Hence it becomes impossible to arrange the far greater number of tellaceous productions by the animals; the attempt must ever prove unsuccessful. Our arrangements would be partial, and three-fourths of the shells known must be either excluded from the system, or be placed at hazard; and of course without order or connection with those whole animals we are acquainted with. The latter are chiefly such as are confined to the coasts of the European seas, and some of the terrestrial and fresh water kinds, which, from their abundance and locality, have obtruded themselves upon the investigations of the naturalist. Even our knowledge of those is exceedingly imperfect. For those of the extra European species, we are indebted chiefly to Adanson, Rumphius, Argenville, and Pauvage, and for the anatomical dissection of various European kinds to Valentini, De Heude, Lister, and Mühler. The investigations of Poli on the shells of the two Sicilies are valuable, in this respect, as also are the observations of Lamarck, and Cuvier, and we may also add Olivier; but what is the amount of all these discoveries, we would ask, in enabling us to form a system of conchology.

The best characters upon which to found all systems of natural history, must be those most obvious and accessible. All ranks of animals, as nearly as can be with convenience, should be arranged by apparent and external characters. While we study shells, without regarding the animal, we are aware they are but considered partially. The animals that inhabit them should guide us in our researches; they alone are the fabricators of the shell, and the shell is only their habitation, to which they give the form, the bulk, hardness,
hardness, colours, and all the peculiarities of elegance we admire. If we were to examine these new and almost unknown objects, we should discover a number of peculiarities as remarkable for their structure as for their functions, and an infinite variety of curious and interesting particulars relative to their general habits and manners of life. It is a subject worthy of the serious contemplation and attention of the naturalist, and should never be neglected when an opportunity offers. But a system of conchology, founded entirely on the structure of the animals, must, we cannot hesitate in affirming, ever remain one of the desiderata of natural science.

In the superficial arrangement taken from shells alone we are not exempt from difficulty. Shells vary exceedingly in form and colour in the different stages of their growth, and in this case we should sometimes derive material assistance from our knowledge of the animal. Young shells have been described as specifically distinct from the parent or older shells by many writers. It indeed requires a greater degree of caution in determining the species, nay even genera, of shells in the different periods of growth than may be imagined; of this we could adduce many very remarkable instances, a few it may be necessary to mention to guard the common observer from forming hasty, and erroneous conclusions.

Many of the epiphragms, or cowries, when young, have the appearance of a volute, the thick dentilicated fold of the exterior lip being wholly wanting, and the column being only partially plated as in the true volutes. The young of the slotted shells, in general, are delirious of that broad expansive, or furcated lip, called the wing. The spires in many of the turrited kinds of shells, when young, are blunt; obtuse, or terminated in a large globular head, exceeding the size of the whorl beneath; but as the shell advances in growth, it develops itself, extending in a spiral direction, and thus in the old shells the number of spires is greater than in the young ones. The variations in the growth of the patella tribe are often so considerable, as to amount to the critical observer to determine them. Still however the conchologist by the dint of application, and nice determination, will be at leisure to fix on certain characters peculiar to every species, and be, by that means, enabled to decide on the species of a shell under every stage of growth.

Linnæus considers the structure of the shell as well as the shell in all his general distinctions; the idea is excellent, and we should approve the design, but the object itself is unattainable; a lamentable proof of which pretexts itself to view, when we consider the number of those very animals which he describes that have been ascertained, by recent observations, to be of a very different nature and structure from what he conceived. This error may be easily accounted for when we reflect that the judgment of Linnæus was guided in many inferences by analogy, and that the different figures, extent in various ways without himself purposing the means of determining their accuracy, or imperfection. We intend nothing to the disparagement of Linnæus in this respect; the structure of the animal was of too much importance in his mind to be omitted, and he availed himself of the best sources of authority within his power, some of which, it has since been proved, are not so accurate as we could wish, and others altogether erroneous.

From all that has been advanced on this topic, the refult will be obvious, that teltaceous bodies may be conveniently arranged, or, in other words, can only be arranged by the organization of the shell; that the primary character must be taken from the shell because this we are acquainted with, while the animal is oftentimes unknown to us. But that the structure of the animal should be regarded in the construction of genera, when it can be ascertained; as a secondary consideration to guide us in the formation of new genera, or in correcting the old, as opportunities of investigating them occur.

Having defined the meaning of a teltaceous animal, and endeavoured to prove that the structure of the shell is the most material object to be regarded in a primary view, we shall proceed next to an elementary elucidation of the several parts of which it is composed.

In conchology, as in any other science, the student must necessarily acquire, in the first instance, a distinct knowledge of the terms employed. These, except such as relate to subordinated characters, or specific distinctions, and which require no explanation in this place, may be simplified and reduced to a small number. In the selection of these terms we can abide by no one particular authority; we must be general, deriving our terms from various sources, or inventing new ones. Hitherto in treating on the different articles of conchology, in the progress of this work, it has been our aim to adhere as nearly to the authority of Linnæus as possible, referring to ourselves an opportunity of expressing our own sentiments under the present article, and laying generally these points upon which we principally differ in opinion from that author. This will appear more fully in our review of his genera. Our attention is at this time confined to the terms employed in describing the several parts of shells, and as it is well known that Linnæus laid down a series of terms for this purpose, it will be expected that we should not pass over them in silence. Upon this subject we shall however only trespass lightly. We would willingly adopt those established by Linnæus, in his "Fundamenta Tellacologini," and other writings; but it must be confessed, with all our respect for the talents of that naturalist, his terms are inadmissible. The wanton of his admirers, and we must, on many occasions, profess ourselves of that number, will not peruse the definitions he has given of the bivalves, of his venus, and some other bivalve genera, of his venus dione, and also of several univalves, without admitting that much of the Linnæan phaenology on this subject is neither applicable to the parts intended, nor if it were, such as modestly would allow us to retain; and that to expunge them is only a necessary sacrifice which the chality of science imperiously demands. Delicacy will pardon the allusion, and defer no further explanation.

All shells or teltaceous bodies hitherto discovered, may be divided into three principal tribes, and which, after the Linnæan manner, may be denominated Multivalve, Bivalve, and Univalve.

Any external part of a shell being of a teltaceous substance, and either itself, forming a shield or covering for the animal, as in univalves, or in union with another, or others connected by ligament, cartilage, hinge, teeth, or other fastenings, is denominated valve; in dehiscing the several parts of a single piece, are called univalve, those of two parts bivalves, and those of many parts multivalves. Between bivalve and multivalve no distinction is drawn, shells consisting of more than two such parts, being called multivalve, without any regard to the number. An amendment is proposed by some of the French writers, in a new order under the name of trivalve.

Shells of the simplest form are arranged by some naturalists in the first class, from which they proceed progressively to those possessing the greatest number of valves, and being of the most intricate structure. This is an ancient, and very simple
simple mode of arrangement, and has its advocates in the present day. Linnaeus reverses this order by beginning with the chiton, lepas, and pholus, which are shells of the multivalvate and molten complex structure, and ending with those of the simplest form. We cannot avoid thinking the former preferable, and shall adopt it in the present instance.

Explanation of the Parts of Shells with Reference to the Elementary Plates of Conchology.

Univalve.

In the examination of a shell of this order, the contour, or outline, is the shell particular to be regarded. By this the conchologist is guided in his definition of simple, spiral, or multivalve shells, (as the Linnaean school divides shells, univalves with a regular spire, and multivalves without a regular spire); discoid, flattened, or tubed shells; those with smooth or uneven asperities; the ventricose, labiate, rostrate, rolled, and many other distinctions, all which strike the eye at the first view. It is indeed, by attending to the contour, that the principal distinctions in shells of this kind are at once perceived, taking into consideration the back and front profile at the same time. Some few shells, as the nautilus pompilius, and others of the same family, have the spire revolving internally, in which the outline offers its assistance in the primary definitions, but the number of such shells is very small. Next to the profile of the shell, the structure of the mouth, the pillar, and expansion of the inner lip, the gutter or canaliculation, and the umbilical opening, and operculum if any, are to be considered, and lastly the work on the outer surface, as well as the colours with which it is embellished.

The base or bottom of the shell we consider that part upon which it rests when supported in an erect position, with the summit or tip of the spire standing vertically. In such shells the tip is called the apex. The course of the spire or wreath is from the left to right in most spiral shells, some few only being of the reversed or heterotrophous kind, the whorls of which are in a contrary direction. When speaking of the right and left sides of a shell, it should be understood as having the aperture downwards, and it will be then seen that in most shells the aperture or opening is on the left side, i.e. facing the right hand of the spectator.

Bafe, the tip of the lowest end of the shell, at the extremity opposite the apex of the spire; in the rostrate kind of univalves it implies the tip of the beak. Some say the shell rests on its base when laid upon a flat surface, with the mouth downwards; this is not correct, except in the patella tribe, and some other univalves which have no regular spire, as the dentalium, &c. The base in several shells is denoted in the Plate, Conchology, fig. 1.

Apex, the summit of the shell. Fig. 2.

Front, the face of the shell with the aperture placed directly in front of the observer. Fig. 3.

Back, that part of the shell which is immediately opposed to the preceding. Fig. 4.

Side, the parts seen longitudinally in profile, to the right and left when the shell is viewed either in a front or back position. Fig. 5.

Body, of the shell, (corpus) the first whorl of the spire at the base. Fig. 6.

Belly, is to be distinguished from the body as it implies only the convex, or swollen part of the first whorl, formed by the convexity of the aperture near the lip. Fig. 7.

Wlroir denotes one of the wreaths, turns, or volutions of the shell. Fig. 8.

_Spicer_, comprehends, in a general sense, all the whorls of the shell, the first or body wreath excepted. Fig. 9.

The form of the spire is of great consideration in the definition of shells, as it affords a prominent and distinguishing character; it is in general flat, thence somewhat depressed or elevated; sometimes convex and slightly pointed; or with the point obtuse; or much elevated and ending in a point; plano-concave, prismatic, subulate, or truncated. Mr. Adamson observes that the disposition of the spires varies according to the plane they turn on, which is either horizontal, cylindrical, conic, or oblique. The he conceives to be the four principal divisions of the spires, but admits there are many intermediate formations. The number and form of the spires vary in the same species, in their different growths. Young shells have commonly a less number than the old ones, neither have shells of the same age always the like number of spires, a circumstance attributable to the effects of sickness, or the difference of sex. Thus in some multivalve shells we perceive that the males have the spires less numerous, smaller, and of a more lengthened form than in the females.

_Suture of the spire or whorls_, is the spiral line which separates the whorls, and which is sometimes foliated, crenated, or somewhat projecting. Fig. 10.

_Piller or Columella_, is the inner part of the left lip, or column, which runs through the shell, from the lower extremity to the tip of the spire, and from which all the spires take their origin; the columella being situated as nearly as possible in the axis of the shell, and serving as its basis and support throughout. It is generally either flat, grooved, folded, or truncated in that part which is visible at the opening. Fig. 11.

_Aperture_, called in familiar language, the mouth of the shell, is the entrance to the chamber in which the animal resides, and is applicable to the openings of univalve and multivalve shells. The aperture is either entirely open, or closed by the operculum attached to the body of the animal, when the animal retires into its dwelling. This aperture varies in form in different shells, being angular, rounded, semilunar, linear, or otherwise, and sometimes appears double, the inner margin being surrounded by an exterior one. Fig. 12.

_Lip_, the expansion of the exterior part of the aperture constitutes the lip in the labiated shells, and the wing in the alated kinds. Fig. 13.

_Beak_, or rollillum, is that part at the base which extends in a straight or slightly oblique direction from the bottom of the aperture, and is larger or smaller in different families. In murex haustellum this projection is very conspicuous. Fig. 14.

_Canal_, or gutter, an elongation of the aperture of the shell descending in a groove or gutter-like process. Some kinds of rolled shells have the canal remarkably conspicuous, forming a fissure from the aperture throughout the whole length of the beak. Fig. 15.

_Umbilicus_, the opening, or perforation in the lower part of the body, or first whorl of many spiral univalves, and is very conspicuous in a number of the trochus and nerita genus in particular. This umbilical perforation runs in a straight line from the base to the summit of the shell, forming throughout a spiral groove or gutter, which is wide at the entrance, and tapers gradually towards the apex. In the Linnaean nerita canarea, the structure of the umbilicus is well displayed, but is still more obvious in the stellariae shell, trochus perspectivus. This opening occurs in many shells at the base of the pillar. Fig. 17.
The umbilicus is either smooth, carinated, crenulated, or bafed with tubercles, and sometimes denticulated. It is either entirely, or only partially discolored, being sometimes half closed up by a gibbosity, or other projection at the aperture, in which case it is termed by conchologists semi-umbilicated, or sub-umbilicated. Sometimes the pillar spreads so far over as nearly to close up the entrance.

A shell without an umbilicus is termed imperforate; sometimes the term imperforate implies that it has neither umbilicus, nor canulation at the base.

Operculum is a teffaceous or cartilaginous appendage peculiar in a considerable degree to the univalve tribe of shells, and those only of the spiral or turbinated kinds. This appendage is not connected with the shell, but the animal, and serves like a lid or little door, to protect or close up the aperture of the chamber when the creature retires within its habitation. Shells of this kind are distinguished by the name of trochus operculate, by some of the elder conchologists. The operculum are often small in comparison to the size of the shell to which they belong; their form various in different species; and their substance in some of a horny texture, and, in others, teffaceous or approaching the nature of flint. Their figure in common is either perfectly round, elliptical, oval, or elongated, and sometimes wrought with spiral work, or concentric lines.

The operculum is commonly adherent either to the upper part of the posterior end of the foot, or, as denominated by some writers, the peda/d of the animal, or at its extremity, so that when the animal moves along, the operculum appears at a distance from the shell. In the nautilus, some of the turbines, and certain other kinds, which have the aperture of a round, semicircular, or oval form, the operculum is usually of a size adapted to the extreme circumference of the opening, or nearly so, and fits close at the entrance; or is very little drawn into the opening when the animal retreats into its chamber. On the contrary, in the volutes and some other shells which have the mouth of a lengthened or linear form, the aperture is comparatively very small, and the operculum might be drawn far into the shell, when the animal retreats into its spiral recess before the channel becomes sufficiently contracted to be completely closed up by this appendage.

The teffaceous opercula easily dissolve in acids; it therefore happens that when put into vinegar they move briskly to and fro for some time, by the ebullition, hence they have obtained the name of creeping flint among the common people. The cartilaginous opercula are not affected by this process. The blatta byzantia, of medical writers, are of this latter kind; being the true operculum of two or three different kinds of shells, very abundant in Palestine, and other parts of the eastern world.

Some of the spiral, or turbinated land shells, are likewise of the operculated kinds, but differ from the foregoing, as they form a new lid, or operculum, every year, or oftener, especially at the approach of winter, when the animal is prompted to make this provision, in order to guard itself from the inclemencies of the weather. It is formed by a vivacious moisture emitted from the body of the animal, and which coagulizes into a kind of tough coagulated substance of pretty considerable thickness; this covering is never attached to the body of the animal; it merely covers the entrance, nor is it ever wrought like the true opercula of marine shells with spiral or concentric lines.

Operculated shells are chiefly the turbinated kinds of univalves; the opercula of the balani among the multivalve shells consist of four pieces, and partake rather of the nature of valves, both in substance and appearance, than of the opercula above described.

Involuted spire, revolved shells (univalvia turbinata clavi- cei intus recumbent, &c. De Coët). These shells turn or revolve inside, or have the whorls concealed within the body of the shell as the nautilus and cypraea. An involuted spire is shown at fig. 18.

Chambers are the spaces or divisions formed in the interior part of shells by intervening partitions, a kind of articulated structure elucidated completely in the nautilus.—By a chambered shell we sometimes understand only that it has some laminiform, sub-spiral, or other process within, as in patella Chincuis. Fig. 19.

Siphunculus, the small canal which penetrates in a spiral direction through the chambers of the nautilus. An organ of this nature is observable also in the ammonite. Fig. 20.

Epidermis is a kind of skin or coating, with which the exterior surfaces of many shells, both of the univalve and bivalve tribe, are covered. It is considered as a sort of peridium or membrane, derived by nature to defend the shell from accidents and aid their growth, and to prevent other teffaceous or marine animals from fixing their habitations on these shells, as they do upon mollusk bodies in the sea, where there is no power of resistance. The epidermis is a genuine covering formed by the animal itself, peculiar to some kinds, and as constantly never observed on others. There is no doubt but the animal to which this fort of covering is peculiar, possesses a proper apparatus for its construction. The nature of this epidermis, it should be added, is very distinct in different shells, consisting in some of a very thin pellucid film, and in others laminated, pilous, velvety, fibrous, or rugged. Few shells, having a rugose surface, are delirious of this external covering or epidermis.

The spines, protuberances, longitudinal ridges, carina- tions, furrows, ridges, punctations, granulations, and other peculiarities of what is termed the “outside work” of the shells, are to be regarded only as specific distinctions of shells; and the variegations of colours, spots, and other similar particulars, are to be considered in the same point of view. These peculiarities are not observable in many shells in their natural state, being concealed beneath the thick epidermis which invests them; in others which have the epidermis thin and membraneous, they are perceptible, but the beauty of the shell is dissolved only upon removing this exterior covering. See fig. 21.

Bivalves.

Or shells of two valves united by means of a cartilage, hinge, connection of the teeth, or other process. In order to constitute a bivalve shell, it is only requisite that it be furnished with two connected valves, without regard to their resemblance in form or dimensions. Some of the bivalves have both valves formed alike; in others they differ only in a slight degree, and again in others they are altogether dissimilar. The first of these is well exemplified by the folio genus; in that of the Linnean taline, we find examples both of the equivale valve shells, and those with the valves slightly different: of the latter-mentioned kinds we have many, as the oyster, spondylus, and anomia. Bivalve shells are often much compressed, some are gibbous, and when viewed at the side, or facing the ligament, have a cordat appearance, as in venus, and the Linnean chamaer. Shells, having both valves alike, as before observed, are called equivale. Equalvalve shells imply those which have both sides of the same valve alike, as for instance, when a longi-

Vol. IX.
Multivalves, we shall allude to the opposite margin, the space on each side the line is distinguished by the appellation of the right and left side; and when the form of both those spaces correspond, the shell is equilateral, as in the scallops (Oreot, Linn.): the inequilateral valves are the reverse of this, a line drawn as above described, from the beak to the opposite margin, presenting two sides of a very different shape, as we see in most of the mastra, the donax, and tellina genera, and in the maa truncata especially. Sub-equilateral shells, or those having the valves nearly equal at both sides, are sufficiently elucidated by shells of the cardinal, or cockle genus, which are strictly "bivalvis subequilatera."

All bivalve shells do not completely close their shells, though most of those before mentioned do so, such as the scallop, the donax, tellina, and cardinalium: in several other tribes of bivalves, when the shells are shut as closely as their form will allow, they still exhibit a kind of hiatus or gaping, either at the anterior or posterior end, or at both; and in some, when the valves are shut, both the anterior and posterior parts are closed, but an opening appears on one side of the beak; this last-mentioned character is very obvious in some gigs.

One of the first circumstances to be considered, is which part of a bivalve shell ought to be deemed the beak, because when this is determined, every other part will fall progressively in their relative order under our observation. We name that part of the margin or limb which is situated in a direct line opposite the beak, the base of the shell. Linnaeus, in order to establish the characters, and afford some apparent reason at least for the application of the terms he beffows on the different parts of bivalves, reveres this position of the shell, and describes the beak as the base of the shell. But the fact is, the natural position of the shell is in immediate contradiction to his axiom, for the beaks are always uppermost, being either immediately vertical, or with a slight inclination obliquely, when the animal moves along with its tectaceous covering on the back. A solitary example will perhaps occur occasionally, in which the beaks may be considerably inclined when the animal crawls, but none, we believe, are known which open the valves upwards, and proceed with the beaks under the body. The beaks, if only for this reason, are to be considered as the summit, and the margin opposite as the base. Many of the bivalves are delitute of the locomotive power, or at least do not possess it in any material degree.

Beak of bivalve shells, exemplified in venus verrucosa. Fig. 22.

Summit, a word applied in a general manner to the top or most elevated part of the two protuberances observable in the greater number of bivalves. Da Costa calls that part of the shell, in which the teeth or hinge is placed; the summit or apex; we regard it as the most elevated part of the beaks. Fig. 23.

Beak, the pointed termination, apex, or tip of the protuberances last-mentioned, and which, in many shells, turn spirally downwards, or obliquely, so that the beak itself is seldom the most elevated part of the shell; though it is so sometimes, as for instance in the mytilus edulis, or common mussel. Fig. 24.

Sides, the lateral parts of the valves distinguished by the epithet of right and left side; in common language, the two valves of a shell are called the sides, but it is not understood as a term in conchology in this view. Fig. 25.

Margin, or limb, the whole circumference or outline of the shell, when laid flat down on one valve. Fig. 25.

Dif, the convex centre of each valve, or exterior surface. Fig. 27.

Anterior slope, that part of the shell in which the ligament is situated; in the front view of the anterior slope, the beaks fall back, or behind. Fig. 28.

Posterior slope, that immediately opposed to the former, and in which the beaks of the shell turn forward. Fig. 29.

Lunate, the lunulate depression below the beaks, either on the anterior or posterior slope, and sometimes on both; they may be distinguished under the appellation of anterior or posterior lunate, according to the slope in which they are situated. Fig. 30. a, b.

Cartilage of the hinge, called also the ligament of the hinge, the substance of a flexible, fibrous, and somewhat horny nature, by means of which, the two valves are united near the beak. Fig. 31.

Ears, the lateral processes near the beaks, as in the scallop tribe: those occur either on one side, or on both. Fig. 32.

Ligament perforation, the opening, or aperture, through which the ligature of the animal passes in the animal genus, by the assistance of which it fastens itself to the rocks, or other bodies; in some, it is situated in the flat valve, in others at the beak of the gibbon valve. Fig. 33.

Length and breadth of the shell. The length is measured from the cartilage or beak to the margin below, the breadth is of course taken in the opposite direction. The breadth of many bivalve shells exceeds their length; some remarkable instances of which occur in the folen tribe. Fig. 34.

Inside of the valves exhibits the concave surface (convexitas concharium), fig. 35.

Hinge, the point of union between the two valves, formed by the connection or articulation of the teeth in both valves, or by the teeth in one valve, fitting into hollows or sockets in the valve opposite. The amazing variety of structure observable in the hinge of different tribes of shells renders this one of the most essential characters in the general definitions of shells. The teeth in some are small and numerous, others thick, solid, and few in number, or sometimes single, long, spatuliform, lamiform, arcular, &c. the principal of which may be divided into inarticulate hinge, when only furnished with cleft teeth; or having no visible teeth; articulate, when it has teeth, but only a small number; and multiarcurate, when the teeth are numerous. These variations will be further explained under the respective genera.

Cicatrix, the impression on the inside of the valves indicating the point of connection between the muscles of the animal, and its shell. In some kinds, as the common oyster for example, there is only one such muscular impression in each valve, in others there are two, and some have more. The cicatrix is not of the same figure in all shells, being either round, semi-ovate, lunate, or elongated, in different kinds. Fig. 37.

Bysius, the appendage called the beard; by means of which some bivalves fasten themselves to the rocks. Fig. 38.

The imbrications, furrows, spines, tubercles, reticulations, striations, or other peculiarities of the same nature, as well as the variations of colours, observable on the exterior surface of bivalves as before stated in speaking of univalves (and which is indeed equally applicable to the multivalves, and consequently to shells of every description), though they afford us the best specific distinctions possible, do not claim our regard as primary characters, and are therefore passed unnoticed in this place.
CONCHOLoGY.

MUltivalves.

The shells of this order are few, compared with either of the preceding; and the terms proposed for those are applicable for the most part to the multivalves. The following require more mention.

Base, that part of the shell upon which it rests: in the lepisi tribe it implies the part immediately feated upon the stem or pedicle; in the balani, the base is generally larger than the summit, and is the bottom by means of which the shell is fixed upon the rocks, or other extraneous bodies. Fig. 39.

Ligament, the substance, whether membraneous or tendinous, which serves to connect the valves together. The connexion of the valves in some multivalves is formed by the parts of one valve locking into another. Fig. 40.

Operculum. The balani have the aperture at the summit closed by means of four small pieces or valves, which are commonly called the operculum; these opercula of the balani are, however, very different from those of univalve shells. Fig. 41.

The various parts of which teataceous bodies consist being sufficiently considered and explained, our attention is next directed to the different modes of arrangement into which those bodies have been distributed by the principal writers on conchology, and a general inquiry into a variety of other particulars connected with the history of the science.

In this investigation we shall avail ourselves in some measure of the method pointed out by the learned author of the "Clases Conchyliorum" (Bergen), the valuable "Bibliotheca Hiift. Natur. Bankhia" of Mr. Dryander; "La Conchologice" of Favenne; the "Historical Account of Teflacological writers," by Dr. Maton and Mr. Rackett, inferred in the "Transactiions of the Linnean Society;" and the labours of many others, in addition to our own, as will appear in the course of the following observations.

The name of Aristotle stands high in the records of philosophy. He is emphatically called by Dr. Pulney, in speaking of teataceous writers, the father of natural science; and by Dr. Maton the inventor of system. Our respect for the Macedonian philosopher is great, nor would we willingly appear to detract from his distinguished merit; yet we must confess we never could conceive it possible, with all the ability this early writer possessed, that, rising as it were from primal darkness, he could at once survey the multiform objects of creation, and produce a system of natural objects to complete as that which we are disposed to acknowledge exclusively as his own. He must have derived considerable aid from sources then extinct, and which are now for ever lost to the world. The history of mankind throughout all ages will testify beyond a doubt that the acquirement of human knowledge is slow and progressive; and the knowledge of Aristotle in natural science was in particular of that kind which in a great measure could be attained only from the observations of many. Under the patronage of Philip, the Macedonian monarch, and of his son Alexander, the hero of the world, no advantages which Aristotle could derive from the study of books would be denied him, and can it be imagined from so many hundred thousand volumes as were extant in his time, and at his immediate command, Aristotle was unable to obtain information; or that among this immense number there were none on the subject of Aristotle's inquiries? This writer would certainly avail himself of the recorded labours and discoveries of former ages, and especially would not neglect to cultivate an acquaintance with the sciences of the Egyptians, upon all which his own ideas might improve. Indeed, if we mistake not, however unwillingly it may appear, the latter was the genuine source from whence his knowledge of natural philosophy was derived. Egypt, not Attica, was the cradle of science.

To the writings of Aristotle the learned world is certainly indebted for the first account we probably ever had of the state of natural science at the early period in which he lived; it is a fortunate circumstance for the cause of learning that his labours have survived the havoc of destructive time. This system is a production that would confer credit on any naturalist of the fourteenth century, much less of a period almost two thousand years before. The classification, or division of shells contained in the fourth book of "Aristotle's History of Animals," has fixed the tells of ages, and, with improvements, rendered necessary by recent discoveries, is in general adopted by very late writers. Linnaeus was in a great measure himself indebted to this system for the outlines of his own, for many of his genera, and for the names under which those genera are retained, even in the most improved state of his "System of Teflacology."

The "Olivaceoderma" of Aristotle, for such is the title of his conchological productions, present us with a valuable scheme of shells. He divides all shells into two principal classes, Monolopa and Diolopa, or univalves and bivalves.

The univalves he separates into two parts; namely, those of the turbinate kind, as Koegion, or limacs, Kacillus, coca lia, the purpore, Nougia, buccinia, Kdaxa, &c., and those as are leftes turbinated, as Arx, the sea-ears, or hailiotis, and Niofia, meriae. Among the latter, he includes several families of the echinus, or sea-eggs, Ezgius, a tribe of crustaceous animals retained by almost every writer among the shells, till they were separated by Linnaeus. He also speaks of the animals inhabiting the cocaia, purpurea, and buccina.

The bivalves he distributes into several families; he has Koia, or peletines, Evon, foliates, and Hina, pinea or feathered, all of which genera have been retained by Linnaeus, and later authors.

Aristotle commits one remarkable error, however, in placing the operculum of some turbinate univalves as a genuine tribe of shells. This error, which indeed we think excusable considering the age in which that philosopher lived, is mentioned by several authors as an objection to his accuracy of discrimination, and is commented on by Bergen in the following observation.

"Ex umbilicis fl; r 20z; videtur Aristoloteles peculiare conchyliorum genus perperum confluatissimum, sunt enim propri opercula quorumdam turbinateorum, quem certe anni tempore foribus coelitacorum quasi illar clarifit, agglutinae inventorem quaeque polles didactet & nullius amplius utus pro ipso animale.\"

Aristotle flourished 322 years before Christ.

C. S. Pliny wrote largely upon conchology; the ninth book of his "History of Animals" is very copious: it is more diffuse than that of Aristotle, and the arrangement is unmethodical, but this is still an useful work, and may be consulted with advantage. Many of the terms employed by modern conchologists are to be found in his work. Pliny classifies thirty-three families, which are distinguished chiefly by the form and superficies of the shell, as plana, corna, longa, and luna, falcis, and rugata; by the shape of the margin, as margin in meucenem cinia; margin foris effuso; and margin intus replicato. The finiitos, or projections of the shell, the connexion of the valves, and other similar characters, were also taken as distinctions of the different families.

In Pliny's time the Romans are supposed to have possessed considerable opportunities of acquiring a knowledge of shells, as their navigation was extensive, at least in the Mediterranean and the Red Sea.
The conchological writing of \( \text{this} \) is held in high esteem either of the preceding; he dedicates some concise chapters to this subject in his work entitled, "Histoire des Coquillages." After the dark ages which succeeded, Vincentius Bellocavendus was one of the earliest writers on this subject. His "Speculum naturale," published in folio, in the year 1494, contains a description of the oysters, purpurae, olrea, and a few other remarkable shells, extracted chiefly from the works of Aristotle and Pliny, and intermingled with the absurd and superstitious notions of the times. The works of Albertus Magnus, entitled "De Animalibus," which appeared in folio in 1495, contains descriptions of some shells; and to likewise does that of Adam Lonicerus, "Historia naturalis opus novum," published in 1571.

The first writers who distinguished themselves by any attention to the study of conchology, after the revival of letters in Europe, were Belon, Rondeletius, and Gesner. Belon is celebrated for his travels in the East, and he was perhaps one of the first learned men who travelled principally with a view to natural science; on his return to Paris, in 1553, he published, besides other works, an octavo volume, entitled "De Aquatilibus." The part appropriated to conchology is not extensive, it is rather elementary and philosophical than descriptive; but contains figures of a few shells engraven on wood. The work of Rondeletius (professor of physic at Montpelier) appeared two years after, A.D. 1555; it bears the title of "Univ. Aquarium Historia," and contains upwards of one hundred species of telescence animals. His residence on the coast of the Mediterranean afforded him abundant opportunity of investigating the shells of that sea, and their animal inhabitants, a subject of inquiry to which he paid some attention. This author received much assistance from the labours of Aristotle and Pliny. The "Commentaries" of Matthus, embellished with a few cuts of shells, contain nothing of material interest, except what has been collected from former writers; several editions of this work appeared between the years 1566 and 1583, in Spain, Italy, France, and the Venetian states. In 1558, the work of Conrad Gesner, "De Piscium et Aquarium Animaantium Historia," made its appearance, and acquired much reputation. Dr. Pulney pays a high compliment to Gesner for his unparalleled industry, and ardent love of natural history, and observes, that he not only collected all the philological, historical, and descriptive evidences of the ancients on this subject; but besides his own obvious comment on their writings, availed himself of what Belon and Rondeletius, his contemporaries, had done, to which he added much original matter of his own, having described and figured many of the Mediterranean shells and several of those discovered in the Indian and Arabian seas. This comment is correct, but of the system proposed by Gesner for the classification of shells, we must speak more fully. This author divides all shells into four classes: univalves, bivalves, turbinata, and anomalies. The first contains only two genera, lepas and auris marina; or the barnacles, and sea ears (kupa derived from the Greeks, and synonymous with patella, being the name applied by old conchologists to the limpets, since called patella by Linnaeus). His bivalvia claus, contains many genera, as ostrea, quadrula, solen, tellina, clamos, pinnæ, folines, and eight others. In the third claus turbinata he has ten genera, as the mili, murex, hippocucum, turbo, turbinus, etc., all which names will be recognized by the Linnaean student as those employed by Linnaeus. His fourth claus anomalies, is exceptional, as it contains, besides the balani, pectus marina, tubata marina, and echinidi, the stellæ marina or starfish, and caput medusa, neither of which have ever been considered by other naturalists as appertaining to conchology. Bergen admits this as a material objection to his system, "peculiarem claus anomalyorum confidit, ad quam, ut mili videtur, adnumerandae. Ideem valet de capite medusa." His separation of the balani from the two first classes is contested by all late writers.

Geoffrey Linoeair, in his "Histoire des Poissons," published at Paris in the year 1529, gives an account only of a small number of shells; the work not being devoted to the subject of conchology: neither is that of Imperator, published at Naples in 1559; though it contains an account of some species, this profession relating chiefly to fishes, it bears the title of "Del. Historia di Ferrante Imperato Napolitano."

The work "De Molibus Cruftaciac, Tellaciac, et Zophytil," of Aldovichus, appeared in folio, in 1567, and is well known. His arrangement consists of three classes, turbinata, bivalvia, and univalva. Among the turbinata he includes the nautilus, and also the bivium, and other spiral shells, together with the echinid. The bivalve is the same as that of all other writers, as ofrea, tellina, and pinna, but besides these includes the multivalve shells of late authors, such as the balani and pholades. The third class, or univalvia, contains the lepades, peltalæ, auris marina, concha venerea, concha perica, and pectieus marinus. The figures consist of cuts on wood, and are rudely executed.

Tabulius Columna, in 1615, published a treatise on shells, or rather a monograph on the purpura, entitled "De Purpura ab animali tellaceo fusia, de hoc ipsis animali, altiquo rariobus tellaribus quibusdam." A new edition of this work, with annotations, appeared in 1675, by John Daniel Major.

In the year 1616, a work entitled "Faciesius rariores et aspecies dignorum vari generis, qua collect et eisimpennis uni ad vivum incidi curavit," from the pen of Baffi Beller, apothecary at Nuremberg, made its appearance; it is in Latin and German, and two of the plates are appropriated to the subject of shells.

Chioceco, the describer of the "Museum Calceolarii," published at Verona, in 1622, gives a full account of the shells contained in that collection, with specific characters in the Latin language, borrowed for the most part from other authors. This museum was begun by Benedict Cereto, a physician, and afterwards enlarged by Calcolari. The figures of the shells occupy fix plates. It appears to be the first work that was written professedly as a description of a museum of natural curiosities, the account of the same museum by J. P. Olivius, published in 1584, alone excepted.

A physician of Hamburg, Schonveld, was author of an account of aquatic animals, both of the marine and fresh water kinds, found in the duchies of Sleueck and Holstein, which contains separate chapters on oysters and mufcles. The observations relate chiefly to the culinary uses of the animals. This book bears date 1628.

The work of Nierembergii, "Historia Nature," contains an account of a number of shells, but does not pretend to any figures. It was published at Antwerp, in 1635.

In the first edition of the "Gazophylacium Renum Naturalium" of M. P. Beller, the brother of Baffi Beller before-mentioned, are twenty-four plates, containing, among a variety of other subjects, natural and artificial, a few figures of shells, with a concise description in Latin of each, under the respective figures. The second edition comprises
six additional plates and a preface in German. The first was published in 1642, the latter not till the year 1733.

The synoptical catalogue of Seger, "Synopsis Methodica rariorum tum Naturalium tum Artificialium que in Museo D. Olei Wormii afferuntur," was printed at Copenhagen in 1653; and, as the title informs us, describes both the natural and artificial curiosities in the museum of Wormius. This was succeeded in 1753 by a more ample account of the museum by Olaus Wormius, from which it appears to have contained many of the telleaceous tribe, one only of which is however figured; this is the Linnaean lepas antiferæ, to which is added tubulifera, baldini, concha antiferæ, dentata, and entalia. His bivalve genera are less raptly defined; in addition to those established by Junon, he forms others in imitation of Pliny, taken solely from the early apertures, fuses, or smooth exterior surface of the shells, after previously dividing the whole classes of bivalves into two orders "concha alperea, and concha leves."

Nothing appeared from this time of material consequence on the subject, till the republication of the treatise of Fabius Columba, by Dr. Major. In the interval, Steno published a work, entitled, "De solido intra solidum naturaliter contenuto Diffractiatiis Prodromus," which contains some pages devoted to an explanation of the fabric and texture of telleaceous bodies. Boyle described some experiments on the phenomena of shell-fish, particularly of the ovifer, under an exhaust'd receiver, in the Philosophical Transactions of the year 1675; and Wills, in 1672, the anatomy of the ovifer, in his "Exercitationes de Anima Brutorum," but these are only physiological dissections. The work of Dr. Major includes a new system annexed to the history of the purpura previously published by Fabius Columba, and likewise a "Dictionarium Oseologiicum," and it besides dentalia and entalia, illustrated with a number of wood-cuts. All shells are divided by this systematized into two classes, univalvia and plurivalvia, the first of which is subdivided into several orders, the characters of which are taken from the form and structure of the opening of the shell, its turbinations, ventricosity, protuberances, or general figure. The genera constitutio of those shells are few, as penicillii marini, pyramidaliter dentata, lepades vel patellæ, auris marina, concha natatæ, concha venera, nautilii, murices, turbo, turbinias terrefles, and buccia. His class plurivalvia is separated into two orders, bivalva and plurivalvia, the first of which consists of his conchæ frigidiæ, conchæ verrucosæ, conchæ rugosæ, pictæ, olivæ, and conchæ anomæ; the plurivalvia only two genera, conchæ antiferæ and bæalæ, or giadae. The two latter genera are those united by Linnaeus, under the name of lepas, and which, before the time of Major, had been improperly arranged, either among the bivalves, or univalves, except by Gmelin, who, aware of this impropriety, places the bæalan at the head of his class anomala. This production of Major's appeared in 1677.

Legati was author of the "Musco Cofipiano," printed at Bologna in 1677. The basis of this collection was led by the celebrated Aldrovandus, whose hand-writing still remains affixed to many specimens that formed the subjects of Legati's description. Ferdinando Colipi, a Bolognae parstician, afterwards augmented it so considerably, that his name became attached to it; and the university of Bologna, to which it was at length presented, considered it one of their most valuable acquisitions. There are not many figures of shells in the "Musco Cofipiano," but the descriptions of this tribe are numerous, and very ample.

In the twelfth volume of the Philosophical Transactions, is a "Relation concerning Barnacles," by Sir Robert Moray. This credulous observer gives a description illustrated by a rough outline of lepas antiferæ, from which he affirms, that young geese may actually be seen to emerge.

"Ilanderus,
Harderus, in a dissertation entitled, "Examen anatomiae Cochleæ teretribis dominort," affords an anatomical description of helix lucorum. This appeared at Basili in 1679. Two years after Grew published his "Museum Regni Sociatis," or "Catalogue and description of the natural and artificial rarities belonging to the Royal Society, and preserved in Gresham College, London." This was the earliest work of its kind that appeared in the English language.

The shells are described in two chapters, the first comprising univalves, the second bivalves and multivalves, illustrated with about forty figures, to which the current English names are annexed.

The descriptions are not entirely approved by late writers; they are confounded too loose and defective, or too concise and uninstructive. His distribution of shells comprehends univalvis non turbinata, bivalvis, and turbinata. In the former divisions, this author, Dr. Maton obverses, "has strangely separated species naturally allied to each other, as, for instance, the fepulcet,Adultis, &c. are left out of the first clafs; and, as well as the porcellane, distributed under the third; and, with equal want of conftancy, the haliotis and nautilus (genera manifeftly turbinated) are placed among those which he terms "univalvis non turbinata." The fame objeclion is urged by Bergen againl the fystem of Buonanni.

"Hic A. tres condidit conchylorum clasfis; univalvis, non turbinatorum, bivalvis et non turbinatorum, fed partim aliena immiffum, partim neceflia omiff. Sic in prima classi merito difiderantur penicilli marini et porcellane, quas perperam ad turbinatas refert. Sic malo confilto auro marini, et nautilus huic præmio fociavit classi, cum manifeffe ex turbinatro fente fit." Buonanni is blamed also for admitting the pholades and conchæ anatiferæ into his second, or bivalve clasf; but it should be remembered, in this respect, he only imitated the example of most systematic writers; Grew places the pholades among the bivalves; Aldrovandus gives both the pholades and conchæ anatiferæ in that clasf; and J. Milton the former. Linnæus, we are to recollect, like the latter, confiders the pholades as bivalves in all the early editions of the Systema; even fo lately as the tenth edition, they fland under the "bivalve conchæ." We may still further advert to Charleton, who yet more abfurdly arranges the conchæ anatiferæ with the univalves, at the fame time that he refers the pholades to the bivalve tribe. Major was the only writer before the time of Buonanni who dispofed of the conchæ anatiferæ in their natural order, which he certainly did, by arranging it in his clasf plurivalvis. In the work of Buonanni will be found many philosophical observa-

tions upon the origin, nature, formation, properties, and other curious particulars relative to fcelous bodies.

The "Scripta Illustrata" of Sir Robert Sibbald, published at Edinburgh in 1684, offers an outline of another system. The author divides shells into two parts, the land and aquatic kind; or "cochleæ teretribes," and "cochleæ aquatæ." The aquatic shells are divided into two distincts, the first containing the fresh-water shells, the other those peculiar to the marine element. The shells of both kinds are distributed into three families, turbinate, bivalves, and univalves. The subdivisions of those families are rudely defined, but upon the whole there is method in the classification; the genera are selected from the writings of former naturalists, but too often inaccurately. Sibbald places the echinides among the turbinated shells; yet this is even more excusable than his introduction of both the pholades and balani among the univalves.

Marigliani's small work on the ova of teataceous animals, appeared at Bologna, in 1683, under the title of "Relazione del Ritrovamento dell'Oova di Chiocciole;" a new edition of which was published at Rome in 1695. Some additional observations on this subject, by Fulberti, "Reflectioni sopra il medesimo Soggetto," usually accompany this work.

Among the "Obervazioni Naturali" of Paolo Boccone, published at Bologna in 1684, are some remarks not altogether uninteresting on the subject of conchology. He was the first writer who described the pediculus ceti (lepis diadema of late authors) with accuracy.

In the same year Dettede gave an anatomical description of the common mule in the Leipsic Commentaries, and which was afterwards re-published in Valentini's "Amphi-
theatrum Zoodomicum.""An elaborate paper on the purple-fish (buccinum lapillus) by Mr. William Cole, pointing out the mode of obtaining, and the nature of this celebrated dye, or Tyrian purple, was inserted shortly after in the Transactions of the Royal Society. This tract was re-printed in quarto in 1689.

A production of very uncommon merit about this period made its appearance before the public, the great conchological work of Dr. Lillier, entitled "Historia five Synopsis methodica Conchylorum," the publication of which commenced in 1685. The author had previously distinguished himself by some excellent dissertations on the same subject; but our attention is principally directed to this, as his most extensive, if not most valuable, undertaking. It was published in folio progressively from the year 1685 to 1692.

Lillier divides his work into four books. 1. "De turbina-

bus teretribis." 2. "De Turbi. aqua dulcis et Bival-

nisis marinis."

There is no text to this work, the whole consisting of engravings, with a concise description of the shells, and reference to their native country, where that could be ascertained, in the Latin tongue; and sometimes their current names in English. The plates, which are of various dimensions, are executed with great force and strength of colour by the hands of the author's two daughters, Susannah and Ann Lillier. It is an extraordinary circumstance, that no two copies of this work are found alike, which renders it very complex, and ill suited for general reference. The plates in the most perfect copies vary in number from 1050, to 1057; or 1607, the different copies having been augmented or diminished, and the plates transfused or corrected at various times, according to the fancy of the author, or his subsequent discoveries. The most perfect of all the copies extant was that...
CONCHOLOGY.

that presented by Dr. Lister himself to the royal library at Paris. This is ascertained by the observations of Davila and M. de Bure, who have taken considerable pains in the collation of different copies of this work. Da Costa names that in the library of the College of Physicians as the most complete copy in London. This last-mentioned writer appears also to have collated many of the early copies of Lister; he treats on this subject at some length; and, considering the importance of Lister's work to the conchological student, it may not be improper to repeat the result of his observations.

"I do not think it unentertaining (says this writer) to relate some circumstances relative to this useful and costly work, which have occurred to me, on the collation of many copies of the old editions of Lister, and on a collation of numbers of his proof prints differed among the curious by Dr. Lister himself before the names and numbers on the plates were added to complete the work; these proof prints, which are what the print collectors style variations, will lead us to some curious particulars that would otherwise be unknown. Dr. Lister in 1678 published his "Hift. Anim. Angl.," in which he treats of English shells, and gives excellent figures of them, and good descriptions; he therefore designed this work, (his "Hift. Conchol.,") only for exotic or foreign shells, as evidently appears from the proof head plates of the first book. N. 8, 25, 33, 40, 43, 63, 74, 83, 99, 108, 125, and 136, which are entitled cockle, buccina, &c. exotic; but the word etoxia was erased when he changed his mind to have a general history of shells, which probably was at the second book, and the crafemen of the work exotica is even now plainly seen in all the quoted plates. Dr. Lister, to complete his intended work, carried home all the shells singly to his daughters to engrave on single or detached copper plates, (as is seen by the work) reserving their arrangement till he had a sufficient number, some not being done to his approbation, or getting better specimens afterwards, he had them re-engraved, and therefore many shells appear twice in his work, and in some only the first engraving, while in others on the second engraving is found; this circumstance is also evident from the proof plates, or variations." Da Costa further states it to be a mistaken supposition that there was only one edition of this work; there were, he says, certainly two, and he concludes with these observations in support of his assertion. "However, there are marks by which these editions may be distinguished by an accurate critic, viz. 1. The second edition has seventy-five shells more than the first. 2. In the preface, plate IV. the third paragraph begins "Septuginta autem, &c." 3. In plate VII., which specifies the places where they are found, the first edition has only one column of names, whereas the second edition has a name, viz. Fret Magel, in a second column. 4. The title and all the head plates, as 1, 2, 3, 100, 106, 139, 140, &c. are printed partly in black and partly in red letters; whereas in the second edition only the title, plate I., is printed in red and black letters, all the others being printed only in black letters.

The plates of this work were bequeathed to the university of Oxford, and were republished in 1770, under the direction of the Rev. Wm. Huddsford, keeper of the Ashmolean museum, who subjoined two indices, one according to Lister's distribution of the shells, the other after that of Linnaeus. This edition differs from the former principally in containing several plates on one page, the whole amount is 108, comprehending altogether 1153 shells, exclusive of the fossils and anatomical subjects; even of the plates, however, which appeared in the original work are omitted in this edition.

After this period, and previous to the work of Rumphius, the first edition of which appeared in 1705, the names of Fehr, Normann, Schelehammer, and others, are recorded as contributors to the elucidation of conchology, yet their productions are to be regarded only as subordinately to more extensive and important investigations. Fehr wrote a dissertation on the argonauta argo, which was printed in "Eph. Acad. Nat. Cur." A. D. 1686. Normann, in the same year, gave an anatomical dissertation on the purpura, which was published at Upsal. The observations of Schelhammer, published in "Eph. Acad. Nat. Cur.," relate to the subject of fresh water shells. Brachius also treats of the ova of some species of ophria. "Le Cabinet de la Bibliothèque de Saint Genevieve," of Du Molinet contains a few figures of shells. In the Philosophical Transactions, vol. xviii., is a communication on the subject of shells, addressed to Dr. Lister, by Mr. Banister who refuted many years in Virginia, and in the same volume is a description of certain shells found in the East Indies by Witten, but these are confessedly too imperfect to merit further mention. Sir Robert Sibbald also published some curious papers on teleology about this time, but his system, and field production, on this subject, have been already noticed. Erius, in a dissertation entitled "Concha antefxia viridicata," refutes the absurd tale of the Bernaee geese hatching in those shells as related by Sir Robert Moray. Leewenhoek published several treatises on the anatomy and intestinal structure of shells. Leigh notices a few of the British shells in his "Natural History of Lancashire," and Wallace an inconsiderable number in his "Account of the Islands of Orkney." The works of Petiver, which are dispersed in the 22d, 23d, and 24th volumes of the Philosophical Transactions, and his "Gasophylacium Naturæ et Artis," may be consulted with advantage, being referred to by Linnaeus and other late conchologists. This brings us to the time of Rumphius.

The popular work ushered into the world under the immediate patronage of the liberal collector last mentioned, claims particular notice. This valuable acquisition, for so it must be considered, bears the title of "Amboinse Rarite it Kamer," the "Rarity Chamber of Amboyna," and contains an account of the more remarkable natural curiosities in his museum, the productions of Amboyna, where they had been collected chiefly by Rumphius himself. The descriptive matter is from the pen of M. Schein Voet, and the plates are engraved in a bold style from the designs of Madame Merian. Of sixty plates with which this work is embellished, no less than thirty-three are devoted to the subject of shells, the total number of which amounts to about four hundred subjects; and many of these were of great rarity and price in those days. The passion for collecting and furnishing cabinets and museums began at this period to be very prevalent in Holland, from whence it afterwards extended over the other parts of Europe. The collection of Rumphius was an object worthy of emulation; and many wealthy individuals endeavored to excel in this pursuit. The forming a collection of rarities at that period was considered a serious undertaking. Articles of rarity of this description will always obtain a considerable price. It is related as a matter of astonishment that Rumphius himself informs us a shell described in his work cost no less than five hundred florins. The sum is great, yet there are few cabinets of any note that do not include articles of equal or much superior value.

Lyonet

of the higher, 

1714, of

The papers Resumur, in fcript in the memoirs of the
the French academy, between the years 1709 and 1717, de-
serve the attention of the conchofift; they relate, for the
moll part, to the formation, growth, and motive powers of
tellaceous animals. The natural iftory of the place, and
the formation of pearls, are amply treated of in a memoir
which appeared in the volume for 1717.

In 1720 Fridericus Rnyich published a description of his
museum at Amsterdam, entitled "Dictaurus Animahum
primum" it relates only in a partial degree to fells,
the figures of which are grouped with coral and other sub-
fances as they flood in his museum.

Morton, the natural Librarian of Northamptonshire, de-
cribes many fells, for the figures of which he refers to
Lieder. This work was published in folo in 1712.

Among the plates illuftrative of various curious fubjects,
contained in the manufcript of Gottward of Dampvrie, dated
1714, forty three are appropriated to fells. Few of the
original copies are complete; that poftifed by Sr Joseph
Banks is perfect.

Three pafes of fells are to be found in the botanical
work of Barreließ, edited by the elder Joufien, which
appeared in 1714, and the ifame number in the "Rariora
Mufci Belliiiani" of J. H. Lockey, published two years after.
The "Amphitheatrum Zoontomium" of M. B. Valentinii, brought forward at Frankfurt in 1720, includes
many extracts from for-forning authors, and fome plates rela-
tive to fells, but which are not confidered to poffefs any
merit of originality, or execution; Bradley, in his philo-
phy fical account of the works of nature, touches on the
fubject of tellaceology though in a fuperficial manner.

The valuable work of Car. Nic. Langius, "Methodus
nova Tellacea Marina in faus Claffes, Genera, et Species
distribui66," was published in quarto at Luccene, in 1722.

To the writings of this able naturalist, Linnaeus fland is highly
indebted. He is an author (lais Dr. Maton) not undue-
erving the title of a feientific one, and whose fystem, fo far
as marine tellaceae are concerned, and of these alone he
wrote, certainly plates at the great clue to simplicity,
which was afterwards fo successfully and admirably fized
by the great reformer of natural history in general": "He
is the fift whole generic characters are founded on com-
monifh dilftinctions: the aperture of univalves, and the hingie
of bivalves, being particularly confidered. These dilftinc-
tions are not allowed their due importance throughout, for
the contour of the fhell is, in many infances, made the
exclusive basis of the definition, and the adoption of this
naturally led, as in other fystems, to a moll inconvenient
and perplexed multiplication of genera. The parts, claffes,
and ficfions, also are far from being well conceived, and con-

5

C O N C H O L O G Y.

borals rather than affift the investigation of the other divi-
sions." After perufing fhefe general flatures the curious
reader may be defirous of acquiring fome knowledge of
this author's fystem. We are inclined to think it entitled
to rather higher prafie.

Langius divides fells into three parts. 1. Tellacea marina
univalvia, non turbinata. 2. Cochleae marina. 3. 
Concha marina.

His firt part is subdivided into two claffes. Clafi 1. Tel-
acea marina univalvia non turbinata, et in fe non fonortia.
Clafi 2. Tellacea marina univalvia, non turbinata in fe con-
torta, in qua ut corum fpira non prominente. His cochleae
marina, or part. 2. confifts of six claffes, vni. 1. Cochleae
marina longae. 2. Cochlee canaliculata. 3. Cochlee marina
ore et tuncure mmcnon elongatis, prima fpira notabiliter
ventricos. Buccina. 4. Cochlee marina ore et mcmone
elongatis, prima fpira notabiliter anguiifior quam in
Buccinis. Stromba. 5. Cochlee marina ore adinodium
breui mcmonc elongatis. Turbinia. Trochi. 6. Cochlee
variae bireore ore et mcmonce contrahitos. The fides
are divided into ficfions, the diftinguifliing characters of which are
taken from the moft prominent features of the various
tribes of fells, as the forma of the fhell itself, the ftruc-
ture of the aperture, the calcification, or lip, &c. in
univalves, and the shape of the valves, their diflimilir-
ty, the beaks, hinge, teeth, &c. in bivalves. The ficfions are divided into many genera, the firl claffes con-
taining seventeen, the fefcd fifty, and the third forty-
three. Many of the genera of old writers are divided, and
sometimes not injudiciously, into two or more genera, to
which new names are affigned, that Linnaeus and later
writers have adopted. We cannot further digrefs on the
merits of this work, but as a fystem recommend it to the
attention of the curious conchofift.

In the work, entitled "Oud en Nieuw Oost-Indien," hy
Valentyn, are sixteen plates of East Indian, or Amb-
boyna fells. This bears date Amsterdam 1724 and 1726,
being published in folio parts. These plates were
afterwards fold separately with defcriptions; the new ed-
iton of the plates appeared in 1754.

"Borne's History of Jamaica" is a valuable work, and
relates to conchofogy, among a miscellaneous variety of
other departments of natural iftory. He was the first per-
fon who vifited the West Irida iflands for the fole purpo-
s of investigating their natural productions, and his plates
and defcriptions relate of course to many fubjects not before
known. His discoveries were submitted to the public in
1725.

In the following year, John Christ. Kundmann published
his "Promptuarium rerum naturalum et artificium," &c.
in quarto. He proposes three principal claffes for the ar-
angement of fells. Claff 1. Tellacea univalvia non tur-
binata. Clafi 2. Tellacea bivalvia. Claffe 3. Tellacea
univalvia turbinata; each of which is divided into a number of
genera, somewhat after the method of Binonanni.

A new arrangement of fells, by John Ernest Hebenfreih,
appeared at Leipzig in 1728; "Differtatio de Ordinibus
Concholarum methodica Ratione iniultmacis." The limits of our observations will not permit us to enter minutely into
this methodus tellaceorum. The fystem of this author comprehends fveral principal claffes: namely. Claffe 1.
Univalvia irregularia. Claffe 2. Univalvia regularia, quae
spira carens. Claffe 3. Univalvia regularia, quae fpira

Minus turbinita epira unica brevis. Ch. 7. Bivalvia valvis per ginglymum connexis. Ch. 8. Bivalvia per ginglymum coherentia. The outline of his arrangement may be collected from his definition of the classes. His families, or subdivisions, and genera are numerous, and are characterized by the figure of the shell, the aperture, hinge, and other remarkable particulars. Dr. Montgomerie's writer of having introduced an useful, if not philosophically distinct, between tests and conchylia, and this exceedingly well. The same object he had in view. "Cl. or often distributed inter testes et conchylia, et notionem generalem tribus prioritibus, quia et malacoltri, et othoorders, conchylia vero solo othooorders sub teste comprehendunt, sed non magni momenti nihil vestrum hoc distinctum. Hic viscaliens considet et perpendo sub notione testes et durum et mollem tellam intelligenti poiste."

The "Dissertatio Physica de Polythalamis, nova testaceorum claffe," by Breyneus, comprehends an arrangement of recent and fossil shells, but the chief merit of the work is allowed to consist in the more exact definition this writer affords of the bivalves, ammonites, and othoorders, than had before appeared. Of the orthoorders tribe, he describes eight distinct species, the two others are treated his copiously. His classification of recent shells is far from peripatetic. This was published in quarto in 1732.

About this period, the attention of many ingenious writers was directed to the investigation of the teredo, or shipworm, then, as it was believed, very recently imported from warm climes into Europe; it was first observed in Holland. The first account was given by the persons appointed to take care of the dykes, who perceived, that the piles which were of the hasted oak, and had been placed to defend the low countries from the incursions of the sea, were eaten through in a few months. The damage occasioned was immense, and the people of Holland thrown into the utmost consternation, till remedies were discovered to prevent the evil. Among the writers on the subject, are Tylfius, Roulet, Potme, Bulmer, Mallet, and Sellius, the last of whom particularly distinguished himself by his work entitled, "Historia Naturalis Teredinis seu Xylaphagi Muniti."

Du Hamel, in a paper inserted in the "Memoirs of the French Academy," in 1736, treated on the purpurs of the ancients. The work of Swammerdam, "Biblis Naturalis," appeared in 1737, and will be found to contain much curious matter, and anatomical research into the nature of testaceous animals. In 1739, the work of James Pallas, "De Conchis Arimincibus minus notis," appeared in Venice. This relates principally to the minute shells found at Rimini in the Adriatic sea. Some of the microscopic shells described by this author, very much resemble the corus ammonis. A second edition was published in 1743, and another at Rome in 1745.

Guettardi's work on shells is a standard book of reference, and as such is well known. This is entitled "Index Testarum Conchylorum qua deivantur in Museo Nicolai," &c. It was published in Latin at Florence, in 1737, and contains 110 plates of shells; the figures of the univalves in which are regularly placed on their summit; they are not withholding tolerably correct; the descriptive matter is less interesting. This author exhibits a system of shells composed by Tournemire, the celebrated botanist, long before this time, from manuscripts on the subject that had been preferred to him by professor Targioni. This arrangement is valuable, and highly worthy the perusal of the inquisitive conchologist. The Linnaean fluentes, in particular, will perceive that to Trunfort, as to Linnaeus, he is indebted for some of the latest amendments of the Linnaean system, and for many of the subdivisions and terms in present use.

"De Conchylologic" of D'Argenville is a voluminous work, and contains a vast number of excellent descriptions, and many figures. The first edition of this work appeared anonymously, under the title of "L'Histoire Naturelle éclairée dans deux de les parties principales, la Lithologie, et la Conchylologie," &c. in 1742; and a second edition, considerably augmented, in 1754. The last edition was published in the year 1780, with many additions, corrections, improvements, and a series of plates containing about 2500 figures, by M. Favanne de Montcvelre and his son.

The name of Bartram occurs to a paper in the Philosophical Transactions, vol. xiii. A.D. 1744, entitled "Observations concerning the Salt-marsh Mucelle, the Oyster-bank, and Fresh-water Mucelle of Pen-sylvania," illustrated with figures. A copious account was also given about this time by Needham, of the lepis anatitae. The "Tentacce-Theologia" of Leffif, is embellished with 137 figures of shells, and abounds with physiological and anatomical observations on the structure of these testaceous animals.

Some mention is made of shells in Dr. Charles Smith's "History of the Counties of Waterford, Cork, and Kerry," A.D. 1745-1756. Two papers, one relating to muddy lithophages, and the other to pholus polyphila, are inserted in vol. iv. and vol. lv. of the Philosophical Transactions. In Sir John Hill's "History of Animals," are an arrangement of shells, and some figures; it appeared in folio in 1732.

The first work of Klein's that claims mention in this place is his "Descripciones Tubularum Mammorum," containing nine plates, which chiefly represent different species of bivalents; with various kinds of recent shells, as, polenes, dactylus, &c., and are introduced in order to complete his arrangement of the tubular coverings of animals. But the principal production of this writer is his "Tentamen Methodol Odracologice, Fide Dipsotita Naturalis Cylindrum & Conchorum," in fours claves, genera, & species, &c., printed at Leyden in 1753. It has been objected against this work that the general divisions forming parts, sectors, classes, and genera, are too numerous; and what is worse, that species are constituted, in some instances, without being referable to any genus, and that, in one of the parts, there is a hystory genus without any clas. (Dr. Motior)—"Claves, genera, & species minimum, ut mihi videtur, multiplicitas; quae sepe fort variations specierum, species vocavit; quae sunt specierum, generum nomine indigent; & ex generibus quibusdam classibus condidit," &c. Ingen.

The outline of an arrangement formed by a naturalist so eminent as Klein should not be passed over unnoticed. All shells are divided by this writer into four principal parts, in the following manner:

 Pars 1. Coelidae, canales tessellati, circa principium teneus & clavati, in gyros gradatim vallories constanti ratione circumacti.

 Pars 2. Conchae. Tellae vesiculorum inflar expansi & concavi, variorum animalium extagnium habituaria, tellarum numero a se invicem differentes.

 Pars 3. Polyconchae, qua pluribus valvulis quam dubius gaudet.
The "Cochlodon," of the former Nautilus, is also the subject of a curious paper, "A Monograph of Cochleodons," by J. H. Cohn. It is printed at Hamburg in 1749, and contains a description of the shells of the Nautilus, and their anatomy. The author has treated the subject in a very scholarly manner, and has given a list of the species, with their characters, and their distribution. The work is well illustrated with plates, and is a valuable contribution to the knowledge of this group of shells.

Linnaean productions on the subject of testacea; it appeared in 1767. In the interval between the times in which the two last mentioned works were published, Linnaeus brought out a third edition of the "Famia Suecica," in which the number of shells described was augmented from sixty to eighty-nine species.

The "Mantissa Altera" contains thirty-five species not described in the other works already mentioned. The "Fundamenta Tellacologia" is one of his latest tracts, and is to be found among the "Differtaciones Academicae."

There are valuable books in a limited view, but the classification of shells in the "Sytema Naturae" from the nature of the undertaking is to be considered the most general of all the Linnean writings on the tellacea. Between the year 1735, in which that work first appeared, and 1767, the Sytema passed through no less than twelve editions, in all of which a progressive improvement, and nearer approach to perfection are manifested, and in no one department is this more unequivocally shown than in the methodical distribution of the shells.

An opinion is pretty generally prevalent that less attention was devoted by Linnaeus to the history and arrangement of the tellacea, than any other order of nature; and that he even thought them unworthy of becoming objects of scientific arrangement. These points have been contested. The truth however still appears to be, that Linnaeus had not really bestowed much critical attention on this subject. We can easily imagine that the mind of Linnaeus might fluctuate between the propriety of establishing his conchological system upon the characters of the animals, and the difficulty, if not impossibility, of accomplishing it, and that in this state of indecision the shells themselves were, in a great measure, disregarded by him. When therefore the completion of the Sytema required that some attention should be paid to tellacceology, he was unprepared, and reporting to the authorities of others, comprized this department in the smallest compass possible, more with the view of filling up a chasm, which the omission of a tribe so generally admired would occasion, than from any idea of elucidating the subject.—A similar reason is well known to have operated on the mind of Linnaeus, with respect to his sytem of mineralogy, which was added principally, in order that this work should comprehend the three kingdoms of nature.

Whether this conclusion be correct or otherwise, one fact inferred is very obvious, that the early attempts at the classification of shells, which the Sytema presents, do not afford that happy result to be expected from the industry, and superior genius, of Linnaeus. — It is time we should lay aside the trammels of servile adherence, and speak decidedly:—those early attempts of this celebrated writer we do not scruple to say, if examined with candour, will be found only a flight and ill conceived compendium of what has been handed down to us by antecedent writers; and which, if he had more closely imitated in the outset, as he afterward found it incumbent upon him to do, would have rebound his reputation as a conchologist from considerable blame. Can we for a moment, dazzled with the splendor of a name, however dignified, deny that merit which is so conspicuously prominent in the classifications of preceding writers, and attribute all the credit of reducing shells into method and order to the genius of Linnaeus? or can we, after duly estimating the tellacceological labours, even of Gmelin, Aldrovandus, and Major, we would almost say of Arilitole, be disposed to commend this naturalist for overwhelming their arrangements in one common ruin; abolishing at the least forty excellent genera established by the different writers, and in lieu of those presented to us with eight genera for the reception of the whole tellacceous tribe! Yet such is the fact, the only genera of shells, included in the first editions of the Sytema, are cecoidea, nautiud, cypraea, basilare, denudata, conus, and liope.

Linnaeus was himself embarrassed in the distribution of shells into such a small number of genera; he even found it impracticable, and hence we perceive, in the later editions of that work, their number progressively augmenting till, in the last publication of the Sytema, they were multiplied to thirty-five. Thus from time to time, as his acquaintance with shells became more general, we see him deriving new strength and support, in the aid of his own sytema, from those very sources which, in the first inconsiderable, he too incautiously attempted to subvert: the genera afterwards admitted into the Sytema, even to those last adopted, being with scarcely an exception to the contrary, drawn from the labours of naturalists who wrote in the century preceding, or much before.

It is an opinion likewife founded in error, that we are indebted for the outline of this tellacceological system (considered in its most improved state) to the native genius of Linnaeus. No one will hazard the assertion, we should conceive, who is in the slightest degree acquainted with the writings before-mentioned. His primary divisions were ready formed to his hands. Let us examine further: in the outline of his sytema, he divides all tellacceous bodies into three principal orders, multivalve, bivalve, and univalve.

If we take the univalves of Arilitole (retained by later writers under the title of turbinata), the bivalves of all writers, from the time of Arilitole inclusively, and the plurivalves of Major, invert their order, and we at once possess the complete outline of the sytema attributed to Linnaeus. Or we may refer with equal certainty to the principles of Major's sytema alone, published sixty years before the first edition of the Sytema made its appearance, in which this inverted arrangement occurs precisely, univalve, bivalve, and plurivalve. Linnaeus, therefore, it may be fairly inferred, was not the inventor of the sytematic outline ascribed to him, for it was long in use before his time.

If we next descend from the primary divisions, or orders of the Linnaean sytema to his genera, these still are to be found in the same, or other early writers, perhaps a solitary transplantation (as in conus and strombus) excepted, and furthermore even under the very names he ascribes to them. His labours of the labours of Langius are too obvious to be concealed. But although, in this particular, Linnaeus has only the more moderate merit of adopting, instead of inventing the outlines of his sytema, he is to be applauded for having condescended to select what it appears he thought, on mature deliberation, superior to his own. And this, in our idea, was so far commendable, that we regret he had not been influenced by the same opinion in his first views of a tellacceological classification. Linnaeus had sufficiently much diffuse and ambiguous matter to wade through in his investigations of former sytema in general, and his selections were at length both clear and judicious, though still susceptible of much improvement. We are also to give the celebrated naturalist his full share of credit for having ultimately improved, and more accurately defined, the characters of the respective genera which he has adopted, than any of his predecessors; the characters of his species also, generally speaking, are not to be excelled for expressive fineness and conciseness. He may be truly said to have reformed the language of natural science, before much too vague, by the introduction of that peculiar brevity of style, so extreme,
ly useful in the nice differentiation of natural objects, and which he seldom fails to apply with the happiest possible effect.

The merits of Linnaeus, as a great naturalist, will shine with undiminished splendour, devvoted of its meteorous luster; the world feels grateful to his genius. But nothing less than an acquittance unworthy of his character, and of ourselves, can lead us to conclude he was equally successful in all his endeavours to develop the mysteries of nature. For our own part, attached to no particular fyltem, we would rather "tame the torrent alone, that glide down the stream with many," in contradiction to the evidence of our own mind; we are the friends of Linnaeus, and of truth. We are persuaded, furthermore, that what the result of calm investigation approves, must redound more to the credit of Linnaeus than that imputed to obversion which bows down our reason, and rejects inquiry. The celebrity so deftively acquired by his writings in general, has stamped his system of zoology with respect. Its reputation induces us to examine it with more than ordinary attention. It is in England, what that of Linnaeus's is in France, and some others in different parts of Europe; the system holds its own, and the more admired. We feel for this reason take a comprehensive view of the whole, regarding every genus separately in the same order as Linnaeus places them; and offering, as we proceed, a few original remarks on each, with a view to enable the commentator to form his own opinion, and judge for himself of the comparative excellence or superiorty of the Linnaean system of zoology.

The primary divisions of this system, in the latest edition of the "Systeın Natural," as before observed, consist of three orders: molusca, brachiates, and arachnides each of which is subdivided into genera. The molusca contain the chiton, lepus, and pholads; the brachiates, mya, solen, tellina, cardium, phoca, donax, venus, familylus, chara, areca, oliva, annuim, matthis, and plia; and the arachnides, argonauta, conus, cymus, cymop, bula, olata, haeccinum, laberum, murex, trochus, turbo, helix, teipia, halotis, patella, dentalium, derma, teredo, and fasa.

**Genus.**

**Chiton.** Animal a doris. Shell consisting of several transverse incumbent valves, disposed in a longitudinal series down the back.

Our knowledge of this genus was very confined till within the last few years; but lately in the tenth edition of the Linnaean "Systema Naturalia" appeared, only four of its species were known, at least no greater number is described by that writer. To the valuable work of Cuvier, we are indebted for the addition of thirteen other species; to Schafhei, for three or four; and to Pennant, for nearly an equal number; all of which are included in the last edition of the "Systema Naturalia à Gmelini," with a few others, amounting altogether to twenty-eight species. Though we are pleased to think such a number of the curious genus, concentrated in one pot of view, we cannot avoid expressing a wish that no few of the species at least were better explained, those especially which are confined to the continental museums; one, if not more of the species described by Pennant, is confusingly erroneous.

**Lepas.** Animal a triton. Shell affixed at the base, and consisting of many unequal valves. Linn.

The propriety of separating the balani, or worm shells, in the entomology, or as vulgarly denominated the "globe bearing shells," has never yet been questioned by any well-informed naturalist; although from motives of caution we, have, with others, submitted to the genus established by Linnaeus. But our reasons for differing from his authority (and which the Linnaean student might deem an innovation) could be explained in its proper place.

We were always at a loss to see the true reason that could induce Linnaeus to place their two very opposite natural families together; the only justification seems to be, that the animals of the two genera (for we shall denominate them) are of the same kind, and that no other multivalve shells are inhabited by this kind of animal, that of chiton being a doris, and of pholad an afide. At the same time, it will be remembered, that shells of the same kind inhabit shells of very different genera, and that it is therefore no argument, because all of the Linnaean genus lepas are inhabited by the triton, that they must be of the same genus. We cannot freely infer this from any similitude in the structure of the two kinds of shells. What, for instance, can be more different than the first very effusiusbular in particular, in which these shells disagree, namely, the manner in which they are disposed; the balani cemented immovably by its base to the rocks, bivalve shells, or any other extraneous substances, while the anarica are connected to, and supported at their base by a tendinous tube, which being of a flexible nature, allows the animal an opportunity of working or turning in any direction in quest of food. Again, the very differing circumstance, which Linnaeus had always himself regarded, as of the first consequence in an arrangement of shells, the presence and absence of the operculum; in the anarica, there is no operculum whatever; while, in the balani, that part constitutes one of the principal features of the shell; it is even the structure, rigidity, or other peculiar circumvolutions observable in this part, that afforded Linnaeus the best of his characters, in defining the species of this family. This operculum or lid of the balani consists of four or fix valves. The above characters are so obviously distinct, that it may be almost considered needless to advert to the form of the two shells, though in this also they differ most essentially; the anarica are wedge formed, and consist of five or more unequal valves; the balani of fix valves, and the general form of the shell is subconic.

**Pholas.** Animal an afideicia. Shell bivalve, decorated, with several leffer, differently shaped, accedent ones at the linge; hinges recurred, and united by a cartilage; an incrustation towards the inside beneath the hinge.

Their shells were formerly called picklocks by the English; they are found below high water mark burrowed in hard clay, lime stone, or sometimes free stones, and also wood; which they perforate in their younger state, and as they increase in size enlarge their habitations. The animal is somewhere cylindrical in form, and furnished with two orifices or openings, capable of eleyation in the manner of a proboscis; from one of which, supposing to be the mouth, it has the faculty of squirting water. The phosphorescent properties of the pholas are very remarkable; it contains a fluid which fluids with uncommon splendour in the dark, and illuminates whatever it touches, or happen to fall upon. This is used by Piran, lib. ix. ch. 61, and M. Remanus has also written copiously on this subject in the Memoirs of the French Academy, for the year 1712.

Only twelve species of this genus are described in the Genus of Syll. Nat. The pholadas were placed by Linnaeus among the bivalves.

**Mya.** Animal an afideicia. Shell bivalve generally gaping at one end, hinge, with a fold, thick, p.BLorous tooth, or seldom two, and not inserted in the opposite valve.
Many of the shells in this genus were arranged with the muscles till Linnaeus separated them; Gmelin, in the latter edition of the Systema Naturae describes twenty-one species of the mya tribe.

The Linnaean now constitute three distinct genera, in the late arrangement of the continental writers, as mya, glycimeris, and vulicula. The mya is distinguished by a transverse shell gaping at the two ends, and having the ligament within; and one valve furnished with a single, compressed, roundish tooth in the beak, perpendicularly to the valve, and having the ligament attached to it. The Linnaean mya truncata is of this kind. In the genus glycimeris the shell is also transverse, and gaping at both extremities, but the hinge is callous and toothless, and the ligament situated on the outside. Vulpella has the shell long and someweb equivocal; hinge callous, broad, without teeth, and forming a straight line in both valves; the ligament attached to a roundish corny hollow; beaks bent and very short. This bill genus is closely allied in many respects to the oyster.

Solæ. Animal an acrid. Shell bivalve, oblong, open at both ends; hinge with a subulate reeval tooth, often double, and not inserted in the opposite valve.

Gmelin describes twenty-three species of this genus, several of which are natives of Europe, where they frequent sandy shores. The Greeks were acquainted with some shells of this genus, as also the Romans. Both of whom valued the flesh of the inhabiting animal as a delicacy. In England they are occasionally eaten either boiled or fried without eggs, but are not found in sufficient plenty to be considered as an article of food. They are called frittate or razor-shells in this country.

The Linnaean solæ are divided by late writers on the continent into three different genera, two of which comprehend the recent kinds, the third is established chiefly for the reception of some fossil shells, supposed to be of this Linnaean family. Those genera are Tellina, Sanguinolaria, and corbula.

The solæ, according to those writers, have the shells transverse, with the upper and lower margins almost straight, with beads not projecting and gaping at both extremities; and the two valves together furnish either two or three teeth in the hinge, the ligament of the hinge in this family is placed between the valves. Sanguinolaria differs in having the upper margin curved, the extremities a little gaping, and two approximate teeth in each valve, which look into each other when the shell is closed. Corbula has the valves unequal, subtransverse, and regular; with a conic curved tooth in each valve; the ligament of the hinge within, and the inside of the shell marked with two muscular impressions.

Tellina. Animal a testace. Shell bivalve, generally flapping on one side; in the fore part of one valve a convex, of the other a concave fold; hinge with usually three teeth; the lateral ones smooth in one shell.

In the Linnaean system the tellina are divided into three families, namely, *ovata* and *tequilis, **ovata* and *comprell * ***subbivalvula.*

A late writer (Dr. Phipps) observes, in his "Catalogue of Shells found on the Coast of Dorsetshire," that the tellina genus is one of those of which the species are yet very imperfectly defined, arising from the great similitude among them; and from the insufficient descriptions of authors before Linnaeus wrote, who, by deducing their characters of the genus, if indeed such they might be called, almost wholly from figures, were necessarily led to throw together shells entirely different, when examined by the characters Linnaeus affixed. Those of this great maker, adds this writer, are yet very imperfect, and since the great additions that have been made to conchological science, by later discoveries, the whole system again wants a total reformation; and the conformation of many new genera. The observation of this naturalist is very just; the writers before the time of Linnaeus have, with too little caution, derived their characters from figures rather than from the shells, a fault we could have wished Linnaeus himself had more frequently avoided; the tellina of Linnaeus is a good genus, but requires to be revised; some of the shells included by this genus have certainly no natural affinity whatever with the others, and the character of the genus itself is not laid down with sufficient precision.

There is one of the continental conchologists who describes the tellina with any degree of accuracy; he defines them to be "shells shaped like wedges," and places them after the pins. (Vahl. iii. b. 2. sect. 8.) Woodward says they have a few teeth on the hinge, and are oblong shells, or with the files lengthened. Davila comprehends the tellina as a very large family, and includes the solæ as a genus of them. Da Cols, in his "Elements of Conchology," attempts to establish a family of tellins under the character of the shells being more broad than long, rather flat, and the hinge having two teeth set close together. This constitutes his ninth family of bivalve shells; and which he again divides into two genera, the shell of which he calls tellina, and the second, to his tellins are thus defined: "Shells with similar files, whose back hinge is central;" his cunei "shells with dissimilar or unequal sides, whose back and hinge are placed near to, or quite at one end."

There is much method, but very little accuracy, or attention to genera, founded on natural affinities and characters, in the arrangements proposed. It was refused for later writers, by a more strict inquiry into the nature and habits of the animals, as well as the nice discrimination of characters in the shells themselves, to fix upon definite general definitions. It has been discovered by Pohi, and others of the continental writers, that the animals inhabiting some of the tellin tribe are of a different fabrication from the others; and another objection to the tellina, as they now stand in that genus, is the difficulties observable in the hinge, teeth, and other parts of the shell, which Linnaeus has hitherto thought essential to be regarded in conchological genera. The principal of the new genera established by the labours of the French writers are *Cylus* (cyl CEOs) of Lamark, and *Pandora* (pandoros) of Lattreile, the animal of which was previously discovered by Pohi; the shell is also described by Linnaeus under the name of *Tellina inequivalvis.*

The tellina genus, as now defined, consists of those bivalve shells which are orbicular, or transverse, having a regular fold or rumple at the anterior end of the shell, with one or two teeth pointing to the beaks; and remote lateral teeth. This will comprehend the true tellina. The *cylus* is of the Linnaean tellin, and is exemplified in the *Tellina cornu* of Linnaeus and Pennant. This genus is of a suborbicular form, without a regular fold or rumple at the anterior end; the ligament of the hinge is inflated, and projects out; it has either two or three teeth pointing to the beaks, and lengthened lamelliform, or plate-like lateral teeth, which are received into sockets in the opposite valve. The genus pandora, as above intimated, is formed principally of that singular shell the *tellina inequivalvis.* This genus is univalve and unilaterally, one valve being convex, the other flat, with flattened *cornu,* two unequal diverging teeth at the hinge, pointing to the beaks in the upper valve, and two hollows in the lower; ligament within, and the inside of the shell marked with two muscular impressions.

Ceramus.
COPHOLGY.

Cardium. Animal a tethys. Shell bivalve, nearly equilateral, equi-valve, generally convex, longitudinally ribbed, dentate, or frilled, with the margin dentate. Hinge with two alternate teeth in the middle near the beak, in most incurved; lateral teeth remote, and inflected or locking into the opposite.

For each species of this genus are described in the last edition of the Systema Naturae.

Da Costa, in his "Elements of Conchology," proposes to establish a new family of cockles, under the title of peclinocolus, whose character is a curved or semicircular hinge set with either two or four teeth. These he divides into three genera. Genus 1. Pectinocolus, or cockles, with a convex or flat-sided shell, of a roundish shape, with similar or dissimilar sides, whose beaks are not very prominent, and curve much upwards towards the hinge; they are the Clamme of Argonauts and Guatier; and do not belong to any particular genus in the Linnaean system, but are dispersed throughout his bivalves, and are only mentioned here to introduce the two: next genera. Genus 2. Cardiformes, or heart-shaped cockles, whose beaks are not very prominent, and curve up greatly towards the hinge, thereby forming a figure perfectly like a heart as vulgarly painted. These are ranked by Linnaeus in the cardiac genus, and are theirs, strictly speaking, of which his genus is chiefly composed. Genus 3. Truncati, or flat-sided cockles. These are such cockles as are flattened, or have a truncated appearance on one side, as we see exemplified in cardium medium.
