ING. STEM several, rising among a considerable number of root-leaves, from three to fix inches high, weak, zigzag, shortly angular, villous, a little branched. LEAVES alternate, smaller, but so much narrowed at their lower extremity as to appear petioled, a little channelled at the base to embrace the stem, furnished with two bracteal leaves, which are in shape and filikenes and extending a little beyond the calyx; besides these there are sometimes two other smaller bractes, shorter than the calyx; calyces small; leaflets egg-shaped, acute, silky, corollas middle-filz'd, half open, villos on the outside. A native of the south of France, and the Levant. 127. C. \textit{spicifolius.} D. fr. 41. Linn. 2039. BRAND. \textit{Leaves} linear-lanceolate, nearly simple; peduncles one-flowered, shorter than the leaf. STEM decumbent at the base, then ascending, a little zig-zag. LEAVES alternate, about three lines long, resembling those of lavender; lower ones the same length as the others. FLOWER rather large; peduncles axillary, nearly half the length of the leaves; bracteate two, linear-lanceolate, situated near the calyx, and a little surpassing it; calyx about one-third of the length of the corolla, with five acute segments; fligmas long, filiform. A native of mountains in Spain. Wilde now thinks this and the preceding the same plant; and they are perhaps nothing more than varieties; but as La Marec and Defroutteaux profess to have been both of them growing in the botanic garden at Paris, in deference to their authority we have kept them distinct. 128. C. \textit{flavicaculea.} Mart. 110. Willd. 87. Vaill. Symb. 3-33. Bar. Lc. 470 Bacch. Mof. 2. 79. tab. 70. (C. laurinoides) Defr. 47. Lam. 2046. C. argentee umbellatus fumus; Tourn. Infr. 84. Lychinus fylvicolis campanulate flor. (Bass. Pin. 262.) "Very white: Leaves inconspicuous; stem terminal heads; calyces acuminate." STEM perennial. LEAVES scarcely a foot long, cylindrical, a little branched. LEAVES an inch long, thin, flat, alternate, fleshy, fatting on the young shoots. FLOWERS white, with a flight tint of purple, fffile, wide, or ten collected into a head at the extremity of the branches, which are commonly without leaves below to the extent of two inches, surrounded with a form of involucre consisting of five or fix rather broad leaves; each flower surrounded with some small linear bractes; calyces divided to the base into five segments, about half the length of the corolla. 129. C. \textit{Carum.} Linn. Sp. Pl. 50. Mart. 47. Willd. 3 Flor. Grec. tab. 100. Bar. Mag. 459. (C. argentee) Defr. 48. Lam. 2047. C. argentee umbellatus cretaceus; Tourn. Infr. 84. Monf. H. 2. 11. tab. 3. fig. 1. Cneorum album, folio argenteo mol. (Bass. Pin. 493.) Dorycium; Cluf. Hf. 3. 254. "Leaves lanceolate, tomentose; flowers umbel'd, calyces buffy; item tomentos." Linn. "Shrubby, silky; leaves oblong, obtuse; flowers in terminal, capitulate umbels; calyx short, somewhat reflex." Stem. Root perennial. STEM about three feet high, slender, firm, upright. Leaves numerous, flattened, about an inch and half long, four or five lines broad, fffile, narrower at the base, soft, clothed with a fine decumbent, silky, brilliant down. FLOWERS white, tinged with a pale red, on short peduncles; bracteate resembling the leaves, but smaller; calyces about a third of the length of the corolla, short, obtuse, deeply divided, villous; corolla silky on the outside; border rather open. A native of Candia and the islands of the Levant. 130. C. \textit{oleifolius.} Defr. 49. Lam. 2048. "Shrubby, silky; leaves linear-lanceolate; flowers in terminal capitulate umbels; calyxes lanceolate." A native of the Levant; nearly allied to the preceding, and scarcely more than a variety. 131. C. \textit{lancinit.} Willd. 89. Bot. Mag. 289. "Stems erect, shrubby; leaves linear, acute, clothed with silky hairs; flowers terminal, umbilicate-panicled; calyces hairy." Conformed by the English nurseriesmen with the next species. Most allied to C. canerium, but differs in having leaves much narrower, more pointed, and less silky. 132. C. \textit{canerium.} Linn. Sp. Pl. 31. Mart. 48. Defr. 46. Lam. 2045. Willd. 90. Jacq. Flor. Aul. 3. tab. 295. (C. linearis folio; Bass. Pin. 205. C. linearis folio affugenus; Tourn. Infr. 57.) "Leaves linear, acute; item branched, somewhat dichotomous, calyxes hairy." Linn. "Hairly; leaves linear-lanceolate, acute; item branched, rather erect; flowers clustered." Lam. B. C. terebellus; Linn. Sp. 27. Whole plant clothed with fine whitish hairs, fast to the Flower scanty, pale white, fbrn a foot high, cylindrical. LEAVES two or three lines broad, alternate, fffile. FLOWERS rose-coloured or white, almost fffile, growing two or three together at the end of the stem and branches; bractes linear, acute, resembling the leaves but smaller; calyces with five acute segments; corollas middle-filz'd, open, almost flat; fligmas two, filiform. A native of the south of Europe. 133. C. \textit{fusifolius.} Smith Prod. Flor. Græc. p. 135. Desf. Att. tab. 48. "Leaves linear-lanceolate; item ascending, villous, peduncles axillary, unflowered, three times the length of the leaf." STEM perennia. A native of Barbary and Greece. 134. C. \textit{Amazanii.} Defr. 40. Lam. 2038. (C. ramosus, erectus, argentee minimus; Amm. Ruth. 5. n. 6.) "Silky; leaves linear; peduncles one-flowered; bractes long; calyx acute." Whole plant armed with a short silky filyvew down. STEM perennial. STEM from four to six inches high, slender, cylindrical, branched, rather erect. LEAVES alternate, fffile; root-ones not less than half an inch long, narrowed at the base, obtuse; those on the stem and branches longer, acute. FLOWERS in terminal, pale white, flarin a foot high, cylindrical. LEAVES two or three lines broad, alternate, fffile. FLOWERS rose-coloured or white, almost fffile, growing two or three together at the end of the stem and branches; bractes linear, acute, resembling the leaves but smaller; calyces with five acute segments; corollas middle-filz'd, open, almost flat; fligmas two, filiform. A native of Siberia. 135. C. \textit{fusifolius.} Defr. 45. Lam. 2044. Willd. 92. (C. originales, humifolius; pilofelius folius; Tourn. Cor. 1.) "Leaves lanceolate, fffile, entire; peduncles elongated, many-flowered, loosely branched." Root perennial. STEM cylindrical, slender, slightly hairy, decumbent. LEAVES alternate, three or four lines broad; fssile especially at the edges, with long separate hairs. FLOWERS small, campanulate; peduncles from four to six short; calyces small, flarin a foot high, cylindrical. LEAVES numerous, flattened, about an inch and half long, four or five lines broad, fffile, narrower at the base, soft, clothed with a fine decumbent, silky, brilliant down. FLOWERS white, tinged with a pale red, on short peduncles; bracteate resembling the leaves, but smaller; calyces about a third of the length of the corolla, short, obtuse, deeply divided, villous; corolla silky on the outside; border rather open. A native of the Levant. 136. C. \textit{dorycium.} Linn. Sp. Pl. 28. Mart. 49. Defr. 38. Lam. 2039. Willd. 95. Linn. Sp. Pl. 291. (C. ramosus, humifolius; pilofelius folius; Tourn. Infr. 57.) "Leaves linear, silky; item shrubby, panicked; calyces almost naked, obtuse." Root perennial. STEM a foot and half high, cylindrical, almost smooth, a little zig-zag, much branched, with few leaves, ascending towards the top. LEAVES alternate, fffile, narrow. FLOWERS generally filitary, fssile in the forks of the branches or at their summit, commonly accompanied with one or two small leaves; calyces very small; corollas campanulate, open, villous on the outside, three or four times the length of the calyces. A native of the Levant. 137. C. \textit{proserpa.} Willd. 34. Vahl. Eclog. 1. 18. "Leaves linear, fssile underneath; heads of flowers
blue on the upper part of the border; peduncles just above the leaves on the same side about two inches long. A native of Spain, Portugal, Sicily, and the coast of Barbary. It is generally called 
Amer. 9. tab. 125. "Leaves oblong-lanceolate, somewhat
halate; peduncles elongated, one-flowered; stem creeping."

Root perennial. A native of South America. 151. C. 
Lam. 2029. Willd. 107. (Ipnoma aquatica: Forsk. Arab. 44. 
Baili: Rheed. Malt. 11. 107. tab. 52.) "Leaves arrow-
shaped, obtuse behind; peduncles one or two-flowered.

Root perennial. Stem creeping, jointed, rooting, angular, 
compressed, subdivided. Leaves crowded, terminal, emargi-
nate, smooth, somewhat succulent, on long-petioled. Flowers 
whitish, rather large; peduncles from the axis of the 
terminal pedicels, erect. A native of the East and West Indies. 
Wild. 108. (Olius vagum: Rumph. Amb. 5. 419. tab. 155. 
fig. 1.) "Leaves lanceolate, auricles rounded; stem 
creeping; peduncles one or two-flowered."

Root perennial. Stem filiform, smooth and even. Flowers 
white, acuminate. Flowers purple, peduncles shorter than the 
based"; Calophyllum. C. soldanella, twilled, with 
two feeds in each cell. A native of the East Indies, 
China, and Cochinchina, where it is used as a potherb. 153. 
Wild. 109. Thunb. jap. 84. "Leaves heart-shaped, entire 
et the leaf; 3-lobed, smooth; stem rooting, angular."

Root perennial, often as big as the human fist, tubercled, fibber like 
C. batatas, eufulent, soft, and fastid. Said to be brought to 
Pl. 38. Mart. 60. Debr. 83. Lam. 2081. "Leaves heart-
shaped, somewhat haleate, villous; stem and petioles hairy; 
peduncles many-flowered."

Root annual; Stem a little 
twining. Leaves but little hairy. Flowers alternate, pe-
dicelled, smooth, on peduncles longer than the leaves; 
involucres of to each pedicel, small, lanceolate. A native of 
Mart. 61. Engl. Bot. 514. (C. maritimus nother rotundifolius; 
Tourn. 83. Soldanella maritima minor; Bauh. Pin. 
293.) "Leaves kidney-shaped; peduncles one-flowered, 
with winged angles." Dr. Smith. Root perennial, long 
creeping. Stems five or six inches long, procumbent, few-
flowered. Leaves alternate, petioled, entire or a little angu-
lar, smooth and even, somewhat thinly. Flowers bell-shaped, 
emarginate, yellowish at the flaps; peduncles axillary, solitary, 
erec; thickened near the top, quadrangular; bracte 
estigate, close to the flower; calyx-leaves large, egg-
shaped. Capeflor three-celled. Seeds black, one in each 
cell. A native of the sea coasts of Great Britain, and other parts 
of Europe. It abounds in a milky juice, which has a bitter, 
acrid, faerie taint, and is esteemed a good purgative. 156. C. 
(C. Stoloniferus; Debr. 43. Lam. 2041. Cyril. Pl. rar.

heart-shaped; peduncles one-flowered; corolla bell-shaped; 
stem creeping." Vahl. "Procumbent; leaves egg-shaped, 
retuse, emarginate; lower ones undivided; upper ones fin-
ately lobed at the base." Lam. Nearly allied to the preceding. 
Root perennial. Stem cylindrical, quite smooth, a lit-
tle branched, extending far on the sand, rooting at the knots. 
Leaves alternate, smooth, shining, on long petioles. Flowers 
white, yellowish white; peduncules axillary, solitary, or in pairs, 
nearly the length of the petioles, with two small bracts; 

Calyx-leaves egg-shaped, obtuse; stigma capitate. A native 
of the sea-shore in Italy. 157. C. annuus. Mart. 83. 
oblong, emarginate, lobed at the base, or entire; peduncles 
pointed; corolla tubular," Whole plant smooth. Stems 
decumbent, filiform, zig-zag, purplish. Leaves clustered, 
veinless; pedicel longer than the leaf. Peduncles in pairs or 
Solitary, axillary, the length of the petioles; calyx-leaves 
equal, oblong, somewhat succulent; tube of the corolla 

enlarged gradually towards the top. A native of the Azores. 
158. C. maritimus. Debr. 44. Lam. 2043. Plumb. phyto- 
tab. 24. fig. 5. "Leaves emarginate, two-lipped, wedge-
shaped at the base; peduncles many-flowered; stem decum-
ent, throwing out roots." Whole plant smooth. Stems 
cylindrical. Leaves alternate, mucronate by the elongation 
of the principal nerve, entire, thick, fleshy; pedicels chan-
nelled. Flowers purple, large, bell-shaped; peduncles from 
to fix-flowered, generally longer than the pedicels, 
cylindrical, divided above the middle, and furnished at the 
divisions with small awl-shaped bracts; calyx-leaves egg-shaped, 
slightly mucronate. Capeflor roundish. Seeds four A native 
of the Isle of France, and of the East Indies. 159. C. 
(C. maritimus S.; Debr. Lam. Ipomea biloba; Fork. C. 
maritimus alatus; Linn. Sp. Pl. 175. C. marititus;

emarginate, crescent-shaped, truncate at the base; peduncles 
often one-flowered." Root annual. Stem somewhat flabby, 
procumbent, creeping, a little villous, red. Leaves thick, 
tomentous. Flowers purplish. A native of the East Indies, 
China, Cochinchina, and the eastern coast of Africa. 160. 
(C. maritimus S.; Debr. Lam. C. maritimus; Brown. Lam. 
C. maritimus; Plumb. Amer. 88. tab. 104. Marcgr. bras. 
51. Pis. bras. 258.) "Leaves slightly emarginate, roundish, 
egg-shaped, often three-flowered." Stem perennial, 
trailing to a great distance. Leaves larger than those of 
the last two species; pedicels marked near the leaf with two red 
spots. Flowers large, purple; peduncles long. Capeflor 
large, three-celled. Seeds one in each cell. Whole plant 
milky and a strong purgative. A native of the coast of 
Brazil, and of the Straits of Magellan. 161. C. multiflorus. 
Willd. 115. Thunb. prod. 55. "Leaves palmate; lobes 
linear, entire; peduncles one-flowered; stem decum-
ent," A native of the Cape of Good Hope. 162. C. 
Wild. 116. "Stem procumbent; upper leaves 
reduced to the tip; flowers capitate."

Root annual. Leaves 
little villous; lower ones heart-shaped; upper ones repand 
and almo lobed. Flowers aggregate, three together, fel-
ile, parallel, with a fix-leaved involucre. Flowers large. 
A native of the East Indies. 163. C. capetis. Willd. 117. 
Thunb. prod. 35. "Leaves haleate; lobes semibifid; ped-
uncles about two-flowered; stem decumbent, villous." A 
native of the Cape of Good Hope. 164. C. nigroflora. 
Willd. 118. Thunb. prod. 35. "Leaves haleate and ar-
row-shaped; peduncles one-flowered; stems prolamate." A 
native of the Cape of Good Hope. 165. C. littoralis. Linn. 
119. (C. albus, folio laciniato, maritimus, Plumb. Cat. 1. 
Burm. Amer. 79. tab. 90. fig. 2. Tourn. 84.) "Leaves 
oblong, lobate-palmate; peduncles one-flowered; stem 
creeping." Stem very long, much branched, nearly the thick-
ness of a goose-quill, white, tender, creeping and taking 
root. Leaves a little larger than the palm of the hand, 
palmate
CONVOLVULUS, in Rural Economy. See Bind-weed and Weed.

CONVOLUTION. A winding or turning motion, proper to the trunks of some plants; as the convoluted, or bind-weeds, and the clasps of ripples, and brobiny.

Dr. Grew thinks, that all those plants whose roots are twined, have such a convolutions; and he assigns two great efficient causes of this winding motion, the sun and the moon. It is very easy to try whether there be any such convolutions or not in the trunks of plants; which may be done, as he hints, by tying a little bit of paper to any of the branches which are exactly north, south, &c. and then seeing whether it will change its position or not, in respect of the point of the compass.

CONVOY, from the French convoyer, to conduct, escort. In Maritime Language signifies one or more vessels of war, entwined with the conduct of a fleet of merchants, serving as a watch, and a shelter from the infults of the enemies of the flate to which they belong, or of pirates.

CONVOY, in Mechanics, denotes a brake, grapple, or regulator for moderating the velocity of tram or rail-way waggons on steep parts of the roads; in some infallances waggons heavily laden with coal, limestone, &c. defend for considerable distances on steep rail-ways, without horses, and regulated only by a man who rides behind them and stands upon the convoy; as from Whitley-stick to the Bradford-Canal in the West Riding of Yorkshire, and other places. Horses are used to drag the empty waggons up the hill again. See our articles Canal and Rail-way.

On some railways, where the trade is a declining one, and the declivity in some places 12 to 16 inches in a chain, the horses, in holding back to moderate the velocity of the trains, are very liable to be thrown down and much injured, and even killed by the momentum of the trains; for obviating this evil, Mr. Charles Le Cain contrived a convoy, check, or flop, a model and description of which he presented to the Society of Arts in 1825. (See Transactions, Soc. Arts, xvii. 316.) in which the convoy, in form of circular wedges, to set before the front wheels of the trains, is suspended by chains from the shafts by which the horse draws the train, so as to cause no impediment to the motion of the wheels, as long as the horse is on his legs, and the shafts nearly in an horizontal position; but in case of the horse falling, and the shafts by that means declining downwards, the convoy instantly drops and stops the further progress of the wheels on the tram-plates; other kinds of convoys and stoppers are described in our article Canal.

In 1805, Mr. F. D. Walker applied a similar principle to that of Mr. Le Cain's convoy, to the shafts of a four-wheeled carriage called a socable; which convoy, on being let down by means of a pedal action on the coachman's foot, checked the motion of the four wheels in descending steep hills, and greatly secured the carriage and passengers. In 1827, two years this contrivance has been used with perfect success by Mr. Walker in frequently descending very steep hills, without locking the wheels.

CONVOY, in Military Language, denotes some succour or supply of men, money, ammunition, provisions, food, &c. conveyed in time of war by land or water, to a town or an army. A body of men, that marches to protect any thing, and prevent it from falling into the hands of an enemy,
CONVOY.

An officer, who has the command of a convoy, should take all possible precautions for its security, and should endeavour, before it marches, or sets out, to procure good intelligence concerning the enemy's out-parties. And as the commanding officer of the place, from which the convoy is to set out, and those of other places, by which it is to pass, are the most proper persons for him to apply to for assistance, he should take such measures as will enable him to keep up a constant intercourse with them. The conducting of a convoy is one of the most important and most difficult of all military operations. The strength of the detachment employed to escort a convoy should have a reference to the importance of the convoy itself. For there are cases when the escort should be commanded by an able and experienced general.

When it may be necessary to pass the night in the open fields, the custom is to encamp, that is, to form a close with the waggon, for the troops to sleep in, and this is a good precaution against any unexpected attempt of the enemy to surprise them. But if they should find themselves on the point of being attacked during the march, urgent necessity alone should constrain them to adopt this method; and especially the consideration of their being very inferior to the enemy, since they would thus tie up their own hands and render it impossible for themselves not to surrender, in case it should happen that they were not feasonably relieved. When the convoy is considerable, when it is to pass places in the hands of the enemy; and when it runs any risk of being attacked; it ought to have a large escort, which is to be disposed in such a manner as to cover the convoy, instead of being covered by it. And as soon as the commanding officer hears of the enemy's being at hand, he is to leave a few detachments to accompany the waggon, and faze them from such of the enemy's parties as might attempt to turn them into a wrong road, or break their chain; and assembling the rest of his troops, infantry as well as cavalry, seize the most favourable post within his power, to stop the enemy, or fight him, if he cannot avoid it. In the mean time, the convoy is to make the belt of its way, and to get as far from the danger as possible. Should the troops, at any time, think it proper to cover themselves with the wagons of a convoy, they should be made to march in two columns, at a small distance alender; and if the files should prove too long in two columns, they must be formed into three or four. In this disposition, which, however, the ground will not always allow of, as soon as the enemy is observed to be preparing for a serious attack, the horses are to be immediately unhamstrung, and removed, not only that the waggon may be brought more closely together, so as to form a rampart, but to fave the horses, of which, otherwise, so many might be lost, as to render it necessary, even after repulsing the enemy, to abandon part of the convoy. This must also be the case, if the troops should be stopped, and obliged to fight in their march, as it would be impossible that several horses should not be maimed or killed. It appears, therefore, that, in order to save a convoy, the troops should not think of covering themselves with it. If at any time a retreat should be necessary with a great number of baggage waggon, the retreating troops should not think fo much of the protection they might afford, as the embarrassments they must create. The 10,000 Greeks rid themselves of theirs; and, confining themselves to some beasts of burden, took the resolution of fighting, uncovered. Moreover, regard should be had to the country which the troops are to traverse, and the kind of enemy with which they have to contend. If the country is an extensive plain, and the enemy very strong in cavalry, like the Turks, the waggon may prove of great service; besides those for the baggage, which in cases of necessity may be used for that purpose, the army should provide itself with some of those belonging to the inhabitants, to carry the chevaux-de-feu, and the sick and wounded.

CONVOY, Order of, in Naval Tactics, denotes that which a fleet holds in making a straight course; the ships being all in the wake of one another, fleeting on the same point of the compass, and forming a right line. This order, according to M. Boucic. de Villeneuve, is the midst simple, and the only one a fleet should form from the following reasons:—it is easily preserved; it cannot be disposed in 20 out of the 32 shifts of wind; and is easily reformed in the 12 other changes; and it is easy to pass from that order to those that are proper for the security of a fleet, in all possible cases, either to preserve one's self, to attack, or to defend. If the fleet be numerous, the ships are to be arranged parallel to one another, that of the admiral occupying the middle, and fleeting all the three course.

To form the order of convoy in one line. When the fleet is in no particular order of faying, the leading ship is to rear sufficiently for the others to get in her wake, and fleeting the fame course she holds. The commanding officer generally takes this post, when the squadron is not numerous. That the order may be the sooner formed, every ship of the fleet or squadron should chase at the same time that which is to be a-head of her, taking care to manoeuvre in such a manner as to avoid running foul of those which cross her fore-foot in endeavouring to join her leaders in the line. Therefore, such ships as are to keeward of others should take care not to perfit obliquely in weathering them; but they must back, or go a-lern, if necessary, by keeping away a little more. Such as should already be in the column, and are to be more a-lern, must bring to till they are in their polls, or fland on under a very easy fail, that each ship may contribute to the celerity of forming the order.

To form the order of convoy in three columns. The leaders of each of the three divisions are to place themselves in a line right abreast of one another; and at a proper distance between themselves, according to the length of the columns, which will accelerate the disposition. Then every ship of each particular squadron, chasing that which is to be next a-head of her, will come and take their station a-lern of one another at the rear of the leading ship of the division, and fleeting directly after her. This order, which in practice is easily maintained, has the advantage of keeping the fleet close and connected, without causing any delay in its progress. The belt sailors can regulate their velocity by that of those which are inferior to them in faying; and they, on the other hand, may, with a little attention, carry as much fail as the weather will admit, by which means all imaginable courses may, without breaking, be fleeting.

To change from the order of convoy, in one line, to the order of battle, continuing on the same tack. The headmost ship is to haul close by the wind on the same tack, and the rest of the fleet are to make the same movement in succession, fleeting the proper distances from each other.

To change from the order of convoy, in one line, to that of battle on the other tack. The headmost ship is to veer and to come to the wind on the other tack; then all the vessels of the fleet are to perform the same manœuvre in succession. Otherwise, after having formed the order of battle on the same tack, as before, the van-ship is to tack; and all the ships of the fleet are to follow in succession, to form the order of battle on the other tack. Or, if you are fleeting a
course in the order of convoy, 4 points large, the order of battle on the other tack may be formed at once, by all the ships veering or flying together.

To change from the order of convoy, in three columns, to the order of battle on the same tack. If the fleet has the wind on the beam, or between close-hauled and eight points large, (See Plate I. Naval Tactics, fig. 1.) the ships of the lee-column are all to bring to at the same time. The other two columns flound on. When the leader of the weather-column brings the lee leader to bear on the close-hauled line, he tacks, and is followed in succession. The centre-column does the same. But as the weather-column has a greater distance to run, it must make all possible sail, while the centre-column need not make so much. Hence, the weather-column is not to begin to haul its wind till the centre-shifl of the weather-column has got on the close-hauled line. The lee-column is to follow in the same manner, when the centre-shifl of the centre-column is close by the wind.

If the wind be more than eight points, or right aft. (fig. 2.); the column which is to form the van-guard in the order of battle is instantly to haul its wind in succession, with all fails fet; while the two others, continuing their course, will put themselves successively by the wind, on the close-hauled line upon which the order of battle is to be formed, and consequentv in the wake of the weather-column.

If the columns be close on a wind, it then becomes a case within the usual fifth order of failing. See Order of Sailing.

To change from the order of convoy, in three columns, to the order of battle on the other tack. The fleet may be put first in order of battle, on the same tack; then, making the ships tack in succession, they will be in order of battle on the other tack. But the time of evolution may be diminished, (fig. 3.) by making the two weather-columns bring to, when failing between close-hauled and eight points large, while the ships of the lee-column veer in succession, and keep their wind on the other tack. The centre-column of the lee-column having veered, the centre-column is to fill, the leader of which bears away, running exactly with the wind right-aft, and is followed in succession by the ships of his division, till they are in the wake of the lee-column, then on the other tack; when the leader of the centre-column hauls by the wind, the ships of his division hauling in succession. When the centre-column of the centre-column has bore away, the weather squadron manoeuvres in the same manner, and thereby completes the order of battle.

To change from the order of convoy to that of retreat. Whether the fleet be the order of convoy in one line or in three columns, they are first to form in the order of battle on the same tack; and thence they are to pass to the order of retreat. See Order of Sailing.

To change from the order of battle to the order of convoy, in one line, on the same tack. The van-ship is to bear away as far as the intended course, and the rest are to execute the same movement in succession; so that when the rear-ship shall have made the same movement, the evolution will be completed, and the order of convoy formed on the same tack.

To change from the order of battle to the order of convoy, in one line, on the other tack. The van-ship is to tack and run one point large, till she can bear away, under the stern of the rear-ship, as far as the course which the fleet is to hold. All the ships are to perform the same manoeuvre at the same points, to charge the order and get upon the other tack. The van-ship, instead of tacking, may veer and run a little time before the wind, before getting on the other tack; then she will have to the wind on the fleet's course, without fear of breaking through the rear. This movement is shorter and preferable, since the order of convoy is nearer held by the wind.

To change from the order of battle to the order of convoy, in three columns, on the same tack. The three leaders of the columns are to bear away together, and flter on the intended course; then the ships of each squadron are to execute the same movement in succession, following the same direction; so that the three rear-ships, veering at the same time in the wake of their respective columns, will complete the evolution. The columns will find themselves too distant from each other; but, as there is nothing which disturbs them, and they have the wind right-aft or very large, it will be easy for them to close as much as may be necessary.

To change from the line of battle to the order of convoy, in three columns, on the weather-tack. The three leading ships of the columns are to have in on the same time, and bear away on the perpendicular of the wind on the other tack; then the ships of each squadron are to perform the same movement in succession; and when the rear-ships shall have turned about and be in a line with their respective columns, and the leaders of the weather-divisions shall, by crowding all the sails, have come abreast of the van-ship of the lee squadron, the evolution will be completed. If the fleet is to bear more large than the perpendicular of the wind, it will be easily formed, by making the leaders and their columns bear away in succession, then putting afterwards the columns at the necessary distance from each other.

To change from the order of retreat to the order of convoy, in one line. One of the wings is to haul together close by the wind, on the same tack as the line of bearing on which they are formed, in order to bear away in succession at the point of the angle, in the wake of the other wing; the ships of which are to run with the wind four points large, on their line of bearing; and, when the last ship of the weather-wing is in the wake of her line, the order of convoy is formed. If it be necessary to bear more large, or if you would not keep away so much, the same ships may keep their wind more, and follow the van-ship in succession.

To change from the order of retreat to the order of convoy, in three columns. First form the order of battle, and pass from that to the order of convoy, in three columns.

To restore the order of convoy in one line, when the wind comes a-head more than close-hauled. The order of convoy, it is plain, cannot be disturbed by all the tiffs of wind as long as it is more abait than the starboard and larboard lines of bearing; because the ships, steering large in the wake of each other, can easily maintain their poHs, having only their sails to trim, whether the fleet be in one line or in several columns. But if the wind draws more a-head than one of the lines above mentioned, it is evident that the ships being obliged to veer, or pay off, all at the same time, on the same tack, the order will be disturbed. In order to restore it on the same tack, when the fleet is in one line in the order of convoy; if we suppose the fleet steering large on the starboard tack, and the wind comes suddenly right a-head, which would throw all the fails flat a-back on their masts, the van-ship is to cast away to port, and bring to on the starboard tack, while all the other ships of the fleet are to box off, together and at the same time, to starboard, and make all fail, in order to come with eckerty close by the wind on the larboard tack, and get into the wake of the van-ship, then to tack and take their stations successively, under an easy fail, and bringing to likewise till the rear-ship, which has a good way to run, be in her port. If you should wish to get on the other tack, then the van-ship is to cast to starboard,
CON

flaard, to bring to on the larboard tack by the wind; then the r.o.l. of the first would call the other way, to tack afterwards successively in the wake of the ship which lies to, and take their station there, as has been said before, with this difference, that, after the relaxing of the order, you would find yourself on the larboard tack. If the sudden shift of wind be not quite a-head, or if it be fixed points, or between fixed and twelve, the van-ship is, nevertheless, to bring to on one tack, while the r.o.l. of the fleet, calling on the larboard, make all fail to gain her wake, to tack there, and thus regain their stations. The order of convoy may be restored by a shorter and more simple method, which, however, will cause the fleet to drop to leeward more than the former does. In the same case as the fail, when the wind comes right a-head, the whole fleet is to pay off on the same tack, if the ships are all on one line, and the rear-ship must bring to, while the r.o.l. of the ships running five points large (if the wind has shifted fixed points beyond the direction of cloe-hauled), will come and bring to successively a-head of the van-ship, on that line of bearing which they are to hold, observing that such ships are to carry a greater and proportionable press of sail, as being nearer the van-ship, they have consequently more way to run before they can regain their poils. To know how many points or degrees the weather-ships have to run large to get into their stations, add eight points or go degrees to the half of the points or degrees the wind has shifted beyond one of the two lines of bearing; and, in regaining your poils, you will have the number of points by which you differ from the first course you steer.

To restore the order of convoy, in three columns, when disturbed by a sudden shift of wind right a-head. In this case, the whole fleet must call the same way all together, leaving the three van-ships of the columns lying to, close to the wind on the tack on which you purpose to continue cloe-hauled, while the ships of the three columns running large all together on a course (to leeward of the first), which must always be determined by half the number of points or degrees the wind has shifted beyond the direction of cloe-hauled, added to eight points or go degrees, will bear away with care for their stations in the cloe-hauled line of bearing, which they are to hold to the windward side of their rear-ship, where they will arrive successively, by carrying more sail according as they may be nearer to the van, be cause in that case they have a greater distance to run.

We shall close this article with some remarks on the convoy of merchant ships, under the protection of men of war. For the due care of a large fleet, the convoy should have a number of frigates, distributed a-head, a-fern, and on the wings of the fleet, which is always to be kept in the order of convoy, on three, four, five, or six columns, according to the number of which it is composed; some other frigates are also to be sent on the look-out, to defend what passes at a distance, and to give timely warning of the approach of the enemy. If these should discover an enemy of superior force, they should make it answer by signal; and it may be advisable that they should steer a different course from that of the fleet, in order to deceive the hostile ships in sight. The men of war are to hold themselves in the order of convoy a little a-head, and to windward of the weather-column of the fleet; because they will then be able readily to attend wherever their presence may be necessary: the frigates will, with alacrity and exactness, repeat their signals from one to another, that their purport may be expeditiously known to the commanding officer, who must not neglect to have all suspected and neutral ships chased, and even flapped by the frigates, which are always to be supported by one or two line of battle ships, according to the exigency of circumstances. The prorefs of the whole fleet will be regulated by that of the war-going ships; which, however, are to be abandoned, when found to be too great a loss of time; for to risk a small and partial loss, is better than to expose the whole fleet by delay. Between the columns, there should be frigates of war and other sort falling light to be, to maintain order, and keep the ships in their stations. Their particular business will be to make the tarry ships fall with greater expedition, to oblige those ships that are out of their poils to resume it, and in the evening to give an account to the frigates, having charge of going the round, of those which have not manoeuvred well; and these will make their report to the commodore.

During the night, the same order will be observed, except with respect to the look-out frigates, which are to be called in within a certain distance of the fleet, and which are to be allowed lights as well as the rest of the men of war. They are to take special care to oblige all frigates ships to return to the convoy, and to fire, without hesitation, on all strange vessels coming from the main sea, in order to give the alarm. Every night they are to be supported on the wings by some line-of-battle ships. Elements and Practice of Rigging and Shippmanship, vol. ii. pt. 1.

CONUS, in Conchology, a genus in the Linnean system, distinguished by that writer as having the shell univalve, conulated, and turbinated; aperture eufuse, longitudinal, linear, without teeth, and entire at the base; pillar smooth. Animal a limax.

Species.

*M. truncatus. Spiire nearly truncated.

Marmoreus. Shell conic, brown with ovate white spots; whorls of the spire canaliculated. Linn.

Inhabits the Asiatic and American seas, and comprehends several distinct varieties. The shell is finely fluted, and varies from fulvous to blackish; the spots are often of triangular shape, and running into bands; whorls emarginate, and armed with fimbrious tubercles.

A scarce species. The shell is generally marked with two yellowish bands. Supposed to be from the East Indies.

Litteratus. Shell conic, white with brown dots. Linn. Voluta mescehia, Rumph.

Inhabits the Asiatic ocean, and varies from white to reddish, or yellowish; the spots or dots are usually of a somewhat quadrangular form disposed in rows, between which are a few pale yellow bands or chestnut coloured lines; the spire is fluted with brown.

Generalis. Shell conic, polished, spire flat and canaliculated; whorls canaliculated. Gmelin.

A native of India. The column of this shell varies from brown to yellow or orange, and is encircled with red, three, or four bands, marked with elongated spots; spire whitish, varied with undulated flaps, and pointed in the middle.

Virgo. Shell conic, with the base bluish. Linn.

Several varieties of this African species are described by Knorr, Litter, and Chemnitz, from which it appears this shell varies from white to yellow, or yellowish, and is sometimes tesselated with white and red, or white with a fawn coloured band; spire blue, or white marked with ochraceous band.

Capitatus. Shell conic, globulce, with the base brown; spire a little convex. Linn.

Vol. IX.
Few distinct varieties of this species are described by Gaullier, Banani, and other writers. It is a native of Africa, and is commonly either of an olive, brown, or chestnut, or varied with these colours, and marked with one or two white bands, undulated spots, and numerous rows of dots; spheric in general triplicate. This is an Atlantic shell.

Triennis. Shell white, with three yellowish bands, spotted with chestnut; spheric a little convex; and the base transversely striated. Gmel.

Described on the authority of Martini, who has given a figure of it in his work on Conchology; its native country is unknown. The shell is marked with a few waved chestnut lines.

Miles. Shell conic, rough, with the base brown; spheric convex. Gmel. Psuedo-archilhalajfus, Argenv.

This shell is a native of India, and is of a white or yellowish colour, with longitudinal undulated lines, the base transversely striated, near the spheric a brown band, the spheric itself spotted with brown.

Cingulum. Shell conic, yellowish, with a single elevated belt in the middle; spheric acute. Gmel.

Inhabits the Friendly Isles.

* * Section Pyriformis, &c. Pyriform with a rounded base, the cylinder half long again as the spheric.

Princept. Shell yellow, with purplish-brown longitudinal ramose lines. Linn.

Length of this shell about two inches and a half; the spheric is obtuse and finely striated transversely; the body marked with two white bands which have few brown spots, the rest of the shell spotted with chestnut. Inhabits the Indies.

Amnikalis. Shell with rough punctures at the base. Linn.

The varieties of this species, according to the character assigned it by Linneus, are numerous beyond example in any other shell, amounting to nearly forty distinct kinds, independently of a much greater number not hitherto well defined. Among the principal varieties the following are most interesting.

Laurius, faciis nullis, &c. Without bands, figured by Martini.

Americanus, with irregular bands, and admitting of several varieties, as those having the shell brown, and clouded or spotted with white. Shell reticulated and clouded with chestnut; white, spotted, dotted, and clouded with brown; white, having the bands marked with orange lines. Another strong variety anglicus, figured in the work of Gaullier, is of a red colour marked with numerous punctured white belts, and has the spheric spotted with brown. The variety coronatus, described by Argenville, is distinguished by a belt of reddish dots, and transverse elevated lines, and is sometimes marked with a yellow band in the middle, and numerous punctured belts; or sometimes brown with a white band, and an oblique row of whitish spots. Regius has two bands, which are generally of an orange colour with darker lines, the interfices white; shell with orange dots and undulated spots. Martini figures a variety of this kind, the shell of which is white with waved brown spots, and the bands varied white and brown; another has the bands yellowish with trifarious brown lines, and the shell white fringed with brown; and a third variety has the shell clouded white and brown, and the bands of a brown colour. In ordinarius the shell is tectaceous spotted with white; the bands white, and somewhat reticulated with an articulated belt in the middle. Guineensis has the shell of a straw colour, the middle band marked with angulated lines in a very beautiful manner. The shell of the variety farinaceus is of a bay colour with numerous dotted belts, the bands spotted and the lower one dotted with brown and white. This kind includes several inferior varieties. The variety fuminus has the shell of a ferruginous colour with scattered white spots, and is marked with yellow bands, very finely reticulated; it varies in the number of the regular bands. Occidentalis is another strong variety; the shell tectaceous spotted with white, and an articulated belt; bands yellow and reticulated. The coat and principal variety of the conus princeps is the cedo nulli, a shell found in the South Seas in amazing variety, some kinds of which are however extremely beautiful and rare, and in high esteem with amateurs. The geographical cedo-nulli is a fine and valuable kind, the prevailing colour of which is white, marbled with orange in a map-like manner. Another kind, called the "king of the south," (Rei du Sud, Argenv.) is of a fine deep golden orange with a white belt, and several distinct circles composed of clear white spots, three of which circles are disposed between the belt and the spheric. Before the revolution in France there were three specimens of this kind known in the cabinets of Paris; one in that of Madame la Presidente de Banderi, another in that of the king, and the third, superior in perfection to either, in the possession of M. le Comte de la Tour d'Auvergne, which last was obtained from the Isle of France, and was known by the title of Le Cedo-nulli aux iles. But the banded cedo-nulli bears the highest value. This shell, called by the French cedo-nulli a bande, or by some more emphatically La reine du midi, is better known in England by the name of Lyomet's cedo-nulli; it was formerly treasurer in the cabinet of that distinguished amateur, and esteemed at a considerable price, the sum of one hundred pounds sterling being actually refused by its possessor, who was nevertheless disposed to part with it at a fair valuation. Lyomet was an ingenious naturalist resident at the Hague, and, according to popular report, obtained this shell from the cabinet of M. de la Faille, auditor of finances to the states general of Holland, at the death of that eminent collector.

A particular account of this curious shell is given by Argenville, who pronounces it unique; this author describes it from a drawing made under the immediate inspection of Lyomet, the original of which we have seen, and are satisfied in the accuracy of his description. The shell from this drawing appears to be very elegant; its size is about that of the other varieties of the cedo-nulli, which vary from an inch and a half to an inch and three quarters in length, and measure rather more than three quarters of an inch in the wide part. The colour is yellow, divided by four distinct bands of marbled white, the one of which crosses the middle of the shell, and another next the base of the spheric, are the broadest and most beautifully variegated; the spheric itself is fuscated longitudinally. At the first glance the yellow appears two principal bands of pretty considerable breadth, one above and the other below the band of marbled white which encircles the middle of the shell. The two lateral mentioned yellow bands are better with four equi-distant transverse lines of brilliant light points, which give the shell in this part a slightly feabrous appearance.

It is only in conformity with popular report, that the shell of Lyomet, as being intimated, is preferred to be the celebrated cedo-nulli of La Faille's cabinet, the truth of which has been contested by respectable authority. Favanne thinks
CONUS.

It species is not the same, and Germain positively declares it is not. The individual shell of so much repute in the collection of La Falle, according to the latter writers, was sold at the same time, with the other articles, at the Hague, about the year 1728, and was bought by a dealer for the king of Portugal’s cabinet, at a price exceeding a thousand French livres. Hence it is imagined that Lyonet procured his famous shell from some other source. If we are not mistaken in our information, there were originally two shells of this same kind in the cabinet of La Falle, which presented Lyonet with one of them, and which, if true, at once re- solves the mystery. The fate of Lyonet’s shell is not exactly known; it is believed, at present, to enrich one of the Parian museums.

We shall lastly mention a variety of the cedo-nulli, formerly in the rich cabinet of Madame de Bandevillle, called le cedo-nulli marbre, from the beautiful variegated or marble-like appearance of its colours, which were blueish and violet on a ground of white. The shell was also embossed with three yellowish zones, and becket with a number of little roundish granulations of a white colour encircled with red. ViCARIUS. Shell tallceous, spotted with white, with four yellow immaculate bands, the second divided angularly. Gmel. Archibaldisse secundus, Argenv.

Said to inhabit the southern ocean. SEMATOR. Shell conic, smooth, glabrous with obtuse sculptured whorls. Martin.

Native place unknown; the shell is yellow spotted with white, and marked with very numerous tranverse fibriz, composed of white and brown dots. NOBILIS. Shell sub-cylindrical, smooth and glabrous. Linn. Tigris lutea, Argenv.

This species is finely polished, of a yellow or brown colour, occasionally shaded with olivaceous, spotted with white, and marked with very minutely punctured tranverse fibriz. GENUANUS. Shell with linear belts articulated with white and brown. Linn. Genus-fiche toot, Rumpf. Janam, Adanf.

Found on the shores of Guinea. The shell is red, with bands alternately tesselated with brown and red. The “A la papallonis” of Argenville, called also by English collectors the butterfly cone, is considered as a variety of this species. GLYCINUS. Shell emarginate at the base, and frriated; spire unarmed, with the whorls contiguous. Linn. Boterviege van Boer. Rumpf.

A native of India and Africa. The shell is varied with brown, chefnet, and red spots, sometimes placed in rows, and the spire, which is tranversely frriated, varies in being more or less convex, and marked with spots, which are sometimes square. MONACHUS. Shell gibbose, clouded with blueish brown, acute, and frriated at the base. Linn. Capacinus f. anicula, Rumpf.

Supposed to be a native of India. Shell sometimes marked with dots disposed in rows. MINIMUS. Shell greyish, surronded with oblong dots. Linn.

Delineated in the works of Martini and Knorr; the native country unknown. RUSTICUS. Shell ovate, rugged, and frriated at the base; the spire conico-convex. Linn.

There are two varieties of this species, one of which, va-luta cinerea of Rumpfius, is without any band, the other has a band, clouded with whiffin, and is varied with blackish lines and dots. This shell inhabits Africa.

MERCATOR. Shell ovate and white, with reticulate yellow bands. Linn. Tilit, Adans.

Inhabits the shores of Africa. Shell of moderate size, sometimes yellowish, with brown or tawny bands. BUTELINUS. Shell slightly emarginate at the base, and frriated; the spire flatish and mucronated. Linn.

This is a native of India; the shell is rather large, and admits of several varieties, being either yellow or ochraceous, with tesselated spotted bands, and intermediate lines of yellow or brown; white, with three rows of violet characters; or white frissed, spotted and dotted with brown. The Conus Melville of Martini is esteemed a variety of this species. FIGULINUS. Shell slightly emarginated at the base, and frriated; spire acuminated, with flatish whors. Linn. Vo- luta jofa, Rumpf.

Length about three inches; brown, ferruginous, or yellow, and rarely olive, with darker lines; within generally whitish. A variety described by Knorr is of a more elongated form, the colour orange, with darker lines, and two yellowish bands; the spire reddish, spotted with black. Inhabits India.

Native of the same country as the last. Shell rather small, and sometimes reddish, with parallelomeric spots, which are often chefnet. There are several varieties of this species. It is known by the name of the Hebrew character cone, among English collectors. STERCUS MUSCARUM. Shell emarginate at the base, and frriated, whors of the spire canaliculated. Linn. Fo- luta arcuata, Rumpf.

Inhabits Asia. This shell is of a long and narrow form, and white colour, with flattered black or red spots, which are sometimes united into bands; whors of the spire obtuse, and in some of its varieties tuberculated.

VARIUS. Shell elongated and muricate, with the spire coronated and acute. Linn.

A native of the Indian ocean. The shell is white, clouded with brown or yellow, and granulated frits disposed over the whole surface. ACHATINUS. Shell elongated, very finely frissed tranversely, and variously clouded and spotted with white; spire short, spotted with brown, and red at the tip. Gmel.

Several varieties of this shell are described by Seba and Chemnitz; the species is a native of the American ocean. RADIANUS. Shell radiated and fasciated with white. Gmel.

Native country unknown; the shell is brown, pale yellow, or cinereous, and is figured by Martini. LEONINUS. Shell with pale yellow or chefnet spots; commonly marked tranversely with white or yellow bands, composed of grains or spots. Linn.

Found in the Indian ocean; and is a species comprehending a great number of varieties, as may be seen by the works of Knorr, Martini, Seba, Chemnitz; and others; about fourteen distinct varieties are ascertained.

JASPIDEUS. Shell light olivse, with multifarious white dots, and an oblique band. Martini.

This is a shell of an oblong form, and small size. The native place is uncertain.

NEBULOSUS. Shell brown clouded with blue, and white spots. Gmel. Bonann, &c. A doubtful species; the country unknown.

412 COFFER.
CONUS.

Coffee. Shell short, brown, with two white bands; that nearest the spire spotted with brown. Martini.

Shell of moderate size; country undetermined.

Amadeus. Shell pale brown, with a broad band, and articulated belts above and beneath; spire acute, crowned with tubercles, and very finely reticulated transversely. Argenv. Zonamorph. Country unknown; shell varies in being more or less reticulated.

Fulminus. Spire acute, and with the pillar-lip spotted with chevron; shell fluted longitudinally with chevrons; base acute, and reticulated obliquely. Martini.

Arsenoides. Shell reticulated with chevrons; with two or three darker bands; spire coronated and acute. Argenv. Zonamorph. Described as an extremely rare shell, and probably not of this tube. Its native place is unknown.

Costatus. Shell brown, with a white band, undulated with reddish, with thick and broad flutes; spire nodulous, with a granulated band. Gmel. Country unknown.

Leucostictus. Shell white, clotted, fringed, and spotted with browns, and marked with numerous rows of white and brown dots; spire crowned with tubercles. Gmel.

Inhabits the Indian ocean; and has the spire of the shell sometimes acute.

Citrus. Shell citron colour, with black lines interrupted beneath; spire crowned with tubercles, and with the base white. Gmel. Inhabits the Caraccas.

Insularis. Shell white, with chevron clouds, spots, and dots; and spire acute. Gmel. Country unknown.

Coronatns. Shell with alternate articulate belts, and teffellated spots; spire crowned with tubercles. Gmel.

A small and extremely variable species, and which is often times marked with a white band. Its country is unknown.

Punctatus. Shell with two yellowish-brown bands, and numerous lines of dots; spire varied with yellow dots and lines. Knorr.

Zeylanicus. Shell snowy, with rosy and brown clouds, and numerous articulated belts, varied with white and chevron; spire pointed. Martini. The base of this species is grooved obliquely.

Solidus. Shell conic, thick and transversely fluted, crowded with white and brown; with a broad white band, and pyramidal spire; the whorls canaliculated. Chemn.*** Section elongata, &c. Elongated and rounded at the base; the cylinder twice the length of the spire.

Clavis. Shell with convex smooth flutes; the base blueish. Gmel. An extremely rare species, found in the Indian Ocean. The shell is long, yellow, with white spots, and two deeper bands spotted with white; the spire spotted, and gradually tapering to an obtuse point.

Nussatella. Shell somewhat cylindrical, red, not crowned with tubercles, rough, with tuberculated flutes. Gmel.

Teredolum granulatum. Rumph. This is a scarce species, and inhabits the island Nussatello in Asia. The shell is pale, clotted, and spotted with red, or rarely entirely white; with yellowish-brown, granulated, transversely fluted; and the spire ending in an obtuse point.

Terebellum. Shell white, fluted with blue, tuberculated, with annulated flutes, and yellow bands. Gmel. Inhabits the Indian seas.

Coccineus. Shell red, with transversely lines dotted with black, with a white band and spire, spotted with red. Gmel., Knorr, &c.

Cassius. Shell somewhat cylindrical, with annulated ribs, red, with darker clouds, and bars of white; spire spotted. Gmel.

Figured by Lillie and Knorr, and is supposed to be a variety only of C. granulatus. Its country is unknown.

Granulatus. Shell rough, unarmed; flutes smooth and grooved. Linn. Voluta granulata, Rumph. Inhabits the African ocean. Shell red, with large fulcra; flutes reticulated with white and purple linear dots.

Oxymyclus. Shell sub-cylindrical, yellow; the base obliquely fluted with a contiguous white band; spire pointed, and marked with fibril spotted. Gmel.

The native country is unknown. A variety of it is found of a chevron colour, varied with decussating flutes, dotted with red.

Laevis. Shell rufous, with fulvous spots, and transverse flutes; spire spotted with yellow; base obliquely fluted. Gmel., Valent. &c.

Affinis. Shell blueish-white, with four fulvous linear bands, and intermediate dull purple dots or marks. Martini.

Violaceus. Shell white, clotted and banded with violet; rays pale brown. Martini.

Polyzonias. Shell white within; externally yellowish-brown, and rough, with very fine granulated lines; white band at the spire, denticulated beneath; another at the base paler, and numerous fibrous bands. Born.

Bifasciatus. Shell white, with angular chevron lines, and two orange bands; spire prominent; base surrounded with orange lines, and intermediate teffellated spots. Born.

Nives. Shell conical and snowy; spire prominent and coronated; aperture large. Born.

Arausius. Shell not crowned, smooth, with whitish bands; whorls grooved at the tips. Gmel. Oranjen admiral, Rumph. A beautiful and rare species found in India. The colour is in general whitish, with two or three orange bands, and white lines, teffellated with brown spots; spire with oblong spots of red, white, and brown.

Morus. Shell sub-cylindrical, with longitudinal bands, dotted with white. Linn. Voluta macula, Rumph. A native of India. Shell white, with dotted lines, and oblong, chevron, yellow, and brown spots; spire acute and spotted.

Striatus. Shell ovate-oblung, gibbous, clotted, with very fine parallel brown flutes. Linn. Voluta tigrina, Rumph. Melur, Adans. Common on the coast of Africa. Shell four inches long, snowy, with sometimes reddish or yellowish flutes; the base edge margined and transversely fluted.

Textile. Shell reticulated, with yellow veins, and spotted with yellow and brown. Linn. Panus aureus, Argenv. Lomon, Adans. A native of Asia. Chemnitz describes a variety of this species, of a white colour, with three orange bands; and another of a brown colour, with two darker bands.

Aulicus. Shell white, with brown reticulated veins, and interrupted longitudinal bands. Linn. Nigella, Argenv. Nearly allied to the former, and supposed by some to be a variety; it likewise inhabits Asia, and admits of many varieties, several of which are figured by Martini.

Tomax. Shell smooth, white, with bay characters, and
The word *nervus* signified a tendon, as well as an elongation of the brain and spinal marrow, which is now exclusively called a nerve; hence the Roman name for convulsions, which signifies dislocation of the tendons. And accordingly, those slighter convulsive motions of the muscles of the arms, which occur in fever, and occasion a playing of the tendons under the finger of a person, feeling the pulse, we now call a fluting of the tendons, *fulguratio tendinis*. But those different forms of spasms and convulsion are frequently mixed, or pass into each other; and similar causes, affecting the brain and nervous system, produce both the one and the other.

It was vain to attempt to give an explanation of the nature or proximate cause of convulsive motions; since we are ignorant of the nature of the nervous power, or of that medium by which the muscles are connected with the common fenestrum, and the volition of the mind is communicated to the muscles. We must be content with the observation of facts: the minute operations of nature are inferrible. The mechanical physicians had, indeed, no difficulty in accounting for the morbid, as well as the healthy operations of the nervous system: their imagination furnished them with a cause for every effect. Thus they supposed, like the natural philosophers, the existence of a subtle, aerial fluid, the motions and vibrations of which produced all the effects which they observed. But further supposition, different phlogiologists explained the mode in which this gratuitous fluid operated. Borri fancied that there might be oblong valves in the fibres of the nerves and muscles, which were rendered spherical by the force of the nervous fluid, and therefore shorter. Others imagined that the influence of the nervous fluid separated the parallel fibres of the muscles from each other, and thus shortened the length of the whole. But it were useless to enumerate the various futile hypotheses, which originated in an erroneous philosophy. All that we know on this subject is, that some of the muscles of the body contract, in a state of health, by the will of the mind, as those of the trunk and extremities, others, apparently without the intervention of an act of volition, although subject in a great measure to the will, in consequence of a local sensation; as the diaphragm, and the other muscles of inspiration; the eyelids, in *scleritis*, and others, again, are excited to contraction, together independently of the will, by an irritation so obfuscated, as to excite no perception in the mind; as the heart, which continues its unperceived motions, in consequence of the irritation or stimulus of the discharging blood, which is returned into its cavities by the vena. The contractions, produced by one or other of these causes, are regular in force and velocity, according to the degree of excitement; and are always followed by a state of relaxation; and are not repeated, except when the will or the irritations again operate. In the morbid or convulsive state, the contractions of the muscles, ordinarily depending on the will, are excited without the concurrence of the will, or in a way contrary to what the will intends; and in the other instances, they are excited disproportionate to the action of the usual and natural irritations. Hence it may be concluded, without any gratuitous hypothesis, that when these convulsive motions are excited, independent of, or in opposition to, the will, some change in the condition of the seat of volition, the brain, and its elongation, the nerves, has occurred; and, if the convulsions are partial, that some great local irritation has been applied.

Now, although it be confessed that the actual condition of the brain, which occasions convulsions of the moving fibres, be unknown, as well as its condition and mode of operation...
operation in health; yet certain conditions of the body, in general, have been observed to be connected with the occurrence of convulsions, which lead to a knowledge of the state of the brain in the groans, and serve as valuable guides in our practice in these diseases.

Convulsions have been chiefly observed to occur, when the body is in a state of repletion, insomnian, or great irritation. It may seem inexplicable, that the two opposite conditions of repletion and insomnian should give rise to similar morbid appearances; but the knowledge of the fact, which is established beyond a doubt, is sufficient for our practical purposes. We shall illustrate the operation of each of these states in producing convulsive diseases.

1. Repletion of the system at large, or of the brain in particular, is a state in which convulsions frequently occur. Numerous instances are on record, in which epilepsies have occurred, where a general pellagic state of the constitution was present. Epileptic convulsions have sometimes succeeded apoplexy, which is known to originate in over-turgescence of the brain. Every occasional fulness, or unusual impulse of the blood into the veins of the brain, such as from a fit of anger, the heat of the sun, or of a warm chamber, violent exercise, a surfeit, or a fit of drunkenness, are frequently the immediate exciting causes of convulsions. (Cullen. Puet. Lines, § 1296.) Hence also, in inflammatory fevers, as in the eruptive fever of the small-pox, where the blood is carried to the brain more abundantly, and with greater impetus than in health, convulsions are frequently produced; especially where the circulation is hurried by a hot regimen. The supposition of accustomed discharges, or the omission of habitual evacuations, have also been the occasion of convulsive affections, in consequence of the general plethora which ensues. But the most marked and striking influence of convulsions, induced by repletion, occurs in the puerperal state. They generally come on in the early state of labour, and are attended with fulness and dilatation of the features, and other obvious marks of determination of blood to the head; they speedily cease when the delivery is accomplished, if they do not prove fatal before that takes place; and copious blood-letting is the only effectual remedy. In all these instances, indeed, which have just been mentioned, the good effects of evacuating medicines, of a spare diet, and cool regimen, in removing the diseased state; and the bad consequences which have ensued, under the employment of an opposite treatment, point out repletion as the cause of the mischief. This is also, still more clearly ascertained from the diffusion of those, who have died in consequence of convulsions, occurring under such circumstances; marks of a conjunction in the brain having been generally observed. See Ehepsys.

2. Insomnia is a frequent cause of convulsions. It has been observed from the earliest ages, that convulsions invariably proceed death, when it is occasioned by loss of blood; and the fact is daily exemplified in slaughter-houses, when animals are killed by opening the large blood vessels. Hippocrates states, in his Aphorisms, Sect. v. Aph. 7, that convulsions, or hicouges (which is, in fact, a convulsion of the diaphragm), succeeding a great hemorrhage, are dangerous, and he repeats the observation in Sect. vii. Aph. 9. From this cause convulsions sometimes occur in the puerperal state, where great hemorrhage from the uterus has occurred. But in such instances, the countenance, far from being flushed, with a fulness of the features, is pallid, and the features are sharp and sunk; there are cold sweats, and other symptoms of exhaustion, which mark the diminution between this form of convulsive disorder, and the proper puerperal convulsions, mentioned under the former head. In these convulsions from inanition, the contrary remedies, cordials, and powerful stimulants, largely and frequently administered, afford the only means of saving life. "Si fluxui mulchcri, fays Hippocrates, "animi diliquum et convululo supervenient, malum." Sect. v. Aph. 65. Other great evacuations also excite convulsions; such as great discharges from the bowels by purging. In the early periods of the history of medicine, when the limited catalogue of the materia medica debared the physician from the choice of expedites, according to the circumstances of the case, it would appear that this unfortunate consequnce of a violent purgative was by no means uncommon, since we find it often alluded to by Hippocrates. "Convulsion from Hel- lebore is fatal." Sect. v. Aph. 1, and again, he observes, in Sect. vii. Aph. 25; "Convulsions from a purgare are fatal." Happily the numerous articles of mild operation, which we now possess, render such an occurrence unknown to the physicians of modern times. Convulsions have been, likewise, observed to occur, in consequence of exhaustion of the animal powers, by other means; such as by excessive fatigue; by want of food; by long continued and severe mental exertion; &c. The cure of convulsions, occasioned by inanition, from any of the causes just stated, will obviously consist, in the use of such remedies as will put a stop to the evacuations; in the administration of cordials and stimulants, to counteract the prevalent failure of the vital powers; and in the employment of moderate quantities of a cordial and nutritious aliment, to restore the masts of circulating fluids, and the strength of the body. Rest, food, and relaxation, will be the remedies required in the last-mentioned instances.

But 3, Irritation, corporeal and mental, is the most fruitful source of convulsions. The degree of corporeal irritation, which is sufficient to occasion convulsions, varies greatly; not only according to the peculiarities of age, and constitution, but according to the part to which it is applied, and sometimes according to circumstances, which are not obvious. Sometimes the irritation amounts to severe agonizing pain; more commonly to a moderate degree of uneasiness; and frequently, it is such as to excite no perception: sometimes it is a titillation, or attended with feelings on the whole pleasurable. It may excite convulsions of the muscles in general, when applied to the brain itself; or to other parts of the body, as to the bowels, flomach, kidneys, and other viscera; to the gums, the skin, and the organs of sense.

Convulsions are among the most common symptoms of irritation of the brain itself, either from external or internal causes. Thus they are frequently excited by blows, or wounds, on the head; by fractures of the cranium when a portion of the bone is depressed, or fragments of it are driven in upon the membranes of the brain; by effusions of blood, lymph, serum, and pus, in the vitreous or on the surface; by Bony excrescences from the internal surfaces of the skull; or by tumours, thickening, or abscusses, in the membranes or submucous of the brain. Mechanical injuries of the nerves, which are elongations of the brain, have also given rise to general convulsions.

Irritations of parts distant from the seat of sensation and voluntary motion, produce the same effects. Thus wounds of the skin, and of the muscles and tendons in the extremities, occasion the most painful and fatal of all convulsive affections, the tetanus: and it is remarkable, that it is not a large discharging wound, which in general excites this disease; but a superficial injury, or a wound just healing, when the irritation would seem to be less powerful. In this disease, all the antagonist muscles of the body are feixed
feized at once with a convulsive action, so that the trunk and limbs become perfectly rigid, and the jaw is locked. Sometimes the muscles of the back overpower their antagonists, the body is then bent backwards like a bow, and the patient rears on the head and the heels; this state is termed spilhstoton. Sometimes, on the contrary, the action of the abdominal muscles is most powerful, and the body is then bent forwards in a similar manner; this condition is called emprophstonos. (See those articles.)

Several instances of convulsions are related by authors, in which flowers, of sharp and irregular figures, were found after death in the urinary bladder, or thickening in the pelvis of the kidney, or in the course of the ureters. In others, convulsions, which had occurred in consequence of ch ris irri-

irritations, ceased upon the discharge of calculi with the urine.

Irritations in the alimentary canal are very frequently the cause of general convulsions, more especially in young children. In children, indeed, it has been said that convulsions are not to be considered so much a disease themselves, as the indication of disease in the bowels, or other parts. (Med. Obs. and Inq. vol. iii. p. 292.) The presence of worms, of undigested aliment, of morbid secretions, or even a retention of the natural faeca, by contumacy, are common causes of convulsions at an early age. The retention of the meconium is said to occasion the locked jaw of new-born infants, in warm climates, the trifurmis nasilenium of authors. Some children, in fact, are so irritable during the first five years of their life, as to be thrown into convulsions by very slight causes of irritation; a disposition which is only removed, as the constitution becomes strengthened by age. The irritation of the rising teeth, when the gums do not readily yield to their pressure, has been frequently observed to excite convulsions in children, which were removed on the appearance of the teeth above the gum, or by the division of the gum by means of a lancet. For it is remarkable, that the greater temporary irritation of a cutting instrument is borne, without any convulsion being excited, while the constant uneasiness of the irritating tooth had frequently been productive of the convulsions. In the same way, when convulsions are occasioned by the irritation of worms, or of undigested food, in the intestines, the additional irritation of a cathartic medicine shall not increase the convulsive affection, which ceases, when its operation is over. In the treatment of the convulsions of children, where the irritating cause is obvious, but cannot be instantly removed, the convulsive motions may be frequently suspended in the mean time, by immersion in the warm bath, by warm fomentations, or by the use of a small dose of an opiate, proportioned to the age and strength of the child, and the violence of the disease. But such measures are only palliative; the radical cure will depend upon the removal of the cause of irritation.

In situations of peculiar irritability, certain irritations of the organs of sense have given rise to convulsions. Thus in regard to the sense of touch, a cafe is related by Van Swieten in which titillation of the fleshes of the feet of a young girl, excited convulsions: he also mentions instances of the same effects being produced by a sudden exposure to great light, or great noise; a boy was thrown into convulsions by the unexpected sound of trumpets. Certain powerful odours have occasioned convulsive motions when applied to the organ of smell. It seems to have been a custom formerly, says the author just mentioned, for those who purchased scents, to try them with the smell of the jet-flame, in order to discover whether they were subject to the epilepsy. Arctatus has remark-
ed that by this odour the epileptic paroxygm was excited; and Apulus, who was accused of magic, in pleading his own cause, made the following observation. "But if I wanted to throw down an epileptic person in a fit, what need could there be for a charm to do it? seeing the jet-flame, when it is burnt, as I read in physical authors, inflames this disease itself; and by the smell of it they commonly try the health of the slaves in the markets." Van Swieten. Com. § 107.

Many poisons, especially the vegetable poisons, by their action on the nervous system, when taken into the stomach, produce the most terrible convulsions. The chinin a quantity, or water-hemlock, is said by Wepfer to have been eaten by several children, who mutilated the roots for parching; they were all seized with severe convulsions, which proved fatal to two of them; the rest having been made to vomit, and eject the poison from the stomach, speedily recovered. Thus vegetable narcotics, even opium itself in an overdose, have produced similar effects.

Mental irritations, or violent emotions of the mind, frequently give rise to general convulsions, especially in females, and those of hysterical habits. The influence of the mind on the body is too obvious to require much illustration. The actions of the heart, the circulation of the blood, and the functions of the visceras, are variously modified by emotions of the mind, and no organ is more fully affected by them in its functions than the brain itself. Different emotions seem to affect the system in different and even opposite ways; some routing it to actions of unusual vigour, quickening the circulation, and strengthening the powers of volition; others, again, paralyzing its strength, and giving languor to all its motions. Hence the poisons have been divided into two classes, exciting, and depressing poisons. Now these opposite poisons, which seem to produce the same effects as repetition on the one hand, and inanition on the other, alike excite convulsions of the body. This may be exemplified in the leading poisons, anger, and fear, both of which are occasionally the causes of convulsions. In a man under the influence of the excitement of anger, the heart beats with greater force and celerity; the pulse is fuller, stronger, and swifter; every part swells and grows broader; a greater heat over- spreads the whole body; almost every muscle is extended; the eyes are prominent from their sockets, and look fierce and sparkling; being charged with blood. These symptoms imply a corresponding fulness and force in the vessels of the brain, which, when carried to a certain extent, induce convulsions. On the contrary, a man under the des- pression of fear, grows pale and cold, and shrinks in every part of the body; his pulse is quick, but small and unequal; the heart palpitates; the lungs are oppressed, and sobs and sighings follow; his strength fails him; his whole body trembles, and he is fearfully able to articulate. These phenomena shew a depression, a collapse of the powers of life, resembling that which occurs from inanition, and, like that, producing sometimes a general convulsion. See Swieten Com. in § 104. Many examples might be quoted of the convulsive attacks occasioned by these passions, and especially by fear. We shall mention one instance from the latter cause; for the sake of illustrating the effects of another principle, the affection of ideas, in re-excitign convulsions, thus originally produced. A boy was so much frightened by a large dog jumping upon him, that he precociously fell down attacked with epileptic convulsions: afterwards, the paroxygm was brought on by the sight of any large dog, or even by hearing him bark. This effect of affection is frequently observed in a minor degree; thus, any substance used as a vehicle for an enetic medicine will, in some per-
CONVULSIONS.

from, when taken alone, excite sickness for some time afterwards. Van Swieten affirms that he has seen a person, who, after having frequently taken a nauseous purging draught, upon seeing the cup out of which he took it, not only shuddered, and became squeezing, but likewise had several ftools; thus the sole idea of a nauseous remedy being renewed, toppled the place of a purge, and disturbed the whole body. Comment, in § 1075.

There is another prolific source of convulsive affections, which must not be overlooked in determining the mental causes of these formidable disorders; namely, the principle of imitation. This principle sometimes operates alone; sometimes its operation is combined with an impression of fear: and sometimes with various other strong impressions made on the imagination. This involuntary imitation is the source of almost all that is learnt in infancy; and its importance in the formation of character, has been well illustrated by Dr. Aikin. See Athenæum, No. xin. Jan. 1828. In after-life we all experience its operation, in the irresistible propensities to yawn, to laugh, to weep, with others. Hence much of the effect of theatrical representations, especially crowded audiences: hence also the facility with which a panic spreads among an army of soldiers; and hence the power, on the one hand, and the cowardice, on the other, of a mob. This tendency to receive impressions and emotions involuntarily from others, and more especially, when they are accompanied with corporal motions, and the tendency to repeat those motions involuntarily ourselves, are principles rooted in the human constitution; and upon them much of the history of insurrections, and also of the propagation of religious enthusiasm, depends, as well as the minor circumstances of convulsive diseases.

Every physician has witnessed the effect of the sight of an hysterical convulsion, on other women predisposed to that disease. It is not uncommon to find several women thus convulsed, one after the other, from this cause. We have even known the scream of one woman, feized with an hysterical paroxysm, excite convulsions in another, who heard it in a different room. The well-known cases which occurred in the orphan-hospital at Haerlem, under the care of Dr. Boerhaave, shew the extensive operation of this principle, and also that these imitative attacks may be effectually prevented, by exciting a strong counter-impression in the mind. That celebrated physician, finding that epileptic convulsions, which had occurred in one boy, attacked, one after another, all the boys who witnessed the paroxysms, by threats of inflicting severe bodily pain on the flirt who should be attacked with these fits, succeeded in preventing the recurrence of the epilepsy.

This principle is still farther exemplified in the epidemic convulsions which have occurred at different times in different countries. In several districts of Scotland such epidemics have frequently appeared. The Rev. W. Archibald, parochial clergyman of Unit, the most northerly of the Shetlands, gives the following account of epidemic convulsions which occurred in his parish, "There is a shocking distemper, which has of late years prevailed pretty much, especially among young women, and was hardly known thirty or forty years ago. About that period only one person was subject to it. The inha masts give it the name of convulsion fits; and indeed, in appearance, it something resembles an epilepsy. In its first rise, it began with a palpitation of the heart, of which they complained for a considerable time; it at length produced swooning fits, in which people feized with it would lie motionless upwards of an hour. At length, as the distemper gathered strength, when any violent passion feized, or on a sudden surprise, they would all at once fall down, toss their arms about, wring their bodies into so many odd shapes, crying out all the while most dolorously, throwing their heads about from side to side, with their eyes fixed and staring. At first this distemper obtained in a private way with one female, but being foretold in a public place at church, the distemper was communicated to others, but whether by the influence of fear or sympathy is not easy to determine. However this was, our public assemblies, especially at church, became greatly disturbed with their outcries. This distemper always prevails most violently during the summer-time, in which season, for many years, we have hardly one Sabbath free." The Rev. Mr. M., giving an account of a similar epidemic in his parish of Delting, says, "It most commonly attacks them when the church is crowded, and often interrupts the service in this and many other churches in the country. On a sacramental occasion, fifty or sixty are sometimes carried out of the church, and laid in the church yard, where they struggle and roar with all their strength for five or ten minutes, and then rise up without recollecting a single circumstance that happened to them." Stat. Acc. Scotland, vol. i. p. 585. See Edin. Med. and Surg. Journ. No. xi. In another parish, Northmaven, a cure is said to have been effected, as in the hospital at Haerlem, by a strong counter-impression upon the mind. "The cure is attributed to a rough fellow of a Kirk-fleer, who told a woman in that flate, with whom he had been frequently tempted, into a ditch of water. She was never known to have the disease afterwards, and others dreaded the like treatment." Stat. Acc. vol. xii. p. 565.

A similar prevalence of convulsive affections, which occurred on the estates of the earl of Uxbridge and Holland Gibb, &c. in the isle of Anglorska, was checked by the judicious precautions recommended by Dr. Haygarth, from a knowledge of the principle which we are illustrating. He advised that all girls and young women should be prevented from any communication with persons affected with those convulsions, and that those who were ill should be kept separated as much as possible. See Treatise on the Imagination as a Cause and as a Cure of the Disorders of the Body, Bath, 1780.

This principle of imitation, especially when the imagination is strongly excited by images of terror or superstition, has been referred to by designing men for the purposes of impressing on the public credulity, with a view to their own profit. Upon this was founded the success of Melmer, De Mainaudne, and other empirics, in the disgraceful practice of animal magnetism, as it was called; the nature and imposition of which were fully detected and exposed by the commissions appointed by the French king for the purpose of investigation. The celebrated Dr. Franklin was one of those commissioners, and his report has fully developed the mystery of the magnetisers. By the aid of circumstances, of situation, g. com. &c. and by their own enthusiasm, they gradually worked on the minds of their company, who were already predisposed to receive any impression, for they did not operate on single individuals, until they brought them, mind and body, to a state of extreme irritability; then, alluming extravagant gestures and violent motions, the speculators were led to an involuntary imitation, and as soon as one of the party showed any symptoms of violent or convulsive exertion, the rest were speedily affected in the same way. This was called the crisis, and the operation was considered as complete. Dr. Franklin shewed, that, without the aid of local circumstances, of numbers, &c. the powers of the magnetiser amounted to nothing.

It were unnecessary to pursue this illustration farther, or it
might be shown that the propagation of religious enthusiasm and fanaticism is effected by the same means; is frequently connected with convulsive motions, or frantic gestures, amounting nearly to convulsions; whence we find jumpers, whippers, and originally quakers, as the distinguishing appellations of sects; and that it depends much upon the contagion of the principle of imitation among crowded assemblies, for its success.

But to return to the subject of convulsions, more strictly within the sphere of pathology. We have mentioned the indications and means of cure, in most cases, as they occurred. In convulsions, which come under the two first heads, as arising from relaxation and inattention, it must be obvious, that an exculcating system must be adopted, and the contrariety of system of support and nutrition, in the second.

The individual expedients to be adopted, on either of these occasions, will readily suggest themselves, according to the peculiar circumstances of the case. In convulsions, which arise from irritation, the discovery and removal of the irritating cause, where it is of a nature to be removed, is not less obvious requisite for the cure. But in the mean time, before any of these intentions can be fulfilled, the violence of the convulsive motions may continue, so as to injure the body, or destroy life. It is desirable, therefore, that some palliative measures should be adopted; and these are chiefly the use of medicines of the antipalpmonic class, such as opium, maff, ether, and other powerful stimulants; the use of the warm bath; or of the opposite expedient, the cold bath. Of these remedies, with the exception of the last, little is required to be said; the efficacy of the former being well understood. But as the cold bath is a powerful expedient, and can be often resorted to more speedily than the others, it may be necessary to mention the nature of its powers.

Dr. Currie, from an experience of eight years, afferts that the cold bath is very efficacious in removing the convulsions of children, whether the disorder originates in worms or other causes; that it seldom fails in stopping the paroxysms, at least for some time, thereby giving an opportunity of employing the means fitted to remove the particular irritation. Several cases of tetanus have also been cured by the cold bath of late years. In the convulsions of hysteria, the cold bath, or indeed a plentiful affusion of cold water, is an almost infallible remedy. Dr. Currie observes, that the efficacy of the cold bath in convulsive disorders is the greatest, when it is employed during the precence of the convulsion; and also that it is of greater efficacy in general convulsive affections, than in those which are only partial. In chojen functi Vit.i, for instance, it has been frequently tried without any success. See Currie, Reports on Water, &c. Append. p. 13. ffeg.

Where the source of irritation is not discoverable, besides these palliative means, other medicines are commonly employed to give strength and vigour, and to leffen the irritability of the moving fibre, so as to render it less susceptible of being excited to extraordinary action. The various articles of tonic and corroborant medicine have been administered with this view, but most frequently, the metallic salts and oxides; as the sulphates of zinc, and iron, and copper; the oxide of zinc; and even the caufic nitrate of silver has been employed in small doses.

CONVULSIVE DISEASES, those diseases in which convulsions are the leading symptoms. See Convulsions. These diseases have received different appellations, and also require different methods of treatment, according to the varieties of their form. Some confiit of general convulsions of the whole muscular system, as tetanus, epilepsy, some forms of hysteria, &c.; others are distinguished by the con-

vulsions being confined to particular parts, as trismus, when the muscles of the jaw are affected with spasm; chorea, or St. Vitus' dance. Hiccough, and even cough, may be considered as partial convulsions. See these articles respectively.

CONVULSIVE AILMENTS. See Asthma.

CONWAY, in Geography, a river in North Wales, called by Ptolemy and Antoninus. Kynew, in the ancient British language, signifies the great river, from which are derived the words Conway and Conwy. This stream, considered one of the most in Europe, rises in the mountains of Pennine, north of Llyn Conway, and is navigable for small vessels to Llanrwst bridge; erected by Inigo Jones with a centre arch 60 feet wide (see Canal); but receiving many tributary streams in the course of 12 miles, it becomes sufficiently deep to bear ships of considerable bulk, and is nearly a mile in breadth at high water, but not more than 150 feet at low water, and eight feet deep, at the ferry opposite the town of Conway, beyond which it flows into the Irish Sea. The spring tides vary from 1.1 to 18 feet; consequently vessels of 400 tons burden may approach close to the town: nevertheless the shifting land-banks make the entrance of the port dangerous. The mya margaritifera of Linnaeus, or pearl mucle, made the river of importance previous to the Roman invasion. Such was its celebrity, that Saxonius acknowledged the pearl-fishery of the Conway to have been one of his inducements for undertaking the subjugation of Wales. According to Pliny, the mussels, called by the natives bregindlia, were fought for with avidity by the Romans, and the pearls found within them highly valued; in proof of which it is asserted, that Julius Caesar dedicated a brass-plate, set with British pearls, to Venus Genetrix, and placed it in her temple at Rome. A fine specimen from the Conway is said to have been presented to Catharine, comfort of Charles II., by sir Richard Wyne of Guedir; and it is further said, that it has since contributed to adorn the regal crown of England. Lady Newborough possesses a good collection of the Conway pearls, which she purchased of those who were fortunate enough to find them, as there is no regular fishery at present. The late sir Robert Vaughan had obtained a sufficient number to appear at court, with a button and loop to his hat, formed of these beautiful productions, about 28 years past.

CONWAY, or ABERCONWAY, an ancient town of Carnarvonshire, North Wales, is situated on the river Conway, near its confluence with the Irish Sea. This place does not appear to have acquired any confluence till the time of Hugh Lupus, earl of Chester, who fortified the mouth of the river about the year 1098; and it obtained more distinguished importance during the reign of Edward I., who enlarged the fortifications, and erected a very strong castle in 1284. The outline of this venerable and romantic place is triangular, and is still surrounded with embattled walls. These are erected in many places upon solid rocks, and are one mile and an half in circumference; they have four gates, and were defended by 24 ballins; in addition to which, two curtains projected into the river, where they terminated with watchtowers: but these and one of the former have fallen. Edward I. evinced great skill in continuing the defensive works of Conway, and particularly by erecting his fine pilla on the base of the triangle next the river, where nature had placed a vast perpendicular rock of slate. He thus protected England from the incursions of the Welsh, who were commanded by Llewelyn; and afforded himself and successees an impregnable post for collecting the means of invasion, when an opportunity offered for entering Wales with any prospect of success. By this castle he laid it in his power.
to occupy the neighbouring pasts of Penmaen-Mawr at pleasure, and by that means to cut off all communication with the interior of the principality: and yet this fortress had once nearly cost him his crown, in proceeding to it at the head of his army. On this occasion, Edward inequitably crossed the river Conway with a few attendants, and was separated from the town by the flowing of the tide. At this critical moment the Welsh attacked the castle; but although the monarch and his little band of soldiers were delirious of every refreshment, except honey and water, they had the bravery and address to refit their opponents, till the ebbing of the tide. Richard II. took refuge in this castle, on his return from Ireland in 1397, and was delivered from the power of his enemies from it, through the treachery of the Duke of Northumberland. During the civil war, Charles I. particularly resolved, Williams, archbishop of York, to put the castle in a complete state of defence, for his use, and pledged his honour that the custody of it should remain with the prelate, or any person he thought proper to appoint, till the sum expended was repaid. When the repairs were accomplished, Williams placed the castle under the government of his nephew, William Hooker. The neighbouring gentry, conceiving it a secure depositary, sent their most valuable writings and plate to the keeping of the archbishop and Hooker; the former giving his receipts, and making himself responsible in case of loss. About a year afterwards, colonel Sir John Owen obtained the appointment of governor of Conway castle from prince Rupert, and, proceeding suddenly to the place, ejected the prelate and his adherents, who were positively denied permission to remove the articles, for which receipts had been given. Greatly irritated at this unworthy conduct, Williams vainly applied to the court for redress. Yielding at length to the representations of general Mytton, who commanded the parliament's army, he adopted their caulk, and fortified his own house, which was garrisoned by Mytton's troops. A conflict soon afterwards occurred, in which the prelate was wounded in the neck. After the ravage of the civil wars, a grant was made of it to Edward, earl of Conway, who, in 1665, demolished the buildings. At present it is held by a private proprietor under the crown. A little hill is planted and laid out towards the mouth of the river, commanding a fine view of the town and castle on one side, and the sea on the other, to which is given the classical name of Arcadia. The ruins are still uncommonly magnificent, and bounded by the river, a creek, and the town. The walls are not greatly injured; and eight vall towers, surmounted by turrets, are yet standing. In one of these is an oriel window, richly ornamented, where the toilet of queen Eleanor is said to have stood, at the period when her lord made the castle the scene of his hospitality: another of the towers, undermined by the inhabitants of Conway, split asunder, and a vast fragment fell upon the beach, where it lies, a wonderful specimen of ancient masonry. The hall, erected over extensive vaults, is lighted by fixed windows towards the country, and three towards the opposite side. Six of the eight pointed arches of the roof are yet entire. The length of the hall is 139 feet, and the breadth 52. The castle is now held from the crown by O. Holland, esq., who pays a rent of 62. 8s., and is bound to furnish lord Hertford with a dish of fish, whenever he passes through Conway. However commanding and beautiful the town appears without the walls, the contrast within is melancholy in the extreme, where ruins and defoliation prevail in every direction. Edward I., when he passed a Christmas here with his queen Eleanor and the whole court, erected the place into a free borough, and the mayor was constituted constable of the castle. The present government is composed of an alderman, recorder, coroner, water bailiff, &c. Mr. Evans mentions, in his "Tour through North Wales," an old house situated in Castle-street, called the college; with a curious window, and several coats of arms of the Stanleys; and another of large dimensions, named Pen Mawr, built in 1582, by Robert Wynne, esq., of Gwydir, which he resupposed, from the inscriptions on the front, to have been erected for charitable purposes, particularly as there are many rude badges within, (probably of contributors); and the supporters of the arms of Dudley, earl of Leicester, decorate the walls and ceiling. The only religious structure in Conway was an abbey of Cistercian monks, founded by prince Llewelyn ap Jorwerth, and the son of Edward I., who was slain before his body remained till the dissolution of the monastery, when it was carried to Llanrwst. Edward I., conceiving the monks improper inmates of his fortress, removed them to a new abbey, which he erected near Llanrwst, but did not deprive them of their privileges and endowments. Their old church was then made parochial, and the presentation granted to the abbot and convent, on condition they provided three chaplains, two of whom were to be Englishmen, and the third a Welshman; one of the former received the title and office of vicar, and, after having been named by the convent, was to be presented by the diocesan. The church of the original foundation is situated in the centre of the town; but it is more remarkable for its remote antiquity, than any beauty in the form or decorations. Cynap ap Owen Gwynedd was buried in this church, 1223; and there are at present several modern monuments of the Wynne family: one of the inscriptions within it records the interment of Nicholas Hooker of Conway, gentleman, in 1637, who is said to have been the 21st child of his father, by his wife Alice, and the father himself of 27 children. The tithes of the church are vested in three trustees, for the benefit of the poor of the town, and three villages in the neighbourhood: indeed the want of trade and manufactories renders the lower classes truly wretched, many of whom obtain a miserable subsistence by collecting and burning into barilla, on the beach, different species of fuel or sea wreck, which is sold for trifling sums to the purchasers, who make a great profit on their labour. The inconsiderable trade now carried on consists of cooper, lead, calamine, and potatoes for exportation; but little or nothing is imported. As Conway has hitherto been the great thoroughfare to Ireland, the inhabitants derived much advantage from the passengers; but the new road through the Owyaun mountains will soon rob them even of this support. Hills of lime-stone abound near this town, and some lead and copper mines, having chert, or a species of black hornstone for a matrix. In a black hinds mountain here marls of porons chert are found; which, on trial, are found as fit for making our mill-stones as those imported from France. Mr. Richard Bowes, who made this discovery, and sent specimens of the marl to the Society of Arts, was rewarded by that patriotic body. See their Transactions, vol. viii. p. 197. Situated 240 miles N.W. of London. Population in 1851 was 889; the number of houses 182. Bingley's and Evans's Tour in North Wales.

Conwy, a township of America, in the province of New Brunswick, Sudbury county, on the western bank of St. John's river. It has the bay of Fundy on the south; and at the westernmost point of the township there is a tolerably good harbour, called Musquash Cove.—Alfo, a township in the N.E. corner of Strafford county, New Hampshire, on a bend in Saco river, incorporated in 1765; and containing 574 inhabitants. It was called "Pig-wacket," by the Indians.—Alfo, a thriving township in Hampshire county, Massachusetts, incorporated in 1767, and containing

Conway, Cape, a point of land on the east coast of New Holland, so called by Captain Cook in 1770, and lying in 8° lat. 26° 36'. W. long. 211° 28'; between which and Cape Hillborough is a bay, which the name navigator called Raffee Bay. Within this cape there lie two or three small islands, which serve to shelter that side of the bay from the southerly and south-easterly winds, that seem to prevail here as trade-winds. Among the many islands that lie upon this coast, called by Cook Cumberland Islands, one is more remarkable than the rest; it is of small circuit, very high, and peaked, and lies E. by S., 10 miles from Cape Conway, at the utmost end of the passage. This passage is from three to seven miles wide, and eight or nine leagues in length, N. by W. 1/4 W., S. by E. 1/4 E. It is formed by the main on the west, and by the islands on the east, one of which is at least five leagues in length. The depth of water, in running through it, was from 20 to 25 fathoms, with good anchorage everywhere; and the whole passage may be considered as one safe harbour, exclusive of the small bays and coves which abound on each side, where ships might lie as in a haven. The land both upon the main and the islands is high, and diversified by hill and valley, wood and lawn, with a green and pleasant appearance. This passage, being discovered on Whitunday, was called Whitunday Passage.

Conya, a river of South America, in Surinam, or Dutch Guiana.

Conybear, John, in Biographia, a celebrated English prelate, born in the neighbourhood of Exeter, and educated at the free-school in that city, from whence he was admitted to Exeter college, Oxford, where he applied himself so diligently to his studies, that, in 1710, when he was but 19 years of age, he was chosen probationary-fellow upon Sir William Petre's foundation. He obtained the several degrees with reputation, and was ordained priest in 1716. During the next year he officiated as curate at Fetcham in Surrey. Upon his return to Oxford, he became tutor to his own college, and gained much celebrity as a preacher. He was afterwards appointed by Dr. Gibson, bishop of London, to the situation of one of his majesty's preachers at Whitehall. In the year 1724, lord chancellor Macclesfield presented him with the rectory of St. Clements, Oxford; and in 1728, he took the degree of bachelor, and in the following year, that of doctor in divinity. In 1730, he was elected to the high and arduous office of master of Exeter college; and in a short time he undertook, at the desire of the bishop of London, and published a very excellent answer to Tindal's "Christianity as old as the Creation," under the title of "A Defence of revealed Religion against the Exceptions of a late Writer, &c." This was published in 1732; and before the end of that year he was raised to the office of dean of Christ-church. He now resigned the headship of his college, and speedily the rectory of St. Clements; and in 1734, he had the honour of entertaining, at his own apartments, the prince and princess of Orange, and of receiving the thanks of queen Caroline for his conduct on that occasion. From this period, to the year 1750, Dr. Conybear received no additional prebend; he was then appointed to the bishopric of Bristol, which, though it increased his dignity in church pretenion, was no addition to his fortune. This high honour was followed by a long train of ill-health, which terminated his valuable life in the year 1755. "The good prelate left behind him a truly estimable character; he fulfilled all the duties of life with honour to himself, and for the advantage of those connected with or dependent upon him. Zealously attached to the church, of which he was a distinguished member, he was, at the same time, candid and liberal towards protestant dissenters, with some of whom he had been educated, and with others he maintained an occasional but friendly correspondence through life. Two years after his decease, were published, for the benefit of his surviving relations, sermons in two volumes, 8vo. The very numerous list of subscribers who patronized this undertaking, flew in what high public estimation Dr. Conybear was held by his contemporaries."

Gen. Ch. Common calyx either imbricated, or in several nearly equal ranks. Cor. Florets of the dish hermaphrodite, numerous, tubular, funnel-shaped; border five-cleft, pataulous; florets of the circumference female, either apetalous or funnel-shaped, not composing a ray; border generally three-cleft. Stam. Filaments five, very short, capillary, anthers united into a hollow cylinder. Pist. in the disk. Germ oblong; style filiform, length of the flaments; stigma two-cleft; in the circumference fylces and stigma more flender. Seeds oblong; down simple. Recept. naked, flat.

Eff. Ch. Seeds of the calyx imbricated, or in several nearly equal ranks. Florets of the circumference female, apetalous, or funnel-shaped, with a three-cleft border, not composing a ray. Down simple. Receptacle naked.

* Leaves not docurrent.

* Herbaceous.

1. C. squarrosa. Linn. Sp. pl. 1. Matt. 1. Lam. 1. Wild. 1. Lam. fl. pl. 697. fig. 1. Gart. tab. 166. Eng. Bot. 1195. Flor. Dan. tab. 622. (C. major vulgaris; Bauh. Pl. 265. Tourn. 454. C. Matthiolii, baccarum Monspel- lium; Cluf. Hift. 2. 21. Lob. ic. 574. Blackw. tab. 102.) Great fleabane, or Plowman's spikenard. "Leaves ovate-lanceolate, downy; stem corymbous; calyx-scales falcate, recurved, and prominent." Root biennial, branched, and fibby. Whole herb soft and downy, in flavour bitter, and somewhat aromatic. Stem two or three feet high, erect, angular, leafy, but little branched, many-flowered. Leaves alternate, somewhat crenate, upper ones often entire. Flowers yellowish; calyx egg-shaped; outer scales green, recurved; inner ones reddish, erect, ciliated. Stigma angular; down falcate. Receptacle tuberous. A native of England, and other parts of Europe, on a dry calcareous soil. 2. C. linifolia. Linn. Sp. pl. 2. Matt. 2. (After dracunculoides; Lam. After foliago-noides; Wild. After americanus albus, mar 1 arabum exasperatia foliis; Pluk. aln. 36. tab. 79 fig. 2.) "Leaves linear-lanceolate, quite entire; corollas rayed." Stems a foot or a foot and half high, erect, hardy, green. Leaves resembling those of mezereon or hyssop, more observing, smooth, and hisp. Flowers on short terminal peduncles; floras white, fleshy, reflexed. Its radiate flower certainly excludes it from this genus; but as it is not infested in our work after After, we have retained it here. A native of North America. 3. C. jobria. Linn. Matt. 113. Matt. 7. Wild. 2. "Leaves oblong; somewhat toothed, saccate, falcate; peduncles one-flowered, elongated." Leaves rugous on both surfaces, four or five teeth on each side. Peduncles axillary, at the top of the branches, becoming finally six times the length of the leaves. A native of the East Indies. 4. C. symphytoides. Matt. 35. Houfion MSS. "Leaves oblong; egg-shaped, falcate; flowers in terminal racemes." Root perennial. Stem three feet high. Leaves four or five inches long, one inch and a half broad in the middle, rough, like
CONYZA.

like thole of comfrey. Flowers yellow; on branched peduncles. Sent by Dr. Houton to Miller from la Vera Cruz. 5. C. fabifolia. Willd. 7. "Leaves oblong, nearly entire, half embracing the item; peduncles one-flowered, finally much elongated." Stem much branched, diffuse, downy; branches thick set with leaves. Leaves alternate, downy on both surfaces. A native of the East Indies. 6. C. panulis Mart. 37. Willd. 4. Hort. Kew. 3. 133. "Leaves plane, terminal, villos under; calyxes somewhat glabrous; scales lanceolate, 3-angled; bracts spreading." Stem annual. Stem foot and half high, taper, slightly covered with a mealy down. Leaves about four inches long, and two broad in the middle, diminishing gradually in size on the upper part of the stem and branches. Flowers purple; peduncles at the end of the branches generally three-flowered; calyxes soft and swollen in the middle; foliis small and acute. A native of the northern parts of China, producing a succession of flowers from July to the end of autumn. 7. C. paniculata. Willd. 5. "Leaves oblong, soft, downy on both surfaces; lower ones petiolate; toothed; teeth reflexed; item panicled; corystes peduncled, axillary. Stem four feet high, about the thickness of a man's quill, erect, cylindrical, hollow, striated; branches alternate, erect, fine. Leaves on the stem petiolate, on the branches sessile. Calyx fleshy linear, 3-angled, spreading, reflexed. A native of the East Indies. 8. C. bifrons. Linn. Sp. Pl. 7. Mart. 9. Willd. 6. (Epapatora conyzoides maximana canadensis; Pluck. alm. 131. tab. 86. fig. 4.) "Leaves ovate-oblong, embracing the stem, serrate, wrinkled." Root thick, fibrous. Stems several, erect. Leaves rough. Flowers yellow, in round terminal branches. A native of Canada, flowering in July. Distinct from Inula bifrons. 9. C. biflorata. Linn. Sp. Pl. 9. Mart. 10. Willd. 7. (Epapatora conyzoides integracaulis facies; Pluck. alm. 130. tab. 177. fig. 1. C. axilariis. Linn.?) "Leaves oval, toothed; peduncles two-leaved; bracts opposite." Linn. "Leaves cupulitate-toothed; lower ones petiolate, roundish egg-shaped; upper ones sessile, oblong, wedge-shaped at the base; racemes axillary, leafy at the base, peduncled; Willd. "Leaves very egg-shaped, unequally and finely toothed, petiolate; racemes axillary, leafy at the base, forming a terminal pannicle;" Lam. Stem a foot and half or two feet high, simple, slightly fringed, downy. Stems alternate, soft, green, and almost smooth above, cinereous and downy underneath. Flowers small; bractes truly alternate, though some seem opposite; calyxes villos, reddish; Lam. Described from a dried specimen in the Herbarium of Comerion. In smaller specimens, probably the growth of a poor soil, the peduncles are one-flowered, with opposite bractes. In larger specimens the racemes are from three to six-flowered; peduncled, furnished with two, either opposite or alternate bractes, and sometimes with four alternate ones; bractes oblong, soft, generally entire; Willd. A native of the East Indies and the Isle of France. 12. C. cabina. Linn. Mact. 113. Mart. 11. Lam. 9. Willd. 8. Linn. Cochinchin. 495. (Sonchus volubilis; Rumphi. Amb. 5. 299. tab. 102. fig. 2.) "Leaves oblong, somewhat toothed, nearly sessile; peduncles woolly, about two-flowered." Branches with a few scattered hairs. Leaves alternate, wedge-shaped at the base, green on both surfaces, with a few scattered hairs, not frizzly; Linn. Stem somewhat shrubby, eight feet high, cylindrical, climbing, branched. Leaves broad-lanceolate, somewhat pubescent, scattered, petiolate. All the florets im- mered in a simple down; Linn. A native of the East Indies and China. 11. C. fructa. Willd. 13. "Leaves linear-lanceolate, attemated at the base, quite entire, hairy; flowers in Corymb; item peduncled, flat." Root annual. Stem 2 foot and half high, erect; branches short, erect, close to the item. Leaves alternate, numerous, an inch long, obtuse, with a point, narrowed at the base. Corymb small, fagitate at the tops of the branches. Flowers small; down reddish. A native of the East Indies. 14. C. canescens. Linn. Jun. Sup. 327. Mart. 5. Willd. 13. Thunb. prod. 153. (C. pini folia; Lam. 18. Elhythrum peregrinum angustifolium flocculis foliaceis in spicis crinitis dentibus; Seb. Mf. 1. 38.) "Leaves linear, whitish, broad laid on the edges; downy underneath; parce fagitate." Whole plant hairy. Stem from twelve to fifteen inches high, nearly simple, cylindrical, thick, with a large, broad, fliform, lateral branches short. Leaves three inches long, a line broad. Flowers purpure; calyx short; scales imbricated. lanceolate, villous, only half the length of the flowers; down intermixed with the florets; giving the flowers a feathered appearance. 15. C. oleifolia. Lam. 27. Willd. 13. (C. orientalis pulina micri oleascosio; Tourn. cor. 32.3.) "Leaves lanceolate, attenuated at the base, obtuse, coryst; coryst terminal; item simple." Root perennial. Stem seven or eight inches high, erect. Leaves not an inch long, three or four lines broad, scattered. Flowers in a close fagitate corymb; peduncles scaly; calyx oblong; scales closely imbricated, egg-shaped, obtuse; down reddish, longer than the calyx. A native of America. 16. C. viroflora. Mart. 14. Hout. MSS. "Leaves eggl-shaped, terrated, villous; flowers axilary and terminal." Root annual. Whole herb viscid. Stem a foot high, branched. Leaves one at each joint, sessile. Flowers white; peduncles slender; generally three-flowered. Seedly chaffy. A native of La Vera Cruz. 17. C. mollis. Willd. 19. "Leaves rhomboid-egg-shaped, nearly seltthy, toothed, pubescent, tomentous underneath; leaf nacked upwards; flowers in a corymb." Branches cylindrical, clefted, Leaves an inch long, very white underneath. Corymb terminal; branches alternate, few-flowered, divaricated; peduncles one-flowered; calyx-fleshes linear-lanceolate; stem long, whitish; 18. C. chenopodifolia. Lam. 12. Willd 20. "Leaves ovate-deltoid, unequally serrated. Soft; racemes short, terminating the item and branches." Stem tomentous upwards. Leaves alternate, petiolate, tomentous when young, afterwards nearly smooth. Flowers white, sessil, four or five together at the top of the item and branches; calyxes linear, very narrow, tomentous, almost equal; bractes cloathed with fine silky decumbent hairs. A native of the Isle of Bourbon. There is a variety with broader, roundish-egg-shaped leaves, a little cut at the base. 19. C. cinerea. Linn. Sp. Pl. 12. Mart. 14. Lam. 12. Willd. 21. (Senecio indica folium ternis crenatis; Burrn. Zeyl. 211. tab. 96. fig. 1. S. indica trium foliis; Mor. Hist. 312. tab. 17. fig. 7); Oines scrophulina; Rumphi. 6. tab. 14. fig. 1.) "Leaves egg-shaped, slightly crenate; lower ones obtuse, upper ones acute; panicles naked, terminal." Lam. Root annual. Stem about a foot high, slender, pubescent. Leaves small, rather dilatant, narrowed into a petiole, cinereous-green, whitish underneath. Flowers purple, small; peduncles branched, almost capillary; calyx-feales acute; down white, longer than the calyx. A native of the East Indies. 20. C. proflera. Lam. 7. Willd. 22. (Sonchus volubilis Javanus; Rumphi. 5. 299. tab. 104. 1") "Branches profleron at the top; leaves egg-shaped, toothed-angular, narrowed into a petiole; corymb close, terminal." Branches finely fringed, full of pith, scabrous, producing near the top some smaller villous branches, and giving the plant a proflerous appearance. Leaves small, acute, green, and almost smooth above, hoary, and cloathed with short hairs underneath. Corymb almost sessile; calyx-feales awl-shaped, down white, the length of the calyx. A native of the island of Java. 21. C. heterophylla. Lam. 8. "Some of the leaves a little heart-shaped; others
others rounder; flowers panicked." Stem about a foot and half high, branched, finely frayed, clothed with very short hairs. Leaves rather small, petiolate, crenate underneath. Flowers small; calyx-scales acute, purplish at the tip; down white, a little longer than the calyx. A native of the East Indies. 22. C. hirta. Lam. 5. Burm. Ind. 185. tab. 59. fig. 1. "Leaves somewhat lyrate, appearing torn, downy; flowers nodding." Stem about a foot and half high, simple, cylindrical, contract. Leaves alternate, obtuse; lower ones petiolate. Flowers in a small terminal panicle or raceme; peduncles axillary, very short; often in pairs; calyx-scales villous; scales imbricated, very narrow, awl-shaped; down whitish, not longer than the calyx. A native of Java. 23. C. bicuspita. Linn. Sp. Pl. 19. Mart. 19. Wild. 2d. Burm. Ind. 180. Loud. Cochinchin. 495. "Leaves oval, quite entire, scabrous, hirtute underneath." Stem a foot high, upright, simple, cylindrical, hairy. Leaves scattered, somewhat acute, sometimes edged with very minute teeth. Flowers yellow, crowded, terminal; calyx short, hairy. A native of Java, China, and Cochinchina. 24. C. paniculata. Willd. 25. "Leaves lanceolate-obovate, attenuated above and below, smooth, scabrous underneath, ferrate; branches one-flowered." Root annual. Stem from half a foot to a foot and half high, erect, frayed, a little branched towards the top. Leaves an inch and half long, green. Flowers large, solitary, terminating the branches; calyx-scales awl-shaped; down scabrous. A native of Africa, about the river Senegal. 25. C. egyppticum. Mart. 27. Wild. 26. Hort. Kew. 5. 1813. (Egeron egypthicum) Linn. Mant. 112. E. ferratum. Fodk. agyp. 148. C. capitate five globos. Docc. Sic. 13. tab. 7. fig. B. Moris. hist. 3. 144. tab. 29. fig. 14. Jacobea gasyp. fol. glauco coronop.; Boehr. lugdub. 99. "Leaves oblong-lpatulate, toothed, hairy; flowers in somewhat globular panicles; calyx-scales awl-shaped, soft." Root annual. Stem a foot and half high, erect, somewhat frayed, green, pubescent, a little vilcid. Leaves alternate, sessile, scarcely half embracing the stem, rather obtuse. Flowers yellow, terminal, four or five together, on purplish peduncles; calyx roundish; scales awl-shaped; florets minute; those of the circumference numerous; pilils yellow, quickly vanishing, surrounding the disk with a broad downy ring. A native of Sicily and Egypt. 26. C. Gounii. Linn. Mant. 169. Wild. 27. (Egeron Gounii; Jacq. Hort. 5. 43. tab. 79.) "Leaves lanceolate, ferrate near the top, scabrous at the edges; lower ones inerribly eggl-shaped; flowers clustered; calyx-scales lanceolate, membranous at the margin." Stem a foot high, simple, with a few erect hairs. Leaves: alternate, half embracing the stem, even-surfaced. Flowers panicled; calyx roundish, imbricated; scales smooth, convex, close; florets of the circumference apetalous, more numerous than those of the disk; ligula bifid, oblong. A native of the Canary Islands. 27. C. fengalenfis. Wild. 28. "Leaves oblong, inerribly eggl-shaped, toothed; teeth near the base; deeper flowers in somewhat of a close corymb." Stem frayed, hairy, hispid. Leaves sessile, hisbrous on both surfaces with calous points; lower ones an inch long. Flowers at the top of the stem; calyx-scales linear-lanceolate, scabrous. A native of Africa, about the river Senegal. 28. C. dentata. Willd. 29. "Leaves lanceolate, embracing the stem, dilated at the base, pubescent, toothed; branchlets one-flowered; peduncles elongated; stem hairy." Stem cylindrical, branched. Leaves an inch long. Flowers on long peduncles; calyx-scales linear-awl-shaped, scabrous; lower ones ciliated. A native of Africa about the river Senegal. 29. C. villa. Wild. 30. "Leaves lanceolate, embracing the stem, dilated at the base, villous, ferratrd; branchlets one-flowered; stem villous." But little different from the preceding. 30. C. aurita. Linn. jun. Sup. 357. Mart. 24. Lamb. 31. "Leaves toothed; root-ones smooth, inerribly eggl-shaped; stem ones oblong, pubescent, somewhat pinnatifid at the base; stem panicked; calyx-scales awl-shaped; outer ones hairy." Root annual. Stem a foot high, erect, red, hairy; branches erect, simple. Root-leaves marked with red veins, widely ferratrd, and crenated between the ferratures; stem-leaves somewhat lanceolate, soft; ferratrd near the top; bifurcated in the middle; somewhat pinnatifid at the base; leaflets-toothed along the whole margin; pinnus two or three on each side. Flowers white, small; those of the circumference linear; pilils longer, erect. A native of the East Indies. 31. C. guineense. Willd. 32. "Leaves toothed; root-ones scabrous, inerribly eggl-shaped; stem of the form lanceolate, villous, somewhat pinnatifid at the base; stem panicked; flowers in corolls; calyx-scales lanceolate; outer ones villous." Root annual. Stem a foot and half or two feet high, erect, villous. Root-leaves an inch and half or two inches long, obtuse, remotely ferratrd; lower stem-leaves inerribly eggl-shaped, an inch long, widely-toothed, deeply auriculate-toothed at the base; those of the branches half an inch long, lanceolate, villous, toothed, somewhat pinnatifid at the base; teeth profound; teeth of the base quite entire, not ferrated as in the preceding. Flowers in a terminal coroll; calyx-scales lanceolate, acute; outer ones shorter, villous. Nearly allied to the preceding, but differs in the form of the calyx, and the teeth of the lower leaves. A native of Guinea. 32. C. amplexicaulis. Linn. 10. Wild. 33. "Leaves lanceolate, nearly embracing the stem, somewhat toothed, hairy; stem branched, divaricated; peduncles one-flowered." Root annual. Stem from half a foot to a foot high. Root-leaves inerribly eggl-shaped, toothed; those of the stem oblong or lanceolate, remotely toothed, almost entire towards the top of the branches. Flowers resembling those of C. aurita; peduncles axillary, solitary, an inch or an inch and half long. A native of the East Indies. 33. C. obliqua. Willd. 34. (Egeron obliquum; Linn. Mant. 572.) "Leaves eggl-shaped, nearly embracing the stem, finely toothed, oblique; stem much branched; peduncles one-flowered." Root annual. Stem three inches long, erect, cylindrical, hairy. Leaves alternate, veined, not wrinkled, fragil, befit with a few scattered hairs. Flowers yellow, solitary, numerous; calyx cylindrical, pubescent; scales numerous, equal, awl-shaped, approximate; florets of the circumference scarcely conpiciuus, the ligulas of the disk erect, of the circumference spreading. A native of the East Indies. 34. C. orientalis. Willd. 35. (C. orientalis Adleri acri folio; Tourn. Cor. 38.) "Leaves scabrous, ferratrd; lower ones inerribly eggl-shaped, petiolate; upper ones lanceolate, sessile; flowers terminal, ciliated." Root perennial. Stem cylindrical, frayed, hispid-fuscous, branched at the upper part; branches short, simple. Flowers yellow, crowded, in a fort of corymb at the top of the stem and branches; calyx-scales awl-shaped. A native of America. 35. C. ficula. Willd. 36. (Egeron ficulum; Linn. C. ficula annua, folius atro-virentibus; Boc. Sic. 62. tab. 31. fig. 4. Moris. hist. 3. 115. tab. 29. fig. 28. Plunk. phyt. 168. fig. 2.) "Leaves linear-lanceolate, scabrous, nearly entire, revolute at the edges; stem panicked; peduncles one-flowered, leafy; lower calyx-scales lax." Root annual. Stems red. Flowers small; peduncles covered with minute linear, recurved leaves. In other respects resembling erigeron gravesens, but without a ray. Allied also to inula punicaris. A native of Sicily and the south of France. 36. C. sativa. Willd. 57. (Egeron festucoid. Linn. Senecio africans.
C O N Y Z A.

African, perenn.; Pluk. aln. 343, tab. 223, fig. 3.)

* Leaves linear, attenuated at the base; mucronate; corollae peduncle, close, terminal. Root perennial, too nearly allied to India festica, but has no ray. A native of Africa. 37. C. pungens. Lam. 21. Wild 38. (C. membranacea; Wall. act. 1719, p. 501.) "Leaves tricuspitate, awl-shaped, pungent; stem flabellated, angular, smooth." Stem a foot high, branched. Leaves alternate, dilatant; two lateral segments very short. Flowers yellow, large, foliose; branches thick, flat, downy; scales crenate, smooth; inner ones mucronate; down reddish, to length of the calyx. A native of Egypt, about Grand Cairo.

** Stems flabellate. 38. C. fasciculata. Linn. Sp. Pl. 1. Mart. 4. Lam. 23. Wild 45. (Hedychrysum flavulens; Baeh. Prod. 147. Hedychrysum syzygium; Tourn. 452. Hedychrysum capitulorum angustiramos; Mart. hist. 3. 87. H. fasciculata; Boce. Mart. 143. tab. 104. Chrysocoma latifolium; Barr. Lc. 425.)"Leaves linear, somewhat toothed; peduncles very long, one-flowered." Root perennial. Stems about a foot high, slender, branched, corymb; a little procumbent when young. Leaves an inch and a half long, two lines broad, green above, whitish beneath. Flowers yellow, foliose, on long peduncles; calyx-follicles oblong, somewhat flattened at the tip, lax. A native of Spain, Italy, the South of France, Portugal, &c. 39. C. rufa-f. Linn. Mant. 123. Mart. 6. Wild 41. (C. fasciculata 2. Lam. C. tamentosum; Forl. Ergyp. 75.)"Leaves fasciculate, somewhat toothed; peduncles elongated, one-flowered." Very like the preceding, but the flowering stems have axillary branches of smaller leaves. Leaves broader, shorter, more obtuse, all except the lowermost white on both sides. Flowers yellow; peduncle shorter and thicker, with one or two lanceolate, not bristle-shaped, bracteae; calyx-follicles not acute and patulous, but rather obtuse and closely imbricated; outer ones egg-shaped, brown at the middle, middle ones oblong, with a brown line on the back. A native of Arabia. 40. C. forfida. Linn. Mant. 466. Mart. 5. Lam. 22. Wild 25. (Glaaphalium forfida; Linn. Sp. Pl. Elschychrynum syzygium angustifolium, capitulos conglabulatos; Baeh. Pin. 264. Stachys cingulata; Spreng. longirostris folia; Bar. Lc. 368. & 277.)"Leaves linear, quite entire; peduncle long, three-flowered." Nearly allied to C. fasciculata. Stem resembling that of lavender, about a foot high, slender, corymbose. Leaves very narrow, soft, cottony, whitish. Flowers small; peduncles long, slender, cottony; calyx-follicles conic; scales imbricated, a little crenate at the tip. A native of the South of France and Italy. 41. C. erythrocarpa. Lam. 51. Wild 42. "Leaves linear, revolute, downy underneath; flowers globular, solitary, terminating the branches." Stem much branched; branches downy near the top. Leaves resembling those of physica eicosides, final, numerous, approximate, flatteret, spreading. Flowers at the top of the lateral branches, which are so disposed as to give the items the appearance of being covered with flowers; calyx-follicles linear, scarcely imbricated; outer ones downy on the back; down reddish. A native of Peru. 42. C. thyoides. Lam. 42. Illus. Fl. 697. fig. 5. Wild 44. "Leaves embracing the stem, egg-shaped, acute, keeled, compressed, imbricated in two rows; flowers foliary, sessile, lateral." A very upright plant in the form and disposition of its leaves, with somewhat of the habit of a Thunia. Stem a foot and half high, cylindrical, cottony towards the summit; branches in two rows, gradually diminishing in length from the bottom of the stem to the top. Leaves small, tufted, somewhat concave, villous on the inside. Flowers axillary; calyx-follicles few, oblong, smooth and even; down reddish. A native of Peru, found by Josephispalln. 43. C. sp. fidei. Lam. 43. Ill. Lc. 697. fig. 3. Wild 45. "With plant smooth; leaves minute, linear, egg-shaped, keeled, imbricated in four rows; flowers blue or terminal." A plant as regular as the preceding, with the habit and foliage of a corymb, and the flowers of an Acanthaceae. Stem a foot high, obtuse, cylindrical. Leaves thickly covering the branches. Flowers yellow, few, serrated; calyx cylindrical. Scales imbricated, obtuse, inner ones the largest. Found by Commerson in the Straits of Magellan. 44. C. hyemalis. Linn. Mant. 44. Ill. Fl. 697. fig. 2. Wild 46. "Leaves spiral, imbricated, prefl close to the branches; flowers solitary, terminal." A shrub fix or seven inches high. Stem bifid; branches erect, generally fasciculated so as to resemble ficaria pelluca. Stem three lines long, smooth, convex at the back, with two lateral furrows. Flowers white or lemon-coloured, sessile; calyx scales imbricated, similar to the leaves but smaller; down white, twisted and appearing ciliated. Tound by Commerson in the Isle of Bourbon. 45. C. brachyca. Lam. 45. Wild 47. "Prostrate; leaves linear, cordoned, hoary underneath; branchlets terminated with a sessile flower." A small shrub. Stem divided into numerous, short, procumbent branches, throwing out fibrous roots; branches erect, in close tufts somewhat in the manner of a Bryum. Leaves small, numerous, placed very near each other, green above, whitish and cottony beneath. Peduncles imbricated, rather short; calyx almost ciliated, containing from fix to fifteen flowers; scales imbricated, oblong; down the length of the calyx. Found by Commerson in the Straits of Magellan. 46. C. linearifolia. Lam. 49. Wild 48. "Smooth; leaves linear, nearly entire, narrowed towards the base; racemes short, leaty, terminal." A small much-branched shrub; branches slender, leafy towards the top, lightly iriately. Leaves an inch long, two lines broad. Flowers fllie or nearly so; calyx oblong, imbricated; inner scales linear-imbricate, white and crenatous at the edges; down reddish, thick length of the calyx. A native of the Isle of Bourbon. 47. C. punctata. Wild 49. "Leaves linear, acuminate, attenuated at the base, slightly marked with concave dots; peduncles very long, one flowered." Branches cylindricated, flattened, smooth. Leaves an inch and half long, alternate, crowded, somewhat flatter, rather feathery, quite entire and feathery at the edges. Peduncles at least half a foot long, solitary or in pairs, becket with awl-shaped dilated scales; calyx-follicles lanceolate, acute; down reddish. A native of Chili. 48. C. canariensis. Wild 52. "Leaves linear, attenuated at the base, rather obtuse, serrated; corymbose terminal." Branches cylindricated, younger ones pubescent. Leaves alternate, crowded, spreading; green on both surfaces, somewhat feathery. Flowers yellow; peduncles sessile; calyx-follicles oblong, closely imbricated. A native of the Canaries. 49. C. incana. Wild 51. (Erigeron incanum; Vail. Lc. 1. 72.) "Leaves linear, attenuated at the base, somewhat toothed, downy; corymbose terminal." Branches downy. Leaves sessile, approximate, rather acute, a little revolute at the margin. Corymbs many-flowered; calyx-follicles linear, somewhat villous; down ferrugineous, longer than the calyx. A native of Aruba Felix. 50. C. imbellis. Mart. 25. Wild 52. Hort. Kew. 3. 182. (Chrysocoma dichotoma; Linn. jun. Supp. 539. Jace. 1. 1c. Kar. I. tab. 171.) "Leaves wedge-shaped-linear, obtuse, crenate-toothed, smooth; anthers two-briddlet." Stem smooth, profligines, dichotomously branched. Leaves rather short, a little obtuse, somewhat feathery, with minute points. Flowers proposed.
Flowers yellow, in terminal simple corymb; peduncles hairy; bracts awl-shaped; calyx purplish. A native of rocky ground in the island of Teneriffe. 51. C. tumentos. Mart. 31. Mill. Dict. Hauft. MSS. "Leaves oblong-egg-shaped, downy, crenate underneath, flowers terminal, on branching peduncles." Stem ten or twelve feet high, much branched. Leaves alternate, on short pedicel. Flowers white, in loose unilateral spikes. A native of La Vera Cruz in New Spain. 52. C. ebracteolat. Willd. 53. Desf. Fl. Atl. 1, 269. tab. 252. "Leaves linear, quite entire, villous, hairs pressed close; peduncles leafy, one-flowered." Whole plant cinnereous, cloathed with thin, soft hairs pressed close to the peduncle. Stem a foot and half high, slender, branched. Leaves spreading. Flowers in loose panicles, on filiform peduncles; calyx ovate-cylindrical, scales linear, awl-shaped, imbricated, pubescent, membranous at the edges; florets of the circumference very small, scarcely conspicuous, without teeth. A native of Barbary. 53. C. coronatus. Lam. 35. Willd. 54. "Vifcid leaves linear-lanceolate, ferrate, flowers oblong, buried upwards; flowers globular in terminal corymb." 54. C. glutinosus. Lam. 32. "Leaves lanceolate, ferrate, green on both surfaces; vifcid when young." A shrub four or five feet high, smooth. Branches lax, cylindrical, slightly flexed, leafy towards the summit. Leaves ever-green, petiolate, acute, shining. Flowers yellow, numerous, small, in a compound terminal corymb; calyx roundish, imbricated with egg-shaped scales; florets of the circumference very small; down white, short. A native of the Isle of France. 35. C. appendiculat. Lam. 31. Willd. 60. "Leaves lanceolate, ferrated, downy underneath, appended at the base." Branches tubercled, corymbs terminal towards the summit. Leaves near four inches long, about an inch broad, green above, cottony and whitish underneath, furnished at the base with some narrow appendages which are decurrent along the pedicel. Flowers yellow, numerous, in a compound terminal corymb; peduncles and calyx cottony; bracts at the division of the peduncles linear. Found by Commeron in the 14th of Bourbon. 56. C. fulcifolia. Mart. 52. Lam. 33. Willd. 55. "Leaves linear-lanceolate, quite entire, revolute at the edges, attenuated upwards and downwards, downy underneath, corymb terminal, compound." Branches cylindrical, tubercled; younger ones downy. Leaves refembling those of Salix viminalis, two inches long, alternate, petiolated. Corymb divaricated; peduncles downy; calyces cylindrical, imbricated; outer scales egg-shaped, pubescent; inner ones longer, linear, smooth. There is a variety with very narrow, almost filiform leaves. 57. C. laurifolia. Lam. 34. Willd. 56. "Leaves oblong-lanceolate, narrowed at the base into a petiole, nearly entire; corymb terminal, compound, spreading." A very large shrub. Branches cylindrical, almost smooth, leafy on their upper part. Leaves about six inches long, rather more than an inch broad, feathered, slightly pubescent, sometimes slightly crenulate. Flowers numerous, globular; peduncles clothed with short, woolly hairs; calyx-ex.cales ovate lanceolate, almost smooth; down reddish. Found by Commeron in the 14th of Bourbon. It seems to have some affinity with Baechara arborea of Linnæus. There is a variety with smooth leaves broader at the top, smaller flowers and longer down, which perhaps may prove a distinct species. 58. C. miniflora. Mart. 38. Mill. Hauft. MSS. "Leaves lanceolate, acute, fcelife; flowers solitary, lateral, calyces coloured." Stem eight or ten feet high, with numerous, long, slender branches. Leaves three inches long, three quarters of an inch broad in the middle. Leaves growing close to the stems of the smaller branches. Flowers white, with a purple calyx,附着近基部的叶子，每片叶子于近枝端每一处基部。花瓣的长度约为六英寸，且略短于一英寸，被短而细的羽毛状物所覆盖。花柄呈圆锥形，并且略微膨大。花序为圆锥状，总体呈现出淡黄色。当花朵开放时，颜色呈现出淡紫色。
C O N Y Z A.

CORYZA.

bractes reflexed." Four or five feet high. Stem erect, branch- ed towards the top; branches divaricated, sub-divided, bend- ing down, diverging, villous, with a blackish flagmyna. Leaves two inches long, alternate, on short petioles, wrinkled, green above; pales, pubescent, and narrowly oblong. Flowers pale purple, in an umbellate spike, or rather racemes. A native of South America. 83. C. mucronata. Lam. 28. "Leaves ovate-lanceolate, petioled, entire, even-furrowed; spikes un- lateral, revolute, raked." Nearly allied to the preceding, and perhaps only a variety, but its leaves are even-furrowed above, and almost smooth underneath. Flowers in linear racemes, recurved like the tail of a scorpion; calyx-scales lanceolate; inner ones a little villous at the tip; down white. Found by Commeron in Brazil. 82. C. triangula. Lam. 57. Mart. 21. Lam. 29. Willd. 72. (C. frutecens, cyanidiofolia; Plum. Sp. 9. Burm. Amer. Tab. 95, fig. 1. Tourn. 457.) "Leaves flag-shaped, quite entire, obtuse; flowers white, alternate; branchlets rigid." A petty shrub, resembling rosemary, but with longer and more slender branches. Leaves numerous, alternate, petioled, white with down. Flowers purple, axillary, solitary. A native of South America. 86. C. incisa. Mart. 20. Willd. 43. Hort. Kew. 3, 1814. "Leaves flag-shaped, somewhat heart-shaped, hairy-villous, toothed, auricled at the base; receptacle honey-colored." Whole plant clothed with viscid hairs. Stem three feet high. Leaves an inch long, peti- oled, deeply cut. Corymb terminal, few-flowered, on long peduncles. A native of the Cape of Good Hope, found by Francis Mollon. 87. C. arborescens. Lam. 52. Willd. 73. "Leaves flag-shaped, veined, thinly toothed, crowded; flowers flag-shaped, terminal, globular." A smooth shrub, a foot and half high, or more. Branches erect, generally incised, leafy on their upper part, naked towards the base, and marked with the flowers of fallen leaves, with a decurrent leaf on each side. Leaves scattered, sessile, approximate, narrowed at the base. Flowers rather large, clustered; calyx imbricated; scales ovate-lanceolate; down reddish. Found by Joseph Jullien in Peru. 88. C. myrtifolius. Lam. 48. Willd. 75. "Leaves lanceolate, two-toothed; flowers globular, somewhat clustered, terminal." Branches slender, leafy on the upper part, somewhat angular. Leaves small. Flowers very small, almost sessile; calyx imbricated; scales egg-shaped, acute, slightly ciliate on the upper edge. A native of St. Domingo. 89. C. magellanica. Lam. 47. Willd. 76. "Smooth; leaves very small, ovate-wedge-shaped, ob- lomely three-toothed; flowers lateral, solitary, terminating the branchlets." A low, much-branched, spreading shrub. Leaves numerous, approximate, obtuse. Flowers oval, sessile; calyx-scales flag-shaped. Found by Commeron in the fronds of Magellan. 90. C. tenuifolia. Lam. 46. Willd. 77. (Erioger trenatum; Liam. jun. Supp.) "Smooth; leaves wedge-shaped, toothed towards the tip; flowers axil- lary and terminal, somewhat clustered." Much-branched, viscid. Leaves sessile. Flowers nearly sessile; calyx flag-shaped, imbricated; scales ovate-acute, a little scarious, fringed towards the tip; down reddish, longer than the calyx. Found by Commeron near Monte Video, and at the fronds of Magellan. The younger Linnæus's plant was found by Mattia in New Mexico. 91. C. reticulata. Lam. 39. Willd. 78. "Leaves ovate-wedge-shaped, retuse, crenated near the tip, pubescent; flowers globular, terminal, and axillary, forming a corystam." Stem a foot or half or two feet high; branches numerous, cylindrical, naked, and knotty below, leafy near the summit. Leaves scattered, thin, flat, succulent, with three or five longitudinal nervae. Flowers white; peduncles branched, pubescent; calyx hemispherical, imbricated; scales egg-shaped, inner ones somewhat scarious and lacerated at the edges; hermaphro- dite flowers of the 1st inflorescence; female ones of the cir- cumference in two or three ranks. Found by Commeron in the Isle of Bourbon. 92. C. brunfelsia. Lam. 50. Willd. 79. "Smooth; branches stiff; leaves oblong-egg-shaped, quite entire; flowers lateral, sessile." About four or five feet high. Branches erect, stiff, somewhat thick, angular, tubercled, leafy towards the summit. Leaves five or seven leaves long, flattened, approximate, almost sessile, narrowed towards the base. Flowers axillary, solitary; atan imbricated; flags ovate-oblong, slightly etiulate near the tip; down white. Found in Peru by Jophs. J. Flue. 93. C. carthagenensis. (C. ferrata; Mart. 53.) "Leaves flag-shaped, three-nerved; flowers in axillary spikes." Stem ten or twelve feet high, dividing at the top into many woody branches. Leaves an inch long, alternate, fitting close to the branches, acuminate. Flowers white. A native of Carthagena in New Spain.

Leaves decurrent.

Herbaceous or Shrubby.

94. C. genistoides. Lam. 56. Willd. 83. (Cassambar. Mary. Brat. 72.) "Stems somewhat shrubby, without leaves, nearly smooth; rings interrupted by joints, terminated by a short spike; flowers sessile, lateral, alternate." Stem from a foot to three feet long. Wings between each joint, broader on one side than on the other, decussated, green. Flowers yellow, situated at the joints in the upper part of the plant, solitary in the axil of the scale; calyx round, almost smooth, imbricated; scales ovate-acute; down reddish. A native of Peru. 95. C. articulata. Lam. . Ill. Pl. 651. fig. 4. Willd. 81. "Stem much branched, irregularly winged; leaves oblong-elliptical, shorter than the joints; flowers panicked." Stem a foot and half high; branches compound, smooth, viscid towards the summit. Flowers pale yellow, sessile, almost globular, often clustered together in a kind of terminal spike or panicle; calyx imbricated, scales obtuse. Found by Commeron at Monte Video. 96. C. fagittata. Lam. 58. Willd. 82. "Leaves decurrent, lanceolate, finely toothed, a little scarious, green on both surfaces; flowers clustered together at the top of the branches." Stem winged in the preceding. Leaves alternate, two or three inches long. Flowers from three to five in a cluster; calyx short, sessile egg-shaped, smooth pubescent; florets numerous; down longer than the calyx. Found by Commeron at Monte Video. 97. C. crispata. Willd. 83. Vahl. 1. 71. Forst. Arb. 119. n. 495. "Leaves lanceolate, serrate-toothed, naked; peduncles one-flowered; stem frubby." Whole plant smooth. Stem erect, frutified; branches and peduncles with curved toothed-inflated wings. Leaves an inch and half long, remote. Flowers two or three at the top of the branches; peduncles half an inch long; calyx-scales linear-lanceolate, the length of the florets in the circumference. A native of Arabia Felix. 98. C. arabica. Willd. 84. (Erioger decurrent; Vahl. Symb. 1. 72.) "Leaves linear, quite entire, downy; flowers panicked." Stem erect, frutified, pubescent, downy near the top; branches woody. Leaves an inch and half long. Pedicel capillary, with two minute bractes near the top; calyx sessile; scales brick- shaped, shorter than the down. A native of Arabia Felix. 99. C. leucantha. Willd. 85. Marsh. de Biberfih Pl. Caucas. "Leaves egg-shaped, mucronate, downy; lower ones serrated; flowers in corynba." Root annual. A native of Mount Caucasus, near the shores of the Caspian Sea. 100. C. vinga. Liam. Sp. 1. 4. Mart. 22. Lam. 53. Willd. 86. (C. helianthiflora; Pl. Sp. 9. 41. Burn.)
Burm. Amer. tab. 98, fig. 2. C. angustifolia subincana; Brown. Jam. 318. Helichrysum caule alato; Shaw. Jam. 125. Ht. tab. 266. tab. 152. fig. 5.) "Leaves linear-lanceolate, finely serrated, downy underneath; spikes terminal, elongated, interrupted." Root perennial, woody. Stem about two feet high, erect. Leaves five or six inches long, alternate, green and smooth above, whitish and downy underneath. Flowers yellow, purple, fleshy, lower ones three together, upper ones solitary; calyx oblong, imbricated; sessile, acute, hairy. A native of St. Domingo, Jamaica, and Carolina. 101. C. rupestris. Willd. 87. Vahl. Symb. 1. 71. "Leaves bipartite, crenated, downy underneath; flowers in a head." Branches woolly; leaves quite entire, smooth on one side, very downy on the other. Leaves an inch and half long, wrinkled, smooth above, downy underneath. Peduncles the length of the leaves, from the axils of the upper leaves. A native of Brazil. 102. C. alopecuroides. Lam. 54. Willd. 83. Plm. Sp. 9. Burm. Amer. tab. 98. fig. 1. "Leaves egg-shaped, finely serrated, downy underneath; spike terminal, dense, interrupted at the base." Root perennial, spindly-serrate, woolly. Stems about two feet high; leaves green on one side, white and downy on the other. Leaves alternate; green, smooth, somewhat wrinkled above, whitish and downy underneath. Flowers yellow, calyx imbricated, downy at the base; inner scales longer and smooth towards the tip; down rather long. A native of Maranhão and Brazil. 103. C. fixiflora. Lam. 54. Willd. 83. Coll. Cav. 1. 8. tab. 12. "Stem somewhat bristly, simple; leaves ovate-lanceolate, finely serrated, downy underneath; spike terminal, dense, entire." Stem a foot and half high, erect, fringed with green and white. Leaves three to four inches long, six or eight lines broad, alternate, green and smooth above, white and downy underneath. Flowers yellow; calyx clothed with a thick down, imbricated; scales narrow-lanceolate, inner ones longer. Female florets intermingled with the hermaphrodites. A native of South America. Obs. As the generic baccharis and conyza now fly, this species belongs to the former. 104. C. redolens. Willd. 90. (Gnaphalium redolens; Forl. Prod. n. 55.) "Leaves lanceolate, quite entire, downy underneath; spikes terminal, glomerated." Stem woolly, branched. Leaves half an inch long, obtuse. Spike half an inch long; calyxes villous. A native of New Caledonia. 105. C. decurrens. Linn. Sp. Pl. 6. Mart. 23. Wild. 91. (C. alopecuroides. B. Lam.) "Leaves lanceolate, finely serrated; stem somewhat dichotomous; flowers axillary, fleshy, glomerated." Root annual. Whole plant downy. Stem about three inches long, erect. A native of the East Indies.

Obs. The only essential distinction between baccharis and conyza confides in the former having the hermaphrodite and female florets intermingled with each other; whereas, in the latter, the female florets are all collected in the circumference, but without producing the compound flower properly radiate. In dried specimens, it is not always possible to determine these characters with certainty; so that, as La Marck observes, some of the foregoing species may belong to baccharis. Jussieu, Gérard, and La Marck, are of opinion, that the two genera are fearfully distinct. The latter, however, fuggles that two genera might be formed out of them. Distinguishing by the form of the calyx: one of them with the calyx of erigeron, i.e. not properly imbricated, having linear, nearly equal scales in several ranks; the other with the calyx of eupatorium, i.e. finely imbricated. It any of the species should be found to have all the florets hermaphrodite, they must be referred to eupatorium. Erigeron differs in having a radiate flower.

Conyza sibirboidea of Linnaeus and Martyn is after conyza of Willdenow. It is excluded from the present genus by its radate flower.

CONZA, in Geography, a town of Naples, in the province of Principato Ulitta, considered as the capital of the province; situated at the foot of the Appennines, near the head of the Ophanto; the site of an archbishop. The chief article of its commerce is marble. Distant 48 miles E. of Naples. N. lat. 40° 50'. E. long. 15° 10'.

COOCH Bahar, or Coos Bayha, a district of Bahar, in the province of Bengal, separated from that of Rungpore, by the river Durlah. In this district, an usage of a very singular kind has prevailed from remote antiquity, and actually exists at this day. If a riot, or peafant, owes a sum of money, and cannot satisfy his creditor, he is compelled to give up his wife as a pledge, and possession of her is kept till the debt is discharged. It sometimes happens, according to report, that the wife of a debtor is not received for the space of one, two, or three years; and then, if during her residence and connection with the creditor, a family shall have been the consequence, half of it is considered as the property of the person with whom she lived, and half that of her real husband. This country has a most melancholy appearance, and its inhabitants are a miserable and pusty race. Those of the lower ranks, without support, dispose of their children for slaves, to any purchaser, and for a very trifling consideration. Nothing is more common, in this unnatural traffic, than to see a mother drive up her child, and bring it to market, with no other view or hope, than to enhance the price she may procure for it. Indeed the extreme poverty and wretchedness of these people will sufficiently appear, when we reflect that the value of the peasant's subsistence amounts to no more than one penny a day, even allowing him to make his meal of two pounds of boiled rice, with a due proportion of salt, oil, vegetable, fish, and chili, the latter of which is a kind of red pepper, in universal use, made from the "caplixum annuum" of Linnaeus. The situation of the district exhibits an union of facts, not unfrequently observed, viz. the great facility of obtaining food, and at the same time the wretched indigence of the lower order of inhabitants. Turner's Thibet, p. 11, &c.

COOCHEN, LEONARD VAN, in Biography, a painter, born at Haarlem in 1610, and scholar of Jac. Jordaeus. He also amused himself with etching, and published three sets of prints in which the style of Salvator Rosa was imitated with the most happy success. These etchings, several of which represent groups of military figures, are dated from 1664 to 1666. He died in 1681. Heinecken.

COOK, JAMES, one of the most eminent navigators and discoverers of unknown territories and seas, recorded either in ancient or modern history, was descended from an obscure family in Northumberland: his father, James Cook, having occupied the humble station of a servant in his boyhood, and his mother, whose Christian name was Grace, being a person of the same rank and condition. The subject of this article claims a more distinguished notice, and a more extended detail of particulars, than we have been accustomed to introduce in those biographical sketches that occur in this work. Indepenently of the singular merit of Captain Cook himself, to which a peculiar tribute is due, his voyages and discoveries are so immediately connected with science, both geographical and nautical, as to entitle them to a conspicuous place in a general Dictionary of the Arts and Sciences. The parents of captain Cook, who were noted in their lowly station for honesty, sobriety, and diligence, were settled for some time before his birth at Marton, a village in the North Riding of Yorkshire; and in this place their son James, destined to give celebrity to their name and family, was born on the 27th of October, in the year 1728. Having received the first rudiments of education at his native place, he was further instructed in writing, and the first rules of arithmetic at Ayton, near which place his father was settled in the service of Thomas Skotow, esq.; and, at the age of 13 years, he was apprenticed to a shopkeeper, at Staithes, a fishing town about 10 miles from Whitby. The sea, however, was the object towards which he manifested an early inclination; and, in consequence of some disagreement with his master, he obtained his discharge, and determining to indulge his natural propensity, he bound himself for seven years to Mifters. Walkers of Whitby, quakers by religious profession, who employed two ships in the coal trade. At the expiration of his apprenticeship, he continued in vessels of this description, as a common laborer, till at length he was appointed mate in one of Mr. John Walker's ships. At this time, he was not distinguished by any
any peculiar traits of character, though without doubt he must have acquired a considerable degree of knowledge in practical navigation. In the spring of the year 1755, when hostilities commenced between England and France, Mr. Cook, and the ship to which he belonged, happened to be in the river Thames; and after concealing himself for some time, to avoid being impressed, he determined to enter voluntarily into the British navy. His first situation in his majesty's service, was on board the Eagle man of war, to the command of which, captain (afterwards Sir Hugh) Palliser was appointed in October 1755. As an active diligent seaman, he recommended himself to the captain's notice; and in consequence of his own acknowledged merit, as well as some private interference, he obtained the 19th of May, 1759, a master's warrant for the Grampus flag; but this appointment not taking effect, he was made master of the Garland, a ship which had failed before he could join her; and therefore, on the 19th of May, he was appointed to the Mercury. This ship was destined to North America, where he joined the fleet under the command of sir Charles Saunders, which, in conjunction with the land forces under general Wolfe, was engaged in the famous siege of Quebec. As it was necessary for the purpose of the expedition, to fortify St. Lawrence, between the island of Orleans and the north shore, directly in the front of the French fortified camp at Montmorency and Beauport, Mr. Cook was recommended by captain Palliser, who well knew his facility and resolution, to this difficult and hazardous service. He performed it, with great personal risk, to the satisfaction of his employers; and furnished the admiral with a complete and correct draught of the channel and foundings. Before this time, it is thought that he had scarcely ever used a pencil, and that he had no knowledge of drawing. He afterwards surveyed those parts of the river, below Quebec, which navigators had found to be attended with difficulty and danger; this business was executed with his customary diligence and skill; and when his undertaking was finished, his chart of the river St. Lawrence was published, with the necessary foundings and directions for navigating that river. This chart has superseeded the necessity of any other. After the expedition to Quebec, Mr. Cook was appointed, by warrant from lord Colvill, master of the Northumberland man of war; and in this station, his conduct was such, as to gain him the esteem and friendship of his commander. During the station of his ship at Halifax, he read Euclid, and devoted his leisure hours to the study of astronomy, and other branches of science. In September 1762, the Northumberland came to Newfoundland, to assist in the capture of the island from the French; and after this service was accomplished, Mr. Cook surveyed the harbour of Placentia, and the heights of the place, with a diligence which engaged the notice of captain (afterwards admiral) Graves, the governor of Newfoundland. The governor formed a very high opinion of his abilities and character; and this opinion was amply confirmed by the concurrent testimony of all the officers under whom he had served. Upon Mr. Cook's return to England, towards the close of the year 1762, he married an amiable woman, who deferred and enjoyed his tenderest affection and regard. Early in the year 1763, he accompanied captain Graves to Newfoundland, as surveyor of its coasts; and having executed the business that had been assigned him, he returned to England. In April 1764, he was appointed, under the orders of commodore Palliser, marine surveyor of Newfoundland and Labrador; and of the satisfactory manner in which he executed this office, the charts which he afterwards published, afford fullest evidence. These services were continued till the year 1767; and whilst he was employed in them, he transmitted to the Royal Society an observation of the eclipse of the sun at Newfoundland, with the longitude deduced from it, (see Phil. Trans. vol. 57.) from which our navigator appears to have already acquired the character of an able mathematician. But a new and more interesting scene opens upon us in the profession of these memoirs. A spirit of discovery had been excited towards the latter end of the 18th century, and in the following century it was very vigorous and active; but soon after the commencement of the 18th century, it began to decline: at a subsequent period, during the reign of king George II., it again began to revive; and two voyages were performed for the purpose of discovering a north-west passage through Hudson's Bay. But the modesty of his spirit was exhibited during the present reign; and it was reserved for Mr. Cook to furnish the most illustrious example of its influence. Soon after the peace of 1763, two voyages round the world were undertaken by captains Byron, Wallis, and Carteret, to whom we are indebted for several discoveries, which served to extend the knowledge of geography and navigation; but before the return of the two last, our navigator, with others, was employed on a more extensive scale than either of the former. The transit of Venus in 1769, was very likely to be observed with the greatest advantage in some of the islands of the South Seas, and afforded a peculiar inducement to this expedition; and after a variety of preliminary consultations and debates, Mr. Cook, who was strongly recommended by Mr. Stephens, secretary to the admiralty, and by sir Hugh Palliser, who had long known his abilities and character, was appointed to the command of it, with the rank of a lieutenant in the royal navy, to which he was promoted on the 24th of May 1768. A vessel of 370 tons, called the Endeavour, was prepared for this purpose; but before the necessary arrangements were completed captain Wallis returned, and upon being consulted he recommended Port Royal Harbour in George's island, now known by the name of Otaheite, as the most proper place for the proposed observation of the transit. Lieutenant Cook was accompanied by Mr. Charles Green, who had been pupil to Dr. Bradley at the Royal Observatory at Greenwich, and also by Joseph Banks, esq. now sir Joseph Banks, bart. and president of the Royal Society, and Dr. Solander, gentlemen who zeal for the propagation of science have been uniform and ardent. Lieutenant Cook had further views in this voyage than the mere observation of the transit, and accordingly, when his business was accomplished, he was directed to pursue further discoveries in the great Southern Ocean. The complement of Cook's ship consisted of 84 persons, besides the commander; she was provisioned for 18 months; and furnished with carriage and 12 small guns, together with an ample stock of ammunition and other necessaries. On the 26th of August our navigators set sail from Plymouth Sound; and on the 11th of September anchored in Tuncialea road, in the island of Madeira. Here they were hospitably entertained; and having landed in a fresh flock of beef, water, and wine, they left the island in the night of the 18th of September. In their way to Rio de Janeiro, they had an opportunity of ascertaining the luminous appearance of the sea, which had been often noticed by navigators, and ascribed to various causes. They determined by experiment, fully to their satisfaction, that the phenomena they observed proceeded from some luminous animal. Their reception at Rio de Janeiro was very different from that which they had met with at Madeira; and it was through mere necessity that they were detained there from the 13th of November to the 7th of the following
following month, when they proceeded on their voyage.
On the 13th of January 1769, lieutenant Cook entered the
frait of Le Mairc, and having contended for some time
with a violent tide, he anchored on the next day, first be-
fore a frant coast, which was understood to be Port Maur-
rice, and after ward the bay of Good News. He was the
content of the Endeavour in this station, Mr. Banks, Dr.
Solander, Mr. Monkhouse the surgeon, and Mr. Green
the astronomer, with their attendants and servants, and two
seamen, ascended the mountains in search of plants. This
excurion has been often related, and the effect of the cold
of the climate is well known. (See Cook. For an account
of the inhabitants of the desolate regions adjacent to
this frant; see Le Mairc.) It has been a question among for-
mer navigators which is the best passage from the Atlantic
to the Pacific ocean; and the doubling of Cape Horn has
been so much de-eded, that it has been thought more eligi-
able to pass through the frait of Magalhaens or Mag-llan.
Lieutenant Cook has settled this point; for he was no more
than 33 days in coming round the land of Terra del Fuego,
from the E. entrance of the frant of Le Mairc till he had
advanced about 12 degrees to the wellward and 38 to the
northward of the fraits of Magalhaens, and during this time
the ship received scarcely any damage; whereas it would
have required three months to reach the Pacific ocean
through this frant, and in passing it his people would have
been much fatigued, and the anchors, cables, falls, and
rigging of the vessel would have been much injured. In
short, lieutenant Cook, by fitting the example of doubling
Cape Horn, and by accurately ascertaining the latitude and
longitude of different places, as well as by his instructions
to future voyagers, has performed the most essential service
to this part of navigation. In the prosecution of the voyage
from Cape Horn to Otaheite, several islands were discovered,
to which were given the names of Lagono island, S. lat.
18° 47', W. long. 120° 28', Thum-b-cap, S. lat. 18° 35',
W. long. 130° 48', Bow island, S. lat. 189° 33', W. long.
18° 14', the Groups, the eastermost in S. lat. 18° 12',
W. long. 142° 42', Bird island, S. lat. 17° 48', W. long.
142° 43', and Chain island, S. lat. 17° 25', W. long.
145° 54'. Most of these islands were inhabited; and the ver-
dure, or groves of palm-trees, which were visible in some of
them, gave them the appearance of a terrestrial paradise to
persons who had hitherto witnessed the dreary coasts of Terra
del Fuego.
On the 15th of April the Endeavour anchored in Port
Royal bay, called by the natives “Matavai,” in the island of
Otaheite. Having fixed upon a place proper for accom-
plishing the grand object of their commission, they erected
an observatory, S. lat. 17° 29' 15", W. long. 145° 32' 36", and
carried their astronomical quadrant, and some other in-
struments, on shore. On the following day, very much to
their surprise and grief, the quadrant was not to be found.
By the judicious and spirited exertions of Mr. Banks, the
instruments was restored. The transit was observed with
great advantage. A particular account of the observation
may be seen in the Phil. Trans. vol. 1st, p. 307. See Ve-
nus. As we shall have occasion to mention some of the
leading circumstances that occurred on this and other visits
to Otaheite, under that article, we shall attend lieutenant
Cook in his departure from the island. Previously to their
setting sail, Tupia, one of the natives, the prime minister of
Oberea, when she was in the height of her power, and chief
priest of the country, who had been a constant companion of
the English during their abode on the island, came on board
the ship, with a boy thirteen years of age, and intreated
that they might be permitted to proceed with them on their
voyage. Lieutenant Cook gladly accepted the proposal.
On the 13th of July the English weighed anchor, and
while they were proceeding on their voyage, Tupia in-
formed lieutenant Cook, that at four of the neighbouring
islands, which he distinguished by the names of Huaheine,
Ulritea, Otahah, and Bobsbola, they might procure hogs,
swans, and other refreshments, in great abundance. Ac-
cordingly, passing the Tellusvrau, they approached the N.W.
part of Huaheine on the 16th of July, and in the af-
ternoon anchored in a small but excellent harbour on the
W. side of the island, called Ohware; and having procured
a variety of necessaries articles of refreshment, they failed on
the 19th for Ulritea, in a good harbour of which the ship
anchored on the next day.
The lieutenant hoisted an English jack on this island, and,
in the name of his Britannic majesty, took possession of this,
and the three neighbouring islands, Huaheine, Otaha, and
Bobsbola, all of which were in fight. The harbour or bay
in which the Endeavour had anchored was called by the na-
tive Opoony, and extends almost the whole length of the easter
side of the island. In its greatest extent it is capable of ac-
commodating any number of ships. After having surveyed the
northern and southern parts of this island, they set sail on
the 24th; but after encountering considerable danger and
discovering several small islands, they returned to Ulritea, and
anchored on the 11th of August in a harbour on the west side
of the island. Tupia had previously apprized them of the
formidable character of the inhabitants of Bobsbola, but on
intercourse with them, and particularly with Opoony, they
found there was no foundation for the terrors which Tupia
had endeavoured to excite. Having finished their necessary
repairs, and obtained a fresh stock of provisions, they pre-
pared for leaving the island. The principal islands, about
which the English had now spent somewhat more than three
weeks, were six in number; viz. Ulritea, Otaha, Bobsbola,
Huaheine, Tuba, and Maurua; which see respectively. Our
voyagers purposed their course till the 15th, when land was
discovered bearing S. E., and which Tupia informed them
was an island called Oheteroa. As the inhabitants manifested
a hostile disposition, lieutenant Cook, with equal wisdom and
humanity, made no attempt for land ing. By Tupia our nav-
igators were informed, that various islands lay at different
distances, and in different directions from Ohe teroa, between
the south and the north-west; and that to the north-west
there was an island called Manua, or Bird island. He also
described several islands towards the west; probably Boi-
cawen and Kepell's islands, which had been discovered by
Captain Wallis. The farthest island towards the south, of
which Tupia had any knowledge, was called Mautou, about
three days sail from Ohe teroa. But his father, he laid, had
informed him, that there were other islands farther to the
south. Lieutenant Cook determined, all circumstances duly
considered, to land southward in search of a continent. On
the 15th of August, our voyagers failed from Ohe teroa, and
on the 30th, in lat. 38° 26', W. long. 145° 6', they ob-
erved a comet, the tail of which subtended an angle of 42
degrees. On the 6th of October they discovered an extensive
tract of land, which they at first conceived to be the “Terra
Antarctica incognita,” but which proved, in the event, to be
a part of New Zealand. Lieutenant Cook, having anchored,
on the 8th, in a bay, at the entrance of a small river, went on
shore, accompanied by Mr. Banks and Dr. S-lander, and at-
tended with a party of men, in order to have some intercours
with the natives. They assumed a very hostile appearance;
and made attempts for running away with the horses, which
had been left at the entrance of the river. On the next day
they exhibited the same formidable aspect, brandishing their
plow...
pikes and lances. Tupia addressed them in a language, which was a dialect of their own and which they understood; inflaming them that their voyagers only wanted provisions and water, in exchange for iron, the properties of which he explained as far as he was able. Their intentions, however, appeared to be unfriendly; and on the iron and beads, which were presented to them, they seemed to get little value. Tupia told them at length, that if they proceeded to any farther violence, some of them must fall victims to the just retaliation of the English. This salutary counsel, however, produced no effect; and some were killed, and several wounded in the conflict that ensued. The severity exerted on this occasion, was very different from the conduct which Mr. Cook’s prudence and humanity suggested in other cases; and, on a calm review, it was not approved by himself; but he pleaded the nature of the service in which he was employed and the necessity of obtaining a knowledge of the country, which he had previously attempted to acquire by kind treatment, and with a view to which he was at length obliged to recur to hostile and fatal measures. The lieutenant finding all his efforts to establish an intercourse with the natives unavailing, determined to re-embark, and on the 11th of the month he left this inhospitable place, which, as it had supplied him with no article except wood, he denominated Poverty-bay, called by the natives Toodaoo, or Long Sand, and situated in S. lat. 38° 43’, and W. long. 181° 30’. In this course he spent nearly six months, and made large additions to the knowledge of geography and navigation. By making the whole circuit of New Zealand, he ascertained it to consist of two islands. While the ship was hauling to the south end of a small island, called Teadeadey by the natives, and by the lieutenant “Portland island,” it suddenly fell into tidal water and broken ground. The inhabitants, perceiving its defects, put off in five canoes, and assumed a very formidable and menacing aspect, and seemed to be prepared for action; and it was to little purpose that guns were fired in order to intimidate them. Whilst some kind of traffic was carrying on with one of the canoes, Tupia’s boy, who was standing on the side of the ship, was seized by one of the New Zealanders, and carried off. Upon this atrocious act the marines were ordered to fire; and during the confusion that ensued, the boy made his escape and swam to the ship; though he was pursued by the largest of the canoes. To the cape where this unhappy transaction occurred, Mr. Cook gave the name of “Cape Kidnappers;” it lies in S. lat. 39° 43’, W. long. 182° 24’. Between this cape and the island Portland Island is a bay, which, in honour of Sir Edward Hawke, the lieutenant called “Hawke’s bay.” While, on the 18th, the Endeavour lay abreast of a peninsula within Portland island, called Tindaadu, two of the natives, supposed to be their chiefs, came so far in Mr. Cook, as to venture on board the ship, and remained there all night, their canoe being hoisted into the bay. On the 23rd, while the ship was in Tindaadu bay, lieutenant Cook went on shore to examine the watering places, and found the water excellent and conveniently situated, and the disposition of the people much more favourable than he expected. This lay in S. lat. 35° 22’ 44”, and W. long. 180° 47’. Here they supplied themselves with as much wood and water as they wanted. On the 28th, some gentlemen of the Endeavour went on shore on an island which lies to the left hand of the entrance of Tolaga bay; and there saw the largest canoe which they had yet observed; her length being 684 feet, her breadth 5 feet, and her height 3 feet 6 inches. While the ship was in Hicks’s bay, the inhabitants of the adjoining coast were found to be very hostile. Early on the 18th of November, they counted 45 canoes coming from the shore towards the Endeavour, and several others following them from another place. Some of the Indians traded fairly; others added derision and insolence to fraud; and though several small shot were fired at them, the canoes merely depended a-far, and set up their song of defiance as they departed from the ship. In standing westward from a small island called Motumobora, the Endeavour encountered some danger amidst the adjacent rocks, but at length it escaped without injury near an island called by the lieutenant the Mayer; the inhabitants of the neighbouring coast displayed in many instances their hostility, and, in their traffic with our navigators, committed various acts of fraud and robbery. Here, viz. in S. lat. 36° 48’ 55”, lieutenant Cook and Mr. Green made an observation of the transit of Mercury. In the mean while the ship was visited by two large canoes, one of which indicated hostile intentions on the part of its crew. In the course of their traffic, they were guilty of an act of fraud, accompanied with menaces and defiance, which induced Mr. Gore to fire at the offender and to kill him. At length, however, in consequence of small shot fired over their heads, they all fled with the utmost precipitation. On the 10th, our commander, accompanied by Mr. Banks, and the other gentlemen, examined a large river that empties itself into the head of Mercury bay, and found the situation abounding with conveniences, capable of an easy defence, which are admirably fitted for retaining beds of excellent oysters; this river Mr. Cook called Oyster river. On the 15th he sailed out of “Mercury bay,” so called in consequence of the observed transit of Mercury over the sun, and lying in S. lat. 36° 47’ W. long. 184° 4’. Another river lies at the head of the bay, which is the bell or safe path for a ship that wants to stay for any length of time. This the lieutenant, observing a number of Mangroves about it, called “Mangrove river.” Before the Endeavour left the bay, Mr. Cook, having displayed the English colours, took formal possession of the place in the name of his Britannic Majesty, King George III. In the range from Mercury bay several canoes appeared apparently for hostile purposes; but their occupiers were instantly dispersed by a musket ball, fired through one of their boats; although Tupia’s oratory had proved ineffectual. While Mr. Cook remained in the “Bay of islands,” he took occasion to examine the interior part of the country and its produce. Some circumstances occurred which produced disagreement between the navigators and the inhabitants, and it required singular exertions of prudence, as well as of humanity on the part of Mr. Cook, to bring them to a termination. The number of inhabitants in the Bay of islands was found to be much greater than in any other part of New Zealand which the commander had hitherto visited; and though they did not appear to be united under one head, and though their towns were fortified, they seemed to live together in perfect amity. The Endeavour on the 9th of December, lying becalmed in “Double bay,” an opportunity offered for making inquiries among the natives concerning their country; and Tupia enabled the lieutenant to learn that at some distance, at a place called “Moore-whenua,” the land would take a short turn to the southward, and thence extend no more to the west. This place the English gentlemen concluded to be the land discovered by Tafman, and which he had named “Cape Maria Van Diemen.” The inhabitants, who seemed to be intelligent, farther informed them, that there was a country of great extent, to the N.W. by N. or N.N.W., called Ulinaaroa, where it was understood the people eat hogs. Our navigators, on the 30th of December, saw the land, which they judged to be “Cape Maria Van Diemen,” and which corresponded with the account given of it by the Indians. The next day, they had demonstrative evidence, from the appearance
once of mount Carmel, that, where they now were, the breadth of New Zealand could not be more than two or three miles from sea to sea. During this part of the navigation, they encountered, in S. lat. 3°, and in the midst of summer, a long-continued and violent gale of wind; but as they were at a considerable distance from the land, they escaped the danger that alarmed them. The shore at "Queen Charlotte's Sound," where the English had arrived on the 14th of January, 1770, seemed to form several bays, into one of which lieutenant Cook proposed to take the ship for necessary repairs, and for obtaining a recruit of wood and water, of which they were supplied with great plenty. On landing they found an Indian family, in which they found horrid and indescribable proofs of the custom of eating human flesh. Evidences of the same custom appeared likewise on several other occasions. While they were near this part of the country, they were entertained with the most enchanting melody of birds, which began their song about two hours after midnight and continued it till sun-rise; thus refembling the nightingales of our own country. Lieutenant Cook, upon ascendimg one of the hills of the country, had a view of the sea on the eastern side of it, and of a passage leading from it to that of the west, a little east of the inlet where the ship lay. The main land, S. E. of this inlet, appeared to be a narrow ridge of very high hills, forming part of the S.W. side of the strait. On the opposite side, the land trended away E. as far as the eye could reach; and to the S.E. was discovered an opening to the sea, which washed the eastern coast. The lieutenant saw, also, on the E. side of the inlet, some islands which he had before taken to be part of the main land. In returning to the ship, he examined the harbour and caves that lie behind the islands which he had seen from the hills; and he employed the next day in farther surveys and discoveries—the gentlemen of the ship also accompanied him in visiting a town, which was built upon a small island or rock, very difficult of access, and which consisted of between 80 and 100 houses; the inhabitants of which were very friendly and attentive, and furnished them with a large quantity of dried fish. From a lull of considerable height, which afforded a view of the coast to the N.W., the farthest land that appeared was an island at the distance of about 10 leagues, lying not far from the main; between this island and the place where the commander dived, he discovered, close under the shore, several other islands, forming many bays, in which there appeared to be good anchorage for shipping. On the 30th of January the inlet where our voyagers now lay was named "Queen Charlotte's Sound," and a memorial was erected of their visit to this place. At the same time Mr. Cook took formal possession of this and the adjacent country in the name of king George III.; thus precluding the claims of future navigators, but revering to the original inhabitants their natural rights. On Monday, the 5th of February, the Endeavour, after encountering a violent storm, got under sail; but was soon obliged to come to an anchor a little above Motuara. Upon inquiring he learnt that there was a distant country, towards the north, called Ultima Thule; but he could not obtain any farther particulars. Lieutenant Cook, on the 6th of February, got out of the Sound, and in the evening saw two small islands, lying off "Cape Koamaroo," at the S.E. head of Queen Charlotte's Sound, and bearing E. at the distance of about four miles. The rapidity of the stream, occasioned by the tide of ebb, endangered the ship, and it was removed by some favourable incidents; the narrowest part of the strait through which it was rapidly driven, lies between "Cape Tic-

CO

\footnotesize{\textit{ante," on the coast of the island of Ekeinoanuoo, and "Cape Koamaroo," the distance between them being estimated at four or five leagues. During Mr. Cook's long and minute examination of the coast of New Zealand, he gave names to the bays, capes, promontories, islands, and rivers, and other places which he saw or visited, excepting in instances where their original appellations were learned from the natives. After having ascertained New Zealand to be an island, Mr. Cook wished to extend his acquaintance with the country. He completed his circumnavigation, by ranging from "Cape Tying-sen," southward along the eastern coast of Pocnamoo, round "Cape South," and back to the western entrance of the strait which he had passed, and which has been very properly called Cook's Strait; which see. In this range an island, lying about five leagues from the coast of Taw-Pocnamoo, was discovered, and it was named "Banks's Island." Lieutenant Cook, pursuing his course to the southward, wished to ascertain whether Pocnamoo was an island or a continent. In the prosecution of this object he passed some dangerous rocks on the 9th of March, and on the same day reached a point of land called "Swin Cape," in S. lat. 45° 19'. W. long. 132° 42', which proved to be the southern extremity of the country. On the 14th the Endeavour passed a small narrow opening in the land, where was a safe and convenient harbour, formed by the island, which lay eastward in the middle of the opening. On the land back of the opening are mountains, the summits of which were covered with snow, that had recently fallen. The land on each side of the entrance of the opening, rises almost perpendicularly from the sea to a stupendous height: and, on this account lieutenant Cook did not chuse to take the ship into the harbour. Before the 27th of March, the commander had circumnavigated the whole country of Taw-Pocnamoo, and arrived within ficht of the island before mentioned, lying nine leagues from the entrance into Queen Charlotte's Sound. With a view of obtaining a supply of water, he hauled round the island, and entered a bay, situated between that and Queen Charlotte's Sound, to which was given the name of Admiralty-bay; which see. Lieutenant Cook now directed his views towards Europe; and it was determined to return by the East Indies. In pursuance of this resolution, it was proposed that they should steer eastward till they should fall in with the east coast of New Holland, and then follow the direction of that coast towards the north, till they should arrive at its northern extremity. If that should be found impracticable, it was farther resolved that they should endeavour to fall in with the land, or islands, said to have been discovered by Quiros. For a farther account of New Zealand; see that article. On the 3rd of March our commandar sailed from "Cape Farewell" in New Zealand, S. lat. 40° 35'; W. long. 18°, and pursued his voyage towards the west. On the 15th of April "New Holland," or as it is now called, "N. W. South Wales," came in sight; and on the 28th, the ship anchored in Botany-bay; which see. During Mr. Cook's stay at this place, he caused the English colours to be displayed every day on shore, and took care that the ship's name, and the date of the year, should be inscribed on one of the trees near the watering-place. On the 6th of May our navigators failed from this bay; and in their farther progress lieutenant Cook gave the names marked upon the map to the bays, capes, points, and remarkable hills that appeared successively in sight. On the 14th, as the Endeavour advanced to the northward, being then in S. lat. 39° 25'; W. long. 266° 30', the land gradually rose in height, so that
that it may be called a hilly country. Between this latitude and Botany-bay, it exhibits a pleasing variety of ridges, hillocks, valleys, and plains, clothed with wood. On the 17th our navigators were in a bay called "Murton's bay," S. lat. 28° 36', W. long. 205° 28'; and from appearances they concluded that this bay opened into a river; but they had not then leisure to ascertain the fact. On the 22d, as they were purifying their voyage from "Harvey's bay," they discovered that the land was covered with palm nut-trees, which they had not seen from the time of their leaving the islands within the tropic. Early in the next day they went on shore, in order to examine the country, and found a channel leading into a large lagoon. Here they discovered a large river of fresh water, and room for a few ships to lie in great security. Near the lagoon grows the true Mangrove, as exisits in the West India islands, and the first of the kind that had been met with by our navigators. Among the islands and shoals they saw many large birds, which they judged to be pelicans, and on the shore a species of buffaloe of a considerable size and excellent food; so that in honour of it they called the inlet "Buffalo bay," S. lat. 24° 4', W. long. 205° 18'. Here they found a number of small pearl-oysters, among others of various kinds; so that Mr. Cook was of opinion, that an advantageous pearl-fishery might be established in this place. On the 26th our voyage, at a distance of one mile from the land, were abreast of the point which Mr. Cook found to lie directly under the tropic of Capricorn, in W. long. 28° 58', and he therefore called it "Cape Capricorn." On the 26th the ship, being under sail, was surrounded with islands, which lay at different distances from the main land; and here Mr. Banks, in fishing, took two sorts of crabs, such as had not been seen before; one of them was adorned with a bright blue band, equal to the ultramarine, which tinged all his claws and joints, while the under part was white and highly polished; the other was marked with ultramarine, more sparingly, on his joints and toes, and on his back were three brown spots of a singular appearance. Lieutenant Cook finding a passage between the islands, failed to the northward, and anchored at about two miles distance from the main. A great number of islands were within sight. Here Mr. Cook observing that the tide ebbed and flowed considerably, when the ship had anchored within the inlet, concluded that it was a river that might run pretty far up into the land. Our navigators having gratified their curiosity with a variety of objects, but being disappointed in their wishes of obtaining fresh water, determined to make a short stay in this place. Before they left it, however, they were drenched of more particularly examining the inlet, in which the ship lay; its breadth was found to be from two to five miles, upon a direction S. W. by S.; but here it opened every way, and formed a large lake, which to the N. W. communicated with the sea. On the south side of the lake was a ridge of hills; and various appearances indicated that the country was inhabited. The country, in general, in this part of New South Wales, appeared sandy and barren, and destitute of the accommodations which would fit it for being peopled by settled inhabitants. This inlet, from its want of fresh water, was called by Mr. Cook "Thirlby Sound." S. lat. 28° 22', W. long. 215° 19'. On the 31st our voyage, left the place and proceeded, till on the 7th of June they perceived on one of the islands, which they had been flying, the appearance of coconut-nut trees; but upon examination, there were mistaken for a small kind of cabbage-palm. On the 8th, when the Endeavour was in the midst of a cluster of small islands, the navigators discerned, with their glasses, upon one of the nearest of them, about 30 of the natives, men, women, and children, standing together and attentively looking at the ship. This was the first instance of curiosity that had been observed among the people of the country. They were wholly naked; their hair was short, and their complexion resembled that of the other inhabitants that had been before observed. In navigating the coast of New South Wales, for an extent of 22 degrees of latitude, or more than 1000 miles, lieutenant Cook had conducted his vessel in safety; but on the 20th of June, as he was purifying his course from a bay, which he had called "Trinity bay," the Endeavour fell into a situation peculiarly critical and dangerous; having been lifted over a ledge of rock, and living in a narrow inlet. The whole board were observed by the light of the moon to be floating away from her, and at last her false keel, to that moment it was expected the whole company would be swallowed up by the rushing in of the sea. The ship was expeditiously lightened as much as possible, and every exertion was made without murmur and with the greatest alacrity to escape the imminent peril to which their lives were exposed. So feebly were the sailors of the awfulness of their situation, that not an oath was heard among them. When morning dawned upon them they had a clearer view of their danger. Providentially, however, it became a dead calm, and high water came on at eleven in the morning: but it was necessary still further to lighten the ship, and two pumps were instantly worked to discharge the water that rushed in. For the tide at midnight they waited with anxious and anxious expectation: in the mean while the leak increased to a very alarming degree; and though the ship righted, it was expected that the sluice must go to the bottom as soon as she ceased to be supported by the rock. The floating of the ship, which in other circumstances, would have been the means of their salvation, was in their situation, a ground of serious alarm, because it might precipitate their destruction. Their possibility of escape was precarious, if the ship sunk; and the coast on which they were to be thrown, if any of them escaped, was inhabited by naked savages, from whom compassion they might derive no relief. The decisive moment at length arrived; and the ship was hove into deep water, without admitting more water than when she lay upon the shoal. The ship and crew experienced long hours of suffering from the weight of water, and the anxiety and fatigue, and in an exhausted state they threw themselves upon the deck, and after short intervals and pauses of rest, renewed their laborious and almost fruitless exertion for the leak gained upon the pumps. In this state of anxiety and labour, an accident occurred, which had almost terminated, at once, all their efforts. The planking which lines the ship's bottom is called the ciling; between which and the outside planking there is a space of about eighteen inches. From this ciling only, the man who had attended the well had taken the depth of the water, and had given the measure accordingly. But the peron, who relighted him, measured the depth to the outside planking, which had the appearance of the leak's having gained upon the pumps eighteen inches in a few minutes. The mistake, however, was soon detected; and this accident, at first so alarming, became, in the event, highly advantageous. New hopes, from a discovery that their situation was not so dangerous as they apprehended, inspired new vigour; and before eight in the morning the pumps gained considerably on the leak. At eleven o'clock the Endeavour was once more under full sail, and tolerably good for the land. They wished, however, to stop the leak; and Mr. Monkhouse, one of the midshipmen, proposed to the commander an expedient which had preferred a merchant ship, which had sprung a leak that admitted more than four feet water
COOK.

in an hour. This was called furling the ship. (See TOTHERING.)

The expedient succeeded; and it was owing partly to a fragment of rock, which had filled up one of the holes of the ship, that the ship did not sink and involve her whole company in inevitable destruction. In consequence of the difficulties experienced by the whole crew on this occasion, lieutenant Cook called a point in fight, which lay to the northward, in S. lat. 16° 6'. W. long. 214° 39', "Cape Tribulation." On the 14th a small harbour was discovered, excellently adapted for repairing the damage which the ship had sustained. Another alarming circumstance, which occurred at this time, was the access of the leaveny, that began to make its appearance among the ship's company, and that rendered it still more necessary to get on shore. On the 17th the ship put in for the harbour, the entrance of which was a narrow channel. Tents were erected for the accommodation of the sick; and all of them, except Mr. Green, manifested symptoms of recovery. On the 20th of June an emersion of Jupiter's first satellite was observed, from which they obtained the longitude of the place 214° 42' 36" W., its latitude being 15° 26' S. A plan of the harbour was taken; and Mr. Cook ascended a hill, from which he observed, to his great concern, innumerable sand-banks and shoals, lying in every direction of the coast. To the northward there was the appearance of a passage, by which lieutenant Cook had the only chance of getting clear, in the prosecution of his voyage. By a large supply of provisions, he was able to distribute 24 pounds to each man; a quantity of greens, being procured, were boiled with the peas; and by these means the ship's company obtained a very considerable refreshment. On the 2d of July our lieutenant entered the matter out of the harbour, to found about the shores; and to search for a passage to the northward. In a subsequent investigation, a passage to the sea was discovered between the shoals, which confided of coral rocks, and which had furnished cockles of an enormous size, infomuch that one of them was more than sufficient for two men. Other shells were also found in great abundance. At high water the ship floated; but a leak having been discovered, it was necessary to lay her afloat a second time. The several damages being repaired, the ship was again floated at high water, and preparations were made for proceeding on the voyage. To this harbour Mr. Cook gave the name of "Endeavour river." The matter, having been dispatched to re-examine the passage, which he had before discovered, reported that he had been mistaken. In the mean while, the inhabitants of the country, who had been very referred in holding any intercourse with the navigators, became more familiar, in consequence of the commander's prudent management. Here they discovered an animal, called by the natives kangooroo, which, being dexterous, proved to be excellent meat; and they were also furnished with great plenty of turtle, superior to any which the gentlemen ever tasted in England. The turtle was of the species called green turtle; and they weighed from two to three hundred pounds. The inward country was agreeably diversified by hills, valleys, and large plains, which in many places were richly covered with wood. The longitude of their situation, determined by an observation of the emersion of Jupiter's first satellite, July the 16th, was 214° 55' 45"; that on the 29th of June had given 214° 49' 30"; the mean of which was 214° 49' 7½" W. The Indians were very hostile and fraudulent; and so daring and insolent, that nothing would deter them but small shot repeatedly fired from the masts. In order to accommodate our navigators, they set fire to the grais, which blazed in various directions. On the 4th of August, after frequent unsuccessful attempts to disengage the ship from the harbour, she got under sail; but many difficulties occurred; and on the 5th, the lieutenant had not kept his course long before shoals were discovered in every quarter, which obliged him, at the approach of night, to come to an anchor. On the morning of the 10th, the weather, which had been boisterous, became more moderate, and the commander weighed anchor, and stood in for the land; determining to seek a passage along the shore to the northward. In pursuance of this resolution, the Endeavour proceeded in her course, and at noon came between the farthermost head-land that lay in sight, and three islands which were four or five leagues to the north of it, out at sea. Here they thought there was a clear opening before them, and began to hope that they were once more out of danger. In this hope, however, they were soon disappointed, and therefore the lieutenant gave the head-land, in 3° lat. 14° 56', W. long. 214° 47'; the name of "Cape Flattery." After flying for some time along the shore, for what was believed to be the open channel, an officer at the mast-head cried aloud that he saw land a-head, which extended quite round to the three islands; and that between the ship and them there was a large reef. Mr. Cook himself discovered the reef, but was of opinion that the supposed land was a cluster of small islands. In this state of uncertainty, however, he thought it most prudent to come to anchor, under a high point, from which he could have an extensive view of the sea and country. This eminence he called "Point Look-out." In the process of investigating the shoals and channel between them, the lieutenant, accompanied by Mr. Banks, discovered an island on which were no animals except lizards; and he therefore called it "Lizard island." In their return to the ship, they landed on a low sandy island, abounding with an incredible number of birds; and as they here found the nest of an eagle, they called it "Eagle island." At length, after much deliberation, it was resolved to quit the coast entirely, till they could approach it with less danger; and in pursuance of this resolution, the Endeavour, on the 13th, got under sail, and successfully passed through one of the channels or openings in the outer reef, which Mr. Cook had previously observed. The situation of our navigators was now happily changed; and after three months' anxiety and suspense, they found themselves in an open sea, with deep water. The passage or channel, through which the Endeavour passed into the open sea beyond the reef, lies in S. lat. 14° 52'. It is distinguished by the three high islands within it, to which, on account of the ufe they may be of in guiding the way of future voyagers, our commander gave the appellation of "Islands of Direction." New dangers, which created alarm and required fresh exertions, occurred; but every man did his duty with as much calmness and regularity as if no danger had been near. It was indeed the high and magnificent spirit of the commander, which inspired his people with such resolution and vigour. On the coast of a new and unknown country he proved all perils, and determined to ascertain whether this country did, or did not, join to New Guinea: a question which he had fixed upon resolving, from the first moment that he had come within sight of land. To the openings, through which he had passed with so much hazard, the commander, under a proper sense of gratitude to the Supreme Being, gave the name of "Proviudential channel." In the prosecution of the voyage, the navigators, on the 19th, were accompanied on every landfall, with rocks and shoals; but they were little moved, as perils had been familiar to them. On the 21st, as no land could be seen, they conceived hopes of having at last found a passage into the Indian sea; but to
determine this matter with greater certainty, lieutenant Cook resolved to land upon an island, which lies in the S.E. point of the passage. Accordingly he, accompanied by Mr. Banks and Dr. Solander, ascended a high hill, from which no land could be seen between the S.W. and W.S.W.; so that Mr. Cook had not the least doubt of finding a channel, through which he might pass to New Guinea. As he was now about to quit the coast of New Holland, which he had traced from lat. 38° to this place, and where he was certain no European had ever been before, he once more hoisted English colours, taking possession of the whole eastern coast, with all the bays, harbours, rivers, and islands situated upon it, from lat. 38° to lat. 10° S. in right of his majesty king George III., and by the name of New South Wales.

Having performed this ceremony upon the island, hence called "Pacification island," they relaunched in their boat; and on the 23d Mr. Cook was confirmed by several circumstances in his opinion, that he had arrived to the northern extremity of New Holland, and that to the westward he had an open sea. These circumstances afforded him peculiar satisfaction, not only because the dangers and fatigues of the voyage were drawing to a conclusion, but because it could no longer be doubted whether New Holland or New Guinea were two separate islands. The N.E. entrance of the third lies in S. lat. 15° 39', W. long. 218° 36'; and the passage is formed by the main land, and by a congeries of islands to the N.W., called by Mr. Cook the "Prince of Wales's islands," and which may probably extend as far as to New Guinea. To the channel through which he passed, he gave the name of "Endeavour straits."

From the coast of New South Wales, the lieutenant steered, on the 23d of August, for the coast of New Guinea; but in the progression of his voyage he fell upon a dangerous shoal, which exposed him to great danger; but he fortunately escaped; and on the 3d of September arrived within sight of New Guinea, and brought to within three or four miles of land. Some of the ship's company went on shore, but they were suddenly attacked by the natives, who had for some time concealed themselves in the woods. See New Guinea. Our voyagers leaving this coast, hallowed to the westward; and pursuiving their course, they discovered on the 6th of September a small island N.N.W.; and another low island, extending from that quarter to N.N.E. Unless these two islands belong to the "Arrau islands," they have no place in the charts; and if they do belong to these, they are laid down at too great a distance from New Guinea. Mr. Cook found the E. part of them in S. lat. 7° 6', W. long. 225°. On the 7th, when the ship was in S. lat. 6° 30', and W. long. 220° 34', our navigators ought to have been in the light of the Weaflile isles, which are laid down in the charts at the distance of 20 or 25 leagues from the coast of New Holland; but Mr. Cook, as he did not see them, concluded that they must have been laid down erroneously. In pursuiving their course, our navigators passed the islands of Timor, Timor-lavat, Rotte, and Seman. When they were near these latter islands they observed a phenomenon in the heavens, in some respects resembling, but in others differing from, the Aurora Borealis. Having passed all the islands between Timor and Java, lieutenant Cook did not expect to meet with any other in that quarter; but on the 17th he observed an island bearing W.S.W., which he thought to be a new discovery. When they came to the N. side of it, they saw hounes and cocou-nut trees, and numerous flocks of sheep. Here they landed; the commandr thinking he might thus supply the necessaries of the ship's company, and remove both the sicknes and the distress which had spread among them. This proved to be the island of Savu; which fee. On the 21st of September our navigators left Savu, and on the 1st of October came within sight of the island of Java; and on the 9th they stood in for Batavia road, where the Endeavour was secured from a stroke of lightning by the chain that was attached to it. The injurious effects of this climate were felt by our voyagers within nine days after their arrival; and Mr. Monkehoule, the surgeon of the ship, fell, on the 5th of November, the first sacrifice to this fatal country.

The repair of the Endeavour, which had been very much damaged, and which appeared to be in a very alarming state, was an object to which Mr. Cook, though himself affected by the climate, directed his particular attention, and it was performed much to his satisfaction. When this business was accomplished, on the 27th of December, the ship stood out to sea; and on the 4th of January 1771, came to an anchor under the S.E. side of "Prince's island," where the gentlemen of the ship, after having paid their respects to the king, commenced a traffic with the natives for turtles, tpows, fih, monkees, small deer, and vegetables. On the 5th the commander weighed, and stood out for sea. In the prosecution of the voyage to the Cape of Good Hope, the feeds of disease, which had been received at Batavia, appeared with very threatening symptoms, and reduced the navigators to a very melancholy situation. The ship was a mere hospital; the water taken in at Prince's island was purified with lime; and in order farther to guard against infection, the commander ordered all the parts of the vessel between the decks to be washed with vinegar. So fatal, notwithstanding every precaution, was the disease, that almost every night a dead body was committed to the sea. The losses amounted in all to 23 persons, besides the seven who died at Batavia. Among these were Mr. Green the astronomer, Mr. Parkinfon, natural history painter, Mr. Monkhous the midshipman, another midshipman, &c. &c. These calamitous events contributed most probably to turn the attention of Mr. Cook to those methods of preventing the health of seamen, which he afterwards pursued with such remarkable success. On the 13th of March the Endeavour arrived off the Cape of Good Hope; and a proper place was provided on shore for the accommodation and recovery of the sick. Lieutenant Cook having landed whilst the sick of his crew were recovered, necessary stores were procured, and the vessel refitted, till the 14th of April, stood out of the bay, and proceeded on his voyage westward.

In the morning of the 29th, he crossed his 6th meridian, having circumnavigated the globe in the direction from eft to west; the consequence of which was that he had lost a day, an allowance for which had been made at Batavia. On the 1st of May he arrived at St. Helena, and on the 4th he departed from this island, and pursued his course in safety. On the 11th of June, land, which proved to be the Lizard, was discovered; on the 11th the ship ran up the channel; next morning he passed Beachy head; and in the afternoon of the same day anchored in the Downs, and went on shore at Deal. Thus ended Mr. Cook's first voyage round the world, in which he had gone through so many dangers, explored so many countries, and exhibited the strongest proofs of his possessing an eminently sagacious and active mind; a mind that was equal to every perilous enterprise, and to the boldest and most successful efforts of navigation and discovery.

Mr. Cook having thus recommended himself to the protection of government, and the favour of his sovereign, was promoted in the progressive order of the naval service, to be a commander in his majesty's navy, Aug. 29, 1771.
an officer inferior in rank only, but equal in advantage to that of post-captain. On the 21st of May 1772, captain Cook communicated to the Royal Society by a letter to Dr. Markleyne, "An Account of the flowing of the Tides in the South Sea, &c." (see Phil. Trans. vol. lxxii. p. 357-8.) The curiosity of the public was much excited by the reports of lieutenant Cook's voyage; and it obtained amply gratified by Dr. Hawkeford's Account, in 3 vols. 4to. Extensive and interesting was the knowledge obtained in consequence of this voyage; but the question concerning a southern continent remained still undecided. The reign of our present sovereign George III. has been favourable to every kind of scientific and literary inquiry; and the earl of Sandwich, who, at the period to which we now refer, was at the head of the admiralty, was eminently capable of comprehending and disposed to encourage the most enlarged views and schemes with regard to navigation and discovery. By his particular recommendation, it was resolved to appoint a commission for determining the long disputed question relating to the existence of a southern continent. Quiros seems to have been the first person who ingrafted the idea of such a continent; but though he was sent out to ascertain it, he failed in the attempt. Mr. Dalrymple had now excited the public attention to this object, by his Historical Collection, in 2 vols. 4to. of the several voyages and discoveries in the south Pacific Ocean, 1770, 1771. When the Board of Admiralty determined to take up the business, captain Cook was immediately fixed upon as the person best qualified for conducting an enterprise which was to give the utmost possible extent to the geography of the globe, and the knowledge of navigation. Two ships, similar in construction to the Endeavour, were provided for this purpose; the largest of the two, which consisted of 442 tons burthen, was named the Resolution; and to the other, consisting of 336 tons burthen, was given the name of the Adventure. On the 28th of November 1771, captain Cook was appointed to the command of the former; and, about the same time, Mr. Tobias Furneaux was promoted to the command of the latter. The complement of the Resolution, in officers and men, was fixed at 112 persons, and that of the Adventure at 81. In the equipment of these ships, attention was directed to every circumstance that could contribute to the comfort and success of the voyage. Lord Sandwich was singularly attentive on the occasion; and both the navy and victualling boards took care to procure for the ships the best stores and provisions, together with an ample supply of antiscorbutic articles, such as malt, four krout, salted cabbage, portable broth, foup, mullard, marmalade of carrots, and infirminated juice of wort and beer. Scientific objects were also duly regarded. Mr. William Hodges, an excellent landscape painter, Mr. Reinhold Fohler, and his son, well informed in natural history, and Mr. William Wales, and Mr. William Bayley, skilful astronomers, were appointed to accompany the expedition; they were furnished with the best instruments for observation, and particularly with four time-pieces, three of Mr. Arnold's construction, and one of Mr. Kendall's, upon the principles of Mr. Harrison. Captain Cook, on board the Resolution, joined the Adventure in Plymouth Sound, on the 3d of July 1771, and there received his instructions, which comprehended, without entering into a minute detail, the most enlarged plan of discovery that is known in the history of navigation. He was instructed not only to circumnavigate the whole globe, but to circumnavigate it in high southern latitudes, making such traverses, from time to time, into every corner of the Pacific ocean not before examined, as might finally and effectually resolve the much agitated question about the existence of a southern continent, in any part of the southern hemisphere, to which access could be had, by the efforts of the boldest and most skilful navigators.

On the 17th of July, captain Cook sailed from Plymouth, and on the 26th anchored in Pencnhiwe road, in the island of Madeira. Having supplied himself with water, wine, and other necessaries, he left the island on Aug. 4th, and sailed to the southward. As he proceeded, he made three potches of beer, and infirminated several gallons of juice of malt, and the liquor was brilk and drinkable; though on account of the heat of the weather, and the agitation of the ship, the juice was in a high state of fermentation. If it could be kept from fermenting, this would be a most valuable article at sea. At St. Jago, one of the Cape de Verd islands, he stopped to procure a fresh supply of water. On the 20th of the month, they were delayed with rain; but to guard against the pernicious effects of rain on any future occasion, captain Cook took care to well air and dry the ship with fires between the decks, and to smock its damp places; besides, the people were ordered to air their bedding, and to wash and dry their cloaths, whenever they had an opportunity; such was the result of these precautions, that there was not one sick person on board the Resolution. On the 8th of September, the ship crossed the line in W. long. 83°, and proceeded on its voyage. On the 29th, being near the Cape of Good Hope, the whole sea, as far as our voyagers could see, became at once, as it were, illuminated. In order to ascertain the true cause of this phenomenon, which had in the former voyage been attributed to luminous insects, captain Cook examined some buckets of water, and found in them a number of globular insects, about the size of a common pin's head, and quite transparent. Mr. R. Forster was satisfied that these were the cause of the sea's illumination. On the 30th, the Resolution and Adventure anchored in Table bay; and the captains on going on-shore, were received by the governor with great politeness. On the 22d of November, our commander failed from the Cape, and professed his voyage in search of a southern continent. He directed his course for Cape Circumcision; but, by tempestuous weather, our voyagers were driven far to the eastward of their intended course, being in S. lat. 48° 41' E. long. 18° 24', so that they had no hopes of reaching this Cape. In this gale, they had the misfortune to lose the principal part of the live stock on board, consisting of sheep, hogs, and geese.

On the 10th of December, in S. lat. 50° 40', and long. 2° E. of the Cape of Good Hope, they began to meet with islands of ice, one of which was judged by captain Cook to be about 50 feet high, and half a mile in circuit. The weather was hazy, and danger was imminent. On the 18th they happily got clear of the field of ice. They were now in S. lat. 55° 9', and long. 24° 5'. An opinion had been entertained, that such ice was formed in bays and rivers, and hence our voyagers were led to conclude, that land was not far distant. But they proceeded without finding it. The whole crew began to complain much of cold, and therefore the captain directed the fleeces of their jackets to be lengthened with baize, and ordered a cap to be made for each, strengthened with canvas. This frosting, it should be recollected, was with them the middle of summer. As some of the crew appeared to have symptoms of the scurvy, fresh wort was given them every day. By the 29th, the commander was satisfied that the field of ice, along which the ships had failed, did not join to any land. Determining to run as far W. as the meridian of Cape Circumcision, a gale sprang up on the 31st, which brought with it such a swell

4 M 2

of
COOK.

After our navigators had been on the lookout for the ice for some time, they had observed it but once, and it was the last of the season which they had observed. It consisted of fluffy, white, frozen drift and was blown on land by the wind. The ice was not thick, but it was a good deal thicker than the ice which had been observed before, and it was not as extensive as the ice which had been observed in the previous years.

On the 18th of January, they were at the Cape of Good Hope, and it was there that they had their first sight of the ice. The ice was seen in the distance, but it was not as extensive as the ice which had been observed before. The ice was not as thick, but it was a good deal thicker than the ice which had been observed in the previous years.

gave orders that they should be boiled, with wheat and portable broth, every day for breakfast, and with peas and broth for dinner. Experience had taught him that these vegetables, thus dressed, are very beneficial to scaven, in removing various scrobutic complaints. The intercourse with the natives of the country was of a friendly nature; and proved advantageous in a variety of respects, particularly in supplying a quantity of fish. On the 2d of June, when the ships were almost ready to put to sea, captain Cook sent on shore a male and female goat; and captain Furneaux left at Cannibal cove, two breeding fowls, and a boar. It is a remarkable circumstance, that during captain Cook’s second visit to Charlotte Sound, he could not recollect the face of any one person he had seen three years before, nor did it appear that a single Indian had any knowledge of him. Hence he infers, that in the interval the natives had either been driven away, or had removed, of their own accord, to some other situation. Not one-third of the inhabitants, formerly observed, seemed to be now there; their strong hold on the point of Matouria was deserted, and in every part of the Sound many forsaken habitations were discovered.

In the captain’s opinion, the place had never been very populous. From comparing the two voyages, it appears that the Indians of Eaheni-nouaue are in some sort of a more improved state of society than those of Tavai-poennamno. During captain Cook’s stay in the Sound, he had observed that the second visit to this country had not mended the morals of the natives of either sex. He had always looked upon the females of New Zealand as more chaste than the generality of Indian women. But he was now told, that the male Indians were the chief promoters of a shameful traffic, and that, for a slipper-mall, or any other thing they valued, they would oblige the women to prostitute themselves, whether it was agreeable or contrary to their inclination. At the same time, no regard was paid to the privacy which decency required. The account of this fact must be read with concern by every well-wisher to the good order and happiness of society, even without advertizing to considerations of a higher nature. On the 7th of June captain Cook put to sea from Queen Charlotte’s Sound together with the Adventure; and on the 1st of August, when they were in S. lat. 25° 14′, and W. long. 134° 6′, they were nearly in the situation assigned by captain Carteret for “Pitcairn’s island,” discovered by him in 1767; but they did not observe it. As our commander advanced in his course, every circumstance concerted to convince him that between the meridian of America and New Zealand there is no southern continent; and that there is no continent farther to the south unifies in a very high latitude. But the investigation and decision of the fact were referred for the employment of the ensuing summer. It was the 6th of August before the ships had the advantage of the trade wind; which they got at S.E. in S. lat. 19° 36′ W. long. 135° 32′. Having obtained this wind, captain Cook directed his course to the W.N.W. and proceeded in the track, pursued by M. de Bougainville. To four of the islands which he passed, he gave the names of “Resolution island,” “Doubtful island,” “Furneaux island,” and “Adventure island,” which see respectively. These are supposed to be the same that were seen by M. de Bougainville; and they, with several others, constitute a cluster of low and half-drowned isles, which that gentleman distinguished by the name of the Dangerous Archipelago. On the 15th of August the ships came within sight of “Osnaburg island,” or Maitaca, which had been discovered by captain Wallis. Having escaped being wrecked on the coast of Otaheite, they anchored, on the 17th, in Oatiippia bay, near the S.E. end of the island; and they were immediately crowded with the inhabitants of the country, who brought with them cocoa-nuts, plantains, bananas, apples, yams, and other roots, which were exchanged for nats and beads. On the 24th the ships put to sea, and arrived the next evening in Matavai-bay; but before they could come to anchor, the decks were crowded by the natives, many of whom were known to captain Cook or by most of whom he was well remembered. At Oparree the tents and astronomer’s observatories remained, on the same spot from which the transit of Venus had been observed in 1769. As soon as the frigate was recovered, the water completed, and the necessary repairs of the ships finished, captain Cook determined to put to sea, and on the 18th of September he ordered the vessels to be unmoored. In the mean while lieutenant Pickett returned from Atahsurau, where he had been to procure hogs; and in this expedition he had seen Oheere, in a very humble situation, compared with that which she had formerly occupied. In the evening of this day a favourable wind having sprung up, the commander put to sea; on which occasion he dismissed his Otaheite friends sooner than they wished to depart; but well satisfied with his kind and liberal treatment. From Matavai captain Cook directed his course for the island Huahine; this he reached the next day, and on the 3d of September anchored in the harbour of Owharre. Both the captains landed upon the island, and being cordially received by the natives, commenced a trade with them. Every thing was conducted with mutual confidence and harmony till the 6th, when several circumstances occurred on the part of the natives, which interrupted the friendly intercourse. Captain Cook at length complained to Oro, the king, of their insolence and frauds, who was much concerned on the occasion; and expected himself to obtain redress and to punish the delinquents. It was from the island Huahine that captain Furneaux received into his ship a young man named Omai, a native of Uliet, of whom so much hath since been known and written. This choice was at first disapproved by captain Cook, who thought that this youth was not a proper sample of the inhabitants of the Society islands; being inferior to many of them in birth and acquired rank, and not having any peculiar advantage with respect to shape, figure, or complexion. The captain afterwards found reason to be better satisfied with Omai’s having accompanied our navigators to England. At Huahine the vessels, though their stay was short, obtained very plentiful supplies of provisions. Not less than 300 hogs, besides fowls and fruit, were procured. From Huahine our navigators sailed for Ulietea, where trade was carried on in the usual manner, and a most friendly intercourse renewed between captain Cook and Oro, the chief of the island. An interruption took place in the intercourse between the ships and the natives, which was occasioned by a misapprehension on the part of the latter, and which upon proper explanation was soon rectified. So that provisions were furnished at Ulietea no less plentifully than at Huahine. Captain Cook estimated that the number of hogs, which had been obtained, amounted to 400 or upwards. Our commander, by his second visit to the Society islands, gained a farther knowledge of their general state and of the customs of the inhabitants. With regard to a certain disorder, captain Cook was not able to determine whether it was known to the islanders before they were visited by the Europeans; but he found upon inquiry that the introduction of it, if of recent origin, was unanimously ascribed to the voyage of M. de Bougainville.
village. Captain Cook wished to satisfy himself, whether human sacrifices constituted a part of the religious customs of these people. From Omai he afterwards learned that the inhabitants of the Society islands offer human sacrifices to the Supreme Being. The knowledge he was able to obtain concerning their religion was very defective. With regard to the character of their women, he was enabled to rectify a prevailing error; and he does them justice by informing us, that the favours both of the married women and of the unmarried, of the better sort, were as difficult to be obtained in the Society islands as in any other country. And as to the unmarried females of the lower classes, there were many who would not admit of any indecent familiarities. This voyage enabled our commander to gain some further knowledge concerning the geography of the Society islands; and he found it highly probable, that Otaheite is of greater extent than he had computed it in his former estimation. On the 17th of September captain Cook failed from Ulietea, directing his course to the west, with an inclination to the south. Land was discovered on the 23d, to which he gave the name of "Harvey's island." S. lat. 10° 7'. W. long. 158° 49'. On the 1st of October he reached the "island of Middelburg." From Middelburg the ship failed to "Amsterdam," the natives of which island were no less disposed than those of the former to maintain a friendly intercourse with the English. A few old rags at this island were sufficient for the purchase of a pig or a fowl.

Although the natives of Amsterdam were of a friendly disposition, they were not entirely free from the thievish propensity which pertained to the islanders of the Southern Ocean. The two islands of Middleburg and Amsterdam are guarded from the sea by a reef of coral rocks, extending from the shore about 100 fathoms. Similar to this, in a great measure, is the situation of all the tropical islands which our commander had seen in that part of the globe; and hence arises an evidence of the wisdom and goodfaith of Providence; as by such a provision nature has effectually secured them from the encroachments of the sea, though many of them are mere points, when compared with the vast ocean by which they are surrounded. The two islands above-mentioned are situated between the lat. of 21° 39' and 21° 53' S., and between the long. of 175° 40' and 175° 15', W. of S. lat. 5° 27', and W. long. 142° 39', S. lat. 3° 35', and W. long. 150° 53'.

On the 5th of October captain Cook proceeded on his voyage; next day he pilot'd the "island of Piliat, discovered by Tasaram, and situated in S. lat. 22° 26'. W. long. 175° 59'. On the 21st he made the land of New Zealand, at the distance of 8 or 10 leagues from Table cape. To a chief, who came off in a canoe, he gave two boars, two fows, four hens, and two cocks, and a quantity of feeds, of wheat, French and kidney beans, peas, cabbage, turnips, onions, carrots, parsnips, and yams. On the 30th of November the Resolution was brought into Ship Cove, in Queen Charlotte's Sound. After his arrival, the first object of the captain was to provide for the repair of his ship, and the next to examine into the state of his bread, much of which had become unfit for use. To the inhabitants, who refided at the Cove, he gave a boar, a young fow, two cocks, and two hens, which he had brought from the Society Islands; and at the bottom of the well bay he ordered to be landed three fows and a boar, together with two cocks and two hens; together with as much food as would last them 10 or 12 days. In the second visit of our navigators to New Zealand, they met with indubitable evidence that the inhabitants were eaters of human flesh; but it was captain Cook's firm opinion, that the only flesh that was eaten by these people was that of their enemies who had been slain in battle. Our commander did not leave New Zealand without making such remarks on the coast between Cape Terawhitre and Cape Palliser, as may be of use to future navigators. As the Adventure had been separated from the Resolution, and was thought to be no where upon the island, captain Cook gave up all hopes of seeing her any more during the voyage. On the 26th of November the captain failed from New Zealand, in search of a continent, and steered to the south, inclining to the east. Some days afterwards, our navigators reckoned themselves to be antipodes to their friends in London, and consequently as at great a distance from them as possible. The first ice island which they saw, was on the 11th of December, in S. lat. 6° 10'. W. long. 175°. In the process of the voyage such islands continually occurred, and the navigation became daily more difficult and dangerous. In S. lat. 6° 5', our voyagers at last got within such a cluster of these islands, and of loose pieces, that they found it almost impossible to escape. However, being relieved, the Resolution, on the 22d of the month, was in the highest latitude she had yet reached, with 67° 5', W. long. 142° 54'. and circumstances became too unfavourable, that captain Cook determined to return towards the north. Here was no probability of finding land, or of a possibility of getting farther south. As our navigators advanced to the N.E., on the 24th, the ice-islands increased very much upon them; and in the midst of about 100, they spent Christmas day. As captain Cook, agreeably to his late resolution, had traversed a large extent of ocean, without seeing land, he again directed his course towards the south; and by the 30th of January, 1774, after encountering innumerable obstructions, he reached to S. lat. 71° 10'. W. long. 160° 54'. Farther it would have been extreme folly to have proceeded. The captain was of opinion, in which most of the gentlemen on board concurred, that the ice now in sight extended quite to the pole, or might join to some land, to which it might have been fixed from the earliest time. Compelled at last by inevitable necessity to tack, and to land towards the north, captain Cook formed a resolution of spending the ensuing winter within the tropic. He was well satisfied, that no continent was to be found in this ocean, but that which must lie so far north as to be wholly inaccessible, on account of ice. If a continent existed in the Southern Pacific Ocean, he was sensible that he must have the whole summer before him, in order to explore it. Upon the supposition, that no land could be found, he might reach the Cape of Good Hope by April; in that case he would have finisht the business of finding a continent, which was indeed the first object of the voyage. But this could not satisfy the comprehensive and magnanimous mind of our commander. He had a good ship, expressly sent out on discoveries, a healthy crew, and wanted neither stores nor provisions. In such circumstances, to have quitted this Southern Pacific Ocean would have been betraying, as he thought, not only a want of perseverance, but of judgment, in supposing it to have been so well explored, that nothing farther could be done. Although he had proved that, if there were a continent, it must lie far to the south, there remained room for very large islands, in places as yet unexamined. He was also persuaded, that his continuing for some time longer in this sea would be serviceable to geography and navigation, and other sciences. Thus he reasoned; and accordingly it was his intention first to go in search of the land, said to have been discovered by Juan Fernandez, in the last century, in about the lat. of 38°; and if he failed in finding this land, he proposed to direct his course in quest of "Easter Island," or "Davis's land." He next intended to go within the tropic, and
and proceed seaward till he arrived at Otaheite, where it was necessary for him to explore the Adventure. It was also in his contemplation to run as far west as the "Terra Australis." He had proposed to steer to the south, and so back to the east, between the latitudes of 50° and 63°. In the execution of this plan, it was his purpose to attain the length of Cape Horn, in the ensuing November, when he should have the best part of the summer before him, to explore the southern part of the Atlantic Ocean. When he communicated this extensive plan, comprehending hazards and difficulties without number, to his officers, they unanimously and cheerfully concurred. In pursuance of his course to the north, Captain Cook became allured that the discovery of Juan Fernandez, if any such was ever made, could be nothing more than a small island. Our captain was at this time confined to his bed by a bilious colic: by the attention of Mr. Patten, the surgeon, he was relieved, and at length the disorder subsided; but his stomach was so weak, that he could take nothing but the broth and flees of a favourite dog, belonging to Mr. Forster. On the 11th of March our navigators came within sight of "Easter island," or "Davis's land." In S. lat. 25° 5' 30", W. long. 150° 46' 20". On the 6th and 7th of April they came within sight of four islands, which they knew to be the "Marquesas." To one of them Captain Cook gave the name of "Hood's island," and as soon as the ship was brought to an anchor in Madre de Dios, or Resolution bay, in the island of "Chritina," a traffic commenced, in the course of which the natives would frequently keep the goods, without making any return. Theft was so common, that it was impossible to guard against it; and one of the thieves was accidentally killed by a shot, in the act of stealing. After some time the trade was carried on in a better manner; and the ship was supplied with yams, plantains, bread-fruit, a few cocoanuts, fowls, and small pigs. From the Marquesas Captain Cook steered for Otaheite, with a view of falling in with some of the islands discovered by former navigators, and especially by the Dutch, the situation of which had not been accurately determined. In the course of the voyage he passed a number of low islets, connected together by reefs of coral rocks. One of these islands was "Tinokera," discovered and visited by Byron. Besides passing by "St. George's islands," so named by Captain Byron, Captain Cook discovered four others, which he called "Palliser's islets." On the 22d he anchored in Matavai bay, at Otaheite, where he took measures for the repairs of the ship. During his stay at Otaheite, he maintained a most friendly connection with the inhabitants; and a continual interchange of visits took place between him and Otoo, Towka, and other chiefs of the island. On the 15th of May, our captain anchored in Owharre harbour, in the island of Huahine, where he procured bread-fruit, cocoanuts, and other vegetables in abundance; but there was a scarcity of hogs. When they were leaving the island, the good old chief, Oreo, was the last man that left the vessel. At parting, Captain Cook told him that they should meet each other no more: Oreo wept, and said, "let your sons come, we will treat them well." At Ulieta nothing particular occurred. It was the last request of Oreo, the chief, to Captain Cook, that he would return; and when he could not obtain a promise to that effect, he asked the name of his burying place. Oreo's anguish at parting was very great: "he looked up at the ship, burst into tears, and then sunk down into the canoe." On the 6th of June, our voyagers left Ulieta, they few land, which they found to be a low reef island, about four leagues in compass, and of a circular form. called "Uawe island," discovered by Captain Wallis, and situated in S. lat. 16° 46', W. long. 154° 37'. Another reef island was seen on the 16th, to which Captain Cook gave the name of "Palmerston island," in S. lat. 18° 34', W. long. 165° 10'. On the 20th land was again seen, called by captain Cook "Savage island," in S. lat. 19° 4', W. long. 169° 37'. Pursuing his course to the W.S.W., Captain Cook sailed by a number of small islands, and on the 26th anchored on the north side of "Anamoona," or "Rotterdam," in S. lat. 25° 15', W. long. 174° 31'. While the captain was on shore at this island, he got the names of 20 islands which lie between the N.W. and N.E.; but two of them are most remarkable on account of their great height, viz. "Amataytanoa," and "Ogian." From the N.W. to the S. of Rotterdam, round by the E. and N., it is encompassed by many small islets, sand-banks, and breakers: no termination of them could be seen to the N., and they may possibly reach as far S. as Amsterdam, or Tongataboo. Together with Middleburg or Enoure and Pitart, these form a group, containing about three degrees of latitude and two of longitude; and Captain Cook called them the "Friendly islands," or "Achipelago." Pursuing his course to the west, our navigators discovered land on the 18th of July, which they found to be a small island, to which Captain Cook gave the name of "Turtle island," on account of the number of turtle which were seen on the coast. On the 18th high land was seen to the S.W., which was the "Australis del" Epiritu Santo of Quiros, or the Great Cyclades of M. de Bougainville. After exploring the coast for some days, the captain anchored in a harbour of the island of "Malicello," which he called "Port Sandwich," situated on the N.E. side of the island, not far from the S.E. end, in S. lat. 16° 25' 20", E. long. 165° 57' 23". On the 23d of July our navigators, having gotten to sea, discovered three or four small islands; and at this time the Resolution was not far from the "isle of Ambrym," the "isle of Paoam," and the "isle of Apoe," the S.E. of which latter island was discovered a group, which Captain Cook called "Shepherd's isles." Amidst the number of islands now observed, one only appeared to be uninhabited: it consisted of a remarkable peaked rock, accessible only to birds, and obtained the name of the "Monument." In the farther course of the ship to the southward, our navigators approached other islands, which they found to consist of one large island, and three or four smaller ones. The two principal of the latter were called "Montague," and "Hinchinbrook," and the large island captain Cook named "Sandwich," in honour of his patron, the earl of Sandwich. Pursuing his discoveries, he came to an island, called by the natives "Erromangyu," in a bay of which he anchored. As the inhabitants behaved treacherously, captain Cook called a promontory, or peninsula, near which a skirmish happened, "Traitor's Head," in S. lat. 18° 43', E. long. 169° 28'. From this place the captain sailed for an island, before discovered, on which he proposed to make some stay, for the purpose of obtaining a supply of wood and water. This island was called "Tanna," and three others near it were distinguished by the names of "Immer," "Errona," or "Footooana," and "Annatom." The harbour in which he anchored was called by him "Port Resolution," after the name of the ship; it was situated in S. lat. 19° 3' 25", and E. long. 167° 44' 35'. To this Archipelago, or group of islands, which captain Cook particularly examined, he gave the name of "New Hebrides." The season of the year came on when captain Cook proposed to return towards the north; but he improved the intervening time in exploring any land which he might yet meet with between the New Hebrides.
Hebrides and New Zealand, at which place it was his intention to refresh his people, and to renew his stock of wood and water for another southern course. Sailing with this view, September the 1st, he discovered land on the 4th; and the Resolution anchored next day in a harbour belonging to it. The inhabitants behaved to him in a very civil and friendly manner; and he returned their kindness with presents to their chief. Captain Cook gave this island the name of "New Caledonia." On one of the small adjoining islands the captain found a species of spruce pine, of which spars and very good masts might be made, and called it the "Isle of Pines." To another, which afforded ample employment to the botanists, he gave the name of "Botany Island." The captain, before he left this island, was enabled to far to survey it as to ascertain, that, excepting New Zealand, it is probably the largest island in the South Pacific ocean. Another island was observed of good height, and five leagues in circuit, to which was given the name of "Norfolk Isle," in S. lat. 29° 29' 30" E. long. 168° 16'. On the 6th of October our captain anchored in Ship Cove, in Queen Charlotte's Sound, on the coast of New Zealand; and his journal states that the inhabitants was altogether peaceful and friendly. Mr. Wales, on this occasion, accurately ascertained the latitude and longitude of this island, and found the bottom of Ship Cove to be in S. lat. 41° 5' 56" W., and E. long. 174° 25' 34". The 10th of November captain Cook left New Zealand, in the prosecution of his great object, or the determination of the question concerning the existence of a southern continent. Having failed in different latitudes, extending from 35° to 55° 48' S., till the 27th, the ship being in W. long. 138° 56', he gave up all hopes of finding any more land in this ocean. He therefore resolved to bear directly for the west entrance of the straits of Magallanes, with a view of coasting the S. side of Terra del Fuego, round Cape Horn, to the Strait of Le Maire. In the prosecution of this voyage, on the 17th of December, he reached the W. coast of Terra del Fuego, and on the 20th anchored in a place to which he gave the name of "Chirnisms Sound." The whole coast and country were defolate and uninteresting. Near every harbour, however, fresh water and wood for fuel were obtained. The country also abounded with wild fowl, and particularly geese. See Chirnisms Sound, and Terra del Fuego. On the 28th, captain Cook left Chirnisms Sound, and proceeded round Cape Horn, through Strait of Le Maire, to Staten land. Having passed this famous Cape on the next day, he entered the Bay of the Pacific Ocean, which he entered. On Staten island he found a port, on the 25th of January, which, from this circumstance, was denominated "New Year's Harbour." In the small islands adjacent to Staten land, and called "New Year's Isles," captain Cook perceived a harmony between the different animals of the place, which he thought deferving of being recorded. He feared, as far as they had entered into a league not to disturb each other's tranquillity. The greater part of the sea coast is occupied by the sea-lions; the sea-bears take up their abode in the ile; the flags are planted on the highest cliffs; the penguins fix their quarter where they have the most ready communication with the sea; and the rest of the birds chuse the most retired places. All these animals were occasionally seen to mix together like domestic cattle and poultry in a farm yard, without any attempt on the part of one to molest the other. Nay, the captain had often observed the eagles and vultures sitting on the hills among the flags, while none of the latter, whether old or young, appeared to be in the least disturbed at their presence. Should it be asked, how do these birds of prey live? The captain answers the question, by supposing, that they feed on the carcasses of seals and birds, which perish by various causes. It is probable, from the immense quantity of animals with which the island abounds, that such carcasses exist in great numbers. On the 4th of January, captain Cook sailed from Staten island, in order to reconnoitre that extensive coast laid down by Mr. Dalrymple in his chart, which is the gulf of St. Sebastian. As he had some doubt of the existence of such a coast, he determined to make the western point of the gulf; but when he came to the different points of it, he could discover neither land nor any unquie vocal signs of it. Proceeding in his voyage, land was seen on the 14th, but being almost wholly covered with snow, it was at first mistaken for an island of ice. This was named from its first observer, "Willis's island," S. lat. 54° W. long. 38° 33'. Another larger island, on which was a very considerable number of birds, was called "Bird island." On the 17th captain Cook landed in a bay of an extensive tract of country, very defolate in its appearance, which he took possession of in his majesty's name. The bay, situated in S. lat. 54° 5' W. long. 33° 48', he called "Pollock Sound," and the country, which proved to be an island 53 leagues in circuit, was called the "isle of Georgia," situated between 53° 57', and 55° 57' S. lat., and 13° 13', and 13° 34 W. long. On the 27th captain Cook, having left Georgia the 25th, computed that he was in S. lat. 63° 6'. Here he was satisfied there could be no land in the direction towards the W., from which there was a long hollow swell; and hence he inferred, that the extensive coast laid down in Mr. Dalrymple's chart of the ocean between Africa and America, and the gulf of St. Sebastian, did not exist. An elevated coast, observed on the 5th, was called the "Southern Whale," S. lat. 57° 13' 30', W. long. 27° 45'. To the more distinguished tracts of country, discovered from Jan. 31st to Feb. 6th, captain Cook gave the names of "Cape Bridel," "Cape Montau," "Saunders's ile," "Candelmas Illes," and "Sandwich's land." The last is either a group of islands, or a point of the continent; for the captain was firmly of opinion, that a considerable tract of land existed near the pole, which was the source of most of the ice that is spread over this vall southern ocean. He thought it probable that this land might extend farther to the N., where it is opposite to the southern Atlantic and Indian oceans. Ice had always been found by him farther to the north in these oceans than anywhere else, and this he judged could not be the case if there were not land of considerable extent to the south. See Southern Continent.

Captain Cook having accomplished the great object of his navigation round the globe, began to direct his views towards England. Many circumstances relating to the state of his provisions, and the health of his crew, contributed to hasten his return. In his course to the Cape of Good Hope, he searched for the islands of "Diana" and "Marieven," laid down in Halley's variation chart, in S. lat. 41° 30', and about 4° of longitude E. of the meridian of the Cape of Good Hope; but after sailing from February 25th to March 13th, no such islands could be discovered. On the 22d of March he anchored in Table bay; having failed from the time of leaving the Cape of Good Hope, to his return thither, no less than 20,000 leagues, which was an extent of voyage nearly equal to three times the equatorial circumference of the earth. It could not therefore be surprising, that the rigging and sails of the Resolution should be essentially damaged, and even worn out; and yet in the whole of this run, made in every latitude between 50° and 71° S., she did not spring either low-mast, top-mast, lower or top-sail yard; nor did she make as much as break a lower or top-mast yard;
COOK.

through; these happy circumstances were owing to the good properties of the vessel, and the singular care and abilities of her officers. Captain Cook having completed the necessary repairs, and supplied himself with requisite stores and provisions, left the Cape on the 27th of April, and reached the island of St. Helena on the 15th of May; on the 28th he anchored on the island of Ascension, and arrived at the island of Fernando de Noronha, on the 9th of June. In the progress of the voyage, he made an experiment upon the fill for procuring fresh water; the result of which was, that the invention is useful upon the whole, but that it would by no means be advisable to trust to it entirely; more especially as captain Cook was convinced, that nothing contributes more to the health of seamen, than a plentiful supply of water. On the 16th of July, the captain anchored in the bay of Fuyal, one of the Azores islands; and on the 19th, proceeded with all expedition for England. On the 30th, he anchored at Spithead, and landed at Portsmouth; having been absent from Great Britain three years and 18 days, during which time, and all changes of climate, he had lost but four men, and only one of them by fickness. The able manner in which captain Cook had conducted this voyage, and the discoveries he had made, could not fail to recommend him to the protection and encouragement of those who had patronized the undertaking. The noble lord who had taken a lead in the plans of navigation and discovery, was still at the head of the admiralty-board; and recommended by him to his majesty, our navigator was raised, on the 9th of August, to the rank of a post-captain, and three days after, appointed a captain in Greenwich hospital; a situation which was intended to afford him a pleasing and honourable reward for his illustrious labours and services. Moreover, so important were his discoveries to science in general, that on the 24th of February 1776, he was unanimously chosen a member of the Royal Society; and on the evening of the 7th of March, when he was admitted, a paper was read containing an account of the method he had taken to preserve the health of the seamen. (See Philos. Tran. vol. LXV. p. 402—406.) Another paper was communicated, at the request of the president, Mr. John Pringle, on the 18th of April, relative to the tides in the South Sea, viz. those in the Endeavour river, on the east coast of New Holland. (See Phil. Trans. ibid. p. 447, &c.) It was also resolved by the president and council to bestow on captain Cook Sir Godfrey Copley's gold medal. The president, according to his custom, delivered an elaborate discourse on the subject of the paper, which was thus distinguished.

The particulars of this voyage were related by captain Cook himself, in a manner that redounds to his reputation as a writer. His style is natural, clear, and manly; being well adapted to the subject and to his own character. The superintendence of the publication was undertaken by his learned and valuable friend, Dr. Douglas, who lately died in the se of Saltibury, and whose promotion afforded pleasure to per sons of literature of every denomination. The history of the voyage was recommended to the public by the accuracy and excellence of its charts, and by a great variety of engravings from the curious and beautiful drawings of Mr. Hodges. It was followed by the publication of the original astronomical observations, which had been made by Mr. Wales in the Resolution, and Mr. Bayley in the Adventure.

The illusion of a "Terra Australis incognita" to any purposes of commerce, colonization, and utility, having been dispelled; another geographical question of very general interest remained to be determined; and that was the practicality of a northern passage to the Pacific ocean. Many persons had conceived that there was a shorter, a more commodious, and a more profitable course of falling to Japan and China, and, indeed, to the East Indies in general, than by the tedious circuit of the Cape of Good Hope. To find a westerly passage round North America had been attempted by several bold navigators from Filibisher's first voyage, in 1576, to those of James and of Fox, in 1633. By these expeditions a considerable reflection was made to the knowledge of the northern extent of America, and Hudson's and Baffin's bays were discovered. But the westerly passage, on that side, into the Pacific ocean, was still unattained. Nor were the various attempts of our countrymen, and of the Dutch, to find such a passage, by falling round the north of Asia, in an eastern direction, attended with better success. Wood's failure in 1676, seems to have terminated the long list of unfortunate expeditions in that century. The discovery had ceased for many years to be an object of pursuit. However, the question was revived in the last century. Accordingly captain Middleton was sent out by government in 1741, and captains Smith and Moore in 1745. But, though an act of parliament had been passed, enacting a reward of $20,000 to the discovery of a passage, the accomplishment of their favourite object still remained to be effected. Previously to the full execution of this design, lord Mulgrave fell with two ships, in order to determine how far navigation was practicable towards the north-pole. In this expedition his lordship encountered many difficulties. Nevertheless, the expectation of opening a communication between the Pacific and Atlantic ocean, by a northerly course, was not abandoned; and it was resolved that a voyage should be undertaken for that purpose. Captain Cook was instantly, and unanimously, thought to be in every respect the proper person to accomplish this difficult and hazardous, but very important and interesting object. He had, however, done so much, and undergone so many trials, that his most zealous friends, and those who were most ardently devoted to the object, could not think of asking him to engage in fresh perils; the undertaking, however, became a subject of congratulation when he became a subject of congratulation when he visited the table of lord Sandwich, when captain Cook was present. The object, with all the interests connected with it, excited the ardour of the captain's mind, and he offered to undertake the direction of the enterprise. The Earl of Sandwich lost no time; the matter was laid before the king; and captain Cook was appointed to the command of the expedition, Feb. 10, 1776. At the same time, it was agreed, that, on his return to England, he should be restored to his situation at Greenwich; and, if no vacancy occurred during the interval, the officer who succeeded him was to resign in his favour. All former navigators round the globe had returned to Europe by the Cape of Good Hope; but captain Cook undertook to accomplish the arduous task by reaching the high northern latitudes between Asia and America; and it is thought that the captain's own reflections on the subject suggested this plan. Instead, therefore, of a passage from the Atlantic to the Pacific, one from the latter into the former was to be tried. Accordingly captain Cook was ordered to proceed into the Pacific ocean, through the chain of new islands, which had been visited by him in the southern tropic. After having crossed the equator into the northern parts of that ocean, he was to hold such a course as might probably fix many interesting points in geography, and produce intermediate discoveries. With regard to his grand object, it was determined, after the most mature deliberation and inquiry, that.
that, upon his arrival on the coast of New Albion, he should proceed northward as far as the latitude of 65°, and not lose any time in exploring rivers or inlets, or upon any other account, till he had gotten into that latitude. In the prosecution of this great design, motives of interest were annexed to obligations of duty. By a new law, passed in 1776, supplying the deficiencies of the act of 1749, it was enabled, that if any ship belonging to any of his majesty's subjects, or to his majesty, shall find out, and fall through, any passage, by sea, between the Atlantic and Pacific oceans, in any direction, or parallel of the northern hemisphere, to the northward of the fifty-second degree of latitude, the owners of such ships, if belonging to any of his majesty's subjects, or the commander, officers, and seamen of such ship belonging to his majesty, shall receive, as a reward for such discovery, the sum of 20,000l. Two vessels were fixed upon by government for the intended service; the Resolution and the Discovery; the former commanded by captain Cook, and the latter by captain Clerke. To the Resolution was allotted the fame number of officers and men, which she had during her former voyage; and the only difference in the establishment of the Discovery from that of the Adventure, was that she had no marine officer on board. Both ships were equipped in the most complete manner, and furnished with such an establishment and apparatus, &c., as might most effectually conduct to the improvement of astronomy and navigation. As the ships were to touch at Otahete and the Society islands, it was determined to carry Omai back to his native country, who returned with deep impressions of gratitude and respect for the liberal treatment which he had received during his absence, and while he continued in England. Captain Cook sailed from the Nore to the Downs on the 25th of June, and on the 30th anchored in Plymouth Sound, where the Discovery was already arrived. On the 8th of July he received his instructions, with orders to proceed to the Cape of Good Hope. On the 12th he sailed off Plymouth Sound, and proceeding in his course, touched at Teneriffe; anchoring on the 18th of August in the road of Santa Cruz. Having procured the necessary articles of refreshment, he sailed from Teneriffe on the 4th; and on the 13th arrived before Port Praya in the island of St. Jago, and then, not finding the Discovery there, sailed out to the southward. On the 1th of September, our navigator crossed the equator in W. long. 27° 28'; and on the 8th, being near the eastern coast of Brazil, he took pains to settle its longitude, which he concluded to be 35° 56' or 36° W. On the 18th of October, the Resolution came to an anchor in Table bay, at the Cape of Good Hope. On the 10th of November captain Cook had the satisfaction of seeing the Discovery arrive in the bay. Besides the attention which our captain manifested to the rate of his ship, and the accommodation of his crew in the further prosecution of his voyage, scientific objects engaged his particular note. On the 30th of November he weighed from Table bay, and on the 3d of December got clear of the land. On the 11th land was seen, which was found, upon a nearer approach, to consist of two islands. That which lies most to the south, and is the largest, was estimated to be about 15 leagues in circuit; the northerly one was about nine leagues; and the two islands are about the distance of five leagues from each other. The largest lies in S. lat. 46° 53', and E. long. 37° 40'; and the smaller one in S. lat. 46° 4', and E. long. 38° 8'. They seemed to have a rocky and bold shore, and their surface is for the most part composed of barren mountains, the fum- mits and sides of which were covered with snow. These two islands, with four others, which lie from nine to twelve degrees of longitude more to the east, and nearly in the same latitude, had been discovered by captain Marion du Fresne, and Crozet, French navigators, in January 1774. As no names had been allotted to them in a chart of the Southern ocean, communicated by Crozet to captain Cook in 1773, our commander distinguished the two larger ones by calling them "Prince Edward's islands." To the other four he gave the name of "Marions" and "Crozets'" islands. Rounding southward of these islands, he shaped his course so as to get into the latitude of the land which had been discovered by M. de Kerguelen, a French navigator. On the 24th he observed land, which proved to be an island of considerable height, and about three leagues in circuit. He soon after discovered another island about the same size, and also a third, besides some smaller ones. Another island was seen in S. lat. 48° 29', E. long. 68° 40', which was a high round rock, and which was called "Ughie's Cap." This he perceived to be the same with Kerguelen's "isle of Ren- dows." As soon as the weather began to clear up, captain Cook decreed in for the land, called "Kerguelen's land." At length a good harbour was discovered, in which the ships anchored on Christmas day. Here the captain displayed the British flag, and named the place "Christmas Harbour." On the 29th he left this harbour, and ranged along the coast, in order to discover its position and extent. In pursuing his course he met with several promontories and bays, together with a few islands, of which he has discovered and named. Another harbour, which the ships anchored for one night, is situated in S. lat. 49° 3'; and E. long. 69° 37', and was called "Port Pellicier." On the 30th, when this harbour was discovered, he came to a point, which proved to be the very eastern extremity of Kerguelen's land. This point was called "Cape Digby," and is situated in S. lat. 49° 23', and E. long. 76° 34'. The result of captain Cook's examination of Kerguelen's land was, that it did not occupy an interval much exceeding 1° in degree. From this defective coast our captain took his departure on the 31st, intending to touch at New Zealand, but on the 3d of January 1777, the wind veered to the north, and on the 12th the northerly winds ended in a calm; the ship being then in S. lat. 48° 46', E. long. 110° 26'. On the 24th our voyagers discovered the coast of "Van Diemen's land," and on the 26th came to an anchor in "Adventure bay." While captain Cook was at this country, he neglected no inquiry which could promote the knowledge of navigation, and other branches of science. He settled the latitude and longitude of places, marked the variations of the compass, and recorded the nature of the tides. Adventure bay he found to be situated in S. lat. 43° 21' 26", and E. long. 147° 29'. On the 30th of January he sailed from this bay, and on the 12th of February came to his old station in Queen Charlotte's Sound, in New Zealand. Here he found that ten men, who had separated from captain Furneaux's crew in the former voyage, had been murdered by the natives, and that their flesh had been consumed as food. The fear of revenge rendered them very averse from approaching the English vessels. On the 27th captain Cook got clear of New Zealand; and having met with unfavourable winds, it was not till the 29th of March that he discovered land, which was found to be an inhabited island, called "Mangerei," in S. lat. 21° 57'. E. long. 201° 53'. Purifying his voyage, on the 30th he again found land, which was an island, called by the natives "Waterooi," in S. lat. 20° 1'. E. long. 201° 45'. The next place which he visited was a small island called "Wenuoo-oette," or "Otakootaia," in S. lat. 16° 15'. E. long. 201° 37'. On the 5th he directed his course to "Harvey's island," which, he
he had discovered in 1777; and which he now found to be well peopled. Having by various adverse circumstances been so much retarded in his progress, that nothing could be done this year in the high latitudes of the northern hemisphere, he determined to bear away for the Friendly islands, where he was sure of being abundantly provided. Accordingly he reached Palmerston island in his course, where he obtained some refreshment; and after leaving this island, he steered to the west, with a view of making the halt of his way to "Amanuoko." On the 28th of April, he touched at the island of "Komango," and on the 1st of May arrived at Amanuoko. The only interruption of the harmony that subsisted between our voyagers and the natives of this island arose from the spiteful disposition of many of them. In order to correct and counteract this propensity, captain Clerke invented a mode of treatment which produced some effect, the putting of the thieves into the hands of the barbar, who completely shaved their heads. They thus became objects of ridicule to their countrymen, and their rogueries were restrained. Captain Cook having exhausted Amanuoko of its articles of food, proposed, on the 11th, to proceed directly for "Tongataboo." But it was recommended to him to touch at another island, or rather a group of islands, called "Hapae," lying to the N.E., where he might be plentifully supplied with every refreshment in the casual manner. Hapae was therefore chosen for the next station, where our commander arrived on the 17th, and met with a most friendly reception. Here the captain took an opportunity of examining not only Hapae, but "Lefonga," and other neighbouring islands. On the 19th of June he arrived at "Tongataboo," where he was kindly received, but somewhat molested by the thievish propensity of the inhabitants. On the 19th he left Tongataboo, and two days after came to an anchor in the island of "Middleburg," or "Eoa," as it is called by the inhabitants. Captain Cook remained at the Friendly islands between two and three months; and his intercourse with the natives was little interrupted. This intercourse was productive of many advantages. See FRIENDLY ISLANDS.

On the 17th of July, captain Cook resumed his voyage; and on the 8th of August, an island was discovered, called by the natives "Tobousi," and situated in S. lat. 23° 35', E. long. 210° 37'. Pursuing his course he reached Otaheite on the 12th, and steered for Oteitepeha bay, designating to anchor there before he went down to Matavai. Omai's reception among his countrymen was not entirely of a flattering nature. Nothing that was peculiarly striking occurred at their first meeting; his interview with his father, however, was agreeable to the feelings of nature; and his aunt threw herself at his feet, and bedewed them with tears of joy. On the 24th, the captain resumed his old station in Matavai bay. On this visit he was fully satisfied that human sacrifices formed a part of the religious institutions of Otaheite; for he was witness to a solemnity of this kind, which he has particularly described with the jeal threats of indignation and abhorrence. Here the captain was cured of a rheumatic complaint, extending from the hip to the foot in an extraordinary manner. The mother of Oto, a chief of the island, his threeisters, and eight other women, undertook the cure. Being desired to lay himself down amongst them, as many as could get round him began to squeeze him with both hands, from head to foot, but more particularly to the part where the pain was lodged, till they made his bones crack, and his flesh became a perfect mummy. After undergoing this discipline about a quarter of an hour, he was glad to be released from his female friends. The operation, however, gave him immediate relief, so that he was encouraged to submit to another rubbing down before he went to bed; the consequence of which was, that he was tolerably easy the whole succeeding night. His female physicians repeated their prescription the next morning, and again in the evening; after which his pains were entirely removed, and the cure was perfected. This operation, which is called "Romor," is universally practised among these islanders: being sometimes performed by the men, but generally by the women. During this visit of our voyagers to Otaheite, such a cordial friendship and confidence subsisted between them and the natives, as never once to be interrupted by any untoward accident. From Otaheite our voyagers passed to the 30th to Emeco, where they anchored. The transactions on this island were, upon the whole, unpleasant. On the 11th of October, the ship left it, and next day arrived at Owharre harbour, on the west side of Huahine. Here they settled Omai to mutual satisfaction; having procured for him a portion of land and built a house, on the outskirt of which was this inscription:

GEORGIA TERRITOR. REV. 2 NOVEMBER, 1777.

NAVIT. [Resolution, first. Cook, Pr.]

After parting with Omai in an affecionate manner, and leaving him comfortably settled among several of his relatives, captain Cook arrived at Batolabola, the last of the Society islands, which he visited on the 8th of December. Upon the whole, it has been observed, that the future felicity of the inhabitants of Otaheite, and the Society islands, will not a little depend on occasional visits from Europe, for it would have been better for these poor people, as captain Cook says, never to have known our superiority in the accommodations and arts which render life comfortable, than, after once knowing it, to be again abandoned to their original incapacity of improvement. On the 8th of December our commander sailed from Batolabola, and in the night between the 22d and 23d, crossed the line in E. long. 203° 15', and on the 24th discovered land, which was called "Christmas island," the west side of it, on which was observed an eclipse of the sun, being in N. lat. 1° 59', E. long. 223° 30'. On the 2d of January 1778, the ships resumed their course towards the north, and in their progress discovered three islands. On the 22d they touched at one of these islands, called by the natives "Atori;" and where captain Cook found the horrid practice of eating human flesh, which the inhabitants denominated "favour eating." But it was ascertained that one of these islanders has been observed to suckle a child in vailits of land, he observed the first object of this abominable custom. "Near this was another island, called "Otehecow," where our commander anchored on the 29th. It is observed, that the islands in the Pacific ocean, which European voyagers have discovered, have generally been found to lie in groups, or clusters. This was the case with those that were now visited; and to which captain Cook gave the name of "Sandwich islands," which lies on the 2d of February, our navigators pursued their course to the northward; and on the 7th of March they discovered the coast of "New Albion," the ships being then in N. lat. 44° 33', E. long. 235° 20'. In ranging on the west side of America, captain Cook gave names to several capes and head lands, which appeared in light. At length, on the 29th he anchored in an inlet, where the country appeared full of mountains, with snow covering their summits, interspersed with valleys which produced high shrub trees, exhibiting a beautiful prospect, as of one vast forest. The ships were now in N. lat. 49° 29', E. long. 232° 29'. The inhabitants on the coast appeared to be disposed to maintain a friendly intercourse with ilrang.
and a trade immediately commenced, the articles of which were the skins of various animals, such as bears, wolves, foxes, deer, raccoons, pelicans, and martins; and, particularly, sea-otters. Garments made of these were also offered for sale; the most extraordinary articles, however, were human skulls, and hands not quite stripped of their flesh, some of which exhibited marks of having been upon the fire. In exchange the natives took knives, chisels, pieces of iron and tin, nails, looking-glasses, buttons, or any kind of metal. Although commerce was, in general, carried on with mutual honesty, some of these people were no less inclined to theft than the islanders in the Southern Ocean. Of all the uncivilized tribes, which our commander met with in his various navigations, he never found any who had such fixed notions of their right to the exclusive property of everything which their country produced, as the inhabitants of the Sound, where he was now stationed. With Captain Cook, very much to the honour of his character and of his country, it was a sacred rule never to take any part of the property of the people whom he visited, without an ample compensation. Whilst the ships were under repair for the prosecution of the expedition, our captain improved every opportunity that occurred for extending his knowledge of the manners and customs of the inhabitants, who, in general, treated him with great civility. The natives were much addicted to singing; and in some instances, the whole body joined, some in a flow, and others in a quicker time; accompanying their notes with the most regular motions of their hands, or with beating in concert with their paddles, on the sides of the canoes, to which were added other very expressive gestures. At the end of each long, they continued silent for a few moments, and then began again, sometimes pronouncing the word _Home!_ forcibly as a chorus. At our captain's first arrival in this inlet, he denominated it "King George's Sound," but he afterwards informed that the natives called it "Nootka." The entrance of the Sound is situated in the east corner of Hope bay, in N. lat. 45° 53'. E. long. 23° 12'. On the 26th the repairs of the ships being completed, every thing was ready for the captain's departure. In the prosecution of the voyage to the north, and back again to the Sandwich islands, the incidents that occurred were chiefly of a involuntary kind. The first place at which Captain Cook landed, after his departure from Nootka Sound, was an island which he called "Kaye's island," situated at its S.W. point in N. lat. 59° 49'. E. long. 21° 58'. To an inlet in which the ships anchored on the 12th, he gave the appellation of "Prince William's Sound." Some days after leaving this Sound, our navigators came to an inlet, which they hoped would be found to communicate with the sea to the north, or with Baffin's or Hudson's bay to the east; and therefore they determined particularly to examine it. In consequence of a complete investigation of this inlet, it was discovered to be a river, which was afterwards called "Cook's river." On the 6th of June they got clear of this river, and pursuing their voyage, they failed on the 15th, amid the group of islands, which had been called by Beering "Schumagin's islands." On the 21st, among some hills, on the main land, that towered above the clouds to a most amazing height, one was discovered to have a volcano, which continually threw up vast columns of smoke. It does not stand far from the coast, and is situated in N. lat. 53° 38', and long. 195° 45'. The mountain is of a completely conical figure, and the volcano is at its very summit. A canoe, from an island in the neighbourhood, approached the ship, and the fickle person on board bowed as he came near. From such tokens of politeness, our captain reasonably inferred, that the Ruffians must have some communication and traffic with these people. On the 27th our voyagers reached an island, known by the name of "Onalaska," the inhabitants of which behaved with a degree of politeness uncommon to savage tribes. The harbour of "Samgamoooda," on the north side of the island, in which captain Cook came to an anchor, is situated in N. lat. 55° 55'. E. long. 193° 50'. On the 28th July our voyagers left Onalaska, and on the 16th were within sight of a promontory, on which lieutenant Williamfon landed; but he found that the land, as far as his view extended, produces neither tree nor scrub, though the lower grounds were not delititious or grass; and of some other plants. To this promontory, in N. lat. 56° 42'. E. long. 197° 36', was given the name of "Cape Newham." When our navigators, on the 31st of August, had advanced to the latitude of 62° 34', they had the misfortune to lose Mr. Anderfon, the surgeon of the Resolution, who had been more than twelve months been lingering under a consumption. Mr. Anderfon, who was a person of a cultivated understanding and agreeable manners, to distinguifhed skill in his own profession, added a very considerabe knowledge in other branches of science. An island, discovered soon after his death, was honoured with the appellation of "Anderfon's island." On the 9th captain Cook anchored under a point of land, to which he gave the name of "Cape Prince of Wales," situated in N. lat. 67° 46'. E. long. 191° 45', and remarkable for being the most western extremity of America hitherto explored. "This extremity is distant from the eastern cape of Siberia only 13 leagues; and there our commander had the glory of ascertaining the vicinity of the two continents, which had only been conjectured from the reports of the neighbouring Asiatic inhabitants, and the imperfect observations of the Ruffian navigators. Resuming his course on the 10th, captain Cook anchored in a bay, the land of which was at first supposed to be a part of the island "Alaachka;" but from the figure of the coast, from the situation of the opposite shore of America, and from the longitude, the captain thought to be more probably the country of the "Tschufki," on the easterly extremity of Asia, which had been explored by Beering in 1728; and this was found to be the fact. From the bay of St. Lawrence, below the entrance of the Tschufki, our navigators steered, on the 11th, to the east, in order to get nearer to the coast of America. Afterwards, proceeding to the north, they reached, on the 17th, the latitude of 70° 31', in longitude 195° 41'. On this day a brightness was perceived in the northern horizon, resembling that which is reflected from ice, and which is commonly called the "bikin." In about an hour's time, the sight of a large field of ice removed all doubt in captain Cook's mind with respect to the cause of the brightness of the horizon. The ships were soon close to the edge of the ice, in lat. 70° 41', and unable to proceed any farther. On the 18th, in lat. 70° 44', the ice near them was as compact as a wall, and judged to be at least ten or twelve feet high. Farther to the north, it appeared much higher. A prodigious number of sea-horses lay upon the ice; and some of them were procured for food, in order to supply the want of fresh provisions. Our voyagers lived on the sea-horses as long as they lasted; and they were generally preferred to salt provisions. Captain Cook continued, until the 29th, to traverse the icy sea beyond Beering's strait, in various directions, and through numberless obstructions and difficulties. The seaon, indeed, was now so far advanced, that it would have been highly imprudent to have made any farther attempts, till the next summer, at finding a passage into the Atlantic. Our commander's attention was now directed to the discovery of a proper
proper place for obtaining a supply of wood and water; and to the manner in which he should spend the winter, with some improvements in geography and navigation, and so as to be in a condition to return to the north, for a farther search of a passage, in the ensuing spring. Before he proceeded to the south, he employed a considerate time in examining the sea and coasts in the vicinity of Bering's Strait, on the side both of Asia and America. In this examination, he ascertained the accuracy of Bering, so far as he went; demonstrated the errors with which Stutchin's map of the new northern Archipelago abounds; and made large additions to the geographical knowledge of this part of the world. "It reflects," as Mr. Cox justly observes, "the highest honour even on the British name, that our great navigator extended his discoveries much farther in one expedition, and at so great a distance from the point of his departure, than the Russians accomplished in a long series of years, and in parts belonging or contiguous to their own empire."

On the 2d of October, our voyagers came within fight of the island of Oonalashka, and anchored again in Samganodah harbour. Here, whilst the ships were repairing, the seamen collected berries, with which the island abounds; and, which, in conjunction with the spruce-beer, contributed efficiently to eradicate every fear of the scurvy that might exist in either of the vessels. They also procured an ample supply of fish. Captain Cook, on the 8th, received a very flimsy present, which was a rye-loaf, or rather a pie in the form of a loaf, for it included some salmon, highly flavoured with pepper. Captain Clerke received also the same kind of present. These presents, it was reasonably supposed, came, by the hands of an Oonalashkan, from some Russians in the neighbourhood. On the 10th corporal Ledlair of the marines returned from his researches with three Russian seamen, or furriers, who, with several others, refuted at "Engooehhar," where they had a dwelling-house, some store-houses, and a sloop of about 50 tons burthen. From these perfons captain Cook derived every possible degree of information. Afterwards, another Russian was introduced to our captain, whose name was Efrem Gregoroff Bin Inmyloff, and who was the principal person among his countrymen in this and the neighbouring islands. From him he obtained two charts, which he was permitted to copy. The first included the "Penfinskiia" sea; the coast of Tartary, down to the latitude of 41°; the Kuril islands; and the peninsula of Kamtchatka. The second chart, which was the most interfering, comprehended all the discoveries made by the Russians to the easterly of Kamtchatka, towards America; which, however, exclusively of the voyages of Bering and Tschernikoff, amounted to little or nothing. Indeed captain Cook was assured, that no Russians had even seen any part of the continent of America to the northward, except that which lies opposite to the country of the Tschinkits. On the 26th, all things being ready for captain Cook's departure, he put to sea, and failed for the Sandwich islands; it being his intention to spend a few months there, and then to direct his course to Kamtchatka, so as to endeavour to reach that country by the middle of May, in the ensuing summer. On the 26th of November, when the ships had proceeded southward to the latitude of 20° 5', land was discovered, which proved to be the island of "Moweck," one of the group of the Sandwich islands, with the inhabitants of which a friendly intercourse was maintained. Another island was discovered on the 30th, called by the natives "Owhyhee." Among the articles procured from the natives, was a quantity of sugar-cane, a strong decoction of which was found, upon trial, to be a very palatable beer; more especially when improved with a few hops. On the 16th of January 1779, canoes in great numbers came out from all parts of the island, so that the two ships were surrounded with no fewer than a thousand, crowded with people and laden with hogs, and other productions of the island. Some of them, however, manifested a thievish disposition, and captain Cook, in order to check it, ordered two or three muskets, and as many four pounders, to be fired over one of the canoes, which had carried away a rudder. Into a bay, affording good anchorage and fresh water, captain Cook resolved to take the ships in order to refit, and to obtain every refreshment which the place could afford. The bay in which the ships anchored on the 17th was called by the inhabitants "Karakaora." The vessels were soon surrounded with a multitude of canoes; and the whole shore of the bay was covered with spectators, whilst many hundreds were swimming round the ships like schools of fish. Our navigators were much impressed by the singularity of the scene; and few of them lamented their unsuccessful endeavours of getting homeward, the last summer, by a northern passage. "To this disappointment," says the captain, "we owed having it in our power to revive the Sandwich islands, and to enrich our voyage with a discovery, which, though the least, seemed, in many respects, to be the most important that had hitherto been made by Europeans, throughout the extent of the Pacific ocean." Such, also, is the concluding sentence of our illustrious commander's journal. Little did he then imagine, that a discovery which professed to annex no small honour to his name, and to be productive of very agreeable consequences, would be so fatal in the result. Little did he think, that the island of Owhyhee was destined to be the last scene of his exploits and the cause of his destruction.

The reception which the captain met with from the natives, on his proceeding to anchor in Karakaora bay, was in a very high degree encouraging. The natives expressed their joy by singing and shouting, and by exhibiting a variety of wild and extravagant gestures. During the long cruise of our navigators s the island of Owhynee, the inhabitants had conducted themselves in their dealings, almost universally, with fairness and honesty; but after the arrival of the ships in the bay, they altered their conduct. The immense crowds of islanders that encompassed the ships afforded frequent opportunities of pillaging without the risk of detection, and held out, especially as their number was much inferior to that of the English, the prospect of clear- ing with impunity. Another circumstance to which the alteration in the conduct of the natives may be ascribed, arose from the presence and encouragement of their chiefs, into whose possession the booty might be traced, and who were probably the inspirers of the depredations that were committed. Soon after the Revolution had gotten into her flotion, three chiefs, one of whom named Koah, who was a priest, and in his youth had been a distinguished warrior, visited the ship; and in the evening, Captain Cook, accompanied by Mr. Bayley and Mr. King, attended him on board. The captain was received with great civility and respect, on the part of the natives, approaching to adoration. The captain was particularly defiers of procuring from the island four salted hogs for sea-fare; and, with this view, of renewing former attempts in the operation for this purpose. The event answered his most sanguine expectations. On the 26th captain Cook had his first interview with Terrecchen, the king of the island; which was conducted with a variety of ceremonies, among which, the custom of exchanging names,
which among the islanders of the Pacific ocean is the strongest
pledge of friendship, was observed. The king, attended
by several chiefs, was conducted in a pinace on board
the Resolution; where they were received, apparently
much to their satisfaction, with peculiar attention and
respect. In the progress of the intercourse which was carried
on between our voyagers and the natives, the quiet and inof-
tensive behaviour of the latter took away every apprehen-
sion of danger and insured an unsuspicious confidence in
the English. A society of priests, in particular, displayed
a generosity and munificence, of which there are few exam-
pies; for they furnished a copious supply of hogs and ve-
tables to our navigators, without ever demanding, or
even suggesting, a return. Indeed, the conduct of the
warrior chiefs, or Earees, was always left satisfactory than
that of the priests. Although the kind and liberal beha-
vour of the natives continued without remission, Terreco-
booo, and his chiefs, began at length to be very inquisitive
about the time of the departure of the English; but this is
not surprizing, when we consider the enormous consumption
of hogs and vegetables, which had taken place during their
abode of 16 days in the bay. When the king was
informed that they were to leave the island in a day or
two, a proclamation was made through the island, requir-
ing the people to bring their hogs and vegetables, that
they might be presented by the king to the Orano, the ti-
tle of respect given to captain Cook, on his quitting the
country. Accordingly, on the 3d of February, being the
day preceding which was fixed for leaving the island,
Terreboobo invited captain Cook and Mr. King to attend
him to the place where Kaoo refided. On their arrival,
they found the adjoining ground covered with parcels of
cloth, and at a little distance an immense quantity of vege-
tables; and near them was a large herd of hogs. At the
close of the visit a great part of the cloth, and all the ve-
tables and hogs were given by Terreboobo to captain
Cook and Mr. King, who were astonished at the value of
the present. Such was the attachment of the inhabitants
of Owhyhee to Mr. King, that Terreboobo and Kaoo
waited upon captain Cook, whole for they supposed him to
be, to solicit his residence in their country. Early on
the 4th the ships sailed out of Karakakoa bay, being follow-
ed by a large number of canoes. It was the captain's de-
sign, before he visited the other islands to make a complete
survey of Owhyhee, in hopes of finding a better sheltered
bay than that which he had left; and upon failure of succ-
ses to take a view of the south-east part of Moorea, where,
as he was informed, he might find an excellent harbour.
After failing about the island of Owhyhee for several days, the
weather being stormy, and the foremast of the Resolution be-
ing damaged, our navigators returned on the 11th to Kar-
akakoa bay; but in coming to an anchor, they found their re-
ception to be very different from what it had been on their first
arrival. Their anxiety, however, was in some measure relieved,
by the return of a boat which had been sent on shore, and
which brought information, that Terreboobo was ab-
fent, and had left the bay under the Tako. The beha-
vour of the natives, however, appeared mysterious and ex-
cited fulpine; the interdict of intercourse, on pretence of
the king's absence, afforded reason for apprehending that
he only wished to gain time for consulting with his chiefs.
On the next morning Terreboobo arrived and immediately
visited captain Cook; this circumstance, and the return of
the natives to their usual friendly intercourse, were con-
dered as strong proofs, that they neither meant, nor appre-
hended, any change of conduct. Some other incidents
confirmed this opinion. Towards the evening of the 13th
information was received, that several chiefs assembled at
the well near the beach and drove away the natives who
had been hired to assist the sailors in rolling down the cars
of the ship. It was afterwards found, that the islanders
had armed themselves with stones and were very tumultu-
ous. Not to mention some instances of theft and subse-
cuent detections which occurred, one of a very serious and
unpleasant nature happened, which it may not be im-
proper to specify on account of the consequences that en-
folded. A canoe, belonging to Pareea, was seized; and he,
protesting his innocence with regard to the theft that had been committed, claimed his property. A feckle
took place between him and the English officer with some
of his companions, in which Pareea was knocked down by
a violent blow on the head, with an oar. The natives,
who had been peaceable spectators, immediately attacked
the English seamen with a shower of stones, which obliged
them precipitately to retreat and to swim off to a rock at
some distance from the shore. The pinace, which was
waiting for captain Cook's return, was immediately ran-
facked by the islanders; and if it had not been for the
reasonable interposition of Pareea, would have been entirely
demolished. Pareea interfered further in restoring the
pinace; and being assured that he would be kindly re-
ceived by the Orano, joined notes (according to their custom)
with the officers in token of friendship, and paddled over
to the village of Kowrowa. Captain Cook, on being informed
of this occurrence, expressed much uneasiness; "I am
afraid," says he, "that these people will oblige me to use
some violent measures; for," he added, "they must not be
left to imagine, that they have gained an advantage over us."
The confidence of our navigators in the natives gradually
abated; and they thought it necessary to be very much upon
their guard. At this time the cutter belonging to the Dis-
cover was stolen, and captain Cook made the necessary
preparations for the recovery of it. On occasions of a similar
kind, it had been his practice to get the king, or some of
the principal Earees, on board, and to detain them as hostages
till the article, that had been lost, was restored. This
method he meant now to pursue; and he also gave orders to
stop all the canoes that should attempt to leave the bay,
with an intention of seizing and destroying them, if by
peaceable means he could not recover the cutter. Captain
Cook and Mr. King, together with Mr. Philips, and nine
marines, left the ship; and when they landed, the captain
instructed Mr. King to quiet the minds of the natives, by
assuring them that they should not be hurt, to keep his people
together, and to be on his guard. Whilst Mr. King was
employed in executing his commission, captain Cook pro-
ceded to Kowrowa, where the king refided, and landed
with the lieutenant and nine marines. The people received
him with the usual tokens of respect; prostrating themselves
before him, and bringing their customary offerings of small
hogs. Having gained an interview with Terreboobo, he in-
vited him to return in the boat, and spend the day on board
the Resolution. To this proposal the old king assented, and
immediately accompanied him. One of the king's favourite
wives, however, befouathed him, with many tears and
remonstrances, not to go on board ; and two chiefs, who accom-
panied her, forced him to sit down. The natives, who were
collecting in great numbers on the shore, and who had been
alarmed by the hostileities that had previously occurred in
the bay, thronged round captain Cook and their king. The
lieutenant of marines, perceiving that they were much presed,
and thus rendered incapable of using their arms, if occasion
should require it, proposed to the captain to draw them up
along the rocks, close to the water's edge; and accordingly
they
they formed a line, at the distance of about 30 yards from the place where the king was sitting. The old king appeared to be much alarmed; and when captain King urged him to proceed, the chiefs interposed, and at first by prayers and entreaties, and afterwards by force and violence, insisted on his going where he was. The captain at length declined it, offering to Mr. Phillips, that it would be impossible to compel him to go on board, without the risk of killing a great number of the inhabitants. Captain Cook's offer had hitherto appeared to be in no danger; but a circumstance accidentally occurred, which gave a fatal turn to his situation. The boats, which had been flattened across the bay to prevent the escape of the canoes, fired at some of them that were endeavouring to go off, and unfortunately killed a chief of the first rank. The news of his death arrived at the village, where captain Cook was, just as he had left the king, and was walking slowly toward the shore. Upon this, the women and children were immediately sent off; and the men put on their war-mats, and armed themselves with spears and swords. One of the natives, having in his hands a stone, and a long iron spike (called a pahoua), advanced to the boats, flourishing his weapon in defiance, and threatening to throw the boats. The captain, after having ineffectually defied him to desist, fired a load of small shot, which, as the man had on his war-mat, served only to irritate and encourage the enraged people. Several stones were thrown at the marines; and one of the Erees attempted to stab Mr. Phillips with his pahoua, but failed in the attempt. Captain Cook now fired his second barrel, loaded with ball, and killed one of the foremost of the natives. A general attack on the boats immediately followed, which was returned by a discharge of musketry from the marines, and the people in the boats. The islanders, contrary to expectation, stood the fire with great firmness; and before the marines had time to reload, broke in upon them with dreadful shouts and yells. Four marines were cut off among the rocks, in their retreat; three more were dangerously wounded; and the lieutenant, who had received a stab between the shoulders with a pahoua, having fortunately recovered his fire, shot the man who had wounded him, just as he was going to repeat his blow. The unfortunate commander, the last time in which he was distinctly seen, was standing at the water's edge, and calling out to the boats to cease firing, and to pull in. If it be true, as some of those who were present imagined, that the marines and boatmen had fired without his orders, and that he was deluded in preventing any further bloodshed, it is not improbable that his humanity, on this occasion, proved fatal to him. For it was remarked, that whilst he faced the natives, none of them had offered him any violence; but that having turned about, to give his orders to the boats, he was stabbed in the back, and fell with his face into the water. On seeing him fall, the islanders set up a great shout, and his body was immediately dragged on shore, and surrounded by the enemy, who, snatching the dagger out of each other's hands, showed a savage eagerness to have a share in his destruction. "This fell," says captain King, "our great and excellent commander!" For other particulars, we refer to "Samwell's Narrative of the Death of Captain Cook." In consequence of the savage disposition of the natives, the whole remains of captain Cook could not be recovered. Although various means, soothing and menacing, were employed for this purpose, little more than the principal part of the bones could be procured. By the permission of the chiefs, our navigators were enabled to perform the last offices to their eminent and unfortunate commander. The bones, having been put into a coffin, and the service being read over them, were committed to the deep, on the 21st, with the usual military honours. What were the feelings of the companies of both the ships, on this occasion, the world must be left to conjecture; for those who were present, know, that it is not in the power of any pen to describe them.

Such was the high estimation in which the character and enterprises of captain Cook were held by neighbouring nations, that, when war was declared between France and England, a letter was issued, on the 15th of March, 1779, by M. Sartine, secretary of the marine department at Paris, and sent to all the commanders of the French ships, which, after doing honour to the importance and utility of his discoveries, ordered, that the ship of captain Cook should be treated with respect at sea. The adoption of this measure was suggested by M. Turgot, who also composed a memorial, in which he proved that honour, reason, and even interdict, dictated this act of respect for humanity; and it was in consequence of this memorial, as we learn from M. Condorcet (in his Life of M. Turgot), that an order was given not to treat as an enemy the common benefactor of every European nation.

The first thought of such a plan of conduct was very probably suggested by Dr. Benjamin Franklin, who, when he was ambassador at Paris from the United States of America, preceded the court of France in giving a similar requisition.

We shall close this article, as far as it respects the discoveries of captain Cook, with merely mentioning, that the Sandwich islands were further explored; that Kamtschatka was visited, and a friendly intercourse maintained with the Russian officers of that country; that our navigators experienced the most generous and hospitable treatment from major Behm, in particular, the commander of the garrison at Bolcharette; that they proceeded to the north, in pursuit of the grand object of the expedition; that, having pafted through Beering's Strait, and attained to somewhat more than 69° degrees of northern latitude, they found it absolutely impossible to penetrate through the ice, either on the side of America or on the side of Asia; that every hope being precluded of accomplishing, in this way, a passage into the Atlantic ocean, captain Clerke was obliged to come to the determination of falling back to the southward; that on the 22nd of April (1779) the captain died of a consumption (see his article); that captain Gore succeeded to the command of the Resolution, and lieutenant King to that of the Discovery; that a second visit was paid to Kamtschatka, which extended our acquaintance with that part of the world; that no small accession of information was acquired, with respect to geometrical science in general; that our voyagers pursued their course by the coasts of Japan and China; that they made some stay at Canton; that thence they proceeded to the Cape of Good Hope; that they came to an anchor at Stromness, on the 22nd of May, 1780; that both ships arrived at the Nore, on the 4th of October, after an absence of 4 years, 2 months, and 22 days; that, during the whole of the expedition, the Revolution lost only five men by sickness, three of whom were in a precarious state of health at their departure from England, while the Discovery did not lose a single man; and that the history of the voyage, from the time in which captain Cook's journal ends, was written with great ability by Mr. King. By the decease of captain King, who died at Nice in Italy, in 1784, this country suffered another loss of an able and scientific commander and navigator, who had left a memorial of his talents and services, which has honourably united his name with that of the immortal Cook.

In sketching the talents and character of captain Cook, strikingly illustrated in the actions and enterprises of his life, we
COOK.

we shall avail ourselves of the attention that is afforded us by his professed or incidental biographers. Captain Cook professed, in an eminent degree, an inventive mind, which, by its native vigour, suggested noble objects of pursuit, and the most effectual methods of prosecuting and attaining them. This faculty he exemplified in a great variety of critical and difficult situations. To this kind of eminence he added unwaried application. By his genius and unremitting affinuity he acquired an extensive acquaintance not only with navigation, but with many other sciences. He was so well informed with regard to different branches of the mathematics, and particularly in astronomy, that he was able to take the lead in various observations of an astronomical kind, in the course of his voyages. In general literature, and even the art of composition, he was so great a proficient, that he acquired reputation, not merely as the performer, but as the narrator, of his various interlacing enterprises. Perseverance and steadiness in the prosecution of the objects to which his life was devoted, were distinguishing features of his character; and such was the invincible fortitude of his spirit, that no difficulties or dangers intimidated him, or deterred him from accomplishing any purpose which he formed, or which the hazardous services assigned him required. His fortitude was of course accompanied with complete self-possession. This latter quality was eminently useful to him in many critical and trying circumstances. Accordingly it is observed, that the calmness and composure of his mind were such, that, after having given necessary directions, he could take his rest, and sleep during the hours which he allotted to himself with perfect freedom. To the great qualities professed by captain Cook, he added the most amiable and conciliatory virtues. His humanity is illustrated in the whole course of his conduct, during his succedaneous voyages; with regard to the inhabitants of the countries which he visited, and with respect to the accommodation, health, and comfort of his own crewmen. In the private relations of life, he maintained an excellent and exemplary character, as a husband and father, and as a sincere and steady friend; and his loquacity and virtue gave stability and security to every moral qualification. He was also distinguished by the simplicity of his manners. In conversation he was unaffected and unassuming; and yet, on necessary occasions, obliging and communicative. To this general account of his talents and virtues, we shall subjoin some delineations of his character by those who were in habits of intimate acquaintance with him, and who had an opportunity of marking his temper and conduct in the various trying circumstances that occurred in the course of his life. Captain King, the continuator of the journal of his last voyage, has given us the following sketch of his character: “The constitution of his body was robust, inured to labour, and capable of undergoing the severest hardships. His stomach bore, without difficulty, the coarset and most unpalatable food. Indeed temperance in him was scarcely a virtue; so great was the indolence with which he submitted to every kind of self-denial. The qualities of his mind were of the same hardy, vigorous kind with those of his body. His understanding was strong and peripatetic; his judgment, in whatever related to the services he was engaged in, quick and sure. His feelings were bold and manly; and both in the conception, and in the mode of execution, bore evident marks of a great original genius. His courage was cool and determined, and accompanied with an admirable presence of mind in the moment of danger. His manners were plain and unaffected. His temper might perhaps have been jutly blamed, as subject to haughtiness and passion, had not thee been disarmed by a disposition the most benevolent and hu-
frequently interposing, at the hazard of his life, to protect them from the sudden remembrance of his own injured people. The object of his last mission was to discover and ascertain the boundaries of Asia and America, and to penetrate into the northern ocean by the N. E. Cape of Asia.

Traveller! contemplate, admire, revere, and emulate this great master in his profession; whose skill and labours have enlarged natural philosophy; have extended national science; and have disclosed the long unfelt and admirable arrangement of the Almighty, in the formation of this globe; and, at the same time, the arrogance of mortals, in presuming to account, by their speculations, for the laws by which he was pleased to create it. It is now discovered, beyond all doubt, that the fame great being who created the universe by his fiat, by the same ordinance of earth to keep a just poise, without a corresponding southern continent—and it was so! "He stretches out the north over the empty place, and hangs the earth upon nothing." Job xxxvi. 7.

If the arduous but exact researches of this extraordinary man have not discovered a new world, they have discovered seas unannounced and unexplored before. They have made us acquainted with islands, people, and productions, of which we had no conception. And if he has not been so fortunate as Americus to give his name to a continent, his pretensions to such a distinction remain unviolated; and he will be revered, while there remains a page of his own model account of his voyage, and as long as mariners and geographers shall be instructed, by his new map of the southern hemisphere, to trace the various courses and discoveries he has made. If public services merit public acknowledgments; if the man who adorned and raised the fame of his country, is deserving of honour, then captain Cook deferves to have a monument raised to his memory, by a generous and grateful nation.

"Virtutis uberrimum alimentum est honos."

Val. Max. I. i. c. 6.

From the numerous poetical tributes, paid to the memory of captain Cook, by our elegant female writers, we must confine ourselves to a single extract from Miss Hannah More's poem on "Slavery."

"Had those adventurous spirits who explore Thro' ocean's trackless waftes, the far-fought shore, Whether of wealth infatiate, or of power, Conquerors who walk'd, or ruffians who devour! Had these poss'd O Cook! thy gentle mind, Thy love of arts, thy love of human-kind; Had these pur'd thy mild and liberal plan, Discoverers had not been a curse to man! Then, blest'd Philanthropy! thy social bands Had link'd disstress'd worlds in brother's bands; Careless, if colour, or if climate divide; Then lovd, and loving, man had liv'd, and died."

Miss Seward's admirable poem in celebration of captain Cook's memory would have furnished many pleasing extracts, if our limits allowed our farther enlarging on this interesting article; but we must refer the reader to this lady's elegy on the occasion.

The Royal Society justified their respect for the memory of their illustrious members by medals, struck on this occasion, some of gold, others of silver, and others of bronze; the expense of which was defrayed by subscription. On one side is the head of captain Cook in profile, and round it, *JAC. COOK OCEANI INVESTIGATOR ACERERUS*; and on the exergue, *REG. SOC. LOND. SOCIO SUO*. On the reverse is a representation of Britannia, holding a globe; round her is inscribed, *NUL INTENTIUM, SOUTER LIQUERUS*; and on the exergue, *AUSPICIAE GEORGINH HII.*

Among the numerous testimonies of regard that have been rendered to the merits and memory of captain Cook, the important object of providing for his family hath not been forgotten. Soon after his death was known, the lords of the admiralty presented a memorial to his majesty; and he was pleased, by the advice of his privy council, to order a pension of 200l. a year to be settled on the widow, and 25l. a year to each of the three sons of the captain.

A considerable benefit also redounded to his family from the fate of the charts and plans, belonging to the voyage to the Pacific ocean, which were provided at the expense of government. On September the 3d, 1785, a coat of arms was granted to the family, with an appropriate device. Our navigator had six children. On the subject of this article fee the fift, second, and third voyages of Cook; the fift included in Hawksworth's Voyages, published in 3 vols. 1773. The second, written by captain Cook himself, and published in 2 vols. 1777, and the third published in 3 vols. 1784; the fift and second being written by captain Cook, and the third by captain King.

To the fift of these volumes is prefixed an introduction by Dr. Douglas, the late bishop of Salisbury, containing a brief historical account of voyages that had been previously performed with a view to the objects comprehended by those of captain Cook, a concise statement of his discoveries, and a detail of the advantages resulting from them. See also Kippis's Life of Captain Cook, and Biog. Brit. vol. iv.

**Cook, Captain Henry**, a choir-man, brought up in the chapel-royal during the reign of Charles I., which he quitted at the commencement of the grand rebellion, and went into the king's army, where he considerably distinguished himself; and in 1645, obtained a captain's commission. At the restoration, he was appointed master of the children of the chapel-royal. He composed the coronation anthem, according to Ant. Wood, for Charles II., and a hymn in four parts, composed by him, is likewise laid to have been performed instead of the litany, in the chapel of St. George at Windsor, by order of the sovereign, and knights of the garter, on the 15th of April 1661. None of his pieces, music, however, was printed, nor has Dr. Tudway inserted any of his compositions in the voluminous MS. Harleian collection of English sermons and anthems. And, indeed, if we may judge of them by the few secular compositions which appear in the collections of the times, he was little fitted for the high office to which he was appointed at the restoration. In the second part of Playford's "Musical Companion," 1667, there are two or three of his songs which are dry, ill accented, and equally defective of melody and masterly harmony. However, he had the merit, or at least the good fortune, to be the master of three boys among the children of the chapel, who gave very early testimony of their genius and progress in composition. Those were Pelham Humphrey, John Blow, and Michael Wise, who, even while they were choristers in the chapel, produced veris anthems, far superior in melody and design to any that our church could boast, anterior to Purcell. Cook died in 1672, according to Ant. Wood, of grief, at being so far surpassed in composition by his young pupil, Pelham Humphrey.

**Cook, Dr. Benjamin**, an eminent organist and contrapuntist, in the style of our best ecclesiastical composers, whom he had studied from Tallis, to Crofts, Weldon, and Green: a very correct harmonist and good organ player, but with
limited powers of invention. He was organist of Welb- 
mutter Abbey, and on the death of Kelway elected or-
ganist of St Martin's in the Fields. He long prede- 
ceded the Crown and Anchor concert, which was originally esta-
blished for the preservation of the best works of the most 
eminent masters of old times. It is a curious circumstance, 
that at this concert of ancient music, Handel was regarded 
as an innovator, and Geminius thought it an honour to 
be allowed to dedicate his last concertos to this society. Dr. 
Peuplish, who established and directed this concert, to 
the time of his death, never allowed Handel another merit 
than that of a good practical musician. The irreconcilable 
enemy between the lovers of old and new music, became 
from the time of this institution, as violent as the rage be-
tween the champions of ancient and modern learning. Dr. 
Cook, a steady votary of the old masters, died September 
1757. He was the son of Benjamin Cook, who kept a 
music shop in New-street, Covent Garden, and who pub-
lished by patent, among other things, six concertos for 
vioins, tenor and bays, by Alexander Scarlatti; the chamber 
lymphs of Porpora, for three instruments; and the two 
books of litanions by Domenico Scarlatti, in long 4to., of 
which Redgrave was the editor. After the decease of 
Cook, Johnson reprinted Scarlatti's litanions, with the same 
title page, and the same errors, as had escaped correction 
in the former edition.

Cook, Henry, a native of this country, born in 1642. 
Having a taste for historical painting, he travelled to Italy, 
for the purpose of improving himself in this branch of the 
art, and fluced under Salvator Rafa; but, on his return 
from England, met with so little encouragement, that for 
many years he remained in want and obscurity. At length, 
however, his talents gained him notice, and he was employ- 
ed by king William to repair his cartoons; he likewise 
feigned the equestrian portrait of Charles II. at Chelsea-
college, painted the choir of New-college chapel Oxford, 
and the haircase at Ranelagh house, besides many other works 
mentioned by Mr. Walpole. He is also said to have tried 
portrait painting, but to have given it up, disquieted with 
the caprices of those who fat to him. He died 18th Nov. 
1700. Walpole's Anecdoles.

Cook, in Ichthyology, a species of fish, which is some-
times taken in great plenty on the coast of Cornwall. It 
is a feyly fish, and does not grow to any great size: 
the back is purple, the belly yellow, and the tail rounded.

Cook's River, in Geography, a river of North America, 
which runs into the northern Pacific ocean, between Cape 
Elizabeth and Point Banks, i.e. between E. long. 207° 
3', and 207° 45'; N. lat. 52° 42', and 52° 12'; and which, 
by its various branches, opens a very considerable inland 
navigation. This name was given to the river by lord Sand-
wich, in honour of captain Cook, who, in the year 1779, 
traced it as high as the latitude of 64° 30', and the longi-
tude of 240°, or about 70 leagues from its entrance, with- 
out perceiving the least appearance of its source. "It was a 
factsation to me," says this perceiving navigator, (Third 
Voyage, vol. ii. p. 397.) "to reflect, that, if I had not ex- 
named this very considerable inlet, it would have been 
ruined, by speculative fabricators of geography, as a fact, 
that it communicated with the sea to the north, or 
with Baffin's or Hudson's bay to the east; and been mark- 
ed; perhaps, on future maps of the world, with greater 
precision, and more certain signs of reality than the invisible, 
becase imaginary, traits of de Fuca, and de Fonte." Mr. 
King was ordered to land on the northern point of the low 
land, on the S.E. side of the river, there to display the 
flag, to take possession of the country and river in the name 
of his British majesty, and to bury in the ground a bottle, 
containing some pieces of English coin, of the year 1772, 
and a paper, on which were inscribed the names of the ships 
and the date of the discovery. Near the shore Mr. King 
observed about twenty of these natives, who, appearing 
with their arms extended, probably to express their peaceable 
disposition, and to shew that they were without weapons. 
When their alarm, occasioned by the sight of musquins, 
had subsided, they allowed their new visitants to approach 
them, and appeared to be cheerful and sociable. Their 
feers and their other battle weapons, as it was afterwards 
discovered, were hid in the bushes close behind them. The 
ground was swamy, and the soil poor, light, and black. It produced a few trees and shrubs, such as pines, 
alder, birch, and willows; rofe and current bushes, and a 
little grafs, but not so much as a single plant or flower was 
discovered. On a future day, several large and some small 
canoes, with natives, came off to the British ships, and 
betook their waif; after which, they told their garments, 
till many of them were quite naked. Among others, they 
brought a number of white hare or rabbit skins, and very 
beautiful reddih one's of foxes; but there were only two or 
three skins of otters. They also fold pieces of salmon and 
fishets. They preferred iron to evry thing else offered to 
them in exchange. The lip-ornaments did not seem fo fre-
quent among them as at Prince William's Sound; but they 
had more of those which pass through the nose, and, in ge-
neral, they were also much larger. They had, however, 
a greater quantity of a kind of white and red embo-
dowed work on some parts of their garments, and on 
other things, such as their quivers and knife-cases. On the 
west side, a volcano was discovered, in lat 66° 2'; and this 
is the first high mountain N. of mount St. Augustine. 
The volcano is on that side of it next the river, and not far 
from the furamitt. It only emitted a white smoke without fire. 
Captain Cook observes, that all the people met with near 
this river, seemed, by every striking token of resemb lance, 
to be of the fame nation with those who inhabit Prince Wil-
jiam's Sound, but essencefully differing from those of Neopta, 
or King George's Sound, both in their persons and la-
nguage. The language of this is rather more guttural; 
but, like the others, they speak strongly and distinctly 
in words which seem to be sentences. These people are in 
possession of iron; that is, the points of their spears and 
their knives are of this metal, and some of the former are also 
made of copper. Their spears are like our spookons; and 
their knives, which they keep in sheaths, are of a considerable 
length. These, with a few glafs beads, were the only things 
seen among them that were not of their own manufacture. 
Their beads and iron they must have received from some 
civilized nation; and it seems most probable, that they 
procured them through the intervention of the more inland 
tribes from Hudfon's Bay, or the settlements on the Cana-
dian lakes; unless it can be supposed (which, however, 
is less likel) that the Russifn traders from Kamtchatka, have 
already extended their traffic so far; or at least that the na-
tives of their molt easterly Fox islands, communicate along 
the coaft, with those of Prince William's Sound; which see. 
The Russiffns themselves, says captain Cook, have never 
been among them; for if that had been the case, we should 
hardly have found them clothed in such valuable skins as 
those of the sea-otter. There is not the least doubt, con-
tinues captain Cook, that a very beneficial far trade might 
be carried on with the inhabitants of this vat coaft. But 
unless a northern paffage should be found practicable, it 
seems rather too remote for Great Britain to receive any 
emolument from it. It must, however, be observed, that 
the
the most valuable, or the only valuable, flns which Cook saw on the west side of America, were those of the sea-otter. All their other skins seemed to be of an inferior quality, particularly those of their foxes and martins. M of the skins that are fitted for sale, are those which are made up for outer garments, and this is the chief use for which they kill the animals. By increasing intercourse with purchasers, they would be more affiduous in procuring skins, and thus a plentiful supply might be obtained in this country.

In Cook's river, the tide is very considerable, and much contributes to facilitate the navigation of it. It is high water in the stream on the days of the new and full moon, between two and three hours; the tide rises perpendicularly, between three and four fathoms. The reason of the tides being greater here than at other parts of this coast, is, that, the mouth of the river being situated in a corner of the coast, the flood from the ocean is forced into it by both shores, and thus swells the tide to a great height. The variation of the compass was 25° 45' E.

Cook-room, in a Ship, is where the cook and his mate drefs and deliver out the meat, &c.

Cook's Strait, in Geography, so called from its discoverer captain Cook, a strait which separates the two islands that form New Zealand. This strait is about four or five leagues broad; and the islands, thus divided, are situated at the latitudes of 34° and 45° S; and between the longitudes of 178° and 190° W. See New Zealand.

COOKE, Sir Anthony, in Biography, governor, preceptor, or schoolmaster, to king Edward VI., and great grand-son to sir Thomas Cook; lord-mayor of London in 1562, was born at Giddy-hall in Essex about the year 1506, and educated, probably, at Cambridge. He became eminent in literature and the arts, being a thorough master of the Latin and Greek languages, an excellent critic and philologist; and equally skilled in poetry, history, and the mathematics. He was no less distinguished for his piety and good-ness. These qualities recommended him to the office of in-structor to king Edward VI., and the royal pupil is well known to have done honour to the talents and character of his preceptor. During queen Mary's reign he was an exile for religion; but upon the accession of queen Elizabeth he returned to his native country, fixing his residence at Giddy-hall, the building of which he completed. He died June 31, 1576, having attained the age of 70 years, and was buried in the chapel of Runford in Essex, where a monument was erected to his memory. He left four daughters, eminently learned in the Greek and Latin languages; viz. Mildred, married to sir William Cecil, baron Burleigh; lord-treasurer of England; Anne, wife of sir Nicholas Bacon, lord keeper of the great seal; Elizabeth, married to John, lord Ruffell, son and heir of Francis earl of Bedford; and Catherine, wife of Henry Killigrew, esq. He also had two sons.

COOKERY of Meats, in Domestic Economy, denotes the application of heat to the several animals taken both from vegetables and animals. The advantages attending the application of heat to vegetable substances are thus rendered more soluble in the human stomach. The only doubt, says Dr. Cullen, that can arise with regard to this, respects vegetables to which in their crude state a boiling heat is immediately applied, so that in many of them a coagulation is produced; in consequence of which they seem to be rendered less soluble in water than they were before—but this, he says, does not seem to have any effect on their solution in the stomach. Whether the difficult solution be observed by some degree of fermentation that necessarily takes place in the stomach, or by the powers of the gastric fluid, it is not necessary to determine, as it is certain that the action of heat separates in some measure the small particles of bodies, and thereby renders them more readily separable by the solvent powers of the stomach. 2. The application of heat separates and dilutes the volatile parts of vegetable substances, which are seldom of a nutritious nature, and, in many cases, have a tendency to prove noxious. 3. The application of heat to a certain degree extricates and dilutes a considerable quantity of air, which, in the natural state of vegetables, is always fixed in their substance; and it is probable, in this way especially, that heat will contribute to the dividing and loosening of the cohesion of the final parts of vegetable substances. It is certainly in this way, by diluting a large portion of their air, that vegetables are rendered less liable to fermentation, and less liable to produce that flatulence, which is occasionally so troublesome in the stomach and intestines. Dr. Cullen observes further, that, as the heat may be employed in two ways, either in a humid or a dry form; the former is always better suited than the latter to all the purposes above-mentioned. The cookery of animal substances also confinis chiefly in the application of heat. Other practices, however, previous to cookery, may be considered as parts of it; particularly salting, drying, and pickling. These practices, however, are merely useful for the purposes of domestic economy, as preserving meat from putrefaction, before it is subjected to heat, for a longer time than it could be preserved without such means. These practices, Dr. Cullen thinks, can never increase the nutritious quality of meat, or render it even of more easy digestion. Drying certainly brings the solid parts of meat more closely together, which must render it of more difficult solution. The addition of salt, which stimulates the stomach, may seem in some cases to promote digestion; but this must be when the salt is added in small quantity, and when the meats preferred by it are taken in moderate quantity only. For when meats have been long salted they are hardened, and rendered in proportion less soluble in the stomach: and a large quantity of salt accompanying them is certainly hurtful to the sytem. There is one part of animal food, which is made without any addition; and that is by its being kept for some time before it is subject to cookery, for a longer or shorter interval, according to the feasons, and the nature of the meat; but always till it has made some advance towards putrefaction. The tendency to this seems to take place from the moment that life is ex-tinguished in the animal; and the allowing of it to take place to a certain degree renders the meat more easily soluble in the stomach: and if the putrefaction be only in a moderate degree, it does not seem to injure the nutritious quality of the meat. The proper degree of putrefaction is not easily ascertained; and it is certainly different according to the constitution of the person. Some can use meats tainted in a considerable degree without inconvenience; whilst the digestion of others is much disturbed by the smallest quantity of putrid meat. Every advance in this towards putrefaction renders them, as Dr. Cullen says, more ready to increase the tendency of the animal fluids to that state which we take to be always hurtful to the human constitution, as it both favours the access of diseases, and aggra-vates their symptoms and danger when they occur.

The cookery of animal substances by the application of heat is of two kinds, as it is applied in a humid form by
boiling and stewing, or in a dry form, by roasting, broiling, and baking. For the processes and effects of boiling and stewing, see Boiling. The application of heat in a dry form is of two kinds, as it is in clove vessels, or as it is exposed to the free air. The skirt is baking, and though commonly in this practice the cover of the meat is merely pledge, any considerable exhalation is prevented, and the retention of the juices under the application of heat renders the meat more tender; and in all cases when the heat applied looses, and, in some measure, extractes the air, without exciting it, the substance is rendered more tender than when with any other application an exhalation is allowed. In broiling an exhalation takes place; but as the heat of a naked fire is more nearly applied, the outer surface is in a degree hardened before the heat penetrates the whole, and thus a great exhalation is prevented, while the whole is rendered sufficiently tender; but this kind of cookery is especially suited to meats that are chosen to be eaten lolling and any other exhalation of sufficient depth of is tufficiently tender. Cullen’s Mat. Med. vol. i. pt. i. c. 2.

COOK-HOUSE, in Geography, a town of America, situated on the Coquago branch of Delaware river, in the township of Colchester, New-York, 18 miles S. of the mouth of Unadilla river.

Gen. Ch. Cal. very small, five-cleft. Cor. Petals five, spreading. Stam. Filaments ten, distinct; anthers roundish. Fig. Germ somewhat pedicelled, bifurc; style one; stigma capitulate. Peric. Berry; Jutf. (Pom. Willd.) five-cleft; three frequently abortive. Seeds one in each cell.

COOLER, among Browsers, Diffusers, &c. a large vessel, usually of small depth and large surface, in which liquors are cooled, after having been boiled.

COOLIES, in the East Indies, are those natives who are employed in carrying of burdens, digging of trenches, and such laborious occupations; and, supplying the place of pioneers, cannot be dispensed with in the operations of military tactics in Hindoostan.

COOLING is the progressive decrease of temperature from a higher to a lower degree. From the highest degree of heat, which human industry has been able to obtain by means of combustion, or by concentrating the solar rays, to the lowest degree of it, which both natural and artificial methods have produced, the space is very considerable; and different parts of it have obtained diverse denominations, which are derived from the most striking phenomena that take place at particular points of the scale; thus we hear of porcelain heat, white heat, red heat, boiling heat, temperate, freezing, &c. and all these transitions from the first to the last, fall under the denomination of cooling; whereas the contrary transition from the lowest to the highest, is called heating. In order to preserve particularity, and to allude to each of the received denominations, the particulars which belong more immediately to it, we have divided the subject into three articles, under the words congealation, cooling, and freezing.

Under the first we have flated the phenomena of natural congelation; the last contains whatever relates to artificial freezing, viz. to the production of cold below 32° of Fahrenheit’s scale; and under the present, we shall principally state all the methods and the effects of cooling from the actual temperature of the atmosphere to a lower degree; but not below that of melting ice, viz. 32°, which is commonly called the freezing point.

The temperature of the atmosphere in the hottest climates, has hardly ever been known to exceed 15°, and it is but seldom that it reaches that most oppressive degree of heat. In the human species, nature has made ample provision, and has furnished them with industry sufficient for counteracting the effects of a very high or a very low temperature; but without any artificial assistance, few are the degrees of heat in which human beings can live with perfect comfort. Making some allowance for the natives of different climates, the whole range of temperature may be said to reach from the 60th to the 70th degree of Fahrenheit’s scale. Below 60° most persons have no objection to a gentle fire in their apartments; and above 70° they generally complain of heat. Yet when the natural temperature of the atmosphere is above 50°, cooled liquors are generally preferred for drink; but when the temperature is above 70°; then not only cooled liquors, but cool apartments also, are articles of great luxury; and it may in great measure be said of necessity. The languor which is commonly induced by heat, is in great measure relieved by artificial cooling. Patients affected with fevers of the intermittent and putrid kinds, which are so very common and destructive in hot climates, receive great benefit from the use of cooled liquors, and such are plentifully administered to them, whenever they can be obtained. The preservation likewise, of meats, fruit, butter, &c. in warm climates, or in the hot season, is considerably assisted by cooling; and it may be extended to a very remarkable long period by actual freezing.

In order to answer all these purposes, mankind has, from time immemorial, endeavored to discover and to apply methods
COOLING.

Methods of cooling, or of refrigeration. These methods, as far as they are at present known, may be comprised under the following heads: viz. 1st, the application of something naturally colder than the actual temperature of the atmosphere; 2dly, ventilation; 3dly, evaporation; and 4thly, the solution of certain saline substances. Sometimes two or three of these means are applied at the same time, to the article which is required to be cooled. In every country of Europe, and especially in the southern part of it, ice is collected during the winter, in proper places, and is used for cooling liquors, &c. in the summer season, or throughout the whole year. And this undoubtedly is the most easy, the most extensive, and the most effectual method of cooling. A little ice taken out of the ice-boule, and placed round a bottle of water or wine, in any convenient vessel, soon cools it to the desired degree; and if the effect is to be increased, fo as to freeze creams, fruit, &c. by breaking the ice into small pieces, and mixing common salt with it, the desired end will be obtained. The ice-boule itself is of very effectual use for preserving meat, fish, butter, fruit, &c. which things need only be laid in it, until they are wanted.

When ice cannot be easily procured, well water forms a useful substitute to a certain degree. When the depth of the well is 40 or 50 feet, or upwards, the constant temperature of its water is very nearly equal to the mean temperature of the country, which, of course, is lower than the usual temperature of the summer season in that country; hence, if a pail of water be drawn, and a bottle of wine, or other liquor, be immediately placed in it; a considerable refrigeration may be obtained, and it may be maintained by drawing fresh water at intervals from the well, &c. Thus in London the mean temperature is about 50°, and fo is the temperature of pretty deep wells throughout the year. Now in the summer season, the temperature frequently rises above 60°, or 70°; therefore, at those times, by applying fresh drawn well-water, the liquors we drink may be cooled about 15 or 20 degrees, which will render them incomparably more pleasant. When articles of food are required to be kept some time longer than the heat of the weather would allow, they may be placed in a basket at the end of a rope, and may be let down into the well, until they come within a foot or two of the water. For the higher pits, deep pits, caves, or grottos may be used; since their temperature is nearly equal to the mean temperature of the country, and suffers little or no variation between winter and summer.

Ventilation is nothing more than a constant change of air; but if the air which has just passed by a body, and that which succeeds it are all of the same temperature, no cooling will be produced by the ventilation; but the refrigeration will take place, when the body is hotter than the air which passes by it, or when an increase of evaporation ensues. Expose a thermometer to the open air, but shelter it from the wind, and when the thermometer is become stationary, let the wind fall upon it; and it will be found that the quicksilver is not lowered in it. But when a human being, or other animal is exposed to ventilation, the quick transition of air cools; first, because it continually removes the air which has been heated by the contact of the animal body, the breath, &c.; and secondly, because the evaporation from the body is increased by the ventilation. So that, upon the whole, the use of ventilation, such as is effected by means of fans, whistles, a particular disposition of apartment, and other machines, is to remove heated or vitiated air from the vicinity of human beings, from close habitations, prisons, slips, &c.

The ingenious Dr. Hales fixed a machine of this fort in the old Newgate prison, which, being put in action by means of
COOLING.

thermometer, at the same time that the evaporation from the cotton tends to lower it. And according as the one or the other of these opposite effects predominates, so the cooling effect is more or less conspicuous. From these observations it naturally follows, that the cooling, occasioned by evaporation, is greater when the evaporation is quicker, and contrarywise; also, that when different fluids are used for the evaporation, in similar circumstances, that fluid which evaporates quickest, produces the greatest refrigeration.

Mr. Cavallo says, "in order to try the degree of refrigeration produced by the evaporation of different fluids, I held up a naked thermometer, (viz. a thermometer, the bulb of which was not in contact with the metal of the scale) and poured upon its bulb a stream of some particular fluid, which spurted out of the capillary aperture of a tube; taking care to throw fluid enough to supply the walls by evaporation. By this means, when the temperature of the air was 64°, I found that the evaporation of water cooled the thermometer 8°; viz. brought it down to 56°; the evaporation of spirit of wine cooled it 16°; viz. brought it down to 48°; and the evaporation of ether cooled it 54°; viz. brought it down to 10°. But, by the use of the bulb pulvined sulphuric ether, when the temperature of the air was about 50°, I brought the thermometer down to 3°.

The cooling produced by the evaporation of other fluids needs not be mentioned; their effect being generally intermediate between the effect of water, and that of spirit of wine." (Phil. Trans. vol. lxxi.) Whatever promotes the evaporation, such as a dry air, and especially a dry wind, tends to increase the refrigeration; and when all the favourable circumstances concur, the effect is prodigious; so that in a dry, warm, and brisk wind, by means of the evaporation of the bulb pulvined ether, the temperature of any kind of bodies may be lowered many degrees below the freezing point; and animals might be easily frozen to death.

Though several of the above-mentioned particulars, and especially the cauls upon which they depend, have been but lately investigated and ascertained; yet the cooling effect of evaporation has been known and used by mankind from time immemorial. Athenaeus says, as being related by Protagoras of Cyzicum, that in the time of King Antichus, it was usual to cool water by evaporation, and to drink it as a luxury. A very easy and familiar experiment to show the effect of evaporation, may be performed in the following manner. Moisten a small space on the upper part of each hand; cover one of those places with an inverted wine-glass, and let a person blow with a pair of bellows upon the other hand. The latter will be fentily cooled, but not the former. Change the glafs and the blowing, from one hand to the other, and the effects will be reversed. Scamen, especially in the night time, frequently employ this natural effect for discovering which way the wind blows. They moisten a finger of their hand by putting it in their mouth; then expose it to the ambient air by elevating it above their head; and thus conclude that the wind blows from that quarter which is opposed to the most cooled side of the finger.

In warm climates, where the dryness of the air generally is very great, the refrigeration arising from evaporation is very considerable, and is of course frequently employed for counteracting the natural heat. The caravans which traverse the parched deserts of Arabia, are obliged to carry their supply of water in earthen jars upon camels; but in order to keep it pleasantly cool, the jars are involved in cloths, which they take care to keep continually moistened with water. It is a pretty common practice in the southern parts of Europe, as well as in the East and West Indies, in America, &c. to wrap up a bottle of wine, or water, or other liquor, in a wet cloth, and thus to suspend it in a shady place, either under a tree or in a passage, so as to expel to the briskest current of air that can be obtained; for by this means the liquor will be cooled several degrees; care, however, must be had to sprinkle more water upon the cloth, which surrounds the bottle, in proportion as the former evaporates. Mr. Walker, of Oxford, describes a peculiar method of producing a very considerable degree of cold by means of evaporation. "Having," he says, "in the course of the preceding winter, frequently succeeded in producing ice, by the cold produced from evaporation with water, when the temperature of the air was 38°; it occurred to me, that it might be possible to freeze water in the middle of summer, by a process which depended on this principle, by the use of water only. Accordingly, I procured a tall cylindrical vessel, holding about two gallons, in which I fixed a small spiral tube, as in the worm-tub of a common well; the lower end of this tube comes out through the vessel near the bottom, sufficient to connect the nozzle of a pair of bellows to it, by the intervention of a bladder, secured air-tight; this spiral tube ends at the top of the cylindrical vessel, where it is somewhat enlarged, like the mouth of a funnel. This vessel, being covered with flannel, was filled with water and hung out in a brisk dry wind, the temperature of the air being 50°; after some time, by repeatedly wetting the flannel on the outside of the vessel, I found the water within was cooled to 40°; air being then forced through the tube (by means of the bellows), surrounded by the cooled water, came out at the upper extremity of the tube at nearly the same temperature.

"A thermometer having its bulb covered with lint, and wetted repeatedly with the cold water in the vessel, placed so as to receive the draught of cold air from the tube, soon fell to 34°; hence by a series of two or three of these vessels, water might, upon this principle, be frozen at midsummer, recollecting that this experiment may always commence at 50°, the usual temperature of springs; and hence it might be possible upon the same principle, to caufe nature upon a small scale, even without the immediate interposition of art, to depart from her usual course, and to allude the hoary garray of winter to midsummer.

"For this purpose a current from the external air might be admitted into the tube, by means of a funnel, communicating with, and receiving, a conlant draught of air.

"In an attempt of this kind, it would be necessary (besides some other variation in the vessels, which circumstances might point out,) that the cylindrical vessels be porous, or pierced with small holes; so that the water may be con-stantly and gently oozing out.

In Spain, in Italy, in Egypt, and probably in other places, certain vessels are made of a porous earthen, which, when full of water, will just permit some of that fluid to ooze out of their external surface, whence it evaporates, and thus cools the remainder of the liquor within the vessel. The Spanish vessels for this purpose consist of a reddish brown earth. They are pretty broad, but not very capacious. In Italy they have been made of a pale yellowish material, but much larger. In Egypt they are made somewhat in the shape of a Florence flask, and not much bigger; but their aperture spreads out in the form of a cone, or rather of an ale glass, which is done for the convenience of drinking out of it. Their beauty is of the colour of ashes, and it is said to be found left on the banks of rivers. But vessels of any degree of porosity may be made by mixing sand and clay in various proportions.
C O O L I N G.

The utility of these vessels in Spain, in Italy, and especially in Egypt, is attended with a notable degree of refrigeration, on account of the great dryness of the air in those climates, which enables it to absorb a great deal of moisture in a short time; but the same vessels having been brought over, and having been tried, in this country, have been found to cool the contained liquor in a very trifling degree; evidently owing to the latitude of the air in this country, which is much less hot, and much less dry than in the above-mentioned places; therefore much less apt to promote evaporation.

One of the Egyptian vessels was tried in London at a time when the temperature of the atmosphere was at a mean, and after about half an hour, when almost three quarters of the water had passed through it, and had dropped down, the remaining quantity of water was found barely 3° colder than the surrounding air.

It is but lately that liquor coolers have been manufactured in this country, and they are at present to be found in most of the earthenware shops in and about London. These are cylindrical vessels, about six inches in diameter, and about a foot high. It is directed to keep one of these vessels entirely immersed in water during one hour. The vessel, being then removed, in that moat rate, without putting any water in it, a bottle of wine, &c. must be placed in it, and this is laid to be cooled by the evaporation of that quantity of water, which the substance of the vessel had imbibed whilst it remained under water. Upon trial, however, it appears that the actual refrigeration which is obtained by means of one of these vessels, seldom amounts to two or three degrees; and that, of course, a bottle of wine may be cooled much more effectually by placing it in a pail of water fresh drawn from a pretty deep well or pump; which may be renewed at intervals. Indeed, considering the form of these coolers, also that the fides of them are at a considerable distance from the surface of the bottle, and the ambient air has a free access to both, it is hardly to be expected that any sensible advantage should be obtained from them.

In India the action of evaporation is used not only for cooling liquors, but likewise for cooling apartments, and the effect, by the testimony of those persons who have experienced it, is said to be very remarkable. The method, (which, however, is practicable only when a dry wind blows,) is as follows. That door of the apartment which is opposite to the wind, and through which the wind enters, is stripped up with a peculiar sort of screen or curtain, which fits it exactly. This screen consists of two surfaces or gratings of bamboo, situated parallel to each other, and about three or four inches apart; then the space between these external surfaces is filled up in a loose manner with the roots of a sweet-scented grass. In short the construction of this screen is calculated to admit the air not in a body, but divided through a vast number of passages. Two men are placed on the outside, each having a goat's skin filled with water, which they keep continually sprinkling upon the screen. A constant and copious evaporation is of course kept up, which previously cools the adjoining room to a very remarkable degree. By this means the temperature of the room has sometimes been lowered upwards of 15°.

Amongst those cooling processes which depend upon the expansion of bodies, that which arises from the expansion of air must not be forgotten; but this is by no means a practicable, we shall barely mention it in this place. The condensation and expansion of air produce the effects which have been mentioned above; viz. the former is attended with an extraction of heat, and the latter with an absorption of it; hence the contiguous bodies are heated by the former, and are cooled by the latter. When air is suddenly condensed, (see Condenser, and Condensation,) the heat which is extricated from it, has been found capable of setting fire to light combustible bodies; and when the air is rarefied either by means of an air-pump, or by liberating it from a vessel, in which it has been condensed; the cold it produces has sometimes been found to lower the thermometer several degrees below the freezing point.

The last method of cooling which remains to be described, is obtained by the solution of salts. That certain saline substances, whilst diffusing in water, or in acids, would generate a considerable degree of refrigeration, and especially that the solution of sal ammoniac would lower the thermometer down to the freezing point, has been long known; but, within the last 15 or 20 years, the subject has received wonderful improvements, in consequence of the experiments instituted by various ingenious persons; and, especially from the laborsious investigations, and successful experiments of Mr. Walker of Oxford, who has examined the cooling powers of a vast number of saline substances both single and mixed; and has been able to freeze quicksilver at Oxford in the middle of summer, merely by the solution of salts. His interesting experiments, and his various freezing mixtures, will be found described under the article Freezing.

A vast number of salts and saline mixtures may be used for cooling liquors; but the most advantageous are those which, after solution, may be recovered by means of evaporation, so as to render them useful for a second refrigeration, a third, and so forth. Yet the price of most of those salts in Europe, the trouble of recovering them from the solution, and pounding them in order to render them fit for another cooling operation, have not rendered this method common in this part of the world; especially where other easier methods are practicable. So that in fact the cooling power of saline solutions is mostly used for particular experiments by the European philosophers, especially when a very powerful freezing mixture is required. In India, where nitre is very cheap, and the heat of the climate prompts the inhabitants eagerly to adopt every possible method of cooling, the practice of cooling liquors, by means of the solution of nitre in water, is very common. For this purpose, the wine, the water, or any other liquor, is put into a metallic bottle, generally a pewter one, having a pretty long neck. A tub is partly filled with water, and a quantity of nitre is thrown in it; then the operator holds the bottle by the upper end of its long neck, and gently moves it about the saline solution, and thus cools the liquor in it to a very considerable degree. As salts will produce cold only during their solution, therefore when the first quantity of nitre has been thoroughly diffused in the above process, more nitre must be added; and when the water is completely saturated, so as not to be capable of diffusing more salt, then the bottle must be removed to another tub with a fresh saline mixture. The nitre might afterwards be easily recovered merely by exposing the solution, in shallow pans, to the hot rays of the sun in that country; this economical plan, however, does not as yet seem to have been adopted.

The salts which might be used for the purpose of cooling liquors in this country, or in long voyages, are nitre and sal ammoniac; the other saline substances being either more expensive or not easily recoverable after solution. Of the effects of nitre alone in water enough may be derived from the above described process. Salt ammoniac by itself gradually
COOLING.

The method of determining high degrees of heat, from the progress of cooling, depends upon the following observation. Sir Isaac Newton, considering the progress of cooling, was led to suppose, that the heat left by any body originally at a high temperature, in equal small portions of time, is as the heat existing in it; (reckoning the heat in the body, equal to its excess above that of the surrounding atmosphere,) that is, taking the times in arithmetical progression. The portions of heat left in those times would be in a geometrical one. The truth of this supposition has been sufficiently shown by subsequent experiments, the result of which has not differed much from the theoretical determinations. Hence we have the following practical rule for determining the high temperature to which a body has been exposed, from its subsequent progress of cooling.

Measure the time in minutes that elapses from the hottest state of the body (which is the degree sought,) to such a state of lower temperature as will allow the application of a common thermometer to the body in question, and call this number of degrees A; then having applied the thermometer, let down the temperature, which is indicated by the scale, at the expiration of each successive minute, until you have obtained three or four terms of the series, which, as has been said above, will be found to be a geometrical one (omitting, however, trifling differences.) Now, since from these few terms it is easy to determine any other terms of the same series, by the well known arithmetical rules; find for many terms of the series ascending, as are equal to the number of units in A; and the last term of the series, thus found, will be the degree of temperature of the body in its hottest state. An example will easily illustrate the application of this rule. Suppose it is required to determine the temperature of a piece of red-hot iron at the time that it came out of the forge. Look at the watch the moment the iron is taken out of the fire, and note the minute. Find by trials when the thermometer may be safely applied to the iron, viz., when the heat is not sufficient to rarify the mercury of the thermometer beyond the limit of its scale, and when this is practicable, observe the temperature of the iron, and the corresponding time as indicated by the watch. Suppose, for instance, that when the temperature of the iron was 350°, four minutes had elapsed since the commencement of the observation; therefore in this experiment A is equal to 4. Let the thermometer continue in contact with the iron, and when one minute more has elapsed, let the temperature be 125°. When another minute has elapsed, let the temperature be 62½ degrees; and after this, the observation needs not be continued. Now we have three successive terms of a geometrical series; viz. 350, 125, 62½; from which four more terms of the series are to be found, (since A was found equal to 4.) and the last of those terms is the number of degrees indicating the temperature sought. By dividing 350 by 125, or the latter by 62½, we have the quotient 2, (or nearly 2) which is the multiplier of the series, and therefore multiplying 250 by 2, we have the term 500, which multiplied by 2, gives the next term 1000, which multiplied by 2, gives 2000; and lastly this term multiplied by 2, gives the fourth term 4000; hence we conclude, that when the iron was taken out of the furnace, its temperature was 4000 degrees. The last term of the series may be found out by other means, but we have chosen the easiest, for the convenience of all readers. The two series are annexed.

Instead of minutes, the intervals of time may be half minutes, or hours, or, in short, of any other denomination; provided they be equal.

Cooling of liquors in Domestic Economy, is a practice of ancient origin, and of general prevalence in warm countries, and during the heat of summer, even in colder climates. This practice, as some have thought, is referred to by Solomon, in the book of Proverbs (ch. xxv. 13.); but however this be, evidences of it are very numerous in the works of the Greeks and Romans. Ice and snow were generally used for this purpose, and repositories were contrived for keeping these cooling materials. That the snow was preserved in pits or trenches is asserted by many; particularly by Seneca (Quæst. Natur. iv. 13) and Pliny (H. N. i. xix. 4.). When Alexander the Great besieged the city of Petra, he caused thirty trenches to be dug, and filled with snow, which was covered with oak-branches, and which was kept in that manner for a long time (Alexangi Deipnous. iii. p. 124.) Plutarch says (Sympoi. vi. Quæst. 6.), that a covering of chaff and coarse cloth is sufficient; and a like method is now practiced in Portugal. Where the snow has been collected in a deep gulf, some graves or green beds, covered with dung from the sheep-pens, are thrown over it; and under them it is so well preserved, that it is tint through the whole summer for the distance of 60 Spanish miles to Lisbon. When the ancients wished to have cooling liquors, they either drank the melted snow, or put some of it in their wine, or they placed jars filled with wine in the snow, and suffered it to cool there as long as they thought proper. The dissipated and luxurious Heliogabalus cau8ed whole mounts of snow to be heaped up in summer to cool the air (Lamprid. Vit. Heliogab. c. 23.) That ice was also preferred for the like purpose is probable from the testimony of various authors, Pliny, Seneca, &c.; but it appears not to have been used so much in warm countries as in the northern. At present snow is employed in Italy, Spain, Portugal; but in Persia, ice. The art of cooling water without snow or ice was soon forgotten to mankind, by observing, that it became cold more speedily when it had been previously boiled, or at least warmed, and then put in a vessel among snow, or in a place much exposed to the air. Pliny (H. N. i. xxxi. 3. 23.) seems to ascribe this to the invention of Nero; and a jocular expression of Suetonius (Vit. Ner. c. 48.) renders it probable, that he was fond of water thus cooled. But this method was much more ancient than Nero; for it seems to have been known to Hippocrates (De Morb. Vulgar. lib. vi. 4.); and Aristotle was acquainted with it; for he says (Meteorol. i. cap. 12.) that some were accustomed, when they wished water to become soon cold, to place it first in the sun and suffer it to become warm. He relates also, that the fishermen near the Black Sea poured boiling water over the reeds, which they used in fishing on the ice, to cause them to freeze sooner. See also Galen, in lib. vi. Hippocrat. De Morb. Vulgar. Comment. 4. 10. Athenæus remarks (Deipnous. iii.) that the pitchers filled with water, which had become warm by standing through the whole day in the sun, were kept continually wet during the night, by fountains defined to that office, and in the morning they were bound round with raph. In the island Cithæon, water which had become warm in the day-time was put into earthen jars, and deposited in a cool corner, where it became as cold as snow. From these facts it appears to have been a general opinion, that water which had been warmed or boiled, was soon it cooled, and acquired a greater degree of refrigeration. The same opinion prevails at present in the southern countries of Asia, and persons there let their water boil before they expose it to the air to cool. The experiments, however, that have been made on this subject, have given different results. Beckmann (ub infra) inclines to the opinion, that the cooling of water in ancient times was not to be ascribed so much to the boiling as to the keeping of the jars continually wet, and to the air to which they were exposed. See Congelation and Freezing, and also the preceding article.

Another method of cooling water seems to have been known to Plutarch. It consisted in throwing into it small pebbles or plates of lead (Sympoi. vi. 3.).

The practice of cooling liquors, at the tables of the great, was not usual in any country besides Italy and the neighbouring states, before the end of the 16th century. In the middle of that century, there were no ice-cellars in France. Towards the end of this century, under the reign of Henry III., the use of snow must have been well known at the French court, though it appears that it was confided by the people as a mark of excessive and effeminate luxury. Towards the end of the 17th century, this luxury must have been very common in France. At that period there were many who dealt in snow and ice; and that was a free trade which every one might carry on; but soon after government forced out a monopoly of cooling waters.

The method of cooling liquors by placing them in water, in which salt-petre has been dissolved, could not be known to the ancients, because they were unacquainted with that salt. This property of salt-petre was first discovered in the first half of the 16th century; and it was not remarked till a long period afterwards that it belongs also to other salts. The Italians were the first persons by whom it was employed; and about the year 1550, all the water, as well as the wine, drunk at the tables of the great and opulent families at Rome, was cooled in this manner. Towards the end of the 16th century this method of cooling liquors was well known. Mr. Beckmann says, that he cannot determine who first conceived the idea of mixing snow or ice with salt-petre, and other salts, which increase the cold so much, that a vessel filled with water, placed in that mixture, is congealed into a solid mass of ice, that may be used on the table, but the earliest account of it he has been able to find is a work of Latinus Tancredus, a physician and professor at Naples, who, in his book, "De Fame et Siti," published in 1667, speaks of this experiment. In 1626 Saint. Sanctorius, in his Commentary on the Works of Avicenna, relates, that, in the presence of many spectators, he had converted wine into ice, not by a mixture of snow and salt-petre, but by snow and common salt. When the salt, he says, was equal to a third part of the snow, the cold was three times as strong as when snow was used alone. Lord Bacon, who died in 1626, says, that a new method had been found out of bringing snow and ice to such a degree of cold, by means of salt-petre, as to make water freeze. This, he tells us, can be done also with common salt; and he adds, that in warm countries, where snow was not to be found, people made ice with salt-petre alone; but that he had never tried the experiment. Mr. Boyle, who died in 1691, made experiments with various kinds of...
kinds of salt; and he describes, how, by means of salt, a piece of ice may be frozen to another solid body. Des Cartes says, that, in his time, this was a well-known phenomenon, but highly worthy of attention. Since that period, the art of making ice has been mentioned in the writings of all philosophers, where they treated on heat and cold. Towards the end of the 17th century, the French began to conceal all kinds of well-taught juices, which were served up as refreshments at the tables of the great and wealthy. This was a grand invention for the art of cookery, and afterwards it became common, especially in the last century, and since that time the confectioners have universally practised it. Beckmann's Hist. of Inventions, vol. ii. See Freezing and Ice.

Cooling medicines, those which have a tendency to diminish febrial heat, to alloy thirst, and to lessen the activity of the circulation. They consist chiefly of diuretics, acids, and neutral salts. With the use of these a cooling regimen is commonly combined, which consists in a free employment of thin watery drinks, and a forbearance from every thing stimulating; such as animal food and fermented or spirituous liquors. Occasional laxatives and gentle diaphoretics contribute to the same purpose. See Refrigerants.

COOLOU, in Geography, a port of Chincoteagery; 5 miles N. of Teling-Hotun.

COOLLO, a town of Hindooollan, in the country of Orija; 39 miles S.W. of Cattack.

COOLOOME, an Indian town, situated on the W. side of Talapoofe river. See Talapose.

COOM, a term for foot that gathers over an oven's mouth: also for that black greaty fulbustance which works out of the wheels of carriages, and with which the axle-trees and boxes have been daubed or smeared over, in order to lessen friction, and make them run easy.

Coom, or foot, is sometimes used in medicine, infused in wine with other ingredients, as an antiphylactic, and against palpitations of the heart, &c.

The spirit of foot is also used for the same intentions, and in cephalic cases.

COOMBE, or Carnack of cubear, according to the 9th and 13th Henry III., 12th Henry VII., &c. was, 250,000 troy = 210,661 lb. avoirdupois = 2 striking = 16 pecks = 32 gallons = 256 pints or pounds.

COOMBE, Com, or sack of corn, is 2 long striking = 4 Winchester bushels = 16 pecks = 32 dry gallons = 128 dry quarts = 256 dry pints = 860,16 cubic inches = 4.97 cubic feet = 1.843624 cubic yards = 17,32142 cubic links. In some of the few districts it consists of 4 bushels, and each bushel of 8 gallons and a quart.

COOMBE HILL Canal, in Geography, is a short canal, in Gloucestershire, whose principal trade consists in carrying coal from the pits to the Severn river. See Canal.

COOMINGS, in Naval Architecture. See Coomings.

COMTAH, in Geography, a town of Hindooollan, in the country of Bear; 45 miles N.E. of Nagpoor.

COOP, in Rural Economy, a provincial term, sometimes applied to a tumblir or cart enclosed with boards, to carry dung, sand, grains, &c. See Cart.

Coop, also signifies a pen, or enclosed place, where lambs, poultry, &c. are shut up, to be fed or fattened.

Coop's Town, in Geography, a town of America in the state of Maryland, and county of Harford; 12 miles N.W. of Harford, and 22 north-easterly of Baltimore.

COOPA, a town of Persia, in the province of Irak; 30 miles E.N.E. of Ispahan.

COOPER, SAMUEL, in Biography, a miniature painter, whose works are deservedly held in the highest estimation. He was born in London in 1699, and was instructed by his uncle, Hokins, who was himself a finner of considerable merit. The scholar, however, soon surpassed his master in the variety of his nuts, the clearness of his caricatures, and the beautiful management of his hair. The works of Vandyke were the models upon which he formed his style; and so perfect, yet to bold, is the imitation, that were some of Cooper's pictures magnified to the size of life, they would scarcely lose by their comparison with the finest heads of the great Flemish master. He was the first who gave to his miniatures the freedom and strength of oil painting; and had his skill in drawing the other parts of the body been equal to that which he evinced in the face, his works might have challenged the most scrupulous eye of criticism. He seems, however, to have been conscious of his defects, and, probably on that account, left many of his finest pictures with the neck and arms unfinished. It would far exceed our present limits to enumerate even the half of Cooper's works. His portrait of Oliver Cromwell, which was lately in the possession of Sir Thomas Frankland, a defendant of Oliver, is described as a master-piece of character, and was engraved by Vertue. Mr. Wulpole mentions some of his other productions in the closet of queen Caroline, at Kensington; particularly a fine portrait of general Monk, of which the head only is finished. He was employed some time by the court of France, and lived several years in Holland. He died in London, May 5th, 1724, and was buried in Pancras church, where a monument is erected to his memory. Wulpole's Anecdotes.

COOPER, ALEXANDER, was the brother of the preceding artist, and, with him, received instruction in miniature painting from their uncle, Hokins. We learn from Wulpole, that Alexander painted landscapes and figures in water colours, as well as portraits. The fame author mentions the story of Diana and Actæon by this master, at Burleigh. He resided some time at Amsterdam, and ultimately entered into the service of queen Chriflina. Wulpole's Anecdotes.

COOPER, RICHARD, a painter and engraver, a resident of Edinburgh, who flourished in 1730. Amongst other works, he engraved the portrait of William Caribares, and that of Andrea Allen, the painter, after William Robinson—Mr. Strutt mentions another Richard Cooper, who resided at London, and flourished in 1768. Like the former artist, he engraved portraits. One of his half prints represents the five children of Charles I., accompanied by a great dog, from a picture of Vandyke. Other artists of the name of Cooper are mentioned by Heinecke. Strutt.

COOPER, or COUPER, THOMAS, a learned prelate of the sixteenth century, was born at Oxford about the year 1517, and educated in grammar learning in the school joining to St. Mary Magdalen College; and afterwards studied in that college, where he took the several degrees, and succeeded to a fellowship. When queen Mary came to the throne, he declined the purports of divinity for the study of phylic, being a found protestant in principle. Upon the death of that sovereign, he resumed his former studies, and became a frequent and celebrated preacher. He was made dean of Christ-Church in Oxford, and was for several years vice-chancellor of the university. In 1569, he was inducted to the deanery of Gloucester; and, in the following February, was consecrated bishop of Lincoln. His distinguished merit and great zeal, in the performance of the duties of his high office, recommended him to the sovereign's favour, who caused him to be translated, in 1584, to the rich bishopric of Winchester, where he became celebrated for his learning, and for the exemplariness of his conduct. Soon after his consecration,
Cooper, Anthony Ashley, first earl of Shaftesbury, one of the ablest persons, and most distinguished ministers of the 17th century, was son of Sir John Cooper of Rockboum, in the county of Southampton, bart., by Anne, daughter and sole heiress of Sir Anthony Ashley of Winborne St. Giles, in the county of Dorset, from whom he inherited an estate of 8000l. per annum. He was born at Winborne, July 22, 1624, and educated with the greatest care under the eye of his parents, during his infancy, in which he discovered such talents, that extraordinary things were predicted of him, while he was yet a boy. Before he was ten years of age, he had the misfortune to lose his father; at fifteen he became a fellow-commoner of Exeter college Oxford, under the tuition of the celebrated Dr. Prideaux, who was then rector of it. At the university, where he remained but two years, he obtained a character for great affability, and extraordinary genius. From Oxford he removed to Lincoln's Inn for the study of the law, and before he had completed his nineteenth year, he was chosen member of parliament for Tewksbury. This was in the year 1642; and, at the commencement of the civil war, he adhered to the king's side, though he was always a friend to peace, and thought conciliations should be made by both parties to attain it. To accomplish this great object, it is said by the great Mr. Locke, that he repaired to the king at Oxford, and proposed a method of putting an end to the war, by treating with the parliamentary garrisons, and promising them annuity for the pint, and full security for liberty in the future. The plan did not succeed; and when Sir Ashley found himself suspected by the court, and that his person was in considerable danger, he went over to the parliament party, by whom he was kindly received as well on account of his great talents, as for the influence which his property must create. He raised forces in Dorsetshire, and in 1644 he rendered the cause in which he acted some very signal services. He seems even at this period to have been looked up to by the royal party, since he was trusted with private negotiations between the king and Duke of York, lord Hainis, at the treaty of Uxbridge, for which he was afterwards questioned, and severely threatened, in parliament. After the battle of Naseby, he attempted to check the overgrown power of parliament, by exciting the "Club men," a body of people in several counties, encouraged to take up arms, to declare themselves as a middle party, and to insist upon a fort of treaty by which they might be reftored to the benefits of the law, and the protection of the constitution. The plan was in some measure executed; Fairfax received their proposals, and promised to communicate them to parliament, but Cromwell, and other leaders of that party, perceiving that no time was to be lost, attacked the club-men without mercy, killed great numbers of them, and dispersed the rest. The scheme was abandoned, but the author of it contrived fo as not only to involve himself in their fate, but to obtain shortly after the office of high fheriff of the county of Wilthire. Owing either to his great influence in the country, or to the warmness of his own well-processed schemes, he was elected a member of the convention, which succeeded to the long parliament abolished by Cromwell; and, in 1654, we find him a member of parliament, and one of those who protested against the tyrannical government of Cromwell. He was on other occasions a strong, though perhaps neither a steady nor uniform, opponent of the protector, as he ceased himself to be fryled. See CROMWELL. Sir Anthony was nevertheless chosen by the protector to be one of his privy council; and it has been asserted, that he even fought an alliance by marriage with the baronet's daughter. Dr. Kippis, however, who investigated the matter, gives no credit to this part of the charge. When Richard Cromwell was deposed, Sir Anthony was appointed by the rump parliament one of the council of state, and a commissioner for the managing army, although, it is now well known, that he was at the time engaged in a plan to restore Charles II. to the throne, notwithstanding the strong protestations which he made of his innocence when questioned on the subject, by which he obtained an acquittal. Like other discrediting men, he foresaw, from existing circumstances, that a change in favour of monarchy must eventually take place, and therefore he took care to secure a claim of merit in the restoration, which he promoted with great zeal and ability, when he perceived an evident tendency to that event. In 1660, he was a member of the healing parliament, and one of twelve who were deputed to invite the return of the king; who, in grateful remembrance of his services, made him a privy councilor; gave him a commission for the trial of the regicides; and, in the course of a year, raised him to the rank of peer of the realm, by the title of baron Ashley of Winborne St. Giles. He was soon after appointed chancellor and under-treasurer of the exchequer, and, upon the death of lord Southampton, one of the lords commissioners of the treasury. He was a member of the celebrated cabal minority, in which, from his superior talents and forcible eloquence, he took a decisive lead. He continued in the councils and confidence of the king his master, during the happiest part of his reign, and stood as high in his favour as any of his ministers. He was afterwards appointed to the lord lieutenancy of the county of Dorset, and on the
twenty-third of April 1672, was created baron Cooper of Pawlet, and earl of Shaftesbury. In the following November, he was raised to the highest office of state, viz. that of lord chancellor of England, the duties of which station he executed with equal ability and integrity. In his other capacities, as a minister and privy counsellor, he has been variously defcried; but he is allowed, on all hands, to have been one of the ablest men, and one of the most accomplished orators that have adorned this country. “The short time,” says one of his biographers, “that he was at the helm, was a厮on of it and tempels, and it is but doing him strict justice to say, that they could neither affright nor disturb him. Whatever he did, he did with his might, and there was a spirit and dignity in his administration, which that government could never recover after he left it. He was the soul and genius of the ministry while he made a part of it; but whether he did not care things too high, and out of the reach of all other capacities but his own, it would favour of rashness to determine.” Some historians attribute to him the arbitrary counsel of shutting up the exchequer, while others affirm that he opposed it with all his power, and drew up a paper of reasons against it. It is certain that he was the author of an sworn promotor of the declaration for liberty of conscience, which, though intended principally to favour the Papists, probably agreed with his own real judgment, as a decided friend to religious toleration. It is generally admitted that he had no concern in the disgraceful treaty with Lewis XIV., of which the main object was to render Charles a penitent on the French monarch; but he was a firm supporter of the Dutch war, and was guilty of advising the illegal measure of using writs for the election of members of parliament, during a recess, and abusing the influence of the crown to procure returns in favour of the court. He had not been more than a year in possession of the seals, when he manifested hostility to the principles which governed the Stuart family; so that the duke of York became his enemy, and at length in Nov. 1673 got him removed from his office. After he had quitted the court, he continued to make a great figure in parliament, and for his warmth in maintaining that a prorogation for fifteen months was equal to a dissolution, he was committed to the tower, where he remained a prisoner full thirteen months, when he submitted and was released, and the precedent made in his case was afterward reversed. Previously to this, he had shown himself a friend to civil and religious liberty, by opposing the tell-bill introduced into the house of peers by lord Danby, and on this business, he failed to have distinguished himself more than he had ever done. He managed the opposition to lord Danby’s administration with so much dexterity and vigour, that it was found absolutely impossible to do any thing effectually in parliament, without chagrifying the JElms which then prevailed. The king accordingly deserted all the privy council at once, and formed a new one, making lord Shaftesbury the lord president. He had, however, already drawn upon himself the implacable hatred of the duke of York, by readily promoting, if not originally inventing, the project of an exclusion bill.” To him also is imputed the contrivance of the Popish plot in 1678; which, if it were not a fiction of his own, was urged by him with the greatest virulence against the court party, so as to be the means of throwing out lord Danby’s administration; and there is no doubt that he was the author and promoter of all the perfections which followed on this business, as well in the inferior courts as in parliament, with a view of quashing the popish party entirely, and of excluding the duke from the succession, which were points he had most at heart, and which he purposed with an indefensible severity. Amidst many violent and very unjust proceedings, he was the author of a measure of formal national benefit, the passing of the “Habeas Corpus act,” to the protection of which he had occasion to appeal shortly after, for his own personal freedom. His new employment was short-lived, as he was dismissed after holding it little more than five months; and some of the practices to which he had recourse against the papists, were turned against himself. He was applied to by a man pretending to make discoveries relating to the popish plot, and the murder of Sir Edmundbury Godfrey, provided that for this service he might obtain a pardon. The man was conducted to the privy council; but instead of giving the information expected, he charged the noble earl with endeavouring to suborn him. Upon this information his lordship was apprehended on the 2d of July 1681, and after an examination by his majesty in council, he was committed to the tower, where he remained four months. Notwithstanding he took every legal method to obtain a trial, or to be admitted to bail, according to the principles of the habeas corpus act. At length, on the 24th of October, a bill was presented to the grand jury for the sessions house in the Old Bailey, against his lordship, for high treason. Witnesses were brought against him, but their characters were too infamous to permit their evidence to have the smallest degree of weight. Considerable stress was laid upon the draught of an association found in his study, which, however, was neither written nor signed by the noble earl; and the jury, after some consideration, threw out the bill, and he was acquitted, amidst the acclamations of the people. A medal was struck on the occasion, which was the cause of a very bitter satirical poem, from the pen of Dryden, which had been pernicious Shaftesbury, as the great counsellor of rebellion, in his “Abolition and Achitophel.”

As soon as he was at liberty, lord Shaftesbury endeavoured to vindicate himself by law, and brought an action against a peron for speaking of him as a traitor: this he thought proper to discontinue before it came to trial. For many years he had resided at Thanet-house in Aldergate-street; but finding his health decay, his spirits declining, and the times becoming more serious, he withdrew into Holland, where he arrived in November 1682, and in the following January he died at Amsterdam in the sixty-second year of his age. His body being embalmed was transported to England, and buried with his ancestors, at Winborne St. Giles, where much has been written concerning the character and conduct of this public man. As a public man, he was, says Dryden, “kippis, guilty of manifold inconsistencies, and submitted to shameful compliances. “There were, however,” adds the same candid and excellent biographer, “three points in which, through the usual tenor of his life, the earl of Shaftesbury was entitled to applause. These were, his attention to the protection and advancement of trade and commerce; his endeavours to counteract the growing power of France; and his attachment to the cause of religious liberty. He wrote an essay on toleration, still preserved in the family, which was evidently the ground work of Mr. Locke’s admirable letters on that subject. Several of the measures, proposed and supported by him, were preparatory to those that were adopted at the Revolution, and he contributed, by his ardour, to raise and animate the spirit which, in the end produced the event, so that amidst all his obliquities and faults, he deserves to be celebrated, as having been no small benefactor to the free constitution of England.” He left in MS. a history of his own times; and some of his speeches have been published. He was thrice married, but left only one son, who succeeded
in his estates and titles, and who died in November 1699, and was succeeded by Anthony his son and heir, of whom we are now to give an account.

COOPER, Anthony Ashley, third earl of Shaftesbury, was born Feb. 26, 1670-71, at Exeter-hou'se, London, which was at that time the town-residence of his grandfather, who undertook the superintendence of his education. He first entered into the care of the lord president of the name of Birch, under whom he made such rapid advances in the Greek and Latin languages, as to be able to read the common authors in each before he was eleven years old. He was then placed in a private school, where he continued till the death of his grandfather, when he was sent to Winchester; where, on account of the infirmities which afflicted, through the hatred borne to his grandfather's memory by the friends to arbitrary power, he remained but a short time, and, in 1686, he commenced his travels under the care of a well qualified tutor. With him he spent much time in France and Italy, improving himself in the languages and accomplishments of those countries, and laying the foundation of the knowledge and taste for which his own subsequent writings were justly celebrated. He returned to England in 1689, and was offered a seat in parliament, which for the present he declined, wishing rather to employ all his leisure in the improvement of his mind, and in extending his knowledge on subjects of the greatest importance. In these views he succeeded, and laid a foundation in learning which was accurate, extensive, and truly liberal. After pursuing the studies congenial to his temper, with much ardour and almost unabating diligence, for nearly five years, he was elected member of parliament for Poole. In this high station he shortly had an opportunity of expressing that attachment to liberty, by which he was distinguished through the whole of his life, and of conciliating the house to the object which he had in view. The occasion was the introduction of a bill for granting, among other things, the aid of counsel to persons indicted for high-treason. Lord Ashley had prepared a speech for the purpose, but when the moment came, in which he was to deliver it, he was utterly unable to proceed. After a short pause, he addaddressed the speaker. "If I, sir, who only rise to give an opinion on the bill now depending, am so confounded, that I am unable to express the least of what I proposed to say, what must be the condition of that man, who, without any affliance, is pleading for his life, and under the apprehension of being deprived of it?" This happy turn of thought, so appropriate to the occasion, is supposed to have contributed more than any of the arguments which were urged in obtaining the justice for which he pleaded. The necessity of this wise and humane law has been of late years amply manifested by the conduct of certain great law officers, who took the very moderate space of seven, nine, and eleven hours in opening cules of high-treason. During the remainder of that parliament, Lord Ashley was indisputable in the promotion and support of every measure in favour of liberty, without regard to the person by whom it was introduced, influenced unquestionably by an attention to the public good, without feeling the palate motives which too frequently actuate political men. At the dissolution in 1696, he resigned his pretensions to a seat in the house, on account of ill health, and with a view also of securing more time for literary pursuits. He went to Holland under the assumed character of a student in physic: here he cultivated an acquaintance with Bayle, Le Clerc, and other men of celebrity, and it was not till a short time before he left the country that he made his name known. Before his lordship's return an imperfect and surreptitious edition of his "Enquiry concerning Virtue," was published in a most unhandsome manner by Mr. John Toland, who, says Dr. Kippis, in this transactiion, repaid with ingratitude a very generous benefactor. His lordship bought up the edition, and set about completing the treatise, which afterwards appeared as the second volume of the "Characters." Soon after Lord Ashley's return to England, he became, by the death of his father, the earl of Shaftesbury, but he did not take his seat in the house of peers till the beginning of the year 1700-1, when his friend, Lord Somers, sent a messenger to acquaint him that his presence was necessary, on account of the Partition-treaty, which, at that time, was under the consideration of parliament. During the remainder of the session he attended his duty as frequently as the state of his health permitted, zealously supporting the measures of King William, who was, at that period, negotiating the grand alliance. That sovereign regarded the support of Lord Shaftesbury so highly, that he wished to appoint him secretary of state. This honour his health did not allow him to accept; but he was nevertheless affianched in rendering to his majesty advice on every important occasion. Soon after the accession of queen Anne, Lord Shaftesbury retired from public life, being no longer a friend to the measures of the court. Ministers now took from him the vice-admiralty of the county of Dorset, which had been held by his family for three successive generations. He went to Holland a second time, where he spent two years among the learned connections, which he had already formed in that country. About this period the French prophets having excited a considerable disturbance, in the nation, by their enthusiastic extravagances; some great men recommended professions and punishments as the only methods of suppressing them; these lord Shaftesbury was decidedly inimical, thinking that such measures would increase rather than cure the malady. This was the origin of his "Letter on Enthusiasm," which he sent to lord Somers, then president of the council, which, being approved by that nobleman and others, was published in 1708, though without the name of the author, or that of the person to whom it was addressed. In the following year he published his "Moralists," a philosophical rhapsody, being a recital of certain conversations on natural and moral subjects; and in a few months afterwards his "Senius Communis; an Essay upon the Freedom of Wit and Humour, in a Letter to a Friend." In the same year he married Miss Jane Ewer, the youngest daughter of Thomas Ewer, esq. of Lee, in Hertfordshire. In forming this connection, it should seem that his lordship was principally influenced by the solicitations of his friends, rather than from any inclination of his own, or high expectations of the happiness of that life. Letters to this effect are preserved in the Biographia Britannica. By his lady, to whom he was previously related, he had an only son Anthony, afterwards earl of Shaftesbury.

In 1710 the noble lord published his "Soliqay, or Advice to an Author;" after which his health obliged him to try the effects of a warmer climate. He accordingly, in 1711, passed through France and Piedmont, and fixed his residence at Naples, where he died on the 4th of February, 1712-13, at the early age of forty-two. During his abode at Naples, he finished his "Judgment of Hercules," and the "Letter concerning Delight," which have since been added to the "Characters." It was in 1711 that the first edition was published of all the Characters, in the same order in which they now stand: but this publication not being entirely to his lordship's satisfaction, he chiefly employed his time abroad in preparing his writings for a more elegant edition, which was given to the world soon after
after his decease, in the year 1712. The several engravings, that were then first interwoven through the volumes, were all invented by himself, and designed under his immediate inspection. The impression of the "Characteristics of Men, Manners, Opinions, and Times," in 3 vols. 8vo., contains the whole of his works which he intended to submit to the judgment of the public. In the year 1716, some of his private letters upon philosophical and theological subjects were published, under the title of "Several Letters written by a noble Lord to a young Man at the University," and in 1721, another collection of the same kind appeared, entitled "Letters from the Right Honourable the late Earl of Shaftesbury to Robert Mofleworth, esq. now Lord Vifcount of that Name; with two Letters written by the late Sir John Cropley: to which is prefixed, a large Introduction by the Editor." That editor, says the candid biographer already referred to, was Mr. Toland, who, in the present, as well as in the former age, assumed a liberty not very agreeable to the family. In their opinion, as the correspondence was almost entirely of a private nature, it was on that account unfit for public view. It nevertheless felt his lordship's integrity in the most amiable point of light. Lord Shaftesbury also wrote a preface to a volume of Dr. Whicliocote's sermons, published in 1698; and in his Letters to a young Man at the University, expatiates on the merits of Burnet, Hoadly, Tillotson, Barrow, Chillingworth, and Hammond, as the great pillars of the church against fanaticism. But however highly he might eele the labours of modern divines, his principal admiration was directed to the writings of antiquity. These were the constant subjects of his study, and on these his philosophy was built. His favourite books were the moral works of Xenophon, Horace, the Commentaries and Enchiridion of Epictetus, as published by Arrian, and Marcus Antoninus. These authors he always carried with him, in his various excursions; and they are still extant, filled with marginal notes, written in his own hand. It remains now to notice more particularly the writings of lord Shaftesbury, which, by one class of critics, have received the most extravagant applause, and, by another, have been the subjects of indiscriminate condemnation. They have been examined with a critical eye, and in rather an elaborate manner, by Dr. Kippis, to whose article, in the Biographia Britannica, we refer the reader, containing ourselves with a brief outline. Lord Shaftesbury's Letter on Truthfulness was written from excellent motives: it contains many admirable remarks, delivered in a neat and lively strain; but it wants precision; conveys but little information; and contains some exceptionable passages. The same character may be given, with truth and justice, of "The Essay on the Freedom of Wit and Humour," designed to defend the application of ridicule to subjects of speculative inquiry, and among others to religious opinions. His "Scholiary, or Advice to an Author," met with more general approbation. It contains a variety of excellent matter; and what the noble lord has advanced in recommendation of full-examination, and in defence of critics and criticism, is particularly valuable: it is evidently the result of the author's knowledge and refined taste in books, in life, and manners. Lord Shaftesbury's "Enquiry concerning Virtue" obtained more general applause. It is able and finely written, and maintains with great force the important truth, that virtue is the greatest happiness, and vice the greatest misery of men. This work has met with much opposition from those who deduce the principles of virtue from self-love only, and refer the obligation of it solely to the will of God. In this "Enquiry," the noble author appeared in the clofe, the logical, and the didactic form. But in the "Moralists,"
cient family in Nottinghamshire. He received the early part
of his education at Wettin school, and finished his
studies in Trinity College, Cambridge. As an author, his
first work was on the "Power of Harmony," formed on
the model of the "Pleasures of the Imagination." In 1739
he published "The Life of Socrates, collected from the
Memorabilia of Xenophon, and the Dialogues of Plato,"
&c. Learned notes were added by the Rev. J. Jackson of
Leiceter. This work was well received, though at present
it is in no great estimation. In 1753, he gave to the world
"Letters on Taste," which were written in an elegant style,
for which, and for the vivacity in the description, they were
more admired than for accuracy and depth of thought.
Cooper wrote some papers in "The World:--" his other
works are all poetical, of which the principal are, "The
Tomb of Shakspeare, a Vision," "Epistles to the Great,
from Ariostus in Retirement;" "The Call of Ariostus,
an Epistle to Dr. Akenfide;" and "A Translation of
Greffet's Ver Vert." Mr. Cooper was not deficient of
fancy, but his fancy was not always under proper
regulation, and he sometimes failed in the precision of his ideas.
He excelled in the light, easy, and epifatory train. His
sentiments have considerable sameness, being derived from
the Shaffeburian school of philosophy, of which he was a
disciple. He was an active member of the Society for the
Encouragement of Arts, Manufactures, &c.; a diligent
and useful magistrate. He died in 1769, of a fit of
the stone.

Cooper, on board a Ship, the person that looks to the
casks and all other vessels, for beer, water, or any other
liquors. He has a mate under him.

Cooper, in Geography, one of the Bermuda islands.

Cooper, a large and navigable river of America, which
mingles its waters with Ashley river, below Charle-
ton city, in South Carolina. These form a spacious and
convenient harbour, which communicates with the
ocean, just below Sullivan's island, leaving it on the N.
7 miles S.E. of the city. Cooper river is a mile wide at the
ferry, 9 miles above Charleston.

Cooper's Bridge, over the Calder river, on the road
between Huddersfield and Leeds in Yorkfhire, is the place
at which Sir John Ramsden's canal connects with the Calder
and Hibble navigation, which now has become a place of
considerable traffic, in consequence of the junction of the
Huddersfield canal with the other end of Sir John Ramsden's
canal. See Canal.

Cooper's Island, one of the Virginia islands in the Wett
Indies, S. W. of Ginger island, uninhabited; about five
miles long, and from one to two broad. N. lat. 18° 7'.
W. long. 63° 5'.

Cooper's, or De Keuper Island, lies on the north coast of
the island of Java, near Batavia; about 1600 feet
from the island of Oorulf, and about one-third lees in size. The
Dutch company have several warehouses in this island, in
which they chiefly lay up coffee. At its south side there
are two pier-heads, where vessels may load and discharge.
Over the island are interposed several large tamarind trees,
which afford an agreeable shade. The workmen that were
employed here in the day-time, are fetched over at night to
Oorulf, and two are left, as a watch, together with a number
of dogs, so remarkably fierce, that no one dares to set
his foot on the island at night.

Cooper's Island, an island in the Southern Pacific
ocean, near the E. coast of the ile of Georgia. It is a rock
of considerable height, about five miles in circuit, and one
mile from the main. At this isle the main coast takes a
S.W. direction for the space of four or five leagues to a
point, called by Cook "Cape Disappointment." Off that
are three small isles, the southernmost of which is green,
low, and flat, and lies one league from the cape. S. lat.
54° 57'. W. long. 36° 4'.

Cooper's Town, a small town, and township of America,
in the state of New York and county of Otsego. It is
the compact part of the township of Otsego, and the chief
town of the country round lake Otsego. It is pleasantly
situated at the S. W. end of the lake, on its banks, and the
outlet: 12 miles N.W. of Cherry valley, and 73 W. of
Albany. It has a court-house, gaol, and academy. In
1789 it had only three houses; in 1791 it contained 292
inhabitants; and in 1795, 50 houses had been erected on
an improved plan, regularly laid out in squares. N. lat.
42° 44'. W. long. 74° 49'.

Cooper's Town, a town of Pennsylvania, situated on the
Susquehanna river. In 1735 this was a wilderness; but in
nine years after, it contained 1800 inhabitants, a large and
handsome church, a market-house, a library of 1200
volumes, and an academy of 64 scholars. Four hundred and
seventy pipes were laid under ground for the purpose
of bringing water from Well mountain, and conducting it to
every house in the town.

CO-OPERATE, to, in a Military Sense, is to carry a
well-directed plan into execution in such a manner, that the
troops or forces, how much forever divided, may act at one
time, on one principle, and towards one end.

CO-OPERATOR, derived from con, and opera, labour,
denotes any cause, natural or supernatural, which concurs
with another to the production of an effect. Thus, nature
and medicine co-operate in the cure of disorders; and the
will of man concurs with the grace of God in the perform-
ance of good works.

CO-OPERIE PALLIO. See Pallio.

CO-OPERERS, Company of, See Company. Coopers are
enjoined to make their vehills of feasuable wood, and to
mark them with their own marks, on pain of forfeiting
36. 4d.; and the contents of vessels are to be observed under
a like penalty, so that the beer barrel shall contain 36
gallons, a ciderkin 18, a frinck 9, &c. The warehous of
the Coopers' company in London, with an officer of the
mayor, are to search all vehills for ale, beer, and foap to be fold there,
and to mark those that are right; and they may burn the
others: and if any cooper diminish a vehill by taking out
the head, or any one of its favel, it shall be burnt, and the

CO-OPERURA, in Antiquity, a thicket or covert of
wood. Chart. de Farel. cap. 12.

CO-OP-TATION, derived from co-opto. I choose, sig-
ifies the admission of members into any college or fociety.
Thus it was anecdotely applied to the choice of the augurs
and pontiffs; and in modern times, to an extraordinary no-
mination and election of persons of disinguished merit into
a learned fociety.

CO-ORDINATE, something of equal order, rank, or
degree, with another. CO-ORDINATION, in respect of caufes, denotes an
order of causes, wherein several of the fame kind, order,
and tendency, concur to the production of the fame
effect.

COORNHAERT, or CURNHEART, in Biography. See
Theodore Dirc.

COORROORAA, in Geography, one of the Pecow isles,
the capital of which is called Pecow; which see.

COOS, in Ancient Geography, an isle of the Egean or
Icarian sea, near Cnidus (now called Zia); in which was
a city of the fame name, from which Hippocrates, the cele-
bro-
brated physicians, and Apelles, the famous painter, were
called gods. Here was a large temple of Asclepius, and
another of Juno. It abounded in rich wines, and here were
made those "Coos vinae," which were transparent, and are
so often mentioned by the ancient poets.

Coos, or Cooshes, in Geography, a country of America,
called Upper and Lower Coos, which lies on the Connect-
ticut river, between 20 and 40 miles above Dartmouth col-
lege. Upper Coos is the country S. of Upper Amooneuck
river on John and the Coos river. Lower Coos lies below
the town of Haverhill, S. of the lower Amooneuck. The
distance from Upper Coos to the tide in Kenn-bach river was
measured in 1793, and found to be but 90 miles.

Coos-Bayzar. See Coos-Bahzur.

COOSA, or Coosa-Hatchee, a river which rises in the
high lands of the Cherokee's country, and joining Tallas-
see, forms Alabama river. Its course is generally S.
through the country of the Natchez, and other tribes of the
Upper Creeks. It is rapid, and full of rocks and shoals, so
that it is hardly navigable by canoes.

COOSADES, an Indian town on Alabama river, in
America, about 60 miles above its mouth, on Mobile river;
below McGillivray's town, and opposite the mouth of the
Oakfilleke.

COOSA-HATCHEE, or Coosa, a river of America,
in S. Carolina, which rises in Orangeburg district,
and after running in a S.S.W. course, discharges itself into
Broad river and Whale branch, which separate Beaufort
island from the main land.

COOSAWATCHIE, or Coosahatchie, a post town
of America, in the state of S. Carolina, and district of
Beaufort, situated on the S.W. side of Coosa river, over
which a bridge has been erected. The place is flourishing,
having about 40 houses, a court-house, and a gaol. The
courts formerly held at Beaufort are held here. It is 33
miles distant from Beaufort, and 77 W.S.W. from Charlec-
ton.

COOSCOOSOO, a common food among the Moors
of Africa, consisting of a paste made of flour in the form
of small grains in the manner of Italian pasties. This is drest
by the vapour of broth in a round dish, with holes like a
collander, and that is fixed in the kettle in which they boil
their meat. The cooscoosoo, contained in the deep plate or
collander, is slowly softened, and prepared by the vapour of
the broth, with which they take care to moisten it occa-
Sionally. This is a nourishing and agreeable food, and eaten
by the common people either with milk or with butter, but
superior persons have it drest by a rich broth made with
mutton, poultry, and pigeons or hedges-hogs, and mix it af-
afters with fresh butter.

COOSY, Coosa, or Ross, a river of Asia, which rises in
the mountains of Thibet, takes its course through Purnesh,
and runs into the Ganges, 20 miles E. of Boghpopour in
the country of Bahar.

COOT, in Ornithology. See Fulica atra.

COOTE, Sir Charles, in Biography, a distinguished
military officer in the 17th century, was the eldest son of sir
Charles Coote, who was created baronet in April 1621. He
was a gentleman of great consideration in Ireland. Upon
the breaking out of the rebellion, in 1641, he had a commis-
sion for a regiment of foot, and was made governor of Dub-
lin. From this period, to the year 1653, he was engaged in
a great number of important services for his country. In
almost all the contests of which he took a part he was suc-
cessful. After Ireland was reduced to the obedience of the
parliament, sir Charles was one of the court of judicature in
the province of Connaught, of which he was made president by
act of parliament. Being in England at the time of the de-
posing of Richard Cromwell, he went post to Ireland, to
carry the news to his brother Henry Cromwell, and to concer-
with him what to do in order to maintain themselves in their
posts. When, however, he perceived that king Charles the
Second's interest was likely to prevail, he endeavoured to in-
nuinate himself into his favour. For this purpose he sent to
the king a letter: "to assure his majesty of sir Charles's affec-
tion and duty, and that if his majesty would vouchsafe to come to Ireland, he was confident the whole kingdom would declare for him; that though the present power in England had removed all the labor men from the government of the state in Ireland, under the character of presbyterians; and had put Ludlow, Corbet, and others of the king's judges in their places, yet they were generally so odious to the army as well as to the people, that they could feize on their personas, and the ca-
tle of Dublin when they should judge it convenient." The
king did not think it prudent to accept the invitation. In
a short time after sir Charles Coote, and some others, so in-
fluenced the whole council of officers, that they prevailed
upon them to vote not to receive colonel Ludlow as com-
mander in chief; they, moreover, made themselves masters
of Athlone, Drogheda, Limerick, Dublin, and other im-
portant places for the service of the king. He immediately
caused colonel Monk to be made acquainted with the pro-
gress of the king's interest in Ireland, who urged them by
every means not to restore the suspended commissioners to the
exercise of their authority. Soon after, sir Charles Coote
and others sent to the parliament a charge of high treason,
against colonel Ludlow, Corbet, Jones, and Thomlinson.
He likewise made himself master of Dublin-castle; and ap-
prehended John Coke, chief justice of Ireland, who had
been solicitor-general at the trial of king Charles I. Not-
withstanding this, parliament thought themselves too far
of him in their interpell that he received their vote of
thanks on the 5th of Jan. 1659—60. On the 14th of the
same month he was appointed one of the commissioners for
the management of the affairs of Ireland. Before those
commissioners declared for king Charles, they infilled upon
certain things relating to their interell as members of that
nation. On the 6th of September 1663, sir Charles Coote,
on account of his many and very valuable services for the
royal cause, was created baron and viscount Coote, and
earl of Montrath in the queen's county. He was also ap-
pointed one of the lords justices of Ireland, but he did not
long enjoy those marks of his sovereign's favour, for he
died in December 1661, and was succeeded in his estate
and titles by his son Charles, the second earl. Dr. Le-
lond affirms that Coote and his father had engaged in the
parliamentary service not from principle, but interest. Dr.
Kippis, however, doubts the assertion upon the ground
that the Cootes were zealous Presbyterians, and therefore
he thinks it highly probable that they were influenced, at
least in part, by their real sentiments, civil and religious,
and especially by their aversion from popery.—Britan.

COOTE-HILL, in Geography, a market and poct town
in the county of Cavan, Ireland, near the borders of Monag-
han. It was much neglected by the late proprietor, but the
present one is improving its appearance by public buildings,
such as a market-house and shambles; and by obliging ten-
ants to build on a plan adopted by him. It contains
six houses of worship, besides the parish church. In the
sale of its markets it is the most considerable town in the
county. The sale of linen alone averages 4000L. weekly,
principally of sheetings, in which branch no market in Ire-
land.
land can vie with it. It is fifty-three Irish miles N.W. from Dublin, and ten miles N.E. from Cavan. Coote's survey of Cavan, &c.

COOTSTOWN, a town of America, in the state of Pennsylvania and county of Berks, is situated on a branch of Sauaboca creek, which is itself a branch of the Schuykill river. It contains forty houses, and a German Lutheran and Calvinist church. It is distant seventeen miles N.E. from Reading, and seventy-three miles N.W. by N. from Philadelphia.

COOTWYCK, or Kootwyck, Jurian, in Biography, a goldsmith, born at Amsterdam in 1774, who applied himself after the example of his countryman Pieter van Amstel, to the imitation of drawings by means of etching and aquatinta. Amongst his works, are several prints from the designs of Backhuysen, Berghem, and other Dutch and Flemish masters; and likewise some, which is supposed he executed from sketches of his own. One of his prints in imitation of black and white chalk, representing an old woman sitting in a chair, with a paper in her hand, is dated 1749. Heineken.

COP, William, born at Bale in Switzerland, took his degree of doctor in medicine at Paris, in the year 1495, and soon became so distinguished by his superior knowledge and abilities, that Ramus, no incompetent judge, called him "Unica nobilium medicorum gloria." He was physician to Lewis the twelfth, and to Francis the first, and ancient to the Faculty of Medicine at Paris. He translated the work of Paulus of Aegina, de Ratione Medicinae, which was published at Paris in the year 1510, in 4to; and the following year at Strasbourg; also, Galen's six books, de Locis Affectis, et de Morborum Causis et Differentiis, and the Prognostics of Hippocrates. He died in 1531. His son Nicholas succeeded him as regent of the University of Paris, but giving into the errors, his biographer says, of Calvinism, he was obliged to leave Paris, and to pass the latter part of his life at Bale. Haller Bib. Med. Eloc. Dict. Hist.

COPE, in Ancient Geography, a town of Greece, in Bocota, situated on the north banks of the lake Copais, to which it gave name. It is mentioned by Strabo, Ptolemy, and Pliny; the latter of whom says, that cars were invented in this place. It had temples of Ceres, Bacchus, and Serapis.

COPAIASA Balsam, in the Materia Medica. See Balsam.

Vol. IX.
drying linseed, or other fixed oil. These are used sometimes separately with the varnishes, but generally mixed.

We shall give some of the processes by which copal may be dissolved in each of these substances.

Alcohol finely, which so readily dissolves the other resins, has but little action on copal; for if this resin in fine powder be digested with the very purest alcohol, with or without heat, scarcely any of it is dissolved, and the copal coagulates at the bottom of the vessel into a tough coagulated mass.

But a solution may be effected by the addition of camphor, the action of which, upon the resin, has been partially described under the article. With some it is more striking than with copal. When the two are separately powdered and mixed, the copal absorbs the camphor, swells, and softens into a pulpy mass, which will remain for months of the same consistence, without hardening. To make an alcoholic solution of copal, dissolve half an ounce of coparner in a pint of highly rectified alcohol; put it in a glass vessel over a lamp, and add four ounces of copal in small pieces, and continue the heat just to that degree at which the bubbles may be counted, till the solution is complete. Part of the copal separates when cold, but most of it remains in permanent solution.

It is necessary first to dissolve the camphor in the alcohol; for, if the pulp mass arising from the mixture of copal and camphor be added to alcohol, the solution will not go on.

A mixture of mallic, elemi, and other resins, will bear a moderate quantity of copal, without being rendered insoluble in alcohol, even without the assistance of camphor.

To dissolve copal in the essential oils, Mr. Sheldrake has given the following process in the Transactions of the Society of Arts.

Reduce two ounces of copal to coarse powder; put it into a glass vessel, and pour thereon a pint of the very best oil of turpentine, with one eighth of spirit of ammonia, previously well shaken. Cork the glass, leaving a pin-hole through the cork to allow of the escape of vapour, and speedily heat it to that point at which the bubbles may be counted. Continue this till the solution is complete, taking care not to increase the heat, otherwise the copal will coagulate at the bottom of the glass, and the solution will not go on. The vessel should not be opened till quite cold. This liquor is of a rich deep yellow when in quantity, but when applied as a varnish, it is nearly colourless. The spirit of ammonia is not a necessary ingredient.

Mr. Tingry of Geneva (Painter's and Varnisher's Guide, 1804) finds that copal may be united to oil of turpentine by the intermedio of some other of the essential oils, particularly oil of spike and lavender. He gives the following process: Take two ounces of oil of lavender, heat it in a glass matras, add thereto an ounce of copal ground powdered, and, at different times, stirring the mixture with a flack of white wood. When the copal is dissolved, add six ounces of oil of turpentine, nearly boiling, and stir the whole thoroughly. This gives a fine gold-coloured liquid, very fit for varnishing.

Camphor also highly assists the solution of copal, in oil of turpentine, as it does in alcohol, and the same precaution is necessary, of dissolving the camphor completely in the oil, before the copal is added. Half an ounce of camphor is sufficient to a quart of the oil, to enable it to take up as much copal as will make a good varnish.

To unite any of the resins with drying linseed oil in the composition of the oil varnishes, it is necessary to expose them to a much greater heat than in the former instances, that is, not less than is sufficient to liquefy the resins. This, however, always gives the resin a certain degree of brown colour, which is often injurious to it when used as a varnish. Copal when melted with as little heat as possible, and then dropped into drying linseed oil, dissolves therein with ease, and this solution mixed with clear turpentine, forms a very fine hard varnish. To avoid as much as possible the discoloration of the copal, Mr. Tingry incloses it in a very slow-well-regulated furnace; and, as soon as any portion melts, it falls in drops into the drying oil heated and set beneath it.

When copal is dropped into water, a small quantity of oil is separated, and floats at top, and the resin at the bottom is thereby rendered somewhat more soluble in the different mercuric.

Copal is liable to be confused with gum ammonium, when the latter is very clear and good. The distinction is of some consequence, as the former, though valuable in varnishing, is much less so than the finest copal, the varnish with the former being darker coloured, and not so hard. Besides the external appearance of each, which is pretty distinct to a practised eye, the solubility in alcohol furnishes an useful tell, the former being readily soluble in this fluid, but the copal scarcely so.

COPALLI, in Botany, Hermard. See Rhus copalina.

COPAR, in Ancient Geography, a village of Arabia Felix, according to Ptolemy,—Alh, a place of Palestine, in the vicinity of Cesaarea Philippi.

COPARCENERS, from coparceny, and party, or a copartner.

COPARCENERS, from co- and participes, partner; or parners; such as have equal portions in the inheritance of their ancestor.

Coparceners are so either by law, or custom. Coparceners by common law, are the issue female; which, in default of a male heir, come equally to the lands of their ancestor; thus, when a person feited in fee-femipie or in fee-tail dies, and his next heirs are two or more females, his daughters, sisters, aunts, cousins, or their representatives; in this case they shall all inherit, and the co-heirs are then called coparceners or parners.

Coparceners by custom, are those who, by some peculiar custom of the country, challenge equal parts in such lands; as in Kent, by the custom of gavelkind, according to which lands descend to all the males in equal degree, as sons, brothers, uncles, &c. In either of these cases, all the parners put together make but one heir, and have but one Heller among them. Co. Litt. § 241, 242, 265; and 163. The crown of England is not subject to coparcenary.

COPARTNERSHIP. See PARTNERSHIP.

COPAS, in Ancient Geography, a river of Asia Minor, in Caria.

COPATZ, in Geography, a town in the island of Cherofo; 8 miles N. of Cherofo.

COPE, an ecclesiastical ornament, usually worn by chanters and sub-chanters, when they officiate in the church-service. It is also worn by the Roman bishops, and other ordinaries; it reaches from the shoulders to the feet. The ancient called it phialon.

In the trial of archbishop Laud, one of the charges alleged against him was his introducing the use of copes and church music into divine worship. To this charge he re-
plied, that the use of cope is prescribed by the 24th canon of 1603, which says, "that in all cathedrals and collegiate churches, the communion shall be administered on principal fast-days, sometymes by the bishop, if precent, sometymes by the dean, and sometymes by the canon or prebendary, the principal minifter using a decent cope;" so that in this respect he had made no innovation.

To this defence it was replied, that neither the common-prayer book, nor book of ordination, nor homilies confirmed by parliament, nor queen Elizabeth's injunctions in her first year, make any mention of cope, though they are evidently derived from the popish wardrobe; and the last common-prayer book of king Edward VI. expressly prohibits them. The 24th canon of 1603 enjoins only the chief minifter to wear a cope at the administration of the sacrament, whereas the archbishop preferred them to be worn by others besides the chief minister, and as well when the sacrament was not administered as when it was. But these canons not being confirmed in parliament, expired with king James, and therefore could be no warrant for their present use.

Cope, in Biography, a Flemish sculptor of the 16th century, who resided at Rome, and is celebrated by Baglione for the beautiful baso-relievo which he modelled, in a small fixe, from the Fables of Ovid; and which were afterwards cast in gold and silver, for the purpose of ornamenting the magnificent furniture of those times. The above-mentioned author informs us, that impressions from these beautiful models were generally dispersed and much admired at Rome. From Baglione's description of these works, we might be led to conjecture, that many of these small baso-relievo in bronze, which are usually attributed to Benvenuto Cellini, are of no other than casts from these models of Cope. I lie said to have succeeded in some small productions in ivory; and, ultimately, to have attempted a statue of a larger size in marble, which, however, after a long and fruitless labour, he left unfinished. He was not less remarkable for his talents, than for his morose and unofficious disposition, and he died miserably at about the age of 60. in the pontificate of Paul V. Baglione.

Cope, St. Martin's, was a relique formerly in great esteem among the French kings; and was often carried with them to war, as a protection and a weapon.

Cope, among miners, is a custom or tribute due to the king, or lord of the soil, out of the lead mines in some part of Derbyshire. This duty amounted, according to Manlove, to sixpence a load, nine dimes making one load.

COPE, in Commerce, a Muscovite coin, valued at about a half-penny; so that 100 cope is equal to a ruble, which is valued at an average at 4s.

COPE-STAKE, a German coin, valued at 12d. Perling.

COPENHAGEN (in Latin Hafnien, in Danish Kjoben- havn), originally Kjodenschavon, the Merchants' harbour, in Geography, is the capital of the kingdom of Denmark, situated on the eastern shore of the island of Zealand, in a bay of the Baltic sea, about 23 English miles from the Sound. E. long. 12° 35'. N. lat. 55° 41'. 160 miles W. of Hamburgh, and 240 S.W. of Stockholm. Its circumference is from 4 to 5 English miles.

In the 11th century Copenhagen was only a mean fishing place. It owed its increase to a cable, which protected its inhabitants against the numerous pirates who infested the Baltic sea. Leve, or Lettura, of which some remains have been found near Roschilb, had been the residence of the Danish kings till the year 950, when that distinction was bestowed on Roschilb itself, from whence the seat of empire was transferred to Copenhagen, in 1443, during the reign of Christophel of Bavaria. From that time the kings of Denmark have continually resided at Copenhagen.

This city was always well fortified by nature and art, but the strong citadel of Frederickshavn, between the harbour and the great gate, was only erected in 1663, previous to which time Copenhagen had often been attacked. In the year 1523 it was besieged by Fredericke, duke of Guttorp, supported by a fleet from Lubeck, consisting of ten ships of war. Tossed by famine, and cut off from all hopes of relief, the citizens surrendered, after a close siege of seven months. Thirteen years after, when, on the death of Fredericke, the inhabitants attempted to replace their old and favourite king Christiiii I. on the throne, Copenhagen underwent the same fate.

In 1568, Charles Gustavus, king of Sweden, having led his army over the ice, overran Denmark, and in the month of August appeared before Copenhagen, whilst his fleet blockaded the harbour. Bombs and red-hot balls were thrown into the city, but the fire was being nstinctly extinguished by the activity of the inhabitants. However, in the month of October of the same year the Dutch fleet, under the command of admiral Opdam, came to the assistance of the besieged, defeated the Swedish fleet, and threw a large supply of provisions into the town. Charles Gustavus at length ventured a general assault in the night between the 11th and 12th of February 1659, when the ditches about the ramparts were thickly frozen. The chief attack was directed against the western rampart which the citizens and students defended with such obstinacy, that the Swedish monarch, giving up all hopes of taking the city, retired, and the year following concluded a peace. As a reward for their bravery, the citizens and students obtained privileges which they enjoy at this day.

During the reign of Frederick II. in the year 1700, Copenhagen was again besieged on the land side by a Swedish army under the command of the renowned Charles XII. and on the sea side by the combined fleets of Holland, England, and Sweden. The Danish king was in Hamburgh, but the queen dowager, Charlotte Amalia, having animated the city and students to a brave resistance, neither the numerous Swedish army, nor the combined fleets, could make any impression on the town. The peace of Travendahl put an end to the frige, and Copenhagen enjoyed a complete century of uninterrupted peace.

On the 23d of April, 1801, the English vice-admiral, Nelson, with 11 ships of the line, 7 frigates, and 10 small vessels, attacked the line of defence before the port of Copenhagen, and, after a most obstinate engagement of three hours and a half, unfurled the white flag, took possession of 11 Danish ships, and, by an equally well-timed and skilful negotiation, detached Denmark from the maritime league into which she had entered with Russia and Sweden against England. The harmony between the two countries was restored, but continued only until the month of August 1807, when a strong English fleet encircled the island of Zealand, having previously disembarked an army of nearly 20,000 men, under the command of lord Cathcart, which invested Copenhagen by land. After a vigorous bombardment of five days and nights, during which Copenhagen made a defence worthy of the acknowledged bravery of the Danes, and the citizens and students displayed the most undaunted courage, a capitulation was agreed upon on the 7th of September, by which the English troops were allowed to take possession of the citadel for six weeks, and the whole Danish army, consisting of 18 sail of the line, 15 frigates, 6 sloops.
and 25 gun-boats, together with all the shores of the naval arsenal of Christian IV, were surrendered to the disposal of the king of Great Britain.

On this occasion Copenhagen suffered severely. In the night of the 4th of September the grand fleaie of St. Mary's, or our lady's church, which was 380 feet high, and stood on the highest spot in the city, was set on fire, and after having blazed for four hours, fell with a most tremendous crash. From six to seven hundred buildings, besides those of the university and one hospital, were burnt to the ground; thousands were damaged, and no more than four hundred houses escaped unhurt. Several valuable libraries fell a prey to the flames, and five or six hundred peaceable inhabitants were killed or maimed.

Anciently, Copenhagen had often been visited by the plague. The last which raged, in 1711, swept away great numbers of the inhabitants. In more recent times, Copenhagen has been frequently exposed to terrible conflagrations. On the evening of the 20th of October 1728, a fire broke out in a low house, not far from the well-gate, which spread with such fury, that at eight and forty hours the most elegant part of the city was laid in ashes; 1050 dwelling houses, four churches, the university buildings, and several other public edifices were burnt down to the ground. On the 26th of February 1794, the church of St. Nicholas, and the royal palace of Christianborg, the gorgeous magnificence of which is sufficiently attested by its stupendous remains, were destroyed by fire, and hardly had the private houses, which suffered in this dreadful calamity, been rebuilt, when another considerable part of the city was reduced to ashes in 1795.

These conflagrations contributed, however, to render Copenhagen one of the finest cities in the north. The houses, though mostly of brick varnished, exhibit a beautiful and uniform appearance, the streets are furnished with lamps; well paved, with a foot way on each side, and running in a straight line; but some of the streets are rather too narrow.

Copenhagen is divided into the Old and New Town and Christianhafen. The Kongens nye Torge, or king's new Market, which connects the Old with the New Town, is a spacious, irregular area, embellished with an equestrian statue in bronze of Christian V., and adorned with several handsome buildings, among which are the palace of Charlottenburg, devoted in part to the Royal Academy of painting, architecture, and sculpture; and the theatre, which, though small, is neat and elegantly decorated within. In the New Town is a beautiful octagon, containing four uniform and elegant buildings, in two of which the royal family resided ever since the palace was burnt down. In the middle of the octagon stands an equestrian statue of Frederick V., in bronze.

Christianhafen is built on the island of Amack, and connected with the Old Town by two bridges. Besides the fine dock-yards, where the men of war are refitted, Christianhafen contains the great West India fuagar house and the East India house. The island of Amack itself is considered as the kitchen garden of Copenhagen, and furnishes the same with greens, fruit, milk, butter, and cheese in abundance. It is 9 miles long and about 2½ miles in breadth. It contains above 800 families or 4000 souls, and is divided into two parishes, Taarnby which is inhabited by Danes and Dutchmen, and Hollanderyke inhabited only by the descendants of a Dutch colony, which king Christian II. transplanted hither from North Holland, in 1516, at the request of his wife Elizabeth, sister to Charles V., who was a native of the Low Countries. The language of the inhabitants of Amack is still a mixture of Danish and Low Dutch. They have preferred their particular dress, manners, and customs. The men wear broad brimmed hats, black jackets, full glazed black breeches, loohe at the knee; the women black jackets, red petticoats, and a piece of blue glazed cloth bound round their heads. There is a particular market place at Copenhagen for the peafants of Amack, called the Amack market.

The harbour of Copenhagen, formed by the braits of Kelleboe, between the islands of Zealand and Amack, is capable of holding 500 ships. It is protected by several batteries, of which that of the three crowns is the most formidable. The naval arsenal, called Chriilliamholm, is much superior to that of Venice. The forges, workshops, rope-windows, are upon an admirable construction. Each ship has her separate magazine, containing all the materials for her equipment. The men are registered and divided into two classes; those who in time of peace are permitted to serve on board the merchants' ships, or to enter into foreign service, subject to be recalled in case of war, and the stationery sailors who are always in the employ of the crown. The latter, 4000 in number, live in barracks at Copenhagen. The academy of marine cadets forms one of the palaces in the octagon of the New Town. It was founded in 1701, for the education of fifty young gentlemen, who are boarded and instructed gratis; but more are admitted, on paying, to share in their instruction. They have to pass through several severe examinations before they are entered as midshipmen in the king's ships.

Copenhagen is the chief commercial town of all Denmark. Its principal domestic trade is with Norway, Iceland, the Faro islands, and Greenland. Since the year 1754, the trade to the West Indies is free to all the Danith ports; yet Copenhagen receives, almost exclusively, the return cargoes from St. Croix, St. Thomas, and St. John. Copenhagen is also the seat of an East India Company, a Jiro Bank, an Insurance Company; and its extensive foreign trade is chiefly with Germany, the countries round the Baltic, and the Mediterranean seas, France, Portugal, and Spain. In the year 1792, Copenhagen had only 218 ships of about 24,000 tons, but during the long wars between France and England their number has been nearly doubled.

The most important manufactures of Copenhagen are the woolen cloth and flax, the calico-printing, silk, and China manufacture. The latter, though in its infancy, is thought to rival those of Dresden and Berlin.

Copenhagen is the seat of an university founded in 1575. It is richly endowed, grants a support of 1 marks Danith, or nearly 3 shillings English, a week to 180 poor students, and since the year 1791 distributes eight premiums annually for the best answer to eight prize questions. There are four colleges, in which 166 students are provided with lodging, fire wood, and pecuniary stipends. The number of students is generally between five and six hundred.

Since the year 1742, several learned associations have been formed at Copenhagen, the oldest and most known of which is the Royal Society, whose researces have thrown great light on northern history. This society superintends all the geographical mentation of the country, and the publication of new special maps. It proposes four quillions annually, and the 'priam for each is a gold medal worth twenty pounds sterling. But besides the Medical Society, founded in 1772, that of Icelandic literature, founded in 1779.
1779, and that of natural history, founded in 1789, the most important is the Royal Economical Society, founded in 1768, whose annual income of 6000 dollars, or 1200l. Sterling, is expended in promoting the fine arts, fisheries, agriculture, and horticulture, and in encouraging every attempt that tends to benefit the country. It is now endeavoring to establish a regular importation of coals from the Faro islands. There is also a board of longitude and a repository for marine charts, founded in 1784, which has published excellent charts of the entrance of the Sound, of the two Belts, the Sound and the Baltic as far as Barnholm, of the Cattegat, of part of the western coast of Iceland, of part of the eastern coast of Iceland, of the Faro islands, and six charts of the coast of Norway. Copenhagen has likewise acquired some celebrity from its royal museum or cabinet of curiosities remarkable for Laplandish dress, implements, and arms; from its excellent theatre of anatomy, founded in 1736, and from its public royal library, which, in 1797, was increased with the celebrated Suhm’s library of 50,000 volumes, collected by himself, and relating chiefly to the antiquities of northern Europe.

There is only one theatre at Copenhagen, which is partly supported by the court. During the year 1806, it brought out nine translated pieces, and only one original Danish comedy. The performances of the seafow amounted to 158. There has been no Italian opera of late; only occasionally, and for a short time, German and French plays are performed by itinerant companies.

Copenhagen is the seat of a supreme tribunal, which is the highest court of justice for all the Danish dominions. Its fittings are opened with great solemnity in the beginning of March, on the ancient Herredag or Dannebøe (meeting of parliament) by the king himself. And besides the inferior courts of justice there are boards of conciliation, or what are called conciliatory committees, whose duty it is to accommodate matters between the parties by all possible means of persuasion. If an accommodation takes place, the expenses are very trifling, and the parties are bound to abide by it. From the 13th of August, 1795, when the first conciliatory committee was established at Copenhagen till the 31st of December 1801, 13,223 litigations were prevented at Copenhagen only in the course of six years and a half.

The bishop of Zealand, who is first in rank among the twelve bishops, of whom the Danish hierarchy is composed, resides at Copenhagen, which, besides the cathedral, counts 20 churches, one French protestant church, and several chapels for the Jews, whose number amounts to 1200. They are most liberally treated at Copenhagen, and there is even a society established by Christians for the purpose of encouraging the instruction of Jews in arts and handicrafts.

In the year 1714, Frederick IV. established at Copenhagen a board of millions or Collegium de Curia evangelii promovenda, which sends missionaries to Greenland, and to the East Indies. The letter are also supported in part by contributions collected at London. In the beginning of 1807, Copenhagen, with its suburbs, counted 3156 houses, and 124,000 inhabitants. The regulars for the year 1806, gave 3440 born, 3109 dead, and 930 couples married. In 1799, Copenhagen counted only 82,608 inhabitants, one-sixteenth, or 5168, of whom were paupers. Yet no beggars are seen in the streets. A board of almshouses over the poor, who are provided for by voluntary contributions. Copenhagen has twenty-two hospitals, and thirty poor-houses. In 1802, the principal infirmary admitted 2349 patients, 1813 of whom were cured, 218 died, and 318 remained in the house. The naval hospital, or Næstved house, contains 300 invalids.

The police at Copenhagen is vigilant and good. A paper published weekly, under the title of the Friend of the Police, has particularly contributed to render the police excellent, by pointing out the most minute objects with regard to which it was thought deficient. Since the year 1804, the prisons have been rendered much more comfortable. They are all wainscotted and boarded, provided with bedsteads, blankets, and mattresses; and no person, whatever may be his crime, is ever confined in a dungeon or cell. In the Raab-house, where capital offenders are shut up for life, the male convicts rap and saw Brazil wood, the females spin, and thus they all contribute towards their support by their labour. There is also a board of health, and a committee for promoting vaccination, under whose superintendence 6489 individuals were inoculated for the cow-pox at Copenhagen, in the course of the year 1802.

Copenhagen is surrounded with country seats, which offer the most enchanting sea-scenes. Its environs are beautiful, the country being finely varied with small forests of beech and oak. Of the summer-palaces in its neighbourhood, Fredericsholm is the most remarkable for its delightful situation.

Without the western gate, close to Copenhagen on the high road, stands an interesting monument in commemoration of the emancipation of the peasants, which was effected under the present king. Four figures of white marble, representing peace, plenty, content, and industry, occupy the four corners of a pedestal, from the centre of which rises a pyramid. On one side of the base are these words: “For Christian den syvende de Danikkes og Norges Konge, af Wihime og taknemmelige Borgere.” To Christian the Seventh king of the Danes and Norwegians from united and grateful citizens; and on the other, “Grund flæske blev hæst af Frederik kongens son, folkerne varet 1792.” The foundation stone was laid by Frederic the king’s son, the friend of the people.

COPPERARIO, Giovanni, or John Cooper, in Biography, an English musician, who, having resided for some time in Italy, on returning to his native country, Italianized his name, and became a favourite performer on the lute and viol du gambe, and a voluminous composer of fantasias, fantasias, for viols, in three, four, five and six parts. He was appointed music-maister to the children of James I.; and Prince Charles, under his influence, made a considerable progress on the viol. Some of his vocal compositions were printed in the musical publications of the times. In conjunction with Nicholas Laniere, and others, he composed the fongs in a Masque, written by Sir Thomas Campion, on the marriage of Carr, earl of Somerset, and lady Frances Howard, the divorced countess of Exford, which was performed in the Banqueting Room at Whitehall, on St. Stephen’s night, in the year 1604. Mr. Fenton, in his notes on Walter, says, that Henry Lawes, having been educated under him (Copperario), “introduced a better mixture of Italian airs than had before been practised in this country;” from which, and from his giving him the title of Signor, he seems to intimate, that he regarded him as an Italian. The following are the titles of his printed works, exclusive of the songs which he composed in conjunction with
with Lanier: "Funeral Tears for the Death of the Right Hon. the Earl of Devonshire, figured in feaven Songs, whereof fixe are so fet forth that the Words may be expressed by a treble Voyce alone to the Lute, and base Viol, or else that the mean part may be added, if any shall effect more fulfemle of parts. "The fanventh is made in forme of a Dialoge, and cannot be sung without two Voyces. Invented by John Coperario." Fol. London, 1606. 2.

"Songs of Mourning, bewailing the untimely death of Prince Henry, worded by Thomas Campion, and fet forth to bee sung with one Uoce to the Lute or Viol, by John Coperario." Fol. Lond. 1613.

**COPERNICAN SPHERE.** See SPHERE.

**COPERNICAN SYSTEM.** is that system of the world, wherein the sun is supposd at ref in the centre; and the planets, with the earth, to move in ellipses round him.

The heavens and stars are here supposd at ref; and that diurnal motion which they appear to have from eft to zef, is imputed to the earth's motion from zef to eft.

This system was afferted by many of the ancients: and particularly Ephraem, Seleucus, Aridarcus, Philolans, Ceanthes Samius, Nicetas, Heraclides Ponticus, Plato, and Pythagoras; from the last of whom it was anciently denominated the Pythagoric system.

It was also held by Archimedes, in his book De Grando in Aeternum Arnum Numero; but after him it became negleced, and even forgotten, for many ages; till above three hundred years ago, when Copernicus revived it; from whom it took the new name of the *Coperican System*. See COPERNICUS.

**COPERNICUS, NICHOLAS, or rather COPERNICK, in Biography, the celebrated astronomer, was born at Thorn in Prudia, near the Old Gate, on the 19th of February, 1473; in a house which was firft extant in 1579, and loan to strangers as one of the greatest curiosities of that town. His father was a gomme; his mother's brother, Lucas Walperebrd, or, as he is fometimes called, Haff-brodt Von Allen, was, fome years after young Copernicus's birth, raised to the dignity of bishop of Ermeland, in Latin, Episcopus Vurmienfis: which circumfances has betrayed molt of the English biographers into a fingular mistake. They make Copernicus cano of Worms, in the fouth of Germany, instead of Frauenburg in Prudia, which is the fce of the bishops of Ermeland.

Copernicus received his firft inftructions in the grammar school of his native city, from whence he was fent to fudy phyfics at the university of Cracow, where he gained the academical honour of a doctor's diploma. But he never practifed as a physician, though he readily gave his advice, and his medicines, without any fee, to thofe friends who confulted him. Mathematics were his favourite study: and he took particular delight in the study of perspective; and this induced him to acquire the art of painting, in which he is faid to have excelled. From the infant he had heard Albert Brufzevus's mathematical lectures at Cracow, he was fired with the noble ardour of emulating the two greatest mathematicians of his time, George Purbach, an Auffrian, and John Regiomontanus, a native of Könifberg, in the Neumark of Brandenburg. To accomplish this arduous defign, he went to Italy, and was at firft the pupil, but foon became the friend and afliliate, of Dominicus Maria, of Ferrara, who was then teaching mathematics at Bologna, and whofe hypothefes about the variability of the axis of the globe, by exciting universal attention, gave Copernicus the first ideas of the motion of the earth. At Bologna, in the year 1476, Copernicus firft observed the ocultation of Pali-rium by the moon.

He left Bologna to teach mathematics at Rome, where he obferved an eclipse of the moon in the year 1500; and such was his dawning celebrity, that, even after his return to Prudia, he was confuted by the clergy of Rome, in the year 1516, respecting the improvement of the calendar. In the mean time his uncle, the bishop of Ermland, had made him a canon of the chapter of Frauenburg; and the town of Thon had named him to the archdeacony of the church of St. John; yet he seldom lived in his native city, but made Frauenburg his principal refidence. Zealously attached to the tenets of his church, he fulfilled the duties of his clerical offices with punctual care. The glorious Reformation, which he witnessed, had no influence on his religious opinions: his mind pursued a different trage. Drawing and painting, the study of perspective, and the making of mathematical instruments, filled his leisure hours; and besides his regular avocations, the conftitution of some aquaducts absorbed his time. "That which feeds the mill of Grandaunz with water has been completely preferred; of another, which supplied the hill of Frauenburg, on which the canons reside, nothing remains but the tower on the banks of the Pfaffage, to the top of which he raised the waters of that river, and which exhibits the following inscription:

"His patimurr aqifum properar propas tocsie, Ne carent fraters Incola montis opa."

Quod natura negat tribuit Copernicus arte, Unum pro culcis Fanis loquitur opus."

Whenever the bishop was absent, Copernicus was entrusted with the government of the diocefe; and after the death of two prelates, he was appointed general vicar during the vacancy. He was also frequently deputed to the provincial diets. Nothing, however, could divert him from his original purpose. He applied his stores of mathematical knowledge to the improvement of astronomy. The garret of his house at Frauenburg, which is still shown, and the iceplool of the cathedral, were his observatories. The epicycles and eccentrics of Ptolemy embarrased and perplexed him; but the hypothesis of the earth being the motionless centre of the universe, was generally received; it had been adopted by Plato and Aridarcus, whose authority was confidered paramount to that of the bible; and Justin's command to the fun and moon confirmed it. To attack this systenl was incurring the imputation of heresy; and it required no extraordinary courage to advance an opinion, for which Galileo suffered a century after.

In this perplexity, Copernicus afiduously searched the lore of antiquity. He found that the Egyptians taught the revolution of Mercury and Venus about the sun; that Apollonius and Pergaus had assigned the fame motion to Mars, Jupiter, and Saturn; that, according to his disciples, Nico-tas and Heraclides, Pythagoras, whose learning was derived from the Egyptians, afferted the earth's motion round its own axis; and that Aridarcus and Philolans went still farther, and maintained that the earth did not only move about its axis, but employed twelve months in revolvin the fun.

On these foundations Copernicus raifed a structure, of which his intense and acute fudy furnished him with the mot correct mathematical evidence. According to his fystem, the fun occupies the centre of the universe; the planets, in their proper fize, occupy all the fpace of the earth, and their motion round them, like epicycle, cece the earths fize; Mercury moves round the sun within three months, Venus within eight, the earth within twelve, and within four-and-twenty hours it revolves round its own axis; the moon is a satellite of the earth, about which the turn

thirteen
thirteen times in a year; Mars takes two, Jupiter almost twelve, and Saturn nearly thirty, years to move about the sun.

It was in the year 1530 that Copernicus laid the first hand to his system, which he had begun to form about the year 1507; but he had not yet ventured to launch it into the learned world, when its fame reached the bishop of Capua, cardinal Nicholas Schönberg, who, in 1534, by a letter which does honour to his sentiments, invited Copernicus to publish his new system. Other great men, particularly Timo- deman Gicle, bishop of Culm, assisted him with their in- treaties to the same purpose. But his model was still re- fining their proficiency, when Rheticus, professor of mathematics at Wittenberg, excited by an ardent thirst of learning, resigned his chair, and visited Copernicus at Frau- enburg, in the year 1539. To him Copernicus at last trusted his work, which, in 1543, was printed at Marien- burg, at the expense of cardinal Schönberg, under the title of “Nicolaï Copernici de Revolutionibus Orbium Coelestium, Libri vi.” But he did not live to read his book in print. A copy of it reached him only a few hours before his death, which happened at Frauenburg, on the 23d of May, 1543, three months and three days after he had entered the seventy-fifth year of his age. He was probably buried at the foot of the altar before which he used to celebrate mass; for, 38 years after his death, Cromeru, bishop of Ermeland, caused the following inscription to be placed on his tomb-flone, which is now shown in the chapter’s room:

D. O. M.
R. D. Nicolai Copernici Tomusenfis,
Artium et Medicinis Doctoris, Canonico Varminæni,
Prefalenti Astrologo et ejus Discipulis inauratorii,
Martinus Cromeru Episcopus Varminæn,
Honoris et ad Politaratem Memorize Caufa psuit,
MDLXXI.

Others pretend that Copernicus, having requested to be interred near his relations, was buried at Thorn, in the church of St. John, where he is represented in his canonical dréts, kneeling before a crucifix, and a globe on his fide, with this inscription:

“Non parem Pauli gratiam requiro,
Veniam Patri nique pofco, fed quam
In crucis ligno dedares Latroni, fedulos ore.”

Nicolai Copernici Thurmenciæ absolutæ subtilitatis math- ematico, ne tanti viri, apud epteros celebres, in sua patri periret memoria hoc monumentum psuit. Mort. Varminæ
ius fuo Canonicoatu, anno 1543, die 4, Ætatis LXIII.

This painting wrouth, in the year 1733, by a pupil of Thorn, named Rubinkowski. A print of it may be seen in Hartknoek’s Ancient and Modern Pruffia. It is supposed that Copernicus’s manuscripts were de- posed at Braunberg, in the Jefuits’ library, with the books of which they may have been removed to Sweden by Charles XI. Whether they be still extant in that country is uncertain. Ludwig von Backzo’s Klein Schriften, 1797, vol. ii. p. 135; Gaffendi Opera, vol. v. p. 499; Bernoulli’s Travels, vol. iii. p. 18. See the order and disposition of the heavenly bodies, as laid down by him, compared with those in the other systems, under the head SYSTEM.

This system has been established by new arguments ad- vanced by Kepler, Galileo, and Newton, in every succeeding age; and notwithstanding the opposition it met with, from the prejudices of men against the earth’s motion, the au-

thority of Aristotle in the schools, the threats of ignorant bigots, and the terror of the inquisition, it has generally prevailed. Galileo, after having demonstrated the motion of the earth, was obliged, by the rancour of the Jesuits, to go to Rome, and there solemnly renounce it. Besides which cruel treatment, he was condemned to a year’s imprisonment in the inquisition, and the penance of repeating daily some penitential psalms. As a specimen of the authority of the Romish church in opposition to this system, we shall only transcribe the declaration of the excellent commentator Le Scar and Jacquier, on the Perniciana, prefixed to the third volume. “Newtonus in lucu tertio libri

telluris motus hypothesim affuit. Autoris propositiones aliter explicari non poterant, sua enim quoque facta hypo-

theki. Hinc alienam coacta funnis generis perfomam. Cac-

turn latissimus summis pontificibus contra telluris motum decretis nos obsequi profiterur.”

COPERNICUS is the name of an astronomical instru-

ment, contrived by Mr. Whiston, for the calculation and exhibition of eclipses, and of the motions of the planets, both the primary and secondary ones, &c.

It was so called by the inventor, as being constructed on the Copernican system; or as representing the heavenly bodies agreeable to it. It consists of several concentrical circles of wood; upon which are inscribed numbers, transferred hither from the astronomical tables: by the various dispo-

sitions of these circles, which are made so as to slide within each other, questions are solved; and thus long calculations are saved, and the work of many hours brought into a few minutes.

For the exhibition of eclipses there is a peculiar appara-

tratus, consisting of a terrestrial globe, so disposed, as that, being turned round its axis, the light of the sun, or a candle, is projected through a glass plane, marked out into concentrical circles, expressing digits of the eclipse; and thus is the path of the eclipse, with its degree or quantity in any part of its path, agreeably and accurately re-

presented.

The instrument not being very common, a particular de-

scription would be superfluous. The author of it has writ-

ten a book to explain it.

COPTHANIA, in Ancient Geography, a port of Car-

mania.

COPTHANTUS, a mountain of Asia, placed by Pliny in Baetria.

COPHENES, a river of India, which ran between Alexandria, and the first scene of the military operations of Alexander, and which, as major Rennell conjectures, oc-

urred pretty early in his march. In Alexander’s arrange-

ment of boundaries, the river Cophenes was the eastern li-

mit of the province of Paropamisus, of which Alexandria was regarded as the capital; and that province, according to the ideas of Plutarch, lay between those which the mo-

derns name Korasan and Cabul. The major therefore con-

cludes, with some degree of confidence, that the river “Cw” of the Turkish geography, and the “Cow-mull” of Baber, which passes by Nughz, and whose principal branches are the rivers of Ghizini and Gardaiz, is the Cophenes; and that we must look for Alexandria in the quar-

ter of Bamian, though it is not possible to assign its particular situation. At all events, the proximity of Alexandria to the northern mountains, a fact which Arrian impresses

very strongly, renders it an impossible cafe, that Alexandria and Candahar can be one and the same place. Leaving Alexandria, at the foot of Caucasus, Alexander came to the river Cophenes, and passed it in the higher part of its course. From Cophenes, Hepleclusion and Perdiccas, with a strong
a strong detachment, were sent into the country of Punico- 
laotis (Arrian) or Punicolaitis (Strabo) near the Indus. 
Alexander marched from the banks of the Cophenes across the 
Alps, Tyre, and Arafai, nations, whose situations and mod- 
ern names are unknown, but supposed by Rennell to be 
inferior divisions of the modern Cabiul, and situated be- 
tween the rivers of Ghizmi and Cabul, at the height of 
Ijub and Dukkah. In his march to Arzauus, Alexander 
croft two rivers, the "Cheo" and "Eupfalia," and de- 
feating the Aipians in a pitched battle, near the latter, 
passed through the territories of the Guriel, and crofted 
the river of the fame name (see GURUS). The Cheo and 
Eupfalia may be two of the nine rivers of the Landharn. 
It is very difficult to determine the length of Alexander's march 
from the Cophenes to the Guriel; but it might possibly be 
100 road miles. As Alexander had crofted the Indus, proba- 
ably at Attock, when he came to the bridge (which was com- 
pleted before his arrival), he made an excursion by land into 
the country adjacent to the western bank of the Indus, in 
order to view the city of Nyfa (fuppofed by M. dAnville to 
be Nughz, or Nagaz, the Nagara, or Donyitized of 
Ptolomy); and he is then fuppofed to have entered the country, 
that lay between the two rivers, Cophenes and Indus. Ad- 
mitting that the Cophenes is the river that runs from Nughz, 
and falls into the Indus, 30 or 35 miles below the city of 
Attock, and as the river Cabul joins the Indus in front of 
the city of Attock, it is clear that, till he came opposite to 
that city, he could not be between the Cophenes and Indus. 
And if it be faid, that the Cabul river was the Cophenes, 
he had all along been between the Cophenes and Indus; 
and Arrian's words could have no meaning. Upon 
the whole we may conclude that the ancient Cophenes was the 
name with the modern Copoii, which fee. Rennell's Memoir, 
p. 175, &c.

COPHOS, a place of Greece, in Attica, situated before 
Pirae.

COPHOSIS, in Medical Writers, is used for defnefs, 
whether beginning, or perfect, or from what caufe fo- 
ever. 

The word is derived from νόσεως, I am defeaf.

COPHRANTA, or COPHANTA, an ancient town of 
Afia, in Carmania. Ptolomy.

COPHIS, Samuel, in Biography, a learned Jewish 
Rabbi of Spain in the eleventh century, was a native of 
Cordova, and published a commentary on the Pentateuch, 
the manufcript of which is ftil extant in the Vatican library. 
Thofe who have examined it commend it as an excellent 
work, except that it too much abounds with allegories.
The author died A.D. 1034.

COPHTH, COPHTHES, or COPTS, a name given to the 
Christians of Egypt; who are of the fect of Jacobites. 
They derive the latter appellation from the learned Jacob- 
bus Zainzalou, bishop of Edeffa, who, when the Coptes party 
had funk in number and credit, appeared in defence of the 
Monophysite doctrine; and by his writings, as well as inde- 
fatigable travels through moft parts of the East, fucceeded 
with fuch a degree in reviving and diffiminating it, that he 
hath been reverenced and efteemed by the whole ft, which, 
from respect to him have affumed the name of Jacobites: 
though the other Christians, as well as the Turks, call them 
by their old name Copts. By way of contempt fome have 
called them "Kuffu" or Girdlers, thus intimating that they 
are Christians only from the girdle upwards, but bear 
the fcare of Jewifh below it.
The critics are extremely divided about the origin and 
orthography of the word: fome write it COPHTH, others 
COPHTHE, COPHTHES, COPTS, &c. Scaliger derives the name

from COPHTH, an anciently celebrated town of Egypt, the 
metropolis of the Thebaid, whether they retired from the 
tyranny of the Greeks.

Kicher refutes this opinion, and 

maintains, that the word originally signifies cut and circum- 
scribed; and was given to one of the Mahometans, 
away of reproach, becaufe of their practice of circumcifion: 
but P. Sollier, another Jesuit, refutes this opinion. 
Scaliger afterwards fubfifted his opinion, and derived the 
word from ΑΥΓΕΤΗ, the ancient name of Egypt, by 
terminating the ft & italic: but this opinion, too, P. Sollier 
confiders.

Volney, concurring in opinion with Scaliger, obferves, 
that the Arabic term Kobi, a Copt, seems to be an 
evident abbreviation of the Greek word ΑΥΓΕΤΗ, an 
Egyptian; for the y was pronounced ou among the 
ancient Greeks; and the Arabs, having neither p nor g before 
a, o, u, always fubstitute for the letters b and j. 
John de Leo and others fay, that the Egyptians anciently 
called their country Edfbib, or Cibib, from Cibith their ft, 
whence Cophite, &c, others ftay from Cobim fcond ft of 
Egypt. Vanl. b derives the word Copfl from Copf, font 
of Mitrain, grandifion of Noah. All the etymologies P. 
Sollier rejects, on this principle, that were true, the 
Egyptians ought all equally to be called Cophites; whereas, 
in effe&, none but the Christians, and among thofe none but 
the Jacobites, bear the name; the Melchites not being 
comprehended under it. Hence he chooses to derive the 
word from the name Jacobites, by terminating the ft ylla- 
ble; whence Cophie, Cophia, Cops, and Copite.

Several families of thofe Copts are to be found in the 
Delta; but the greatest number inhabit the Said, where 
they in fome places occupy whole villages. Both his 
ftory and tradition attest their defcent from the people who 
were conquered by the Arabs, that is, from that mixture of 
Egyptians, Perfians, and, above all, Greeks, who, under the 
Ptolomies and the Conftantines were fo long in pofterifion of 
Egypt. Their name, according to the etymology given of 
it by Scaliger-and by Volney, fees to indicate that they are 
the remains of the ancient Egyptians; and this is the more 
probable, flince we find them in the Said before the time of 
Diocletian; and it is certain the Greeks were left numerous in 
the Said than in the Delta. This opinion of their origin is 
rather more probable, by confidering the diftinguifhing 
features of this race of people; and they are found 
to be all charafterized by a fort of yellowlefh dusky complexion, 
which is neither Grecian nor Arabian; they have all a 
puffed fignage, fwoman eyes, flat nofes, and thick lips, or, in 
short, the exact countenance of a Mulatto. Volney, when 
he faw the figure of the ipixus, and obferved its features to 
be precisely thofe of a negro, recorded the remarkable 
profile of Herodotus, in which he fays, (lib. ii.) "For my 
part, I believe the Colchi to be a colony of Egyptians, 
because, like them, they have black fkins and brizaded hair." 
Hence he concludes, that the ancient Egyptians were real 
noegos, of the fame fpecies with all the natives of Africa; 
and though, as we might naturally expect, after mixing for 
fo many ages with the Greeks and Romans. they have loft 
the intodity of their ft colour, yet they ftill retain 
strong marks of their original conforation. "And how 
are we astonifhed," fays Volney, "when we behold the pre- 
female and ignorance of the Copts, derived from 
the profound genius of the Egyptians, and the brilliant 
imagination of the Greeks; when we refpect that to the face 
of negroes, at preftent our slaves, and the objeds of our ex- 
reme contempt, we owe our arts, fcienccs, and even the 
very ufe of speech; and when we recollect that, in the 
midft of thofe nations who call themselves the friends of 
hberty and humanity, the moft barbarous of slaveries is jufti-
tified; and that it is even a problem, whether the understanding of negroes be of the same species with that of white men? The language formerly spoken by the Copts forms another argument in favour of the origin above ascribed to them. On the one hand the form of their letters, and the greater part of their words, demonstrate that the Greek nation, during the thousand years it continued in Egypt, has left deep marks of its influence; but, on the other, the Coptic alphabet has five letters, and the language a number of words, which are to be considered as the remains of the ancient Egyptian. These, when critically examined, have a sensible analogy with the dialects of the ancient neighboring nations, such as the Arabs, Ethiopians, Syrians, and even those who lived on the banks of the Euphrates; nor can it be doubted that all these languages are derived from one common stock. For upwards of three centuries, that of the Copts has fallen into disuse. The Arabs, disdaining the language of the nations they subdued, imposed on them, together with their yoke, the necessity of learning that of their conquerors. This obligation became even a law, when, about the end of the 6th century of the Hegira, the Caliph Waled I. prohibited the Greek tongue throughout his whole empire. From that time the Arabic became universal; and the other languages, confined to books, fulfilled only for the learned, who neglected them. Thus has been the fate of the Coptic. The priests and monks no longer understand it, in their scriptures and books of devotion in which alone it exists.

Mr. Browne, a late traveller in Africa, (p. 71.) does not admit this hypothesis of Volney; for he observes, that the Copts, or original inhabitants of Egypt, have no resemblance of the negro features or form; though they have some peculiarities of feature common to all. Their hair and eyes are of a dark hue, and the former is often curled; but not in a greater degree than is occasionally seen among Europeans. The nose is often aquiline; and though the lips be sometimes thick, they are by no means generally so; and on the whole, a strong resemblance may be traced between the form of visage in the modern Copts, and that presented in the ancient monuments, paintings, and statues. Their complexion, like that of the Arabs, is of a dulky brown; it is represented of the same colour in the paintings, seen by Mr. Browne in the tombs of Thebes. The Coptic women have interesting features, large black eyes, and a genteel form.

The Copts differ from the Arabs by their religion, which is Christianity, and which they embraced at an early period; but they are again distinct from other Christians by their opinions, which are those of the Euchyrians or Monophysites. Their adherence to these opinions has exposed them to the persecution of the other Greeks; and thus they are rendered irreconcilable enemies. When the Arabs conquered the country, they took advantage of these enmities, to enfeoff them both. The Copts, however, have at length expelled their rivals; and as they have been always intimately acquainted with the interior of the country, they are become the depositaries of the registers of the gilders of the lands and tribes. Under the name of "Writers," they are at Cairo the intendants, secretaries, and collectors of government. These writers, defiled by the Turks whom they serve, and hated by the peasants whom they oppress, form a kind of separate class, the head of which is the writer to the principal Bey. He dispenses all employments in that department, which, according to the spirit of the Turkish government, he bestows on the belt bidder.

The Copts endured many suffering, and were reduced to extreme poverty and distress by the intolerance and persecution of the Greeks; but when Ammon invaded Egypt, A.D. 688, the Copts availed themselves of the opportunity which was afforded by their voluntary submission to the conqueror for retaliation on their persecutors. The Saracens were received by them as the deliverers of the Jacobite church; and during the siege of Memphi a secret and effectual treaty was opened between a victorious army and a people reduced to the most abject distress and bondage. "The Greeks," said Mokawwas, a rich and noble Egyptian, connected with the Coptic sect, in his first conference with Amrou, "are determined to abide the determination of the sword; but with the Greeks I defire no commixion, either in this world or in the next; and I abjure for ever the Byzantine tyrant, his yoke of Chaledon, and his Mekhite slaves. For myself and my brethren, we are resolved to live and die in the profission of the gospel and unity of Christians. It is impossible for us to embrace the revelations of your prophet; but we are defirous of peace, and cheerfully submit to pay tribute and obedience to his temporal successors."

The tribute was ascertained at two pieces of gold for the head of every Christian; but old men, monks, women, children, of both sexes, under 16 years of age, were exempted from this personal affliction; the Copts above and below Memphis swore allegiance to the caliph, and promised an hospitable entertainment of three days to every Mussulman who should travel through their country. By this charter of security, the Copts obtained a triumph over their enemies, and the sacred edifices, with the patrimony of the church, were restored to the national communion of the Jacobites, which enjoyed without moderation the moment of triumph and revenge. From the superiority thus acquired, and the conduct by which it was obtained, and by which it was succeeded, proceeded that permanent and ineradicable animosity which hath subsisted between the Copts and the Greeks ever since their subjection to the Turks; and which the Romish millionaires have endeavoured to terminate, by using every method likely to reconcile both those sects to the church of Rome. In the 17th century attempts were made for uniting the Monophysites of Asia with the Romish church, and they were accompanied with a partial and temporary success; but the African Monophysites, and more especially the Copts, notwithstanding that poverty and ignorance which exposed them to the seductions of popery and gain, maintained their principles with firmness, and made an obstinate resistance to the promises, presents, and attempts, employed by the papal millionaires to bring them under the Roman yoke. The Copts, ever since the Saracen conquest above-mentioned, have had churches, priests, bishops, and a patriarch, who fixed his seat of residence at Cairo, when that city became the capital. In their worship they blend a number of superfluous customs, which have been transmitted to them from their ancestors and which they obstinately retain. In other respects, says Savary (Letters on Egypt, vol. ii.) the Copts are gentle, humane, and hospitable. Paternal tenderness and filial love constitute the happiness of their families. They honour and cherish all the ties of blood. The internal commerce, the art of hatching chickens, and that of bringing up bees, form almost their only sciences. They often acquire considerable wealth in the management of the affairs with which they are entrusted, but they are never allowed to enjoy the fruit of their labours in tranquility. The Bey, who feels their opulence, strips them without pity:—happy if they can secure their lives by the sacrifice of their fortune. These vexations, however, never excite them to revolt.

Then
C O P H T I.

Their want of energy keeps them chained down to servitude and misery, which they endure without murmuring. Mr. Browne represents the Copts as an acute and ingenious people, who get money readily without extortion, considering, that, under an arbitrary government, obscurity is safety. In their temperment, he says, they are melancholy, but, if called into action, indomitable and laborious. However, they are fond of their distilled liquors, and rather licentious in their amours. They are zealous in their faith, this writer adds, and their ecclesiastics are numerous. The populous city of Cairo, as we have said, affords a refuge, or rather a shelter, for their indigent patriarch, and remnant of 10 (some say 12 or 13) bishops; 40 monasteries have survived the depredations of the Arabs; and the progress of servitude and apathy has reduced the Coptic nation to the despicable number of twenty-five or thirty thousand families; a race of illiterate beggars, whose only consolation is derived from the finer wretchedness of the Greek patriarch and his diminutive congregation.

The Coptic patriarch, though he resides at Cairo, takes his title from Alexandria; and the body of the inferior clergy, whether secular or regular, is composed of the orders of St. Antony, St. Paul, and St. Macarius, who have each their monasteries.

Besides the orders of priests, deacons, and subdeacons, the Copts have likewise archimandrites, the dignity whereof they confer with all the prayers and ceremonies of a priest ordination. This makes a considerable difference among the priests; and besides the rank and authority it gives them with regard to the religious, it comprehends the degree and functions of archpriests. By a custom of about seven hundred years, if a priest elected bishop be not already archimandrite, that dignity must be conferred on him before episcopal ordination.

The second person among the clergy, after the patriarch, is the titular-patriarch of J rualem, who also resides at Cairo, because of the few Copts at Jerusalem; he is, in effect, little more than the bishop of Cairo: only he goes to Jerusalem every Easter, and visits some other places in Palestine near Egypt, which own his jurisdiction. To him belongs the government of the Coptic church, during the vacancy of the patriarchal fee.

To be elected patriarch, it is necessary the person have lived all his life in continence: it is he confers the bishoprics. To be elected bishop, the priest must be in the celibate; or, if he have been married, it must not be above once.

The priests and inferior ministers are allowed to be married before ordination: but are not obliged to, as Ludolphus erroneously observes. They have a great number of deacons, and even confer the dignity frequently on children. None but the lowest rank among the people commence ecclesiastics; whence arises that exclusive ignorance found among them: yet the respect of the laity towards the clergy is very extraordinary. Their office is longer than the Roman office, and never changes in any thing; they have three liturgies, which they vary occasionally.

The monastic life is in great esteem among the Copts; to be admitted into it, there is always required the consent of the bishop. The religious Copts make a vow of perpetual chastity; renounce the world, and live with great austerity in deferts: they are obliged to sleep in their cloaths and their girdle, on a mat stretched on the ground; and to prostrate themselves every evening a hundred and fifty times, with their face and breast on the ground.

They are all, both men and women, of the lowest class of the people; and live on alms. The monnaries are properly hospitalls; and few enter but widows reduced to beggary.

In the present habitation of the Coptic community is situated in the desert of Nitria, called also after the name of a famous saint denominated Macarius, and is distinguished by the appellation of "Za'di el Baramous," and called by the Arabs, "Kafr Zu'tit." It is an enclosure of high walls without any gate, unless that name should be given to a small wicket, which is opened only twice or thrice in the course of a year. Perons entering or leaving it are hoisted up and lowered down by means of a strong rope and a pulley. The building is entirely constructed of soft calcareous stones, several of which contain sottile shells. Within the walls there is a kind of small fort, surrounded by ditches, over which is built a drawbridge. Here the monks retire, when the Arabs succeed in forcing the outer walls. In this little fort are a church, a cellarm, and provisions; in short, everything for enabling the monks to sustain a long siege. Here they also keep their books, written in the Coptic language; which they cannot on any consideration be prevailed on to part with, although they never read them, and suffer them to lie on the ground, eaten by vermin and covered with dust. The cells of the monks are vaulted and very low, and are indeed no better than a sort of dens, not unsuitable to the ignorant and sottile wretches who inhabit them. The church is simple in its construction, and has no other ornament besides a few oil-rich's eggs, and bad pictures of saints. It is impossible, says Sommi, (Travel in Upper and Lower Egypt, p. 354,) to give an idea of the confusion that sometimes prevails in their church: they often know not what they are to sing: one will have a particular anthem or psalm, and another a different one: they then dispute and come to blows; in the mean time a third chants a prayer, which is followed by the choir, and thus the quarrel terminates. Their singing consists of Turkish and Arabic airs, accompanied by cymbals, the noise of which, mixed with their squalling voices, and their discordant music, makes the church re-echo with a medley of jarring sounds. The priest celebrates mass with water. They confecrate common bread; which the priest eats in pieces and mixes with water, which is likewise consecrated. This makes a kind of soups, of which he eats a few spoonfuls; and afterwards admixes the sacrament, also with a spoon, to all that are present. After the communion the priest washes his hands, and standing at the door of the chancel, extends them to invoke the face of every one who passes. During mass, the priest also blest little laves which are distributed at the close of the service. The priest who celebrates mass is drest in a kind of white shirt, made with a cowl, and covered with little croffles. During the other prayers, he only wears a large fillet of white linen, with similar little croffles, half twirled round his head in the form of a turban, with the two ends hanging down before and behind. In this convent there were only three priests and some friars, with a seclusion of persons who come either from time to time to do penance, and who bring the monks the means of subsistence. Their fare consists of bread, or rather biscuit, made of flour of lentils, and rice boiled in salt and water, bad cheese, and a little honey; and their only beverage is a brackish and ill-tasted water. Their supplies are conveyed to them from the alms of the rich Copts at Cairo. In these monasteries, several of which are found in this desolate country, the Coptic travellers through the desert are sure of finding necessaries for themselves and their horses; which they obtain by ringing a small
small bell, the cord of which hangs down on the outside.

F. Roderic reduces the errors and opinions of the Copts to the following heads: 1. That they put away their wives, and espouse others while the first are living. 2. That they have seven sacraments; viz., baptism, the eucharist, confirmation, ordination, faith, fasting, and prayer. 3. That they deny the Holy Spirit to proceed from the Son. 4. That they only allow of three ecclesiastical councils; that of Nice, Conantinople, and Ephesus. 5. That they only allow of one nature, will, and operation, in Jesus Christ, after the union of the humanity with the divinity: in other words, they are Monophysites, Monoothelites, or Eutychians. Mr. Browne (ubi supra) says, that they embrace transubstantiation; in which, and other points, the Catholics of Cairo think they apprehend their faith nearer than the Greeks. As to their errors in discipline, they may be reduced, 1. To the practice of circumcising their children of both sexes before baptism, which has obtained among them from the twelfth century. 2. To their ordaining deacons at five years of age. 3. To their allowing of marriage in the second degree. 4. To their forbearing to eat blood: to which some add their belief of a baptim by fire, which they confer by applying a hot iron to their forehead or cheeks.

Others palliate these errors, and show that many of them are rather abuses of particular persons, than doctrines of the sect. This seems to be the case with regard to their polygamy, eating of blood, marrying in the second degree, and the baptism of fire: as for circumcision, it is said not to be practised as a ceremony of religion, nor as of any divine appointment, but merely as a custom which they derive from the Jummalites; and which, perhaps, may have had its origin from a view to health and decency in those hot countries.

The Copts have adopted, from the Mahometans, the custom of frequent profrations during divine service; of ablution after the conjugal rites, &c. In many respects their faith, discipline, and worship, resemble those of the Abyssinians; see that article.

The Copts, at different times, have made several reunions with the Latins; but always in appearance only, and under some necessity of their affairs. In the time of pope Paul IV., a Syriac was dispatched to Rome from the patriarch of Alexandria, with letters to that pope; wherein he acknowledged his authority, and promised obedience: deferring a peron to be dispatched to Alexandria, to treat about a re-union of his church to that of Rome: purport to which, Pius IV., successor to Paul, chose M. Roderic, a Jesuit, whom he dispatched in 1561, in quality of apostolical nuncio.

But the Jesuit, upon a conference with two Copts deputed for that purpose by the patriarch, was made to know, that the titles of father of fathers, pater of fathers, and master of all churches, which the patriarch had bestowed on the pope in his letters, were no more than mere matters of civility and compliment; and that it was in this manner the patriarch used to write to his friends: they added, that since the council of Chalcedon, and the establishment of several patriarcha independent of one another, each was chief and master of his own church. This was the answer the patriarch gave the pope, after he had received a sum of money remitted to him from Rome, by the hands of the Venetian consoli.

COPHTIC, or Coptic, the language of the Copts, the ancient language of the Egyptians, mixed with a great deal of Greek; its alphabet being manifestly nothing else but Greek, with the addition of some few letters, to express sounds, which the Grecians had not, and which probably came to be used in Egypt after the time of Alexander, though we know that the Greek language, and perhaps also the Greek letters, were taught there long before, in the reign of Pharaoh Acheutschechenn. Of this affinity the reader may judge, by the following table of the Coptic alphabet:

The old Coptic, which Kircher maintains to be a mother-tongue, and independent of all others, had been much altered by the Greek; for besides that it has borrowed all its characters from the Greek, with a very little variation, a great number of the words are pure Greek.

Vossius, indeed, affirms, that there was no Coptic language till after Egypt became subject to the Arabs. The language, according to him, is a mixture of Greek and Arabic: the very name thereof not being in the world till after the Arabs were masters of the country. But this, Mr. Simon observes, proves nothing; except that what was anciently called Egyptian, has since by the Arabs been called Coptic, by a corruption of speech. There are, it is true, Arabic words in the Coptic; which he by no means proves but that there was a language before that time, either Coptic or Egyptian. Pietro de la Valle observes, that the Copts have entirely left their ancient tongue; that it is now no longer understood among them; that they have nothing extant therein but some sacred books; and that they still say massa in it.

All their other books have been translated into Arabic, which is their vulgar tongue; and this has occasioned the originals to be lost; it is added, that they rehearse the Epistles and Gospels in the massa, twice; once in Arabic, and once in Coptic.

Indeed, if we believe F. Vandt., the Copts say the massa in Arabic, all but the Epistles and Gospels, which they rehearse both in that and Coptic.

It sufficiently appears, that, after the conquest by the Saracens, the ancient language so far continued to be that of religion, that it was used in the divine service; and in the country of the Copts, the gospel, according to Niebuh, is even now read in Coptic: but he observes, that this tongue is not understood even by the priests, and that the service is afterwards read in the Arabic, which is the present language of Egypt. Mr. Browne says, that in the Coptic monasteries, the prayers are read in Arabic, and the epistle
and gospel in Coptic; but the præfix is a mere parrot, respecting a dead letter.

The Coptic tongue, at present, confines chiefly of the old Egyptian and Greek, still bearing evident marks of primitive antiquity in its structure and constitution, with regard to which it differs so much from all the Oriental and European languages, that it is impossible to conceive it derived from any of them. For the Copts neither decline their nouns, nor conjugate their verbs, (not even those of foreign extract,) otherwise than by prefixing particles sometimes of one or more syllables, and sometimes of a single letter, which denote the case, gender, number, and person; several of them being often joined together in one word, and the primitive word usually placed last. Hence the difficulty of this tongue confounds in the incredible combination of the words and particles, in the change of the vowels, and in transposing the middle part of the word, and in adding superfluous letters: so that it requires great labour and skill to distinguish them.

From numerous and minute researches, Mr. Browne is led to affirm, that the Coptic language may be considered as extinct; although in Upper Egypt, they unwillingly return from Coptic words.

F. Kircher is the first who published a grammar and vocabulary of the Coptic. There is not known any book extant in the Coptic, except translations of the Holy Scriptures, or of ecclesiastical offices; or others that have relation to these, as dictionaries, &c.

Dr. Weid, who began his Coptic studies at Leyden, and was affiliated in them by Sahlorz, the editor of La Croze's Coptic lexicon, returned his obligations to the services which he rendered to him in that publication. He superintended the impression of the abridgment of it, which was published at Oxford, and there applied himself to the study of the Sahidic dialect, or that of the Upper Egypt. In 1758, he published the celebrated Coptic and Sahidic grammar of Sahlorz, under the following title: "Chris. Saholzos Grammatica Egypti orientis Diachil, quam breviariis, iliaque formaci. editi C. G. Weide." An excellent Coptic grammar was also published at Paris, in 1753, under the title, "Didacta Tauroctica Literaturae Copticae Rudimenta."

Coptic, or Coptic Bible. See Coptic Bibles.

Coptic Liturgies are three; one attributed to Bâl; another to St. Gregory, and the third to Cyril: they are translated into Arabic for the use of the priests and people.

COPHTOS, in Geography. See Coptos.

COPIA CLAUDIA AUGUSTA COLONIA, a name given to the modern Lyons.

COPIA CORNA. See Cornucopia.

COPIA libelli deherrandae, in Law, a writ that lay where a man could not get the copy of a libel at the hand of a judge ecclesiastical, to have the same delivered to him. Reg. Orig. 51.

COPLE, in Ancient Geography, a town of Italy, in the gulf of Tarentum; called also Sybaris.

COPM MILITAES, military forces, a military body instituted particularly by Augustus, for the defence of the Roman empire. It was divided into three classes or descriptions. The first, called cœpi cœlificæ, was destined to defend the seas and rivers against the incursions of pirates, and to protect navigation; the second, called cœpi provinciæ, defended the frontiers, and encamped on the midland towns, as necessity or occasion required; and the third, called cœpi urbana, remained at Rome, as a guard for the capital, and also for the emperor, in case of need.

COPM Provinciæ. See COPM Militæs.

COPM Urbana. See COPM Militæs.

COPF, in Geography, one of the thirteen provinces into which the kingdom of Chili in South America is divided. It is situated in the most northern part of the kingdom, and is one of the richest metallic countries in the world. In this province are two mountains entirely composed of crystallized sulphur, so pure that there is no occasion for refining it. It has also mines of gold, silver, iron, copper, and lead. The whole field is impregnated with sal-gem; and salt-petre is common. It furnishes also turquoises, that is, teeth or bone coloured green by metallic vapours. In this province and that of Coquimbo little rain falls; and earthquakes are seldom known in either of them. It has two ports; one of the same name, and another which lies 30 leagues further to the south, and confils only of a few huts.

COPÔPA, a town of Chili, in the former-mentioned province, to which it gives name; situated about 12 leagues from the sea-coast, very irregularly built, but containing between three and four hundred families. S. lat. 26° 50'.

COPÔPA, a river of S. America, in Chili, which runs into the Pacific Ocean, a little to the north of the town of Copiapo.

COPIATA, under the Western Empire, a grave-digger. In the first ages of the church, there were clerks defined for this employment. In the year 357, Constantine made a law in favour of the priests copiato, i.e. of those who had the care of interments, whereby he exempted them from the hultra contribution which all other traders paid.

It was under him also that they first began to be called copiato, q. d. clerks defined for bodily labour, from copâ, of copes, feon, evedo, ferio, i aci, bent, &c. Before that time they were called decani and delicatorii; perhaps, because they were divided by decades or tens, each whereof had a bier or litter for the carriage of the dead bodies. Their place among the clerks was the next in order before the chanters.

COPING over, in Carpenter, a fort of hanging over, not square to its upright, but bevelling on its under side till it end in an edge.

Coping, among Builders, signifies the top or covering of a wall. The best copings are of hewn stone, where it can readily be procured; in other situations, where large paving-bricks are made of a good and durable quality, these may with propriety be used flat for coping. Bricks of particular shapes are often made for coping, either to be used finely, or first a course of two bricks in width, to form a projection for shooting the wet off the faces of the wall, and then a half cylindrical brick for completing the coping. Several years ago, Mr. Peter Wych communicated to the Society of Arts in London (Doddie's Memoirs, vol. ii. p. 163) a method of making a durable coping for garden walls, of a mixture of baked gypsum and coal-ashes. We lately observed on the Grand Junction Canal, that several of their bridges have been repaired, where the coping stones were broken by accidents, with Parker's Roman cement, and that others of their bridges and walls were wholly coped with this composition, which appeared little inferior to stone in hardness, and less brittle than most kinds of coping-stones are. See CANAL, in Flony districts, where the fields are separated by rough and dry stone walls, the same are usually coped by a row of rough and triangular stones, set edgeways on the top of the wall. The cementing of these together with a little good mortar is a good practice. Where the stone is less hard or durable, these kinds of dry walls are sometimes coped with a circular ridge of good but very coarse mortar, prepared for the purpose. The practice of properly securing and
and attending to the copying of dry-built walls cannot be too much enforced, for want of which the rubbing of cattle and other accidents soon make breaches in such walls, that are very expensive to repair. In some counties, where stone is very scarce, and fuel for burning bricks very dear, garden and other walls are made of mud or tempered clay, with a mixture of chopped straw or flouke to hold them together; and fish are sometimes thatched with straw, by way of copying: for both thefe, and the peb walls, compos'd of dry earth rammed together in a mould, which have lately been introduced in England, must be carefully preserved from the wet by a secure copying, or they soon moulder into their original dirt.

COPLAND, in Geography, the name of a cluff of small islands in the north Channel, nearly opposite to Donaghadee, in the county of Down, Ireland. One of them has a few cabins upon it; and another has a light-house, which is very useful to those going to Belfast, or crossing the Channel between Donaghadee and Portpatrick. That which has the light-house on it is in W. long. 5° 24'.

N. lat. 51° 39'.

COPE, a vicarage in Bedfordshire, in Wixamtree Hundred, is remarkable for being formerly the residence of Sir Samuel Luke, and of Butler, the author of Hudibras, which celebrated poem is supposed to have been written at Wood-End house, in this parish. The Oufe navigation passes the northern extremity of this parish; and some years ago, a canal was made, a mile or more in length, for conveying barges up to a new house and premises, intended as a wharf, (now the Dog ale-houfe;) but for want of previous consent on the part of the owner of this part of the Oufe navigation, it was not permitted to be used. See Canal. The subtil or strata in this parish is clay throughout, with lime-stone at a considerable depth beneath the surface: for a considerable width next the Oufe the clay is covered with gravel, and produces good turnip land.

COPOS, from avoir, labour, in Medical Writings, is used for a weariness of the body, when the muscles, or their fibres rather, are loaded and obstructed with viscous humourous, so as to render them unfit for motion.

COPPA, in Cavalier, called Ant. Girolama, in Biography, an historical painter, who was born at Verona about the year 1503, and became successively the scholar of the celebrated Bolognese masters, Guido and Albano. He is considered one of the best imitators of the graceful and delicate manner of the former, although in his compositions he is sometimes too crowded; and he was ranked by his second master, Albano, amongst his most favoured disciples. He was one time painter to the court of Mantua, the churches of which city are enriched by many of his principal works. He died in the year 1665. Lanzi. Storia Pitt.

COPPA, in Law, a cop or cock of grins, hay, or corn, divided into tichetable portions; as the tenth cock, &c. This word in French denotes the gathering or laying up the corn in cops or heaps, as the method is for barley or oats, &c. not bound up, that it may be the more fairly and justly tithed: and in Kent they still retain the word, a cap or cap of hay, straw, &c.

COPPERBERG, in Geography, one of the twenty-eight governments into which the kingdom of Sweden is divided, comprising the province of Dalcarlia, is also called Fabhus, and Gamla Copperberg, old copper mines. It is a large, populous mine town, situated between two lakes and two mountains; 56 miles W. of Gelé, 24 N.E. of Hedemora, in N. lat. 6° 50'. The streets are regular, but the houses are all of wood, except the town's hall and two churches, the roofs of which are covered with copper. It is the fifth

teenth among the towns that vote in the Swedish diet. The governor resides at Neary, a royal manor near the town. The famous copper mine, which Gustavus Adolphus used to call the Swedish exchequer, lies a little to the west. It has been worked one thousand years, and its copper is still reckoned the best in Europe. From 1633 to 1761 it yielded 1,480,724 Swedish thippounds. Its greatest produce was in the year 1650, when it gave 20,381 thippounds. Since the year 1760, it yields nearly 6,000 thippounds annually; but the expenses increase in proportion, as the miners must go to a greater depth. In 1801, the mine was said to be 1000 feet deep, and to give employment to 1,000 workmen. The copper is found in large masses. Cattaneo Tableau de la Suede. Schlozer's Briefwechsel.

COPPEY, one of the small western islands of Scotland; 3 miles N. from the S.W. extremity of the island of Lewis.

COPPS, COPPEL, or COPPEL, in Chemistry. See CUPPELL.

COPPELLING. See CUPPELLATION.

COPPERBRUGGE, in Geography, a town of Germany, in the circle of Wedelphah, and county of Schleswig: 19 miles S.W. of Hanover.

Copper is a ductile and malleable metal, of a pale yellowish red colour. It is soluble in hot acids, and is precipitable from them in the metallic state, by iron or zinc: its oxyd is soluble in ammonia, to which it communicates a bright blue purple colour.

§ 1. Ores of Copper.

Its colour is a clear copper-red, often tarnished, externally yellowish, blackish, or whitish.

It occurs in mafs, disseminated, in leaves and grains, also capillary, moss-like, dendritic and crystallized. The regular forms that it presents, are the cube, the octahedron, and the pyramidal dolcatedehedron often with a short fix-sided prism interposed.

The crystals are small, and generally implanted in each other, forming clustered masses. Its lustre internally is glittering and metallic; its fracture is hackly: when cut or rubbed, it acquires a high metallic lustre. It is not very hard, is malleable and flexible, but not elastic, is tough and difficultly fusible. Sp. gr. 5.72—5.8.

It is fuitable before the blow-pipe, and appears to be pure copper.

It occurs in veins and beds in various primitive and secondary mountains, accompanied by many of the other ores of copper, also by galena, Born silver, native silver, calcareous, liegy, and floor spars.

It is very extensively, but not very abundantly, diffused; the largest masses appear to be procured from the copper mine river, within the arctic circle in North America; it is also of frequent occurrence in Japan and Brazil, in Siberia, Hungary, Norway, Sweden, Saxony, and Cornwall.

Its colour is dark lead-grey, passing into blackish-grey; it is often covered superficially by a fleck-coloured tarnish. It occurs in mafs, disseminated or crystalized. The forms of its crystals are the cube, the octahedron, and a hexagonal prism, sometimes terminated by trilateral summits. The crystals are small; externally they are shining, internally they exhibit a glittering metallic lustre. The fracture is fine-grained, uneven, passing into conchoidal. It gives a shining
COPPER.

Shining flake, is blackish when pulverized; is somewhat brittle, and easily friable. Sp. gr. 4.1—5.4.

It effervesces with nitrous acid, and when exposed to the blow-pipe, gives a metallic lustre of a steel-grey colour, and generally attractive by the magnet.

When pure, it appears to be a simple sulphuret of copper, containing, according to Chenevix, of

It occurs in veins and beds in primitive and secondary mountains, accompanied by copper pyrites, and other ores of this metal. It is not very abundant, but is found in various places, especially Cornwall, Hungary, Saxony, Norway, and Siberia.

Sp. 3. Variegated copper. Buschkupfererz. Its colour is intermediate between copper-red, and Tombeck brown; by exposure to the air it acquires a superficial tarnish, which is first reddish, then violet, afterwards blue, and lastly green. It occurs in mafs, disseminated, superficial, or crystallized in octahedrons. Internally it is shining, with a metallic lustre. Its fracture is small, and imperfectly conchoidal, passing into fine-grained, uneven. It takes a polish by friction, and gives a reddish coloured flake. It is soft, somewhat brittle, and easily friable. Sp. gr. 4.9—5.4.

It effervesces with nitrous acid, and melts readily before the blow-pipe, without vapour or odour. Two specimens, the one from Hitterdahl in Norway, and the other from Rudcladt in Siberia, have been analyzed by Klaproth, with the following results.

...This ore occurs in beds, veins, and disseminated through rocks, for the most part belonging to the class of primitive. It is usually accompanied by vitreous copper, and copper pyrites. It is found in Cornwall, in Hungary, Saxony, Norway, and Sweden.

Its colour is deep brafs-yellow, passing into gold-yellow. Its surface is often iridescent tarnished. It occurs in mafs, disseminated, superficial, foliaceous, clustered, reniform and crystallized in tetrahedrons, and the derivative octahedron, and dodecah-dron. The crystals are usually very small and imperfect. The surface of the crystals is smooth and shining; that of the other varieties is rough and glimmering. The fracture is coarse or fine-grained, uneven, passing into conchoidal, and imperfectly foliated. It is brittle, and with difficulty gives a few feeble sparks with the flint: it may be readily cut by a knife. Sp. gr. 4. — 4.1.

When exposed to the blow-pipe on charcoal, it decrystallizes, emits a sulphurous vapour, and melts into a black globule, which, by further application of heat, acquires the colour and lustre of copper. It does not appear that the crystallized varieties of this ore have been regularly analyzed, and the proportion of its constituent parts cannot be eliminated from the other varieties, on account of the iron pyrites, with which they are always more or less mixed. A specimen analyzed by Lapidus afforded

| 44 | Copper |
| 17.1 | Iron |
| 45.1 | Sulphur |
| 125.2 |      |

...The richest ore is in copper, the softer it is, and its colour approaches the more to that of gold. It is feldom, however, in the large way, affords more than 20 per cent. of copper. It may readily be distinguished from iron pyrites (the only substance with which it is likely to be confounded) by the pale brafs yellow colour, and superior hardness of the latter.

Copper pyrites is the most abundant, and most generally diffused of any of the ores of this metal. It occurs in veins and beds in primitive, transition, and secondary rocks, in most countries of the world.

Its colour is intermediate between silver-white and brafs-yellow. It occurs in mafs or disseminated. Internally it has a slight metallic lustre. Its fracture is small, and fine-grained uneven. It yields readily to the knife, is brittle, and easily friable. Sp. gr. 4.5.

Before the blow-pipe it yields a white smost, and an arlenical colour, and melts into a blackish flag. According to Henckel it yields about 40 per cent. of copper, the rest being iron, arsenic, and sulphur.

It occurs in veins and beds, in primitive mountains, and is generally accompanied by copper pyrites and vitreous copper.

It is found in Cornwall, Saxony, Sileia, Hungary, Siberia, and Chili in South America.

Its usual colour is steel-grey, which passes into iron-black and lead-grey; some varieties incline towards yellow and others again present superficial iridescent colours. It occurs in mafs, disseminated or netting, or crystallized in regular tetrahedrons and their modifications. The crystals are small, with shining surfaces. Internally it is glistening, or shining with a metallic lustre. The fracture is coarse, and small-grained, uneven, inclining to imperfectly conchoidal. It gives a black or reddish-brown powder. It is moderately hard, brittle, and easily friable. Sp. gr. 4.45—4.36.

The only necessary ingredients of this species (as appears from an analysis by Chenevix; of the crystallized variety) appear to be copper, iron, and sulphur in the following proportions, v i.

| 52 | Copper |
| 33 | Iron |
| 14 | Sulphur |
| 99 |      |

...The uncrystallized varieties, however, generally contain also antimony, silver, and lead, but in very variable proportions.
COPPER.

In several varieties from Germany, Mr. Chenevix found antimony varying in proportion from 5 to 38 per cent., but neither lead nor silver. Two specimens, the one from Andeeesberg, and the other from Crannitz, have been analyzed by Klaproth with the following results.

96.8

Those specimens that give a reddish-brown streak, are generally the most abundant in silver.

It occurs in veins in slates, and some other of the newest primitive rocks, and in beds in the transition and flint rocks. It is accompanied by copper pyrites, galena, manganite, fpa-thoe iron, and rarely by malachite. When it contains a notable proportion of silver, it is considered and worked as an ore of this metal.

It is found in Cornwall, and in the county of Ayr in Scotland; also in Bohemia, Hungary, Transylvania, Saxony, Hesse, the Hartz, France, Spain, Piedmont, Sweden, Norway, Siberia, and Chili.

Its colour is intermediate, between blueish and brownish black. It occurs in mafs, disseminated or involving. It is composed of dull moderately coherent particles. It is friable, slightly soles the fingers, is meagre to the feel, and heavy.

Before the blow-pipe it emits a sulphurous odour, and melts into a flag that colours borax green. It has not been regularly analyzed, but is said to contain from 40 to 50 per cent. of copper.

It occurs with other ors of copper, particularly copper pyrites, malachite, mountain green, and vitreous copper.

It is found of remarkable beauty, at Kupperberg, in Silesia, also in Saxony, Hungary, Norway, and Siberia.

Of this species, there are the three following varieties.

Var. 1. Lamellar.

Its colour is dark cochineal red, inclining sometimes to lead grey; when crystallized it is often of a full carmine red. It occurs in mafs, disseminated and crystalized in cubes, and aluminous octahedrons. The crystals are small, and for the most part laterally aggregated: their faces are smooth and shining. Its internal lustre is more or less flinty, and is intermediate between metallic and adamantine. Its fracture is imperfectly foliated, passing into granular uneven. When in mafs it is usually opaque, or at most translucent on the edge; the crystals are transparent, verging into translucent. It gives a brownish brick-red streak, is moderately hard, brittle, and easily friable. Sp. gr. 3.05.

By exposure to the blow-pipe on charcoal, it is easily reducible to a metallic bead, without emitting either odour, or fume. It dissolves in the nitrous and muriatic acids, in the former with, and in the latter without, effervescence. According to Mr. Chenevix, it consists of

<p>| | |</p>

100.

It is met with chiefly in veins, and appears to be peculiar to primitive mountains. It is accompanied by native copper and other ores of this metal. It is found in Cornwall, in Hungary, Saxony, the Hartz, Siberia, Peru, and Chili.

Var. 2. Capillary.

This variety differs from the preceding in being of a somewhat lighter colour, superior lustre, and being composed of small capillary crystals and thin flakes.

Var. 3. Compacè.

It occurs in mafs and disseminated, but never crystallized. Its internal lustre is glimmering, semi-metallic: its fracture is even; and it is opaque. In other respects it agrees with var. 1.

This species presents two varieties, indurated and earthy.

Var. 1. Indurated.

Its colour is intermediate between hyacinth and brownish-red, passing on the one hand into lead-grey, and on the other into reddish-brown. It occurs massive and disseminated. The reddish kind has a glimmering lustre and flat conchoidal fracture; the brownish kind has a somewhat pearly lustre and a small conchoidal fracture. It acquires a lustre by friction, is moderately hard and brittle.

When exposed to the blow-pipe it becomes black, and is insubstantial without addition. Borax is tinged by it of a dirty green. It appears to be an intimate mixture of compound ruby copper with brown iron ochre, and its produce of copper varies from 10 to 50 per cent.

It occurs in veins with ruby copper, malachite, copper pyrites, and iron ochre.

Var. 2. Earthy.

Its colour is hyacinth-red, passing into reddish or yellowish brown. Its texture is between friable and solid. It occurs in mafs, disseminated, and involving copper pyrites. It is without lustre, has an earthy fracture, and slightly soles the fingers. In its other characters it agrees with the preceding variety.

Of this there are the two following varieties.

Var. 1. Radiated.

Its principal colour is sky-blue, which passes into Prussian and indigo-blue. It occurs in mafs, disseminated or involving, more frequently botryoidal, flake-like, and cellular, but most frequently crystallized in oblique rhombohedral prisms or octahedral prisms with dihedral funnels. The crystals are generally very small and aggregated into globular masses or bundles. The crystallized varieties are externally shining, but the rest are dull. Internally it is shining or glittering, with a lustre between vitreous and resinous. Its fracture is straight or divergently radiated, rarely lamellar. The crystals are translucent and semi-transparent, the other varieties are
COPPER.

are opaque, or at most translucent on the edges. When pulverized it is of a sky-blue colour. It is soft, brittle, and easily frangible. Sp. gr. 3.2—3.4.

It is very difficult of fusion before the blow-pipe, per fe; but with borax it gives a bright green glafs, and a metallic globule.

According to Pelletier it consists of

66 to 70 Copper
8 — 20 Carbonic acid
8 — 10 Oxygen
2 — Water

Var. 2. Earthy.

Its colour is smalt-blue: it occurs rarely in mafs, generally disseminated or superficial: it is conftructed of fine pulverulent cohering dull particles. Its fracture is fine-grained earthy, paffing into even and imperfectly conchoidal. It is opaque, lightly clay, and is easily frangible.

Before the blow-pipe it becomes black, but does not melt. In borax it dilolves with great ebullition, and forms a green glafs.

Mountain-green occurs in the newer primitive rocks, but more commonly in flotz mountains. It accompanies other ores of copper, efpecially malachite, grey copper, and copper pyrites. The most beautiful fpecimens come from the Bansat in Hungary, and from Siberia. In the Tyrol it is found in sufficient plenty to be manufactured into the pigments called mountain-blue.

Sp. 11. Malachite.

Of this there are the two following varieties.

Var. 1. Fibrous.

Its common colour is grafs-green paffing into emerald-green, and sometimes into dark leek-green. It seldom occurs massive or diffeominate, but generally infert, and coarsely crystallized in short capillary needles, dиффузо in divergent bundles, or ftars. Externally they are fhining, but internally only glifthing with a silky luftr. Its fracture is delicate, diverging fibrous, paffing into coarser fibrous. It is opaque or translucent on the edges; the crystals are for the most part translucent. When pulverized it retains its colour, only the tint is somewhat lighter. It is very soft, brittle, and easily frangible. Sp. gr. 3.5.

It efteffes with acids, and forms a blue folution with ammonia. Before the blow-pipe it blackens and decrpetiates, but is infubfible, per fe. With borax it melts into a green glafs. Its confluent parts, according to Klaproth, are

| 58 Copper |
| 18 Oxygen |
| 12.5 Carbonic acid |
| 11.5 Water |

100

It occurs ufually in the newer primitive and flotz mountains, accompanied by other ores of copper, also by carbonat of lead, calcareous fpar, brown fpar, and quartz. The finest fpecimens of this variety of malachite are found in the Siberian and Hungarian mines; it occurs also in Saxony and other mining districts in Germany, in Norway, and in Shetland, and the counties of Cornwall and Derby in Britain.

Var. 2. Compact.

Its colour is emerald-green paffing into grafs and verdigris-green, the fame fpecimens exhibiting different shades of colour: its external surface is commonly overfpread with a greenish-white crust. It occurs massive and diffeominate, but more frequently reniform, bontroyidal, mamilated, talcoidal, or globular. Externally it is rough and dull; inter-

nally it is, according to the fracture, either dull, glifthing, or fhining. Its fracture is conchoidal, or fine-granular uneven, or minutely fibrous. It generally occurs in thin lamellar concentric distint concretions, each of which has ufually a different shade of colour. It is opaque, soft, brittle, and easily frangible. Sp. gr. 3.5—3.6.

Its chemical characters and component parts are nearly the fame as those of the preceding variety, with which it also agrees in its geognolical and geographical fition.

Its beautiful colour, luftr, and the high polifh that it is capable of receiving, render it much sought after for various ornamental purposes; it would however be much more efteffed if it was harder.

Its colour is verdigris-green, paffing occasionally into emerald-green, and sky-blue. It occurs in mafs, diffufed or infert. Internally it is fhining paffing into glifthing, with a refulous luftr. Its fracture is small conchoidal. It is translucent and semi-transparent; is soft and easily frangible.

Its chief chemical character is that of giving little or no effeconomy, while diffufing in acids. It has not been analyzed. It is found in similar fitions with malachite, but is of much rarer occurrence.

Its colour is emerald-green. It occurs crysfallyzated in lengthened dodecahedrons. It is fhining both externally and internally, and has a vitreous luftr. It is translucent, paffing to semi-transparent; fcratches glafs feebly, and with difficulty; is brittle. Sp. gr. 3.3.

Before the blow-pipe it becomes of a chefnut-brown colour, and is infubfible, per fe. With borax it gives a bead of copper. According to an analysis by Vauquelin its consists of

25.57 Oxyd of copper
42.85 Carbonat of lime
28.57 Silex

96.09

It has hitherto been found only in Daauria on the Russian and Chinese frontiers in a vein accompanied by malachite.

Its colour is deep emerald-green paffing to verdigris-green. It occurs massive, diffufed, and crysfallyzated in hexahedral tables. Externally it is smooth and fhining with a pearly luftr. Its fracture is foliated. It is translucent paffing into semi-transparent. It is fofter than calcarious fpar. Sp. gr. 2.54.

It decrpetiates ftrongly when suddenly heated, and is compofed, according to Chenexis, of

| 58 Oxyd of copper |
| 21 Arfenic acid |
| 21 Water |

100

It is found in Huel Gorland mine in Cornwall, in veins accompanied by vitreous copper, copper pyrites, arfenic pyrites, and Ifon ochre.

Sp. 15. Octahedral arfienat of copper. Limonerz of Werner.

Its colour is deep sky-blue, paffing into Prussian-blue, blueish-white, apple-green, and grafs-green. It occurs in obtuse pyramidal octahedrons. The crystals are small and aggregated into clufers; they have a fhining vitreous luftr, and

5
and a lamellar fracture, are semi-transparent passing into transparent. In hard slate they are inferior to fluor spar. Sp. gr. 2.88.

It is composed, according to Chenevix, of

<table>

It is found in the same mine as the preceding species. Sp. 16. Foliated arseneut of copper. Blaufrei olivaceus of Werner.

Its colour is olive-green, palling to oil and leek-green. It occurs rarely massive, and generally crystallized in acute rhombohedral oblique quadrilateral prisms. The surfaces of the crystals are smooth and shining. Internally, it is glintening with a silky lustre. Its fracture is fine and diverging fibrous. It is opaque, and moderately hard. It contains, according to Klaproth, of

It has hitherto been found only at Fincberg in Cologne, in white dusty quartz. Sp. 19. Sandy copper. Salt-hotpern. Werner.

Its colour is emerald-green, palling into leek and olive-green. It occurs massive, disseminated, and crystallized in extremely minute fix or four-sided prisms. The surfaces of the crystals are smooth and brilliant, and their fracture lamellar. The massive variety is opaque; the crystals are transparent. It is soft and easily frangible. Sp. gr. 4.43.

Before the blow-pipe on charcoal, it tinges the flame of a bright green and blue colour, and a metallic globule remains behind. It is soluble in nitrous acid, without effervescence. The following are its constituent parts, according to Proult and Klaproth.

It is found loose in the bed of a river at Kornolino, in Chili, and elsewhere, though rarely in Spanish South America.

§ 2. Assay and Analysis.

The assay of copper ores, (though by no means so accurate a method of ascertaining their metallic contents as a regular analysis) being the method by which the market price of the ore is always determined, requires the first notice. The best method, upon the whole, of conducting it, is as follows.

First, expose a small piece of the ore, under examination, to the action of the blow-pipe, and by the appearance and odour of the vapour given off, it is easy to discover whether it contains any arsenic or sulphur. It may very probably contain both, in which case, take 300 grains of the ore coarsely pulverized, mix it with half its weight of fawdull, and keep it at a moderate red heat in a earthen crucible, till the disengagement of arseneut vapour entirely ceases. Then pour the contents of the crucible into an iron mortar, and reduce them carefully to a fine powder. Transfer this powder to a tell, and expose it to a good red heat, with occasional stirring, till both the charcoal and sulphur are burnt off. The residue is then to be accurately mixed with \( \frac{1}{2} \) of its weight of lamp-black, half its weight of pulverized glafs of borax, and a drop or two of oil; the mals thus formed, is to be put into a found earthen crucible, a cover is to be luted on, and the whole is to be placed in a good wind furnace. The heat should be moderate for the first quarter of an hour, to allow the borax time to combine with the earthy impurities of the ore; then a moderate white heat is to be applied for about twenty minutes. After this, the crucible being withdrawn and cooled, is to be care-
fully broken, and will be found to contain a button of copper, covered by vitreous scoria. The purity of the copper thus procured, it is to be estimated from its colour, lustre, malleability, and tenacity; after which, a part of it may be employed with pure lead, in order to ascertain whether it holds any silver or gold. If the ore contains sulphur, but no arsenic, it may be mixed with half its weight of charcoal, and roasted on a tekst, without being previously heated in the crucible. If the ore contains neither sulphur nor arsenic, it should be first moderately ignited in a covered crucible, to drive off any moisture, and then be treated with burax and lamp black, as already described.

The proper analysis, by means of liquid menstrua, is however much more accurate than even the most carefully conducted alloy, and the general mode of proceeding with the ores of copper is, upon the whole, very simple. The copper, together with the other metals with which it may happen to be mixed, is to be separated from the flux and sulphur, by means of an acid, the other metals are then to be got rid of by their appropriate reagents, and the copper is then to be procured either in the state of green borax, of black oxide, or of pure metal; of the first, 150 parts are equivalent to 100 of metallic copper; and of the second, 100 parts contain 85 of metal.

Preceding to undertaking an analysis, a part of the specimen, under examination, should be subjected to the usual reagents, in order to ascertain not indeed the proportion, but the nature of the ingredients of which it consists; and, in few cases, it is more necessary than in the analysis of the ores of copper, both as they are so numerous and so various in their composition. This previous examination being duly performed, the analysis may be conducted in the following manner:

For the analysis of the prismatic, and other sulphurized ores of copper, provided they contain neither silver nor lead, take 200 grains of the pulverized ore, and digest it at a boiling heat with muriatic acid, (adding occasionally a few drops of nitric acid) till every thing soluble in this menstruum is taken up. Of the insoluble portion, a part, consisting chiefly of sulphur, will be found floating on the liquor; and this being washed, dried, and weighed, is to be ignited on a stool, by which the sulphur will be burnt off, and its amount may be estimated from the loss of weight sustained by the process. The incombustible residue is to be digested in a little warm muriatic acid, and what remains insoluble, is to be added to the other insoluble residue. The muriatic solutions being mixed together, the whole is to be decomposed by carbonated potash, and the precipitate, hence resulting, is to be digested in repeated portions of caustic ammonia, as long as this latter acquires any blue tinge. The whole of the copper, and nothing else, will thus be taken up by the ammonia, from which it may be obtained in the state of black oxide, by the addition of a little caustic potash, and a boiling heat. The residue, insoluble in ammonia, consists of oxide of iron, with perhaps a little alumine, which may be separated from caustic potash, the alumine alone being soluble in this fluid. Finally, the portion insoluble in muriatic acid, may be considered as little else than flux.

The ores which, besides copper, sulphur, and iron, contain silver, lead, and antimony, may be thus analyzed. The ore, reduced to fine powder, is to be repeatedly digested with moderately diluted nitric acid, as long as any thing continues to be taken up by this menstruum. To the nitric solution as then to be added muriat of soda, which will throw down the silver in the state of luna cornea; this being separated, the lead is to be precipitated in the form of sulphate, by sulphate of soda; the solution is now to be supersaturated with ammonia, which will diffuse the copper, and raise behind the oxide of iron, with probably a little alumine and flux. The copper is to be procured from the ammoniacal solution, in the manner directed in the preceding paragraph; and the oxide of iron may be separated from the admixed earths, by caustic potash. That portion of ore, insoluble in nitric acid, is to be digested in muriatic acid, which will take up every thing except the sulphur, flux, and probably a little luna cornea. Of this insoluble residue, the sulphur is to be burnt off by gentle ignition, and the remainder is to be fused with twice its weight of pearl ash, by which the silver in the luna cornea will be reduced to the metallic state. The muriatic solution being concentrated by evaporation, and then poured into a considerable quantity of water, will deposit the anniversary in the form of a white oxide.

The simple oxides of copper, are best analyzed by digestion in nitric acid, and then supersaturating the solution with ammonia, by which any casual admixture of iron will be separated.

The carbonates of copper are to be thus treated. One portion is to be gently calcined in a covered crucible, and the loss of weight sustained, indicates the united amount of the water and carbonic acid. A second portion is to be thrown into a known quantity of dilute sulphuric acid, and the loss of weight, by the effervescence which ensues, shows the amount of carbonic acid. The fulminate of copper thus obtained, may be subqently decomposed, either by a flick of zinc, or by liquid ammonia.

The arseniates of copper are most conveniently analyzed by first moderately heating them, in order to drive off and thus estimate the water, and then digesting the residue in dilute nitric acid, by which it will be entirely dissolved; nitrat of lead is then to be dropped in as long as it occasions any precipitation, and this latter being removed, the fluid is to be evaporated nearly to dryness, after which, warm alcohol is to be added, which will take up the whole, except a little powder; this powder, and the precipitate on the addition of nitrat of lead, are arsenat of lead. 33.66 per cent. of which is arsenic acid. The alcoholic solution is then to be evaporated nearly to dryness, and then to be digested with ammonia, which will take up the copper, leaving behind any oxide of iron that may have happened to be contained in the ore. The ammoniacet of copper, being decomposed by caustic potash, gives the copper in the state of black oxide, which is that in which it exists in the ore.

The analysis of muriat of copper is very simple. It was thus effected by Klaproth. The ore, being pulverized, was distilled in cold nitric acid, with the exception of 1.5 per cent. of oxide of iron; the solution being then diluted, nitrat of silver was added, till it occasioned no further precipitation; the luna cornea thus obtained, indicates, according to the known proportions of this salt, the amount of muriatic acid in the ore. The nitrous solution was then decomposed, and the copper obtained in the metallic form, by means of a bar of iron.

Phosphat of copper was thus analyzed by Klaproth. On digestion in nitric acid, the whole was taken up except a few grains of quartz; the excess of acid in the solution was then saturated with potash, and acetate of lead was poured in till it had quite ceased to occasion any precipitation; the phosphat of lead, thus obtained, was separated from the solution, and sulphate of soda was added to decompose and precipitate
precipitate the small excess of acetate of lead which had been made use of. A little sulphuric acid was then added to the solution, and the copper was precipitated in the usual way, by means of a bar of iron.

§ 3. Reduction of Ores.

The only ores of copper that are in fact worked in the large way, and from which the copper of commerce is for the most part supplied, are the sulphurous and arsenical ores of this metal. The method of reducing them, though consisting of a great number of processes, on account of the powerful affinity, both of the arsenic and sulphur, is yet harmless the solubility of copper, and renders the obtaining of the metal by the aid of repeated roastings and fusions, till the metal has acquired the necessary ductility, for it is never brought to a state of absolute purity, and the commoner forms contain both arsenic and antimony, in such proportions, as to be wholly unfit for alloying with either gold or silver.

The rough ore, if simply sulphureous, is broken into pieces not larger than an egg, and leached as much as possible from the adhering earthy impurities; after which, it is piled in large kilns, and heat being applied at the bottom, the whole mass becomes gradually heated, and a large portion of the sulphur sublimes out, and may be either collected by proper flues, or allowed to escape; this first process occupies about six months, at the expiration of which time, the evaporation of the sulphur ceases, and when the ore has cooled sufficiently, it is in a state to be smelted.

If, however, the ore is largely combined with arsenic, it is not capable of keeping up a long combustion of itself, nor is the heat thus generated adequate to the expulsion of the arsenic; a somewhat different method, therefore, of roasting must be had recourse to. For this purpose the ore is first more carefully dried than in the former case, and is reduced to pieces not larger than a hazel-nut. It is then spread on the floor of a large reverberatory furnace, and exposed to a dull red heat, with frequent stirring, in order to offer fresh surfaces to the action of the flame. The arsenic and sulphur by this treatment are rapidly driven off, and in about twelve hours the roasting is completed.

The ore is now transferred into the fusil furnace, which is a reverberatory of the common construction; a little bruised line-shaped is generally added by way of flux, and in the course of four or five hours the fusil is ultimately complete; the flag, now the confine of the hot dough, is raked off, and the copper is discharged through a plug-hole into water, by which it is reduced into small drops or grains.

The copper, however, though in the metallic state, is still very impure, being largely mixed with sulphur and arsenic, which give it a grey colour, and render it perfectly brittle. In order to separate these impurities, it is remelted and granulated twice more or oftener, the considerable quantity of flag being separated at each fusion; but as this flag contains some copper, it is not thrown away, but worked over again with the next charge of calcined ore. The number of fusions and granulations entirely depend on the quantity of impurities, and the ability in which they combine with the copper; but when these processes have been repeated the requisite number of times, the granulated mass is melted and cast into pigs. These again are broken to pieces, and roasted for one or two days in a low red heat, and again melted and roasted several times, till the metal approaches to the state of malleable copper. It is now cast into oblong plates, about 14 inches in length, and is fit for the refining furnace. In this it is again melted, with the addition of a little charcoal, till it acquires the necessary degree of malleability, and thus becomes fusible copper.

Sometimes lead is employed with good effect in the refining of copper, as it combines with, and separates iron, and the other unly oxide metals in preference to copper. For this purpose the rough copper is laid on the floor of a furnace, and when it is in a complete fusion, about 6 or 8 per cent. of lead is blown in, and well mixed with the melt. In a short time the surface of the melted mass becomes covered with a semi-vitreous blackish brown layer, consisting of the mixed oxides of lead, iron, and other impurities, together with a little copper. The first copper being removed, a second is formed, which is in the manner comminuted off, and on successively, till, after ten or twelve hours, the copper is sufficiently purified; this is ascertained by the thinness of the film with which the melted copper is covered, and by its being of a brick-red colour, also by the circumstance that if a rod of polished iron is dipped into the fused mass the portion of copper that adheres to it immediately falls off when the rod is dipped in cold water.

The colour of copper is yellowish red; its hardness is superior to that of silver, but somewhat inferior to that of platinum; it is very tough, ductile, and malleable; hence it may be beaten into plates or drawn into wire of great strength and compactness. It breaks with a half-cleavage fracture. When rubbed, it emits a disagreeable odour; to the touch it is naiscent and hypsody. The specific gravity of Swedish copper, which is the purest that is met with in commerce, amounts to about 8.6; that of the commoner forms does not exceed 8.6 to 8.8; while that of the Japanese copper, on the other hand, amounts, according to Bergman, to 8.9.

The fusil point of copper is nearly the same as that of gold, namely, a low white heat; before it melts, changeable prismatic colours appear on its surface. When in fusion, or even at a full red heat, if exposed to the air, it is soon covered with a thin brittle plate of brownish oxide, that readily separates from the metal when cold.

This substance is an imperfect oxide, and was formerly called copper after, or fusion, or cina oxide, and by repeatedly heating and cooling a bar of this metal, the whole may be thus changed. These scales, according to Prout, are composed of about 65 per cent. of perfect or black oxide, and 35 of copper nearly in the metallic state; hence, when they are dusted in cold dilute sulphuric acid, only the former portion is taken up. By subsequent calcination, the scales are wholly converted into black oxide, the weight of which is one-fourth more than that of the original copper. At a very high heat, this oxide runs into a bright redish-brown opake glass.

Copper, when in high fusion, and in contact with the air, like all the other easily oxideable metals, is actually combustible; it burns with a beautiful light green flame: the same delicate tinge is visible when a little of the oxide, or any of the salts of this metal, is ignited on burning coal. The green flame thus produced deposits a small portion of greenish-grey prevalent oxide, and hence it gradually collects as a kind of foot in the chimneys of furnaces employed in smelting this metal.

Copper soon rusts in a damp air, and becomes covered with a green crust of carbonated oxide, but this coating, by its fluid adhesion to the metal beneath, long preserves it from further alteration; hence it requires a length of time, and the concurrence of circumstances peculiarly unfavorable to preservation, in order to corrode entirely a thick plate of this
C O P P E R.

this metal. Water is not decomposed by copper even at a
white heat.

With the exception of a few cases, that will be mentioned
previously, copper appears to unite very uniformly with the
same proportion of oxygen, forming (when unconjugated
and with water and every other substance) a brownish-black oxyd,
of which one-fifth, or 20 per cent., is oxygen, and the remainder
copper. This oxyd is produced, as has been already men-
tioned, by boiling the precipitate from any of the cuprous
salts by an alkali, or the ammoxid of copper, with caustic
potash or soda.

Copper, or rather its oxyd, combines with every acid,
forming salts, many of which are both curious and im-
portant.

Sulphuric acid acts upon metallic copper only when con-
centrated and boiling hot. For this purpose take copper
flings, or thin sheet copper, put it into a glass vessel with
twice its weight of strong sulphuric acid, and heat the
mixture. As soon as it begins to boil, much sulphuric acid
gas is given out, and at length the whole diffuses into a
dark-coloured liquor, which, by dilution with water, becomes
a fine blue. If common copper is used for this purpose,
there always remains a black sediment, which consists for
the most part of sulphuric copper. If the pure cuprous
oxyds are employed, instead of the metal, they will be found
to be soluble even in cold and diluted sulphuric acid. The
solution, in whichever way it is formed, deposits, by evapo-
ration and gradual cooling, rhomboidal crystals of a deep
sky-blue colour, which are sulphat of copper, the blue or
Roman viriad of the shops.

The same salt is also met with native in copper mines,
partly crystallized, but more generally dissolved in the water
which drains more or less into all mines. When native, it
appears to be formed in consequence of the iron pyrites be-
ing first vitrified, and the resulting sulphat of iron re-acting
on the copper.

Sulphat of copper has a very strong, flyptic, somewhat
acridulous, and excessively nauseous taste. It is soluble in
about four times its weight of water. When dried at a
heat not exceeding that of boiling water, it looses, according
to Proust, about 36 per cent., which is mere water, after
which the residue, which is a white pulverulent mass, is again
soluble and crystallizable, as at first. But if it is calcined
with a strong white heat, the acid itself is expelled without
undergoing decomposition, and at length there only remains
black oxyd of copper, in the proportion of 32 per cent. of
the original crystallized salt. Hence 100 parts of sulphat
of copper, cold, according to Proust, of

\[
\begin{align*}
\text{Copper} & : 25.61 \\
\text{Oxygen} & : 6.43 \\
\text{Water} & : 32 \\
\text{Sulphuric acid} & : 32 \\
\text{Water} & : 36
\end{align*}
\]

\[
\frac{100}{14.5} = 100
\]

Bergmann's analysis of this salt nearly agrees with that of
Proust in the proportion of copper (26 per cent.); but of
the other ingredients he reckons 28 parts of water, and 46 of
acid.

Besides the common sulphat, Proust describes a sub-sulphat
of copper. This is prepared by adding to the common sul-
phat some caustic potash, but not sufficient entirely to de-
compose it. A green precipitate is in consequence deposited,
which is the sub-sulphat in question. This salt loses by
distillation only 14 per cent. of water. The residue, boiled

with caustic potash, gives 68 per cent. of black oxyd; hence
its component parts are

\[
\begin{align*}
\text{Copper} & : 54.41 \\
\text{Oxygen} & : 13.63 \\
\text{Sulphuric acid} & : 18 \\
\text{Water} & : 14
\end{align*}
\]

\[
\frac{100}{54.41} = 100
\]

Sulphat of copper is decomposed by the alkalies, whether
pure or carbonated. If either of the fixed alkalies in their
basic state is made use of, the precipitate is not, as might
be supposed, a simple oxyd of copper, but that peculiar com-
position first discovered by Proust, and named by him hydrat
of copper. It is thus prepared: to a cold solution of sul-
phat of copper add liquid potash, also cold, to complete
saturation; a blue precipitate falls down, which, when
thoroughly washed with boiling water, is the pure hydrat.
Its constitution, when dried at a heat not exceeding 21°
Fahr., is nearly that of Prussian-blue; at a somewhat higher
temperature it shrinks, and is gradually converted into black
oxyd, by the evaporation of its water. By dry distillation
it is found to give out about 24 per cent. of water, and 1 of
carbonic acid, which it probably has absorbed from the air
during its preparation, if this latter is again moistened with water, it does not
return to the state of hydrat. Hence it appears that the hydrat
is a true chemical combination of copper and water, and oxyd of copper,
in the proportion of about one part of the former to three of
the latter, and as such enters into the composition of the
cuprous salts. The hydrat is decomposable not merely by
heat, but also by boiling with either of the fixed alka-
lies.

Carbonic acid and oxyd of copper unite together without
difficulty. This combination is found native, forming
the mountain-blue, the malachite, and some of the other ores of
copper. It may be prepared artificially by exposing the
metal to a damp confined air, in which case it constitutes a
rust of copper; or more expeditiously by decomposing any
of the acid salts of copper by a carbonated alkali. A copious
bulky precipitate falls down, which, when well washed and
gently dried, is a fine powder of a bright pale apple-green
colour. One hundred parts of copper, dissolved in any acid,
and precipitated by carbonated potash or soda, produce in-
vitably 180 of the green carbonat, dried at a boiling-water
heat. This carbonat, when distilled by itself, with a heat
gradually increased to redness, gives out 10 parts of water,
and 46 of carbonic acid; the black oxyd, remaining behind
in the retort, amounts to 125 parts, of which 100 are
copper, and 25 oxygen.

When hydrat of copper is gently heated with a solution of
super-carbonatated potash, a portion is dissolved, forming a
greenish-blue liquor, whilst the undissolved residue becomes
almost as dark in colour as the black oxyd. The solution,
if slowly evaporated, yields a singular salt, consisting of 52
per cent. potash, 43 carbonic acid, and 5 oxyd of copper.
It is crystalizable and slightly deliquescent. A similar salt,
with a base of soda, is produced, when this latter alkali is
employed instead of potash.

Copper is very readily soluble in nitric acid, even when
cold and considerably diluted. Much heat is excited, and a
torrent of nitrous gas given out, the liquor becoming of
a bright blue colour in proportion as the copper is dissolved.
The oxyds of copper are equally soluble in this acid as
the metal is, but without the evolution of nitrous gas.
When this solution is hastily evaporated to a certain point,
COPPER.

and then suffered to cool, it congeals into a deep blue fialine mass, which deliquates rapidly when exposed to the air. By a slow and careful evaporation this salt may be obtained in the form of hexahedral prisms, but equally deliquescent as the former amorphous variety. If this blue nitrat be evaporated beyond the point at which it would crystallize when cold, nitrous gas begins to be produced, and a green scaly concretion separates from the thick blue liquor. If the evaporation is here stopped, this green matter may be separated by water, either hot or cold, which diffuses only the undecomposed blue nitrat. This green substance is considered by Proust as a subnitrat of copper; that it still contains nitric acid is proved by its still giving out this acid when mixed with sulphuric acid and heated. By thorough calculation all the acid and water are expelled, and the black oxide of copper only remains. The proportions of the subnitrat, according to the above-mentioned chemist, are:

The blue or perfect nitrat, on the other hand, contains only 27 per cent. of black oxide.

Nitrat of copper is very soluble in alcohol, to the flame of which it communicates a very delicate green colour.

The decomposition of this nitrat by tin is so violent as to exclude all cafes to produce actual combustion. This forms an amusing experiment, and was, we believe, first discovered by Dr. Higgins. It is thus performed: spread out a piece of tin-foil four or five inches square, lay in the middle a small heap of the black oxide nitrat, sprinkle the tin with a few drops of water, spread over it a little tow, then double up the tin-foil round it on all sides, twisting it as tight as may be without breaking. In a short time the mass will feel burning hot, small bubbles of blue liquor will be seen oozing through, and will presently be succeeded by a copious eruption of nitrous gas, attended by minute sparks of fire and deflagration.

A fine blue pigment is prepared from nitrated copper, called verditer (vendeur blues, Fr.) It is made in quantity by the refiners, who, after the process of separating silver from gold by aquafortis, recover the silver from its solution by means of copper, and thus obtain a residuum of nitrat of copper. This solution is decomposed by lime (the precise method of doing which is kept secret), and the produce being made into cakes and dried slowly constitutes the best kind of verditer.

This pigment has been analyzed by Pelletier with the following results. It was totally soluble in nitric and muriatic acids, with a copious effervescence of carbonic acid; when distilled by itself 600 hundred grains lost 200, and afforded 2 French pints of carbonic acid together with some water. The calcined residua was a black powder, which, being fused with a reducing flux, yielded a button of pure copper, amounting to about half the weight of the original verditer. A fresh part was then treated with fulphoric acid, which afforded sulphat of lime, the earth of which formed about 7 per cent. of the original verditer. Of the 200 grains lost by distillation, Pelletier considers 180 as carbonic acid. Hence 100 parts of verditer contain

Remains for oxygen $9\frac{1}{2}$ 100

But in this estimate the amount of carbonic acid is by some oversight greatly overrated. The quantity obtained from 600 grains was about 2 French pints, the weight of which, according to Lavoisier, would be only 66 grains; consequently 100 grains would yield only 11 grains of this acid. The water was obviously only estimated at random, and as the copper was in the state of hydraz, certainly amounted to much more than Pelletier has allowed for it. The corrected results of the above analyses therefore would be:

which corresponds very closely with the quantity analyzed.

The muriatic acid diffuses copper with difficulty except when concentrated and boiling, and then hydrogen gas is given out. The oxides, however, of this metal, and especially the green carbonat, are very readily soluble in this acid. The colour of muriat of copper when hot or highly concentrated is brown, but by dilution becomes a greenish-blue. By careful evaporation and cooling it crystallizes in lengthened rhomboids, and when halfly evaporated in feathery crystals. This salt is commonly deiquefcent, but when both the copper and acid are quite free from iron is permanent in the air. It is readily soluble both in water and alcohol; the latter takes up its own weight when boiling, a part of which afterwards separates in a crystalline flake as the liquor cools. The composition of the crystallized salt is, according to Proust:

100

A dilute solution of muriated copper in water makes a kind of sympathetic ink, which is colourless in the cold, becomes yellow by warming, and again loses its colour on cooling. Besides the common muriat, the ingenious researches of Proust have discovered a second muriat, in which the copper appears to be at a lower state of oxidation than in the former salt. It affords a nearly colourless solution, and when solid is of a greyish white; it may therefore without impropriety be called the white muriat of copper. It is prepared from the common muriat by means of muriat of tin, a salt remarkable for the eagerness with which it absorbs oxygen from almost all the other metallic salts. If therefore some of this latter is poured into common muriat of copper, a precipitate falls down which is at first white, but by subsequent exposure to air passes through
through different shades of violet and blue to black. This precipitate is for the most part a muriated sub-oxide of copper. On exposure to a moderate heat it melts like luna cornea. If digested in warm muriatic acid it readily dissolves and is deposited on cooling, in the form of tetrahedral crystals. With nitrous acid some nitrous gas is given out, which shows that the metal was not previously saturated with oxygen. Another remarkable character of this white muriat is, that when diffused in ammonia the solution is colourless; though, on exposure to the air, it gradually acquires the sky-blue colour of common ammoniac of copper. Its composition, according to Proult, is

| Muriatic acid | 21.75 |
| Oxid of tin | 1.00 |
| Copper | 67.00 |
| Oxygen | 11.25 |
| Total | 100.00 |

Assuming this analysis as correct, it is obvious that the copper exists in a much lower state of oxygenation in this salt, than in any hitherto mentioned, for in this the oxid of copper is composed of 63 of metal and 11.25 of oxygen, or (reduced to the hundred) of 84.86 copper, and 15.16 oxygen, whereas the black copper, to which all the common cupreous salts are reducible by lots of their acid and water, consists of 80 per cent. copper, and 20 oxygen.

There appears to be yet another state of composition of muriatic acid and oxid of copper, also first noticed by Proult. It is the sub-muriat of copper, differing from the common muriat not by a lower degree of oxygenation in the metal, but in a smaller proportion of acid. It is produced by adding a little water (less than required for saturation) to the green muriat. A green powder falls down, which is the submuriat in question. This salt when boiled with potash loes about 28 per cent. of its weight, and is reduced to the black oxid. A similar submuriat is laid by the same chemist to be spontaneously deposited when copper is diffused in nitro-muriatic acid. The composition of this salt is as follows:

| Black oxid of copper | 79.00 |
| Muriatic acid | 12.50 |
| Water | 8.50 |
| Total | 100.00 |

The native green muriat of copper from Peru appears to be nearly in this state.

Copper seems to have a stronger affinity for muriatic acid than even for the nitric or sulphuric. Thus, if either the solid nitrat or sulphat of copper be digested in muriatic acid a solution takes place, and then, on the application of heat, the liquor immediately looses the blue colour, characteristic of these two salts, and acquires the green of the muriat: also by slow evaporation muriat of copper is obtained in crystals.

Acetous acid has no action on regular copper, but its oxid is easily soluble in this fluid, to which it communicates a beautiful grass-green colour. There are two species of acetic copper, the one with an excess of acid, the common verdigris of the shops, and the other in which the acid and oxid are in a state of mutual saturation, forming the crystallized or diffused verdigris.

The manufacture of verdigris is carried on to a considerable extent in most of the southern provinces of France, and a very exact account, apparently, of the process has been published by Chaptal, from which the following particulars are extracted.

The materials for this manufacture are the marc or cake that remains in the wine-press, after the greater part of the juice has been liquefied out; and plates of copper of convenient size and hammerd well, in order to smooth the surface, so that the corroded portion may be readily detached from the back.

The marc of the grape is first fermented by being laid as lightly as possible in a large barrel and moistened with common wine, and then set in a warm airy place. In a few days, varying according to the heat of the weather, it begins to flow; turns hot and exhales a brown colour of vinegar; the fermentation then declines and the marc is fit for use. A layer of this is then put into an earthen pot and a plate of copper, previously made scorching hot, is laid upon it; to this succeeds another layer of marc, and then a plate of copper, in regular alternation till the pot is filled, observing that both the top and bottom layers are of marc. The mouth of the pot is then loosely stopped with straw, and the whole is left at rest from ten to twenty days.

When the marc begins to whiten the pots are unpacked, and, if the process has gone on well, the copper-plates are found covered with a green crust, intermixed with fusty green crystals. The marc is thrown away; the plates are let on end on wooden racks in a cellar, and when dry are dipped in water and again set to dry; this is repeated once or twice, or eight times, which makes the crust of oxid swell and increase both in quantity and quality: after which it is scraped off by a knife without difficulty. Each pot yields about 5 or 6 lbs. of rough verdigris, and the plates will serve again repeatedly till they are corroded quite through.

This rough verdigris is further prepared for market by being ground in wooden mortars, and exposed to the air till it is sufficiently dry; and in so doing it loses about half its weight.

Verdigris thus prepared, may be considered as copper oxidated by the action of the acetic acid, and combined with water, with carbonic acid, and with part of the extractive or mucilaginous part of the marc. It is nearly insoluble in water and its colour is blueish green. If this verdigris is digested in distilled vinegar it diffuses readily in this fluid, and by evaporation and cooling a crystallized salt of a deep green colour may be obtained, which is known in the shops by the name of distilled verdigris. The method in which this valuable salt is prepared at Montpellier is as follows: Common vineger is first distilled in a copper alembic, and the acid thus produced is put with common verdigris into a copper boiler; when a hot saturated solution is thus made, it is strained and transferred to another copper evaporating vessel, where it is boiled down till a brown crust begins to collect on its surface; a light frame of crofts falls is now sunk into the liquor and the fire is put out. On cooling, the acetate of copper crusts round the flasks in clusters of rhomboidal crystals of a deep blue-green colour. It requires about 3 lbs. of verdigris to make 1 lb. of the crystallized acetic.

The composition of common verdigris is subject (as might be expected from the method in which it is prepared) to a considerable variation, and this difference is still further increased by variations in the way of manufacturing this salt. Thus, at Grenoble, verdigris is made merely by dipping plates of copper in a proper room, and moistening their surfaces.
COPPER.

Copper is a highly valuable metal, used in various industries due to its unique properties. The extraction and refinement processes are crucial in obtaining pure copper. Historically, copper has been extracted using methods that involve the use of heat and chemical reactions. The natural combinations of copper with arsenic and arsenic acid are well-documented, with Scheele's green being a famous example. The elucidation of these processes is essential for both historical and practical contexts.

To the above particulars may be added some observations, by Proult, on the properties and composition of this falt.

When common verdigris is put into cold water, it gradually falls to pieces and nearly half of it is diffused, the remainder is a fine green powder which diffuses itself through the liquid and subdides very slowly. This green powder appears to be pure subacetite of copper, and when washed and dried weighs about 42 per cent. of the original verdigris. When sulphuric acid is poured on it, pungent vapours of vinegar are given out. Boiled with potash it affords 63 per cent. of black oxyd; and when diffused, after all the volatile products have passed over, there remains about 52 per cent. of copper, principally in the metallic state. From these data therefore the subacetite appears to consist of:

- Copper: 59.4%
- Oxygen: 12.0%
- Remaining for acid and water: 37%

With regard to the crystallized acetite, Proult found that 39 parts of black oxyd produce, with diffilled vinegar, 100 parts of acetite, and on the other hand, that 100 parts of this falt, when decomposed by boiling with potash, yield 39 or 40 parts of black oxyd. Hence it is composed of:

- Copper: 31.2%
- Oxygen: 7.8%
- Acetous acid: 61%

The diffiluation of the crystallized acetite furnishes the most pungent acidetic, or radical copper, as has been already described under Aceturus Acid. Acetite of copper, besides being made by direct combination of its ingredients, may be prepared in various ways by double affinity; of thefeth the belt upon the whole is the following: Make a cold solution of sugar of lead (acetite of lead) in distilled water, to which add, by degrees, a cold solution of blue vitriol (fulphat of copper), as long as any precipitation takes place; then pour the whole on a filter, and a green liquor passes through, the fulphat of lead remaining on the filter, in the form of a white powder. The green liquor, being concentraded by evaporation, deposits, by cooling, very pure and beautiful crystals of acetite of copper.

The natural combinations of copper with arsenic and arsentic acid have already been noticed. With regard to the artificial arsentic, Scheele discovered that when arsenic acid is diffused with copper filings, a green solution is formed, and a blue powder, which is also an arsentic, is precipitated. The fulphat, nitrat, and muriat of copper undergo no apparent change, when added to arsenic acid; but the acetite is decomposed, and arsentic of copper is precipitated. All the cuprous salts, however, are decomposed by arsentic alkali, and a blue arsentic falls down. To these facts Mr. Chenevix has added the following: If arsentic of ammonium and nitrat of copper are added, there falls down a blue crystalline arsentic of copper. On evaporating the supernatant liquid, and adding alcohol, another copious deposition of crystals took place, of a deeper colour than the former, and of a rhomboidal shape. Each of these arsenites was examined separately, first by calculation at a low red heat to expel the water, then by potash for the black oxyd of copper, and lastly by nitrat of lead for the arsentic acid. By this method, the first arsentic was found to consist of:

- Oxyd of copper: 50%
- Arsentic acid: 27%
- Water: 23%

= 99%

The second arsentic afforded:

- Oxyd of copper: 35%
- Arsentic acid: 39.5%
- Water: 24%

= 98.5%

Arsenite, in the state of white oxyd, combines with oxyd of copper into a pale green powder, called, from its discoverer, Scheele's green. It is prepared in the following manner: Dissolve 24 ounces of sulphat of copper in water, and heat the solution in a copper vessel; also boil in another vessel 24 ounces of pearlash, 11 ounces of white arsenic, and about 3 pints of water; when the whole is dissolved, strain each solution separately through linen, and then add the arsenticated potash, little by little, to the sulphat of copper, with constant stirring; an effervescence will take place, and then a green powder will be deposited. When the mixture is mixed, let it stand some hours, then separate the precipitate by the filter, edulcorate it well with clear hot water, and dry it very gently in a warm room. The above quantity of ingredients will afford about 1½ ounces of the powder, which may be used as a pigment.

Phosphat of copper may be prepared by adding phosphat of soda to the nitrat, or any other readily soluble falt of copper, a blueish-green sediment falls to the bottom, which dries to a powdery semi-crystalline mass. A low red heat turns it brown, and drives off about 15.5 per cent. of water: there remains a phosphat of copper, composed of 35 parts of phosphoric acid, and 49.5 of oxyd of copper.

A skirking decomposition of nitrat of copper also takes place, when a thick of fresh melted phosphorus is immersed in a solution of this falt, and exposed to the light. By degrees the copper is precipitated on the surface of the phosphorus, in the metallic falt, and in the form of crystalline grains.

All the fals of copper are decomposed by the alkaline proflatas, and the retart is a sediment of a reddish-brown colour, which, by drying and exposure to the air, acquires a dark
COPPER.

dark chocolate hue. This prussian of copper mixed well with oil, and has been employed with force success as a pigment.

The solution or infusion of galls throws down from all copperous solution a precipitate of a dirty yellow colour.

Oxide of copper is soluble in all the other acids, forming with them, however, salts little known, and of little importance: the predominating colour in all of them is green.

The alkali, neither potash nor soda have any action on copper or its oxides, except that already mentioned, of taking away from the hydrat its water of combination, and reducing it to black oxide.

Ammonia has no action on metallic copper, but diffuses its oxides without difficulty. The usual colour of this solution is a deep blue-purple. The most direct method of preparing it is by digerizing together liquid ammonia and any oxide, or carbonated oxide of copper: the liquor becomes blue almost immediately, and its colour deepens till saturation takes place. By flow and careful evaporation, blue silky crystals of ammonium of copper may be procured. This salt, by exposure to the air, gradually loses its alkali, and absorbs carbonic acid, so that at length it is wholly converted into green carbonate. The aqua funginita of pharmacy and surgery consists, for the most part, of ammoniated copper, to which its colour is owing: it is made chiefly in two ways. The first is to digest in a glass vessel quick-lime, muriat of ammonia, verdigris, and water; the lime decomposes the muriat of ammonia, disengaging the alkali, which, in its turn, decomposes the verdigris, and dissolves the oxide of copper; hence the clear liquor consists of ammoniated copper and muriat of lime. The second method, where a weaker solution is wanted, is to employ lime-water instead of lime. Another way of producing ammoniated copper immediately is to superinate with this acid any of the salts of copper, in consequence of which the first portions of alkali decompose the cuprous salt, throwing down an oxide, and the succeeding portions redissolve the oxide, forming a dark-blue solution. As there is no other metal besides copper and nickel which produces this particular colour, and as the latter of these metals is not common, the production of this beautiful tinge, by the addition of ammonia, may be considered as a very probable indication of the presence of copper.

A singular circumstance takes place with regard to ammoniated copper. If a bottle be filled with liquid ammonia, and a few clean copper filings be added, no solution ensues, as long as the bottle is kept close corked. But if the bottle be opened for a while, and then shut again, a solution indeed of part of the copper takes place, but without any change of colour in the liquor: but when the bottle is again opened, the characteristic blue tinge appears first at the surface of the solution, and gradually spreads down to the bottom. If now a few more copper filings be added, and the bottle again corked, the solution will in a short time again become colourless, and continue so till it is again exposed to the air. The reason of these changes appears to be the following: copper requires some, but only a very small quantity, of oxygen to be soluble in ammonia; and when in this lowell state of oxydation, it forms with ammonia a colourless solution, as it forms with muriatic acid a white sub-muriat: but if this solution is exposed to the air, the metal absorbs oxygen, and is thus brought to that state in which it tinges ammonia blue; being again shut up with a few copper filings, the oxygen is partly absorbed by the recently added metal, and reduces the whole to the state of white oxyd.

Many of the neutral salts, especially the muriats, are capable of oxydation, and, in part, of dissolving copper: this is especially the case with muriat of ammonia, which, when made into a mass with copper filings and a little water, and kept warm, perfectly converts the copper into a green muriated oxyd.

Copper and sulphur readily unite. If equal parts of copper filings and flowers of sulphur are mixed and heated in a crucible, much of the sulphur burns off; but the remainder melts into a blue-black mass, which is sulphuret of copper.

According to Priest, 100 parts of copper take up in this way 28 of sulphur, so that the sulphuret is composed of about 79 of metallic copper, and 21 of sulphur. No oxygen appears to be present. This substance is more fusible than copper, melting readily at a red heat. By roasting in the open air, the sulphur is expelled: the last portions, however, adhere with great obstinacy. According to Dr. Thomson, sulphur and copper filings unite together, by being merely mixed together with or without water, and exposed for a long time to the air.

Hydrosulphurated water, or any of the liquid hydrosulphuric acids, when added to the solutions of copper, produce a deep blue-black precipitate, which is a hydrosulphuret of copper.

Phosphorus is capable of intimate combination with copper. If 5 parts of this metal in filings, 8 of vitreous phosphoric acid, and 1 of charcoal powder, are intimately mixed together, and then put into a crucible, and exposed to an intense heat, the phosphoric acid is decomposed by the action of the charcoal, and the phosphorus in part burns off, and in part unites with the copper, forming a hard, field-grey, brittle article, capable of a high polish. A simpler way of preparing the same is to make copper filings red hot in a crucible, and project upon them small pieces of phosphorus, which combines with the metal, and melts down into a grey mass, similar to the former. One hundred parts of copper may thus be increased to about 125; but if this phosphuret is kept for some time melted under charcoal powder, or melted gla$; part of the phosphorus burns off. When this excess is thus got rid of, the ingredients of the remaining phosphuret appear to be in a state of mutual saturation, no more phosphorus being dissipated by a continuation of the fusion. In this state the mass appears to consist of 92.1 of copper, and 7.7 of phosphorus: it retains the grain and colour of steel, is susceptible of a high polish, and does not readily tarnish in the air, but is brittle. With a slight less proportion of phosphorus, it becomes malleable, and of a yellowish-white colour. Phosphuret of copper, if kept in fusion, with free exposure to the air, loses gradually most of its phosphorus, which burns away with the bright flame and colour peculiar to this substance.

The mixed oils, when kept long in contact with copper, oxide it, and dissolve a portion, by which they acquire a green colour.

The utes of copper, in its various states, are so numerous and important, as to be scarcely inferior to those of iron. All the salts of copper are more or less poisonous, producing violent nausea, with severe pain and inflammation of the intestinal canal. Yet from the sudden vomiting that they excite, a large dose may be given with safety; and this is sometimes done, when there is an immediate necessity of emptying the stomach.

Copper, however, is very little used medicinally in any form.

§ 5. Alloys of Copper.

The alloys of copper are, upon the whole, of more importance than those of any other metal: we shall, therefore, treat of them with some minuteness.
Copper, when added in small quantity to either of these metals, greatly increases their hardness, without materially debating their colour or malleability: hence it has been generally adopted as the alloy for that portion of the precious metals which is employed with current coin, and for plate.

Copper with arsenic.

On account of the volatility of arsenic some precautions are required in the preparation of this alloy. The best way, upon the whole, is to melt some copper in rather a large crucible, and then to wrap up in paper some reglumine arsenic, or white arsenic, either with or without a mixture of charcoal powder. and to immerse the paper, with its contents, in the melted copper, either by means of a pair of long tongues, or by ramming the paper into a small crucible, and then inverting the crucible in the fluid metal. The arsenic preferably rises through the copper in dense white fumes, and is in a great part deliquescent; a portion however is retained by the copper, and by repeating the process once or twice more, the alloy will be fully saturated with arsenic.

This alloy is of a silvery white colour and a close texture; it is however very brittle, and, in proportion to the perfect whiteness of its colour, liable to tarnish in the air. As soon as it is brought to fusion the arsenic begins to escape, and the copper regains its malleability: the last portions however of arsenic are not driven off even by long continued heat, and although the copper regains its malleability, its colour remains of a dingy yellow.

Vauquelin has discovered that if to an alloy of copper and silver, in equal proportions (the colour of which is a pale yellow), there be added 2 per cent. of arsenic, the result is a perfectly white ductile and malleable alloy. If this latter ingredient exceeds 5 per cent. the alloy begins to be brittle.

Copper with iron.

These two metals only unite when the former of them is greatly in excess. The result is a hard, grey, and somewhat brittle alloy. According to Mr. Keir, the tutenag of the Chinefe is a white alloy of copper, zinc, and iron; it is hard, tough, and sufficiently malleable to be wrought into candlesticks and various other articles of domestic furniture, which take a high polish, and are scarcely to be distinguished from silver. The inferior sort of tutenag has, however, a very perceptible brassy tinge.

According to D'Azé, the alloy of iron and copper only ceases to be acted on by the magnet, when the proportion of the former is less than \( \frac{3}{5} \) of the whole mass. Iron is much inferior in its power of whitening copper to tin or even to arsenic.

Copper with lead.

These metals unite, to appearance, very intimately by fusion; but when a mass of this alloy is exposed to a very low heat, the greater part of the lead, with a small portion of copper, sweats out, leaving the rest in a porous honeycombed state. When the copper holds a little silver, the lead carries the latter out with it: this process is called eliquation, and will be treated of more at large in the article Silver. Copper, with about a fourth of its weight of lead, forms an alloy of a deep red; this alloy is called pot-metal. The Roman pot metal was composed, according to Pliny, of 100 parts copper, 2 lead, and 2 tin. The same ingredients, but with larger proportions of the two latter, were the materials of many of the ancient Greek and Sicilian coins, as appears from analyses of them by Klaproth.

Copper with zinc.

Copper, when nearly saturated with zinc, that is, when the latter amounts to about one-fourth of the alloy, forms brass, of which an account has been already given. With a smaller proportion of zinc, the colour of the alloy approaches more nearly to that of gold, and its malleability increaseth. Mixtures, chiefly of these two metals, are employed to form a variety of gold-coloured alloys, known by the names of tombac, Monbein or Dutch gold, tinsel, similor, prince Rupert's metal, pinchbeck, &c., the precise composition of which varies according to the fancy or experience of different artists. The Dutch gold may be beaten into extremely fine leaves, which when fresh are a cheap and good imitation of gold leaf; but they tarnish very soon. The mixture may be made either by melting together copper and zinc, or copper and brass. In either case the copper should be melted first, and the other ingredient added afterwards: being then carefully stirred together with a flick, the alloy is to be poured out into proper moulds without loss of time, left the zinc should burn off.

A fine malleable tombac may be made with 16 parts of copper, one of zinc; and one of tin; if a larger proportion of this latter is added, the alloy becomes harder and brittle. Several Roman coins struck, during the first century of the emperors, have been analyzed by Klaproth, and appear to consist of nearly pure copper, others of copper, with from a fifth to a sixth of zinc. A little tin and lead were found in some, but in such small proportions as to appear only an accidental impurity.

Copper with tin.

The alloy of copper and tin are extremely important in the arts, and curious as chemical mixtures. Tin added to copper makes it more fusible, liable to rust or be corroded by the air and other common substances, harder, denser, and more fonorous. In these respects the alloy has a real advantage over unmixed copper; but this is in many cases more than counterbalanced by the great brittleness of the mixture which even a moderate portion of tin imparts, and which is a singular circumstance, considering how very malleable both metals are before mixture.

The feasible qualities of the different mixtures of these two metals are the following: Copper, alloyed with from one to five per cent. of tin, is much harder than before; its colour is yellow, with a cast of red, and its fracture is granular: it is still considerably malleable. This appears to be the usual composition of many of the ancient edged tools and weapons before the ufe of iron; whence it appears that the ancients did not possess (as has often been supposed) any peculiar art of hardening pure copper, otherwise than by mixture. An alloy in which the tin is from \( \frac{1}{5} \) to \( \frac{1}{2} \) of the whole is hard, brittle; but still a little malleable, closely-grained, and yellowish white. When the tin is as much as \( \frac{1}{3} \) of the mass, it is entirely brittle, and continues so in every higher proportion. The yellowness of the alloy is not entirely lost till the tin amounts to \( \frac{1}{2} \) of the whole.

Copper (or sometimes copper with a little zinc) alloyed with as much tin as will make from about \( \frac{1}{3} \) to \( \frac{1}{2} \) of the whole, forms an alloy which is principally employed for bells, brass cannon (so called), bronze statues, and various other purposes. Hence it is called brosses or bell-metal, and is excellently fitted for the use to which it is applied by its hardness, density, and fusibility. For cannon a lower proportion of tin is commonly used. According to Dr. Watson, the metal employed at Woolwich consists of 100 parts of copper, and from 8 to 12 of tin; hence it retains some little malleability, and therefore is tougher than it would be with a larger portion of tin. A common alloy for bell-metal is 80 of copper and 20 of tin: some artists add to these ingredients zinc, antimony, and silver, in the proportion of 

Vol. IX.
COPPER.

Small proportions, all of which certainly improve the fonorous offsets of the compound.

When in an alloy of copper and tin, the latter metal amounts to about 1/3 of the mass, the result is a beautifully white alloy, with a lustre almost equal to that of mercury; extremely hard, very close-grained, and perfectly brittle. It takes an exquisite polish, which well adapts it for the reflection of light for all optical purposes. It is called speculum metal, and, besides the above ingredients, generally contains a little arsenic, zinc, or silver. The application of an alloy, similar to the above, to the construction of mirrors, is of great antiquity, being mentioned by Pliny. From the actual analysis, by Klaproth, of a portion of an ancient speculum, it appeared to consist of:

| Copper | 62 |
| Tin   | 32 |
| Lead  | 8  |

Of these ingredients the last is considered by Klaproth, with high probability, as only a casual adulteration of the tin.

When the amount of the tin exceeds that of the copper, the alloy begins to lose its splendid whiteness, and acquires a bluish-grey hue; its texture likewise becomes rough-grained, and, as it were, rotten and incapable of receiving a polish.

A perfect speculum metal should be quite white, without flowing any cast of yellow when polished, not very liable to tarnish, quite free from pores, even when examined by a lens, of a certain coherence or toughness to bear the grinder, and, for the convenience of working, as soft as may be consistent with the other requisites.

Mr. Mudge, whole specula were celebrated for their goodneifs, observes, that the extreme of whiteness is given by 32 parts of copper and 16 of tin, but this compound is too hard and brittle; 32 parts of copper with 14 2/3 of tin form an alloy quite white, and as hard as can be wrought. In order that the metal should turn out free from pores, it ought to be twice fused, once for mixture of the ingredients, and afterwards, with as little heat as possible, for casting.

The following observations on the same subject are extracted from an elaborate paper by Mr. Edwards, published in the Nautical Almanack for 1787.

The quality of the copper should first be tried by adding successively from 1/16 short of half of its weight of tin, that the mixture proves a little yellow, to the full half of tin, and by comparison of the various samples ascertaining the maximum of whiteness. When this is found, take 32 parts of copper, melt it, then add one part of brass and the same of silver, with a little black flux to cover the surface; when these are melted stir them together with a wooden rod, and pour in from 1 1/2 to 1 5/10 parts of tin (as ascertained by previous experiment) fud in a separate crucible, at a low heat; then stir the mixture again, and immediately pour it into cold water. Re-melt, with as little heat as possible, the alloy thus formed, and for every 16 parts take one of white arsenic, wrap it in paper, thrust the packet to the bottom of the fluid metal with a wooden rod, and stir it well as long as any arterial vapours arise; when these cease pour the metal into a mould of sand, and as soon as it has solidified lay it in a pot full of very hot embers, and cool it very slowly; unless this precaution is particularly observed, the metal will fly in pieces when cold, or will split in the polishing.

The brafs, the silver, and the arsenic in this composition appear to have their distinct use; the brafs makes the mixture tougher, and somewhat foth from, the silver improves its colour, and the arsenic renders the texture remarkably finer, closer, and less porous; a larger proportion of this however would make the metal inable to tarnish.

Sir J. Newton's specula were composed of 6 parts of copper, 2 tin, and 1 arsenic; they are upon the whole very good; but after being polished exhibit a rather yellow cast.

The other alloys of copper are not of much importance, and will be found under the respective metals to which they belong.

COPPER white, a kind of metal white as silver, frequently brought from China, and supposed by many to be natural. But it is only an alloy of copper, zinc, and arsenic, in certain proportions. It is made with difficulty, because of the volatility of the two metals; and, as its quality is noxious, it is not much used.

Copper, in Military Affairs. No other metal is allowed in magazines, or for barrels of gun-powder.

Copper, in Calico-Printing, a veal which the operations of dyeing, mordanting, &c. are performed, and which derives its name from the material it is generally contrasted of. As these veals are used indifferently for any of the above purposes, their size, form, and arrange-ment, are generally the same, and vary little throughout the whole kingdom. They are always circular, from 4 1/2 to 5 feet diameter at the top; 2 to 4 feet deep, and about the whole in width, across the bottom, which is the thickest and flowered part of the vessel. This circular form, though in general use, is perhaps the word that could have been devised for the purpose of calico-printing. It is no doubt the first that was employed, and has advantages in point of solidity of form, and ease of transportation from one place to another, over any other. For the purpose of dyeing, however, or any operations where goods are kept for a long time at a boiling heat, and turned over the winch, it is the most inconvenient that could have been adopted.

In a veal of this size, and form, it is customary to dye from six to twelve pieces of twenty-eight yards each, at one operation. The goods are diposed either in two lengths of four or fix over the winch; or, when quick turning is necessary, in one length only, in which case, fix pieces, or at most eight, are diposed equally over the whole surface of the winch. In this latter case, the inconvenience of the circular form is particularly felt. It is evident that when six or more pieces are crowded upon a winch, those which are at the extremities will have little or no space in which to float, without disturbing those which are nearer the centre; whilst, on the other hand, those which are in the middle will have more than sufficient, and will float in the copper, scarcely ever touching its sides. In consequence of this, the pieces at the extremities of the winch, being crowded, will press along the sides of the copper, and thus be exposed to greater heat and hazard of copper-marking, than those which are in the middle. Their disposition on the winch will also be deranged, and the copper-man, with all his care and attention, will be unable to preserve that order and regularity in the distribution of their folds, so efficaciously re- quire in good dyeing. When the copper is in a state of ebullition, these evils increase, and it rarely happens that the most experienced dyer can keep his goods diposed in such manner as prevent their getting completely salted, when he has two lengths of fix over the winch, and keeps them twenty or thirty minutes at an actual boil. By
COPPER.

By adopting a square, or, what is still better, an oblong vessel of the same capacity as the former, these inconveniences are in a great measure done away; the goods have all equal space to float in, are equally removed from the centre and sides of the vessel, and preserve their order and disposition on the winch, even in a state of ebullition, with ease, certainty, and comparatively trifling attention.

Dyecoppers are generally set up in brick work, with each their separate and direct fire-place, chimney, &c.

The same principles apply to the heating of these vessels as to all other boilers, but we need not enter here upon a subject which will be more fully treated of in another part of this work. The recent improvements in the application of steam, as a vehicle of heat, are however of such importance, and have at this moment excited such general interest amongst dyers, and calico-printers, as to claim a short notice in this place.

Mr. Gott, of Leeds, was the first who applied steam in the large way, to the heating of dyecoppers, and the success of his experiment was so complete, as to induce many others to follow his example. This mode, which is the simplest and most economical that can be employed, consists in throwing the steam directly into the dyeing vessel. One steam boiler, situated at the extremity of the building, supplies his numerous copper-tubes which are disposed promiscuously about the dye-houset, unincumbered with fire-places, altars, chimneys, &c. and simply surrounded with a casing of brick, to support the copper, and confine the heat.

The steam is conveyed in horizontal pipes, carried along the ceiling of the dye-houset, from which descend vertical tubes of from 3 to 3½ inches diameter, according to the size of the copper they belong to. These steam-tubes all pass down on the outside of their copper, and enter them horizontally at the level of their bottoms; and are furnished with brass cocks for regulating the admission of the steam, or entirely interrupting it when the copper is not wanted.

The rapidity with which these coppers are heated, is truly astonishing. One of the largest in Mr. Gott's dye-houset of 1800 gallons capacity, according to count Rumford, was brought to the boiling point in half an hour. The saving of fuel, though in general overrated, is another advantage gained by this mode of applying heat. Mr. Gott rates this at two-thirds of the quantity consumed when the coppers are heated by separate fire-places; but this is evidently too much. The saving consists in the application of fire to one vessel only of large dimensions, instead of to a number of small ones; and though this is certainly accomplished with less expense of fuel, yet, if the fire has been well and properly applied in the latter case, the saving will amount nearer to one-third than to two.

The burning of the copper sides and bottoms, when heated by a naked fire, is a heavy expense in a large establishment, and often a source of serious inconvenience. By the application of steam, this is entirely done away, and even copper vessels themselves, for many operations, rendered wholly unnecessary. Wooden vessels have been substituted, with great advantage, in their stead, and when the use of copper cannot be dispensed with, it may be employed in thin sheets, supported by a frame work of brick or wood. Important as these advantages are in an economical point of view, the system of steam-heating has, if possible, filled more powerful recommendations. The cafe, elegance, and regularity, with which the heat can be transmitted by a steam tube, are of themselves sufficient to entitle it to decided preference.

By the adjustment of the steam-cock, the rate of heating is so regulated, that the copper may be brought to the boiling point in any given time, with an exactness as well as certainty, unattainable by the other mode. The heat may in an instant be withdrawn, or rendered stationary at any fixed point, by a single turn of the cock, the effect of which is impracticable, and the latter extremely difficult, when the coppers are heated by separate fire-places. The sides and bottom of a dyecopper, exposed to a strong and naked fire, are always much hotter than the dye-liquor, and occasion copper-marks and unevenness in the goods, in some cases difficult to avoid. This inconvenience is entirely removed by the use of steam, since the dye-vehicle deriving all its heat from the heated liquor within it, can never, it is evident, acquire a higher temperature.

The success of Mr. Gott's experiments was such that many of his neighbours, at first much prejudiced against it, immediately adopted the plan. With a liberality worthy of imitation, his dye-houset was open to all inquirers; and thus was the interest excited by this new and extraordinary mode of applying heat, that experiments were immediately instituted in different parts of the country, with a view of extending this improvement to other branches of the art of dyeing. Mr. Gott had proved and established the practice as far as the dyeing of woollen goods was concerned, and little more remained to be done; in its application to calico-printing and the dyeing of lighter goods, however, difficulties occurred, of such a nature, as wholly to discourage many whole trials were made in a hasty ill-considered manner, and considerably to embarrass those whole experiments were conducted with greater skill and patience.

The great, and only well-founded, objection arose from the agitation which the water was thrown when it approached the boiling point, by which the goods were entangled and fattened, much more than in the ordinary mode. This inconvenience was not felt in Mr. Gott's dye-houset, where the goods being woolen, and of much greater weight and fulness, were less liable to be tossed about by the ascending currents from the steam-tubes than the thin and lighter goods manufactured from cotton. The evil was often increased by want of sufficient attention to the regulation of the steam-cock; thrice the quantity of steam necessary to maintain the copper at the boiling point being admitted, which, retaining its elastic form at that temperature, passed through the copper uncondensed, and threw the goods into the greatest confusion.

To diminish the agitation, it has been found necessary to break the force of the current, by introducing the steam in small quantities, through two or perhaps three different openings, or in some cases by introducing a false bottom, pierced full of holes, between the goods and the end of the steam-tube; by this means, and still more by carefully admitting only the necessary quantity of steam, the agitation may be so far reduced, as to be no longer troublesome.

The accumulation of condensed water in the dye-copper, is a necessary consequence of this mode of applying steam, and cannot be avoided. Where it is an object to diminish this as much as possible, it may be accomplished by using strong, or which is the same thing, very hot steam; but it does not appear that any great inconvenience results from this trifling increase, which escapes when the copper has attained the boiling point, due allowance being made for it in the first instance, when the vessel is filled with cold water.

When strong steam is rapidly thrown into a vessel filled with
with cold water, the condensation is instantaneous, and attended with a loud noise, and violent shock.

We have seen a flume of dimensions, and firm junctions, nearly shaken to pieces by the incalculable expansion of steam, and many of the early experimenters complained that their coppers were nearly knocked to pieces, and that few would hold water after being heated once or twice.

This inconvenience may be corrected by stopping the end of the steam tube, and piercing the sides full of small holes, or, which is still better, by turning up the end of the pipe, and fixing a valve in it. In either case the steam is emitted through the openings in the steamlets, or jets of small volume, whose condensation is attended with trifling noise, and little agitation of the vessel. Several dye-houses in Lancashire and Cheshire have been fitted up on these principles, and, the coppers, thus heated, are used, with few exceptions, for every purpose of calico-printing.

Mr. Gott, as we have before stated, was the first who introduced this improvement on a large scale, the idea of which, count Rumford informs us, was derived from the peculiar process of his seventh Essay. We know not what share the count's publication might have in deciding the trial, but the idea of heating water by steam had occurred long before that time to Mr. Watt; and, if we mistake not, a warm bath at Soho had been heated in this way, and seen by Mr. Gott, and many others, to whom the idea of its application to more useful purposes had naturally occurred.

For some few purposes we believe this mode of applying heat, by throwing steam directly into the dye-copper, is less advantageous. When goods, for example, are kept a long time at a low heat and never boiled, the accumulation of condensed water, in this case, continues to the end of the operation, and weakens considerably the effect of the dye. All the advantages of this mode may, however, be obtained without any of the inconveniences we have before alluded to, by surrounding the dyeing-vessel with a casing of cast iron, and throwing the steam in between this and the copper. The heat in this case is transmitted through the sides of the copper, as in the ordinary mode of heating by a naked fire, and the condensed water is carried off from the casing either by a reversed syphon, eight or nine feet long, or, when the situation will not admit of this, by a floating valve. In this way the noise and shock, from the rapid condensation of steam in cold water, the agitation in the dye-copper, and the condensed water, are all completely got rid of. The apparatus is, however, less simple and much more expensive than the former.

A strong steam is necessary to produce the boiling heat in a dye copper cooled by the continued exposure of the goods on the winch, and the vessel and joints must be found and strong to support this pressure. Both modes have their advantages, and will, we have little doubt, in a few years entirely supercede the ordinary mode of heating by separate fire places.

Copper mark is a stain, discoloration, and unevenness in dyed goods, caused by contact with the sides of a hot or dirty copper, during the operation of dyeing. In the ordinary mode of heating, as has been observed in the foregoing article, the bottom and sides of a dyeing-vessel, when exposed to a strong and naked fire, are much hotter than the dye liquor. When this is the case, and the colours pale and delicate, simple contact with the hot copper is sufficient to cause unevenness, either by affecting the hue by the excess of heat, or enabling the mordant to combine with an extra portion of colouring matter. This inconvenience is in general remedied by placing a basket of wicker work within the copper, which prevents the goods from touching the sides of the vessel; it is still more completely guarded against by heating the copper with steam, in the manner already described.

The sides of a copper will often occasion marks or flaws when the vessel has been negligently washed out, and especially when it has not been used for some time. A dye-copper not in use should always remain filled with clean water. It prevents the formation of a rust on its surface, which simple washing will not remove, and which acts as a mordant, and fixes the dye whenever it touches the cloth.

Copper Island, in Geography, otherwise called Mednoi Okrug, i.e. Mednoi Island, lies in the sea of Kamtschaks, which separates the two continents of Asia and America. It takes its name from large masses of native copper found upon the beach; and as it lies full in sight of Beering's life, it was early and speedily discovered by those who succeeded Beering. These two uninhabited spots, to which the sea-otters and other marine animals were accustomed to resort in great numbers, and which were first visited in 1745, were for some time the only islands that were known, until a scarcey of land and sea-animals, whose numbers were greatly diminished by the Russian hunters, occasioned other expeditions. Besides the native copper which is found on the coast of this island, the true right campfire-wood, and another sort of wood, very white, soft, and sweet-scented, are found among the floating bodies which the sea calls upon the shore. The copper lies on the shore in such abundance, that many ships might be laden with it; and an Indian trader might make a profitable voyage from thence to China, where this metal is in high demand. This copper is mostly in a metallic or malleable state, and many pieces of it seem as if they had been formerly in fusion. This island is not high, but has many hillocks, each of which has the appearance of having formerly been the funnel of a volcano. This island, as well as the others in its vicinity, are subject to frequent and violent earthquakes, and abound in sulphur. (Coxe's Russian Discoveries.) From the account in Captain Cook's Third Voyage (vol. iii. p. 347,) we learn, that, on Mednoi and Beering's island, scarcely a sea-ottter is now to be found; though it appears from Muller, that in his time they were exceedingly plentiful.

Copper Plates for Engraving. We are favoured with the following account of the method of preparing copper-plates, as practised at present in London, by Mr. Harris, form-in-law and successor to Mr. Whittow of Shoe-lane.

A sheet of copper must be chosen as free as possible from flaws, and of a somewhat greater thickness than the finished plate is intended to be: it is then to be scraped all over with a file, in shape something like the head of a spear, and fixed in a handle long enough to go under the arm, the other hand holding the tool near the cutting part. When this has been perfectly freed from the outward crust, scales, or rust, it must be carefully examined to see if there are any holes or flaws in it; if there are (which is almost always the case), they must be scooped out by a tool called a scoop, or scoop. This being done, it is next to be well and regularly hammered all over on an anvil, of a considerable degree of convexity, in order to harden it; and afterwards on a broad and nearly flat anvil, to flatten and planish it. After this has been performed, it is to be cut to the size wanted, and the edges a little chamfered or bevelled, and is now to be floured, that is, rubbed all over with a fine cutting, but not very coarse, grit flour, care being taken to use a great quantity of water, to float off the particles mutually abraded from the copper and flone. When it is judged that all the marks of the scoop and
COP

are rubbed out, a stone of a fine grit is to be used in the same manner; and after this a third.

The two flint-mentioned stones are found at the ironmongers in London, under the name of "Carpenters’ stone"; the best kind are brought principally from the coal fields in the neighbourhood of Bilston in Staffordshire. The flint used is called "Water of Aye stone," and brought from Dumfriesshire. All the three kinds contain a considerable quantity of argill in their composition. Lastly, a fine grained argillaceous grit, brought from the neighbourhood of Sheffield, has been used instead of the Bilston flint.

After the operation of flinting has been performed, the plate is to be "polished." This is done by rubbing it first with charcoal of birch-wood, or elder, and water, and then with charcoal of willow; the latter gives the finer polish, particularly if oil instead of water be used. Sometimes the plates are finished by burnishing, but this is not now often done.

The charcoal is not prepared by the copper-plate makers, but is procured from the dealers in that article by the workmen, who take a plate of copper, and by trial discover which pieces are fit for their purpose.

**Copper-Plate Printing.** See **Rolling-press Printing.**

**Copper-Plate Works,** in Calico-Printing. The application of engraving has given birth to a new and important branch of calico-printing. It first introduced those machines whose subsequent improvement has so much contributed to the perfection of the art, and which surpass the ordinary mode of block-printing, not only in neatness, accuracy, and precision, but still more in the economy and activity with which the labour is performed.

These machines are of two kinds, the flat presses, and the rolling or cylinder presses. The flat presses, in its original form, was merely a modification, considerably enlarged, of the press for ornamental prints or engravings; to which was added a contrivance for joining, with accuracy, the numerous and facsimile impressions necessary to cover a piece of cloth. It was confined at first to one colour, but later improvements have extended it to two and even three. The single colour presses are, however, principally in use.

The cylinder, or rolling-press, is of later invention, and differs from the former chiefly in the substitution of an engraved cylinder for a flat plate. With the latter the cloth is printed by facsimile impressions, in which the accuracy of the joining is of great importance: in the rolling-press, the revolution of the engraved cylinder forms one continuous impression, from one end of the piece to the other, in which there are consecutively no joinings. This is a great advantage, especially in small and delicate patterns, where a variation of a hair's breadth in the joint is readily perceived; but its great superiority over the flat presses consists in the economy of time and labour. With a well-constructed cylinder-press, and proper arrangement for accelerating the work, one man and a boy will print 200 pieces, of 28 yards each, in the same time that a flat press man will print 12 pieces, or a block printer 8; that is, in one day. They are constructed to work one, two, and even three colours, but are generally confined to one; the difficulty and delay in adjusting the several cylinders to each other, when more than one colour is worked, counteracting, in great measure, the chief advantage of the machine. For a description of these presses, and the mode of working them, see **Press.** See also the article **Engraving.**

**Copperas,** a term employed popularly and by the old chemists synonymous with vitriol. Of Copperas there are three kinds, the **Green or Sulphat of Iron,** the **Blue or Sulphat of Copper,** and the **White or Sulphat of Zinc,** which bee.

The former is distinguished in common by a variety of names, as Martial vitriol and Roman vitriol, but most commonly by the names of green copperas or green vitriol. It is seldom made by the direct combination of sulphuratic acid, with the oxd of iron, which constitutes this substance, except for the purposes of experiment in the laboratory of the chemist. The common, as well as the refined, is manufactured on the large scale, as an article of commerce, in the neighbourhood of collieries, and is in some instances found native. It was known to the ancients, as Pliny informs us, (N. H. i. xxiv. c. 12.) and denominated by them Mity, Sory, or Caleanthum. Concentrated sulphuric acid has scarcely any action on iron; when it is heated the acid is decomposed, part of its oxygen combines with the iron and formphorous acid gas is evolved, but when diluted sulphuric acid is added to iron filings, a violent effervescence takes place, and hydrogen gas is disengaged; in this process the water, with which the acid is diluted, is decomposed, the oxygen of which combines with the iron; and converts it into an oxide, whilst the hydrogen escapes in the form of gas, the solution is of a green colour, and by evaporation affords crystals of sulphate of iron which are transparent, of a fine green colour, in the form of rhomboid prisms, having an acid astringent taste; this salt almost always reddens vegetable blues, is very soluble; two parts of cold water, or less than its weight of boiling water, being sufficient for its solution.

The mode of preparing it, as an article of commerce, is pursued principally, as before observed, in the neighbourhood of coal pits, in many of which a substance is found in great abundance, which, though injurious to the coal, forms nevertheless a valuable material as being the basis of copperas, known by the name of pyrites or brasses; these are carefully separated from the coal, and the necessity which this labour occasions, is amply repaid by the produce of the manufacture; the procxes is at once simple and economical, and does honour to the intelligence of those who flirr feggeht it. A large area of ground is inclosed, to which a gentle but sensible declivity is given; the surface is made quite level, and covered with an uncultivated clay, which is every way extended and smoothed, as if plattened, in order to prevent the water from infiltrating into the earth; at the same time a funnel is formed in the midst of the area, for collecting all the water in one point, and conveying it to a reservoir; the area being thus prepared, the pyrites are spread all over its surface, in layers one above another to the height of several feet; care is taken in placing the different pieces to leave intervals for the adnmission of the air: now these pyrites contain iron in combination with sulphur, when they are exposed to the alternate action of water and the atmosphere, they undergo a material change, the water is decomposed, one of its constituent parts, namely, the oxygen, combines with the sulphur, and forms sulphuric acid, or oil of vitriol; the hydrogen escapes into the atmosphere, by this means a soluble powder is formed, the tinge of which is aulbre and alptic; the decomposition is materially assisted by occasionally turning the pyrites with rakes having long iron teeth, like those used in Glasgow and neighbouring places, for stirring the boiling ingredients of the glue maker, by which means new surfaces are presented to the action of the atmosphere. In summer, when it is long dry weather, it is necessary to sprinkle the brasses frequently with water, to wash away the salt which is already formed, and also to produce that humid warmth which accelerates still further the decomposition; gentle showers are therefore excellent for bringing forward this part of the operation. The water loaded with vitriol, finding
finding a clay bottom, which prevents its losing itself in the earth, flows down the inclined plane, and falls into the reservoir, in which a quantity of old iron is placed, purchased principally from the smiths and the cooperers, as their refuse. It is well known that, during the decomposition of the pyrites, more sulfuric acid is produced, than can be contained in them; it neutralizes; the refuse iron is therefore placed in the reservoir and the liquor run upon it, in order to combine with the superabundant acid. The natural evaporation which takes place here adds to its strength, and, when it is conceived to be properly prepared, it is drawn off into a second reservoir, attached to the workhouse of the manufactory; from thence it passes into leaden boilers, where it is made to boil and evaporate by a large fire, formed of the most inferior kind of coal; when the liquor is brought to a proper flatness, it is run out by flypoops, or drawn out by pumps, into long wooden troughs, where it is crystallized by the operation of cold, the crystals attaching themselves to twigs and branches of trees, which are suspended in the troughs for the purpose of being hung over pieces of wood, several of which are laid across the top of each trough; from these branches they are taken and dried, and are then ready for the market.

Refined Copperas is an improvement in the mode of preparing copperas, and was discovered by the late Mr. Thomas Barnes, of Walker, near Newcastle-upon-Tyne, a coal vessel of the first eminence in that neighbourhood; this is effected by merely evaporating hill further than in the common mode, the water of crystallization, and attending about the whole proceeds to a little more cleanliness and exactness in the manipulations.

Two or three men are sufficient to manage a manufactory of either kind, and to produce a great quantity of the articles; considering which, and the rate it sells at, present (1806) from 10 to 14d. per ton, it ranks with the most beneficial manufactories.

Amongst the few places in which this salt is found native, we shall only notice that at Hurlet near Paisley, in a stratum of scinitus, sunk through in 1765 to a seam of coal, pyrites abound so much, that native copperas is sometimes found; it does not in this instance lie in any regular bed, but is intermixed through the stratum, and separated from the coal by the workmen. These works were established in 1757 by a company of gentlemen from Liverpool, for the sole purpose of making alum, but finding both pyrites and native copperas, they added the manufacture of that article also.

COPPERAS. See PYRITES.

COPPERMINE, in Geography, a large river in the central parts of N. America, reckoned to be the most northern in the American continent. Pursuing a northern course, it falls into the sea in lat. 72°, and W. long. 120°, according to Mr. Hearne, and 113° according to the position alluded to by Mr. Arrowmith. In 1771 Mr. Hearne arrived at this river, who found that it flows into the Arctic ocean, or rather, as he intimates in the preface to his book, published in 1795, into an inland sea like that of Hudson. From his journeys, performed in 1769—1772, we may infer, with a great degree of confidence, that the search after a N. W. passage is not likely to succeed. Upon his arrival at the copper river, on the 14th of July 1771, the savages who attended him murdered, in a shocking manner, some Mikem families. On the 17th he was within sight of the sea; and commencing his survey, pursued it to the mouth of the river, which he found so full of shoals and falls, that it was not navigable even for a boat, and that it emptied itself into the sea over a ridge or bar. As the tide was out, he perceived

by marks on the edge of the ice, that it flowed about 12 or 14 feet, and of course could reach but a little way within the river’s mouth, and he found the water perfectly fresh.

He concluded that this river ran into the sea, or some branch of it, by the quantity of whalebone and seal-skins which the Thayers (Elkseers) had at their huts, and also by the number of seals which he saw on the ice. It has been suggested that, as he did not take the water, which seems somewhat surprising, this sea, or branch of it, as he conceived it to be, might have been a fresh water lake. Seals, it is observed, are not uncommon in the sea of Baikal, and the whalebone might have been procured in barter. The supposed tide is not unknown on occasion of high winds in the southern lakes. However this be, Mr. Hearne says, that he had an extensive view of the sea, and that, from the mouth of the river, it was full of islands and shoals, as far as he could see with the assistance of a good pocket telescope. The ice was not then broken up, but was thawed for about 3 of a mile from the main shore, and a little distance round the islands and shoals. The Ikimos here were of a dirty copper colour, and rather shorter in stature than those to the south. Their kettles were made of lapis sullaris, of a mixed brown and white; and their hatchets and knives were of copper. The dogs have sharp creet ears, sharp noses, and bushy tails, being a fine breed of that sort. Many kinds of sea fowl were observed; and in the ponds and marshes swans, geese, curlews, and plovers. The quadrupeds are mule cattle, rein-deer, brass wolves, wolvereens, foxes, Alpine hares, squirrels, ermines, mice, Mr. Hearne, in the prosecution of his survey, visited one of the copper mines, about 30 miles S.E. from the mouth of the river, which was merely a hill that seemed to have been rent by an earthquake, or perhaps by subterraneous water. The copper is found in lumps, and is beaten out by the help of fire and two stones.

COPPER, MINE hills, hills of N. America, in N. lat. 68° 50’. W. long. 112°.

COPPET, a small town of the Pays de Vaud, in Switzerland, delightfully situated on the banks of the lake of Geneva, 12 miles N. of Geneva. It is an ancient Swiss barony, comprising eight villages besides the town; its territory produces excellent red wine. The castle which commands the lake sustained an obstinate siege in 1558 against the troops of Berne, who at last reduced it to ashes. In the year 1657 the barony of Coppet was bought by Frederick, count of Dohna. He rebuilt the castle in a modern style, but his son sold the estate to an inhabitant of St. Gall, from whose descendants it was purchased some time before the French revolution by the celebrated Necker, who expended large sums in embellishing the seat, the situation of which is truly enchanting, and where he closed his chastened career.

He left it to his daughter, the baroness of Stahl Hollein, whose name is dear to French literature, and who was banished to this estate in 1807, for having produced the interesting novel of Corinna. Durand. Statistique Elemenarle de la Suisse 1795.

COPPI, JACOPO, in Biography, confided by Lanzi the fame person with Jacopo del Megio, was born in the Florentine state in 1527, and was employed, in concurrence with the other expert mannerists of his school, in the large altar pictures of the church of Santa Croce at Florence. If, however, we may judge from the critiques of Borghini and other writers, his merit upon this occasion appeared less conspicuous than in some small pictures of fabulous subjects, which formed part of the ornament of an elevato executed, under the inspection of Vafari, the chief of the Florentine seigniour of that period, for the prince Francescone de Medici; but his masterpiece is a picture representing the crucifixion in
in the church of St. Salvatore at Bologna, which, according to Lanzi, is nowise inferior to the finest works of Vajari himself, and may indeed rank with the best productions of the Bolognese artists prior to the Caccia. It is dated 1579.

The artist died in 1611. Lanzi, Storm Pittorese.

COPPICE, in Rural Economy, a low form of inclosed wood, which is cut over at stated periods, for different purposes.

Thickly covered woods, wherever there is much demand for the various small fluffs which they are capable of affording, yield considerable returns to their owners; particularly where proper care is taken in felling and preserving them against live flocks.

In cases where new coppices are to be raised, it is necessary to bestow great attention on the nature of the soil, and the exposure of the land; adapting the trees and plants to the nature of these, as much as possible; and at the same time, taking into consideration the sorts that are the most useful, and most in request in the particular district or vicinity: as this sort of wood is in general disposed of to the greatest profit and advantage, where there is little trouble of carriage. The ground should be well drained, where it is inclined to be wet, and also well inclosed from the cropping of cattle. Some likewise advise, that where it is covered with bushes or briars, that they should remain to shelter the young growth of wood; and that if there happen to be a moderate quantity of young oak and ash-trees on the spot, to let them stand by all means; always keeping in mind how necessary shelter is for the growth of wood of all kinds and sorts.

But that in newly planted coppice-woods, where all the plants are of the same age, there is not the same reason for letting them stand before they are felled off for underwood, as for young trees planted to fill up old woods. Those which are intended for underwood may, in such newly planted woods, be cut off when planted, or at any age from eight to fourteen years, without injury. Indeed, young woods should not stand too long previous to the first cutting. It is observed in the seventh volume of the Letters and Papers of the Bath Society, that the kinds of wood to be planted in coppices, either in making new ones, or filling up old ones, should be regulated partly by the demands of the country, but chiefly by the peculiar aptitude of the soil and situation to produce particular sorts. Let nature be the guide, says the writer, in planting, and you will seldom do wrong. Particular soils and particular situations will always favour particular kinds of trees; we need not look for the reason, but only for the fact.

The chalk hills of Hampshire are peculiarly proper for beech; the flinty loams and clays of the county, for oak and ash; the sandy steep sides of the Wiltshire downs, for hazel; and the sands of the same district, for alder; the rugged and almost naked rocks of Mendip, in Somersetshire, produce the lime tree and the walnut in the greatest luxuriance; and on the highest parts of the same Mendip hills, where no other tree can land the sea-breeze, lycamore flowering as well as in the moister fertile valley. Taking the general demand of counties, and the peculiarities of different soils, into consideration, it is affected that there is no kind of wood so generally proper for planting in coppices as ash: the value of ash poles being at least one-third more, and frequently as much again, per hundred, as that of other poles, as being applicable in all sizes to some useful purpose or other; the timber being always in request, and saleable at any age or size, at almost the price of oak; and the wood itself being as quick a grower as any, and quicker than most; and, above all, there being but few foils, from the blacket and wettet bogs to the highest and most exposed mountains, where it will not grow, are reasons why ash is one of the most profitable woods to plant in such coppices as are favourable to its growth. In soils and situations where ash does not grow kindly, let such other sorts of wood be planted as appear to thrive best in similar soils and situations in the same county. Spanish chestnut, though not for general a grower as ash, is a most excellent wood, either for timber or underwood, and wants only to be more known to be higher in estimation. It parts much of the properties of oak, but excels it in two points, namely, that it grows faster, and that the sap part of the timber is firmer and less corruptible. To fill up woods that are become thin by age or neglect, the proper time is one year, or at the utmost two years, after the underwood is cut. The young plants should be eight or ten feet high, and an inch and a half diameter at the ground, and should be planted without cutting off. If the soil be dry, no other preparation is necessary than barely digging the holes for the plants; if wet, deep drains should be made, to take off the superabundant water. The earth dug from these drains should be thrown out on the lower side of them, and upon this new earth the plants should be planted. If land of this latter description be black and peaty, ash is peculiarly proper for it; and will, if planted on the earth thrown from the drains, make a most surprising progress. If it be a stiff yellow clay, it is generally more favourable to the growth of oak than of ash. In such soils, oak for timber, with a mixture of willow, birch, alder, and Spanish chestnut, for underwood, will perhaps be the most proper. All these kinds should stand one round of the underwood; and if still weak, should stand two, before those are cut off which are intended for underwood. Birch plants are indeed an exception to this rule: they should always be cut off the first round of the underwood; for, if they are large when cut off, the flocks frequently decay and die. In all mixtures of kinds of wood for coppices, those sorts should be used which are not unfriendly to each other, and which will come round fit to be cut together at the same periods; and such kinds should be allowed to stand for timber, and that at such distances as to injure the underwood as little as possible. The plants for filling up old decayed woods of the coppice kind, should be the strongest and best of their kinds. Those which are weak at first will be drawn up by the surrounding underwood, and become, from their increased height, still weaker. At the next cutting of the underwood, they will be blown down; or, if cut off, the shoots will too soon and too fast grow up with the other underwood. Oak, ash, and Spanish chestnut, should be kept in a nursery for this purpose. Alder and birch plants grow plentifully spontaneously in some countries, and may be taken up for use; if none fresh are to be obtained, they may be raised from seed sown on a moderate hot-bed, in the open air. Alder is sometimes propagated by taking up old roots, and dividing them into several parts; and hazel may be propagated the same way. Willow is generally planted in cuttings; but a much better way, where there are any out willow flocks, is to plash down the shoots, and fill up the vacant places round such old flocks. The wild cherry, which will grow on almost any soil, and is easily propagated, makes an exceedingly good underwood, though as yet it is but seldom used for that purpose.

It is remarked by the author of Modern Agriculture, that the coppice-woods, when the flocks are young, whether of oak, ash, elm, or birch; or a mixture of these with other sorts, are very little attended to in any part of the island, fencing being the only particular which marks the difference between a good and a bad manager. But, he says, when the wood can be sold for different useful purposes, at various prices,
flashes of its growth, as is the case in many parts, an essential improvement in the management of coppices might be introduced with great propriety. In all such situations, if it would be profitable to the owners, were the shoots thinned two or three times between each general cutting. The weedings or thinnings would do much more than delay the expense, while, by admitting a more free circulation of air, and by cutting off the supernumeraries, the principal shoots would advance more rapidly, and become by that means fit for sale, perhaps, two or three years sooner than they do by being allowed to remain in a neglected state. This is a circumstance that particularly merits the attention of those who are favorably situated, in regard to market, for the various productions of coppices; as having two or three years in the regular cuttings would materially enhance the value of the land so occupied.

He further states, that several other improvements in the management of coppices might certainly be effected, were the owners to bestow due attention. It frequently happens, that, from mismanagement in cutting, many of the ftools become useless, while scraggy thorns, brambles, &c., are allowed to spring up, and occupy the place of more valuable plants. Were the owners of coppices in general to permit their labourers, or other indigent poor people in the neighborhood, to dig up the decayed ftools and useless fbrush-wood for fuel, under condition that they plant healthy vigorous ftools in their places, the coppices by this management would necessarily become more valuable. Much damage also frequently happens from allowing the unfelling wood to remain scattered over the surface of the ground, for a considerable time after it is cut. Every person must be sensible, that if the cuttings are allowed to remain in this situation till after the young fshoots begin to spring, it is scarcely possible to remove them without breaking or otherwise injuring these tender sprigs. In all auctions of coppices, it ought, therefore, to be an article of sale, that the whole should be carried off the premises in a limited time; and the forester, or wood-officer, should receive injunctions to see this condition of the sale strictly fulfilled.

Much greater care is requisite, the same writer says, in cutting coppices properly than the owners, in many cases, are disposed to bestow. It cannot be supposed, when fifty or a hundred purchasers, with their attendants, are allowed to use their axes with no other view than to cut the wood which they have purchased, without regard to the successe of what may be called the next or following crops, that any regard will be beclawed as to the proper manner of cutting. It is certainly of much importance, not only for the future vigour, but also for the durability of the ftools, that the items or fshoots should be cut in that manner which experience has proved most effectual for answering both purposes. The fshoots ought to be cut as low as possible, without injuring the ftools. When that practice is adopted, the ftools remain nearly even with the ground, and consequently in a much better state of preservation than by cutting the fitems at the height of six, eight, or ten inches; as, by this method of cutting being frequently repeated, the ftools get in process of time, as he has frequently seen, to the height of several feet above the surface soil. Another common error, and which woodcutters of the above description may be supposing very guilty of, is to leave the butt ends of the fitems jagged and uneven, and part of the bark torn off, or loosened all the way down to the floor, in which nothing can be more injurious. The butt-ends of the fitems ought rather to be brought to a point in the middle, and the bark remain quite close and firm, otherwise dew and rain drop into the hollows, and either rot or otherwise prove ruinous to the future health and vigour of the ftools. In short, to render a coppice both valuable and lasting, a larger system of management ought to be adopted. For the reasons mentioned above, they ought to be thinned two or three times between every general cutting. The useless fbrush-wood ought to be rooted out, and other more useful plants substituted. Where too much water abounds, drains ought to be opened; the fences at all times kept in a substantial state of repair; and on no consideration whatever should the purchasers of coppices be allowed to cut the underwood.

Men employed by the owners, and who are properly bred to the businefs, ought only to be employed; who, by following proper pains in dressing and pruning the ftools and ftools as they go along, would thereby ensure the springing of numerous and vigorous fshoots the following season.

The periods of cutting coppice underwood must be regulated, it is observed in the work first mentioned, by the luxuriance of its growth, and by the demand of the country, and the uses to which the wood is to be applied when cut: but, in general, the common rule of trade will hold good here, viz., “that small gains and quick returns make the dealer rich, but long credit ruins.” In the article of underwood, not only the interest of money, but the loss of the trees, and the advantage of the wood will be cut as early as it is fuitable. As soon, therefore, as any kind of wood is fit for the uses of the country, it should then be cut; unless it can be made appear, that it will pay compound interest for standing longer, or, in other words, will pay not only the simple interest of the first value, but also the loss of so many years growth of the wood, as far advanced towards another crop. Wood merely for fuel can scarcely be cut too young.

Hazel is usually fit for hurdles and dead hedges, from nine to twelve years old; ash for sheep-cribs, at the same age; and ash and other woods for hop-poles, from eleven to fourteen years old: while ash for carpenters, and other large uses; alder, birch, and willow, for rafters, turner’s uses, pattens, clogs, coal-pit uses, &c. muft stand from sixteen to twenty years, before the poles are large enough for their respective purposes. It therefore behoves every owner of woods of the latter description, unless he is public-spirited enough to give up his own profit to the good of the public, to consider well before he suffers his wood to stand to the age of sixteen, eighteen, or twenty years, whether the value of such wood, when cut younger, and sold for other purposes, added to the interest thereof up to the usual period of cutting, and the gain by the growth between those two periods, will not more than equal the value the wood will be of, if suffered to stand so long; and if so, whether he ought not to cut his wood at shorter periods. He will have this additional satisfaction, that, by more frequent cuttings, his wood will be the less liable to decay, by the strong shoots smothering the weak ones, as is before explained: and will have an opportunity of letting up more fapolings for timber than he could otherwise do. There are many opinions respecting the most proper time of the year for cutting underwood, but there is one rule which, on the feller’s part, is without exception, viz., that the older the wood is, the later in the spring it should be cut. When old wood is cut early in the winter, and a hard winter follows, the damage done to the ftools is very great: young flourishing wood will bear cutting at any time. But on the part of the buyer, it is allowed that all woods are more durable, when cut in the most flagrant state of the sap; and in all cases where heding is required, such as hulks, hoops, and even dead hedges, the wood cannot be cut too early in the winter, being,
ing, if cut when the sap is rising, brittle, and unfit for those purposes. Oak underwood will, at the present price of bark, pay well for standing till the sap is up for barking it; and it seldom happens that the flocks are injured by cutting it fo late in the year.

The best way of disposing of coppice-underwood, to answer the purpose of the farmer, is, in the opinion of this writer, to cut it at the seller's expense, before it is fold; to lay it out in ranges or drifts, according to the custom of the country; to value it in that state, and fell it in such fixed lots as the number of buyers may warrant: always keeping up a sufficient number to make a competition, and particularly to oblige the buyers to clear the whole out of the wood by the 24th day of June; and never to furnish them to bring their horses into the woods, after any new flocks are shot out, without puzzling them, or at least tying up their heads.

But in the View of Modern Husbandry, Mr. Donaldson thinks, that the more approved method of disposing of coppice, or other under-sized wood, is that which is practised in Northamptonshire. When the season for cutting arrives, which is during the winter months, or before the sap begins to ascend, that operation is performed by people employed by, and who work under the direction of, the owner of the woods or his agent. The part of the wood intended to be sold, is parcelled out into regular fixed lots, to suit the convenience of the intended purchasers. The whole of the underwood, growing upon each lot, is indiscriminately cut, and laid in one direction. As soon as the operation of cutting is completed, and the wood parcelled out in a proper manner, a valuation is put on each lot or parcel according to its quality, and the whole is then sold by public auction to such persons as incline to become purchasers, who, over and above the price of the underwood, repay the expense of cutting. This is, however, by no means the general mode in which woods of this description are cut. It is a very common, but a very bad, practice, to fell the coppice under the condition that the purchasers are to be at the expense of cutting it down. This is often performed in such a careless manner, that the flocks are so greatly injured, that they either rot or die, or a few weak flinted shoots only springing up.

The price of coppice or underwood varies so exceedingly, that it is almost impossible to form any idea of the value of the acre. Perhaps 8 or 10l. may not be far from the average price of coppices, not remarkably situated in regard to market, and when they are cut every twelve or fourteen years. But the value of coppices depends on many circumstances; as the roots of wood, the ufs to which they are applied; the price of bark, &c. In some parts of Kent, where hop-poles are in great request, an acre of coppice will yield sometimes 30 or 40l. at a cutting. Whereas in Scotland, where the coppices are for the most part oak, and where the wood is chiefly used for fuel, or converted into charcoal, the value of the coppices consists almost entirely in the quantity and quality of the bark, the wood being little more than sufficient to defray the expense of cutting and peeling.

Mr. Mathlill, in his "Management of Landed Estates," has remarked, in respect to flub or coppice wood, that "the proper harvesting it as of timber, depends on situation and other circumstances. And that the age or fire of cutting must ever be guided by the demand in a given district; whether it be for the use of coal-mines, or for cord-wood, hop-poles, hoops, flocks, faggot-wood, or other ware."

"The mode of disposing is," says he, "to be determined upon by the succeeding crop. If the land be intended to be appropriated wholly to coppice wood, it is generally the most eligible to dispose of the crop, as it stands, by auction or proposal. But if seedling plants are to be set out for timber stands, or the young flubs from the fubs to be trained up, in the grove manner, it is requisite that a proprietor should employ his own people in reaping the crop, and making it up into such wares as are the most saleable and profitable."

"In cutting down coppice-woods, the main objections are," he thinks, "to cut them in seafon, to take off the flems, clean and smooth, with upward strokes of the axe, that the flubs may shoot with the greater certainty; and to cut them off as low as convenience will allow, in order that the shoots may be few and vigorous."

Coppice-Wood, is that sort of small woody growth, which is raised in inclosed woods of the coppice kind, and which is converted to various purposes of the farmer and manufacturer, such as cord-wood, hop-poles, hoop-fluff, hedge-fluff, faggot-wood, and various other wares.

COPPLE-STONES, in Natural History, globuli lapid. rotul. lapidae, boulder-stones, rolled-stones, or pebbles, as some call them, are rounded and worn fragments of stones and rocks, that are not invested with an exterior flinty crust or skin, occasioned by concentric laminae of the stone, but which the internal plate laminae broken off and rounded at their edges by attrition. It is of the utmost consequence, in all researches relating to the strata of the earth, to distinguish carefully between Coppie or boulder-stones, and original nodules of the strata.

COPY, in Rural Economy, is a term sometimes provincially employed to signify a wood of the coppice kind. Thus to copy, in some districts, signifies to cut over for underwood.

COPRATAS, in Ancient Geography, a river of Asia, in the Parthian territory, mentioned by Strabo and Diodorus Siculus; the latter of whom says, that it discharged itself into the Tigris.

COPRIS, a name given by Strabo to a shore of Sicily before Taormenium, because the wrecks of vessels that were lost in the gulf of Charybdis were collected in this place.

COPROCRITICA, from ἐκκατέρωσις, excrement, and ἐκκατέρωσις, separate; medicines which purge away the excrements in the guts.

COPROPHAGOS, from ἐκκατέρωσις, and ιππ. ἐκτρ., the dung-fly, in Natural History, the name given by many authors to the common yellowish fly found on human excrements. There are several other species found on the excrements of various animals, and hence called merdices.

Gen. Ch. Hermacrpidia-flowers. Col. Perianth inferior, one-leafed, short, live-touched, permanent. Cor. monopetalous, b-loll-shaped, much larger than the calyx, five, six, or seven-ellipt. segments seate, erect. Stam. Filaments five, or seven, capillary; anthers oblong, bised at the base, erect, a little incurved, acuminate. Fil. Gom. superior, oblong; styles two, ribiform, slightly cohering at the base, longer than the corolla, divergently; stigma simple. Peric. Berry ovate-globular. Seeds two, flat on the inner,
under, and convex on the outer side, separated from each other by the pulp of the berry. Male flowers, Cal., Cor., and Stam., as in the hemiphrodite. Pitt. abortive.

Eff. Ch. Calyx one-leaved, five-toothed. Corolla five, six, or seven-eleft. Stamens five, six, or seven. Styles two, long. Berry with two seeds.

COPSE, in Agriculture, a term applied to the regulating iron apparatus, which is fixed to the end of the beam of a plough, and to which the team is attached. These irons are of very different forms and contructions according to circumstances.

COPTIS, in Botany, (from κόπτω, fendo; a name taken from the cut leaves of the plant.) Linn. Trans. vol. viii. p. 355. A genus formed by Mr. Salisbury for Helleborus trifolius of Linnaeus, which differs from the other helbores, in having a caducous corolla. See Helleborus trifolius.

COPTISES Nomos, a name of Egypt, extending along the bank of the Nile, which derived its name from Coptos or Coptis, its capital.

COP'TOSKILL, in Geography, a town of America, in the state of New York; 42 miles N. of New York.

COP'TOS, Coptus, or Coptis, in Ancient Geography, now Kepes, a city of Upper Egypt, three miles distant from the Nile, and connected with it by a navigable canal. It was the centre of communication between Egypt and the Red Sea, by a N.E. route to Myos Hormus, situated on the western coast of the Red Sea, and by a S.E. course to Berenice, which was the staple of the trade with India. If Ptolemy is to be credited, Isis, upon receiving the news of the death of Ophiis, cut off one of her locks in token of grief; and hence the place was named Coptos, which, in the Egyptian language, is said to denote want or privation. This city was inhabited both by the Egyptians and Arabs, and Ptolemy calls it the emporium of commodities brought from India and Arabia, which were conveyed by the Nile to Alexandria. Ptolemy mentions Julopolis, as being two miles distant from Alexandria, and says that from Julopolis to Coptos, the voyage of 303 miles was performed in 12 days, when the northerly winds blew; the distance between Berenice and Coptos was, according to the same author, 258 Roman miles, and the journey was performed in 12 days. The road, however, lay through the defant of Thebais, almost entirely delitnate of water; but Ptolemy Philosophus not only repaired the road, but made provision for supplying the want of water by farrishing for springs; and wherever these were found he built inns, or more probably in the exterior style caravaners, for the accommodation of merchants. (Strabo, lib xvii. p. 1157.) In this channel the intercourse between the east and west continued to be carried on during 250 years, as long as Egypt remained an independent kingdom. The Cnibrians were formerly very numerous in the city of Coptos. The rubbishes of this ancient city may fill a circumference of two miles, and sufficiently evinces its former extent. Amidst the ruins are seen several small columns of grey granite lying on the ground, and some large stones, engraved with hieroglyphics. Near it is also a small part of a bridge over the canal by which water was conveyed from the river into a large basin. This place has occasionally afforded medals, small fragments of earthenware, pieces of rock crystal, and precious stones.

COPULA, in Logic, a verb that connects any two terms in a proposition, either negative or affirmative: as, A rofe is foon; where it is the copula.

COPULATION. See COITION, CONGRESS, and COMMUNICATION.

COPULATIVE Propositions, are those which include several subjects, or several attributes joined together by an affirmative or negative conjunction.

Thus, v. gr. Power and riches do not make a man happy.

Where and is the conjunction that couples power and riches.

COPULATIVE Conjunction. See CONJUNCTION.

COPY, in Law, a transcript of a writing or instrument, made for the use and satisfaction of some of the parties concerned; or in order to preserve the memory thereof. See COPIA.

The copy of an inrolled deed is admitted in evidence; but not the copy of a will of lands nor the probates, nor of a common deed where the original may be procured. Few ancient documents do now subsist otherwise than in copies.

Copy is also used for an imitation of any original work; particularly a painting, draught, figure, &c.

The following proofs for taking a copy of a recent MS., was communicated to the Philomathic Society at Paris, by M. Charles Coquebert. 1 It consists in putting a little sugar in common writing ink, and with this the writing is made on common paper, fixed as usual, when a copy is required; this unfixed paper is taken and lightly moistened with a sponge. The wet paper is then applied to the writing, and a flat iron, such as is used by launderers, of a moderate heat, being lightly passed over the unfixed paper, the counter-proof or copy is immediately produced. This process is the more interesting, as it requires neither machine nor preparation, and may be used in any situation. That sugar prevents ink from speedily drying, has been long known (i.e. ink); and this method of imprefion has been used in some of our public offices, and elsewhere in England, for some years.

Copy, among Printers, denotes the manuscript or original of a book given to print from.

To call off a copy, is to make a computation of the number of sheets a manuscript will make in print.

In the bookmakers' style, a good copy is that which produces a faleable book.

Tenent by Copy of court roll. See Tenant.

COPY-HOLD, is a tenure for which the tenant has nothing to shew but the copy of the roll made by the reward of the lord's court.

The reward of the court is, among other things, to inroll and keep a registar of all such tenants as are admitted to any parcel of land, or tenement, belonging to the manor; and the transcript is called the copy of the court-roll, which the tenant keeps as his own evidence.

This tenure is called a life tenure, because the tenant holds, in some sort, at the will of the lord. Fitzherbert says, it was formerly called tenement in villanous; and that copy hold is but a modern name.

This
This is the land which the Saxons called *folkland*, as being held *sine frigio* in contradistinction to *boculand*, or charter-land, *sine ecrifta*, and new free land, or *free hold*. However, it is not simply at the lord's will, but according to the custom of the manor; so that if the copyholder does not break that custom, and forfeit his tenure, he seems not to stand at the lord's court. These customs are infinite; varying in one point or other, almost in every maner.

Copy-holders are, in reality, no other but villeins (*villeg*), who, by a long series of immemorial encroachments on the lord, have at last established a customary right to those estates, which before were held absolutely at the lord's will.

This affords a very substantial reason for the great variety of customs that prevail in different manors, with regard both to the defendant of the estates, and the privileges belonging to the tenants. By various means the generality of villeins in the kingdom have long ago sprouted up into copyholders; their persons being分支机构 by manmination, or long acquiescence; and their estates, in *fringe*, remaining subject to the same servile conditions and forfeitures as before; though, in general, their villein services are usually commuted for a small pecuniary quit-rent. In some manors the copy-holders are bound to perform the most servile offices; as to hedge and ditch the lord's gardens, to chop his trees, and reap his corn, and the like; the lord usually finding them meat and drink, and sometimes, (as is still the case in the highlands of Scotland) a minareel or piper for their diversion. Thus also, in the kingdom of Whidah, on the coast of Africa, the people are bound to cut and carry in the king's corn from off his demesne lands, and are attended by music during the whole time of their labour. See *Whidah*.

The custom of the manor is the life of copy-hold estates; for, without a custom, or if copyholders break their custom, they are subject to the will of the lord; and as a copyhold is created by custom, it is also guided by custom. (4 Rep. 21.) A copyholder, whilst he performs his services, and doth not break the custom of the manor, cannot be ejected by the lord; if he he, he shall have trepals against him:—but if a copyholder refuse to perform his services, it is a breach of the custom, and forfeiture of his estate. Some copyholders hold by *the verge in ancient demesne*; so that though they hold by copy, they are a kind of free-holders; some others hold by common tenure, called "mercy copyhold," whose land, upon the commiss of felony, echeats to the lord of the manor.

It should be recollected, however, that copy-hold land cannot be made at this day; for the foundation of a copyhold is, that it hath been demised time out of mind, by copy of court-roll; and that the tenements are parcel of, or within the manor. 1 Init. 58. 4 Rep. 24.

Estates held by copy of court-roll, and not at the will of the lord, have been demised free-hold by lord Coke (1 Init. 59 b.) and also by others; and by way of deputation from the ordinary kind, they have been denominated "customary free-holds." Tenants of this description have claimed the right of voting at the election of the knights of the shire. But the flat. 31 Geo. II. c. 14, enacts, that no person holding by copy of court-roll, should have this privilege.

In some manors, where it has been the custom to permit the heir to succeed the ancestor in his tenure, the estates are called "copy-holds for life," in others, where the lords have been more vigilant to maintain their rights, they remain "copy-holds for life," only; for the custom of the manor has, in both cases, so far prevailed the will of the lord, that the services be performed or stipulated for by fealty, he cannot, in the first instance, refuse to admit the heir of his tenant upon his death; but, in the second, he must remove his present tenant, so long as he lives, though he holds nominally by the precarious tenure of his lord's will. If the lord refuses to admit, he shall be compelled in chancery. (2 Cro. 358.) And if the lord refuse to admit a surrender, on account of a disagreement about the fine to be paid, the court of B. R. will grant a mandamus to compel the lord to admit without examining the right to the fine. (2 Term Rep. 484.) But that court will not grant a mandamus to admit a copy-holder by defect; because, without admittance, he has a complete title against all but the lord. (2 Term Rep. 193.) Copy-holds descend, according to the rules and maxims of the common law (unless in particular manors there are contrary customs of great antiquity) but such customary inheritances shall not be affected; to charge the heir in action of debt, &c. (4 Rep. 22.) though a lease for one year, of copyhold lands, which is warranted by the common law, shall be affects in the hands of an executor. (1 Vle. 63.) Copy-holders hold their estates free of dower, being created by custom, which is paramount to title of dower. (4 Rep. 24.) By particular custom, there may be a dower and tenancy by the curtesy. (Cio. Eliz. 361.) There may be an estate-tenant in copyhold lands by custom, with the co-operation of the flat. W. II. And as a copyhold may be entailed by custom, so by custom the tail may be cut off by surrender. (1 Inf. 61.) A copyhold may be barred by a recovery, by special custom; and a surrender may bar the issue by custom. A fine and recovery at common law will not destroy a copyhold estate; because common law adjudgments do not work upon the assurance of the copyhold; though copyhold lands are within the flat. 4 Hen. VII. c. 24, of fines and proclamations, and five years non-claim, and shall be barred. (1 Rol. Abl. 506.) Copy-holds are not within the statute 27 Hen. VIII. c. 10, of jointures; nor flat. 32 Hen. VIII. c. 28, of leases; copy-holds being in their nature demissable only by copy; they are not within the statute of uses; nor are copyholds extendible in execution; but they are within the statute of limitation of actions, and the statutes against bankrupts. The lord shall have the custody of lands of ideots, &c. And a copyholder is not within the act 12 Car. II. c. 24, to dispose of the custody and guardianship of the heir; for, if there be a custom for it, it belongs to the lord of the manor. (3 Lev. 359. 1 Nelf. Abl. 493, 522.) A copyholder cannot convey or transfer his copyhold to another, otherwise than by surrender; which fee.

A manor may be held by copy of court-roll, and the lord of such manor may grant copies; and such customary manor may pass by surrender and admittance, &c. The fruits and appendages of a copyhold tenure, which it hath in common with free tenures, are fealty, services, (as well in rents as otherwise,) reliefs, and echeats. The two latter belong only to copyholds of inheritance, the former to those for life only. Besides these, copyholds have also heriots, wardships, and fine. See each of these articles. See also Forfeiture, Freehold, Surrender, and Tenure.

**COPY-HOLDER**, is defined by Weel, a person admitted tenant of any lands, or tenements, within a manor, which, time out of mind, by the use and custom thereof, have been devised to such as will take the same by copy of court-roll, according to the custom of the said manor.
COPYING of LETTERS, and other curiosities. The celebrated Dr. Franklin made several essays, many years ago, for speedily multiplying the copies of his own hand-writing, which he exhibited to M. Alexis Rochon, of the French National Institute, and director of the Marine Observatory at the port of Brest; an account of which he has given in his memoir on the Typographic Art. This method consisted in writing upon smooth paper, with ink containing much gum, which was afterwards heated with emery, or powder of cast-iron, and by means of a rolling-press, such as is used by the copper-plate printers, the strokes of the writing were transferred to a plate of soft copper or pewter. This plate supplies as many copies as the depth of the engraving can allow; but the copies are far from being beautiful, and the ground is spotted and foiled. Before Dr. Franklin’s process was communicated to M. Rochon, he showed him that by writing with a steel point on a copper-plate previously varnished, a more satisfactory result might be obtained, by etching the strokes with nitric acid and to a sufficient depth, for the subsequent use of a liquid ink similar to that of the printers. In this case, the plate may be wiped without precaution, and twelve or more copies may be pulled off upon coarse paper. These proofs are found and reversed; and, therefore, in order to have them neat and in the proper direction of the writing, it becomes necessary to place the same number of leaves of white paper, wetted and prepared, upon the twelve proofs; and while the ink is still fresh, the whole being passed together through the rolling-press, the same number of leaves of counter-proofs are obtained as there were proofs; so that instead of twelve turns of the press, thirteen will be required to supply twelve counter-proofs, very black, neat, and legible, even when the plate has not been perfectly wiped. This method is certainly not to be compared with fine engraving; but it may be useful in military operations, and all other cases in which a speedy multiplication of copies is required. No precaution is here necessary; whether the nitric acid be more or less strong, or remain a longer or shorter time upon the plate, or whether the plate be somewhat heated to increase the strength of the foment, the proofs of the operation will never fail; provided the steel point made use of to trace the characters through the varnish, shall lay the copper perfectly bare. It is of advantage that the nitric acid should bite deep, because the counter-proofs are, by these means, much darker. This might not be well wiped, because it is not of consequence whether the proof which is used to afford a counter-proof should be very clean, provided that it does not spoil the copy intended to be procured. The most liquid kind of printers ink may be used. See ENGRAVING and STEREOTYPE.

In 1780, Mr. James Watt, of Birmingham, obtained a patent for a new method which he had invented to this purpose; of which the following description is given in his specification: Let the letter or other writing, that is intended to be copied, be written with the ink heretofore described, or with any other writing-ink fit for the purpose. Take a piece, or pieces, of thin paper which contains no size, or glue, or gum or mucilaginous matter, or which at least does not contain so much size, or other matter, as would make it fit for being written upon. Cut this paper, or papers, to the size and shape of the writing of which a copy is wanted; moisten or wet the same thin paper with water, or other liquid, by means of a sponge or brush, or by dipping, or otherwise. Having moistened or wet the thin paper, lay it between two thick unsize thickness papers, or between two cloths, or other substances capable of absorbing the superficial moisture from the thin paper; when it has been slightly pressed between such thick unsize paper, or other substances, by the hand or otherwise, lay the said thin paper, so moistened and pressed, upon or under the side of the writing which is to be copied, and in such manner that the one side of the said moistened paper shall be in contact all over the side of the said writing, so intended to be copied; and that to the other side of the said moistened thin paper, there shall be applied a piece of clean writing-paper, or cloth, or other smooth uniform substance. Lay the said writing intended to be copied, with the thin moistened paper intended to receive the copy, (placed respectively as above directed,) upon the board of a common rolling-press, or of such of which a description and drawing are hereunder written and drawn, and press them once, or oftener, through the rolls of the said press, in the same manner as is used in printing by copper-plates; or, instead of using the said or any rolling-press, squeeze the said papers, placed respectively in the manner above described, in a screw-press, or subject them to any other prelure sufficient for the purpose, by means of which prelure, in what ever manner applied, part of the ink of the writing intended to be copied shall press from the said writing into, upon, and through, the said thin moistened paper, so that a copy of the writing, more or less faint, according to the quality of the ink and paper employed, shall appear impressed on both sides of the said moistened paper, vis. upon one of the sides in the natural or proper order and direction of the lines, as they are in the original writing, and on the other side in the reverse order and direction. But, in order to make the impression or copy of the writing more strong, legible, and durable, it is proper and useful to moisten the said thin paper, which is to receive the copy or impression, with the following liquid, instead of water or other liquid, and to proceed in all other respects as is above directed; or to moisten the said thin paper with the following liquid, and to dry the said paper, and, when a copy of a writing is required to be taken, the said paper, thus previously prepared and dried, ought to be moistened with water or other liquid, and to be proceeded with in all other respects as has been directed. The said liquid to be used for moistening the said thin paper, or for preparing the said paper previously to its being used, is made in the following manner: Take of dilute vineger two pounds weight, dissolve in it one ounce of the solid fat of borax; then take four ounces of oiler-shells, calcined to whiteness and carefully freed from their brown crust, put them into the vineger, shake the mixture frequently for four and twenty hours, then let it stand until it deposits its sediment; filter the clear part through unsize paper into a glass vessel, then add to the said mixture or solution two ounces of the best blue Aleppo galls bruised, and place the liquor in a warm place, shaking it frequently for twenty-four hours; then filter the liquor again through unsize paper, and add to it, after filtration, one quart, ale measure, of diffusil or other pure water. It must then stand twenty-four hours, and be filtered again if it shews a disposition to deposit any sediment, which it generally does. The liquor, thus compounded and prepared, is to be used as hath been directed.

N. B. In place of the vineger, any other liquor impregnated with a vegetable acid may be used; and, in place of the galls, oak bark, or any other vegetable astringent, or substance which is capable of becoming black, or deep coloured, with solutions of iron; and, in place of the oiler-shells, any other pure calcareous earth may be used. But if the imprefsums are not wanted to be very black, and the writing ink is good, water itself may be used to moisten the thin paper, as herein first directed. It may be found neces-
fairy to add more or less water, in the preparation of the above liquor to be used for moistening the thin paper, or to vary the proportions of the other ingredients, according as the paper is more or less perfected strong, or as the impression is required to be more or less deep colored. The writing-ink, which the patentee uses for letters or writings intended to be copied, is prepared as follows: Take four quarts of a meal mixture, of spring water; one pound and a half, of a tiny and coarse, of Alepog galls; half a pound of green copperas of green vitriol; half a pound of gum-arabic; four ounces of roach-alum; pound the solid ingredients, and infuse them in the water six weeks or two months, during which time the liquor should be frequently shaken; strain the liquor through a linen cloth, and keep it in bottles, closely corked, for use.

Plate III. Misellaneous, fig. 1. represents a front or end view of the rolling-prea invented by Mr. Watt, and referred to in the above specification. A B C is one of the ends of an iron or wooden frame, which serves to connect the two rollers. D D, are two wooden or metallic rollers, turned extremely exact, or truly cylindrical, and which are mounted on iron axes, firmly fixed in them. E E is a double-ended lever, by means of which the roller, on whose axle it is applied, may be forcibly turned round. F F represents the board of the rolling-preas, on which the writings to be copied are to be laid. N N is a piece of cloth, or other elastic pliable substance, placed next the roller, and above the writings to be copied: and the board. G, is a strong plank of wood, or plate of metal, serving to connect the two end-pieces of the frame at bottom. H H represents the edge of a common table, to which the preas may be fastened by the iron screw-crams I I. K is a slit, of which there is one in each end-piece of the frame; these slits are filled with elastic flax, or other metallic filings, or with some other elastic substances which serve to prea the two rollers forcibly together. L is a brass bolster, supported upon the springs, and serving to support the end of the axis of the under roller.

Fig. 2. represents a side view of the rolling-prea, in which A B, A B, are the two end-pieces of the frame. D D, are the two rollers. E is the double-ended lever. G is a strong plank, or plate of metal, which forms the bottom of the frame. H H is the table on which the preas stand. I is one of the iron crams which fasten the preas to the table; and M is a bar of iron which connects the upper part of the frame.

Fig. 3. represents a screw-preas, which may be used, instead of the rolling-preas, in tracing off impressions from writings. A A is a double-ended lever. B B the screw. C a block of wood, or metal, which the screw acts upon, and which is attached to it. D D the frame of the prea, made of iron or wood. E E is a moveable board, on which the writing to be copied is to be laid, with a cloth over it. F F the bottom or side of the prea, made of wood or metal. Be it remembered, that these preas are made of different sizes, according to the sizes or largeness of the writings intended to be copied. Those now referred to are drawn from one sufficiently large to take an impression from a folio page of writing or print paper, and are drawn to a scale of one inch and a half for each foot, or one-eighth of their natural size.

Fig. 4. represents one of Hawkins’s patent polygraphs, for making two or more copies of any writing at once. A A B, is an upright frame, from the upper piece of which is suspended a double parallel ruler, D D, E E ; a o, c, is another similar parallel ruler, of which fig. 5. is a plan, fastened to the board, F F, of the instrument. These two rulers are connected to a short bar, G; the vertical one, D D E E, by pivots at the end of the bar, I, and another two pieces of brass, g g, at each end of G; and the horizontal one, d d, e e, by pivots at the ends of its corresponding bar, b, working in holes in another arm of the same brass. The pens are connected with the bar, G, by a curved brass limb, a, turning on a screw put through the bar, G, as a centre. On the other side of the bar is a short arm, b, in the same piece with the limb; this is joined at its upper end to the end of a small rod, b, the other end of which is joined to another exactly similar limb, carrying the other pen. The pens are fitted into a small tube, called the pen-tube, having a shoulder at its upper end. This fits tight into a other tube, in the same piece with the curved limb, and is pulled in as far as the shoulder of the pen-tube will allow.

The weight of the machinery is suspended by eight small spiral springs, I, fastened to a ring fixed to the bar, G; their upper ends are connected with the end of a double jointed lever, K, which can follow the motion of the bar, G, without stretching the springs too much. The rod, L, by which the perpendicular motion is suspended, turns upon pivots working in pieces of brass beneath the piece, B: the right-hand one is called a regulator, and has two screws, one moving the pivot vertically, and the other horizontally, for adjusting the instrument. The two bars, d d, of the horizontal motion are connected with d d, by pivots at the end of b, so that d d can be lifted up without moving the other, while weight is supported upon two small brass wheels t t. The frame, A A B, when the instrument is not in use, turns down on the board, F F, and is kept fast by a spring lock, which is opened by pulling in a round button, L. The frame now forms the sides, and the front board becomes the lid, and, when shut down, is locked by a lock, M. In explaining the use of the instrument, we cannot do better than copy the printed directions fold with the instrument. Choose two goose quills, taking care they are of the size wanted; make them into pens, and put them into the pen-tubes. Having introduced them with the nibs first, apply the shoulder of the pen-tube against the semi-circular hollow, in the upright part of the gauge, Q, fig. 4.; and pull the pen through the tube, till the nib reaches a line drawn across the end of the gauge; slide the pen-tube into the fixed socket, until the shoulder of the pen-tube lies flat; holding the fixed socket, and not by the work, as so not to jar the machinery. If the polygraph is in order, the pens will now write, draw, or copy whatever may be required, with the greatest exactness. To prove the machine’s being in order, bring the pens to the upper part of the paper, and try if they both touch; if not, with a small screw-driver turn the perpendicular screw of the regulator, till they touch equally. Bring the pens to the bottom of the paper, and move the horizontal screw till they both touch. When a pen wants mending, nothing more is necessary than to take the pen-tube out of the socket, mend the pen, gauge it, and return it into the socket again. When the machine is out of use, wipe the pens clean, and place the left one, with the curved limb, on the hook beneath the horizontal rulers. Let down the frame. A A B, which falls by a spring-lock, and at the same time has the writing-board, which then becomes the lid of the portable case for the polygraph.

The patent now belongs to Mr. Farthing, Cornwall, who manufactures the instruments.

These instruments are made with three, four, and five pens, and answer the purpose very well.

COPIVIST, in Diplomatic Science, signifies a transcriber or copyer of deeds, books, &c.

COPIVIST, a transcript of Major. Whatever improvements have been made in literary typography, no mue print
COQ

printed with types has equaled that of writing, engraving, or dampening. Rouilleau has extended this article to a greater length than seems necessary. It is indeed necessary for a copyist to know practical music well, and to be sufficiently acquainted with composition to avoid gross mistakes himself and detect them in others; to write a neat and legible hand; to know the Italian and French technique, to form all the characters in a bold and clean manner; and, by understanding the language of music, leaving no bar incomplete, by omission or redundance. These seem to be all the necessary requisites of a good copyist, if to them be added care and accuracy, particularly in forming a score, where quantity must be attended to in the exact arrangement of the notes over each other. Much has long been very neatly engraved in France, on copper; and in Holland, though less neat, with more force and distinctness: 60 or 70 years ago, the Dutch editions of the works of Corelli were much sought all over Europe; and 30 or 40 years ago, there was no music printed in Italy or Germany; all was MS. By which employment so many copyists obtained a livelihood, that it was thought a cruelty to shorten labour by the press; as in the first attempts at engraving Silk and cotton-mills. Works in literature, till the invention of the press, must have been disseminated very slowly by transcription; perhaps by the medium of the press, works of little merit, and of corrupt and vicious principles, have been too easily multiplied, and put in circulation. And indeed the cheapness has not been eventually the consequence of musical typography, dampening, or engraving; as printed music is now dearer than written was, early in the last century.

COPY-RIGHT. See Literary Property.

COQ, ad med. confumt., an abbreviation among Physicians, signifying that the thing is to be boiled till half of it be consumed.—Coy. in S. Q. Ag. implies it to be boiled in a sufficient quantity of common water.

COQUALLIN, in Zoology, the Scincus variegatus of Gmelin, and variegated squirrel of Pennant.

COQUANTOTOTL, in Ornithology, a bird of the warmer climates of America, described by Seba under this name: it is a small freckled-bird, shaped like a sparrow; the Pipra Grisa of Gmelin, the manicus crispatus griseus of Buffon, and the gray manakin of Latham.

COQUAR, the variety hybridis, of Gmelin's Phaisanus Colibiaca and the pied-pheasant of Haye's British birds.

COQUATOTOTL of Hernandez and Ray, the variety of Gmelin's Ampelis garrulus, the chat of Carolina of Edwards and Catesby.

COQUES, GONZALO, in Geography, a painter who was born at Antwerp in 1618, and became the disciple of David Ryckaert the elder. He soon gave proofs of extraordinary talents in small pictures; and the early friendship which he formed with the son of Ryckaert, whose name was likewise David, did not a little contribute to rouse his emulation, and quicken his diligence. His first essays, after the example of his master, were domestic subjects and conversations, in the manner of Teniers and Ofsade; but his admiration of the works of Vandyke, soon cauited him to adopt a style, in which the beautiful and picturesque grouping of his former models acquired additional interest, by being united to greater elegance and dignity of character. In this manner he painted a picture for Jacques Le Mercier, a rich merchant of Antwerp, which gained him great applause. It represented his employer with his wife and children at table: the painter himself was introduced in profile. From this period he devoted himself princi-pally to the painting of small portraits, which he executed with such delicacy and happy effect, that excepting Vand yke, no artist of his time enjoyed a greater reputation. He was employed by the court of Bruges, Charles I. king of England, and several other potentates. He died in 1684, leaving considerable riches to his family, etc.

COQUET, in Geography, a river of England, in Northumberland, which runs into the sea seven miles S.E. of Alnwick, at Hawksey, and is navigable for about 12 miles up to Warkworth bridge.—Alto, a small island of England, in the German ocean, about a mile in circumference, near the coast of Northumberland. It was taken by the Scots in the reign of Charles I. N. lat. 55° 13'. W. long. 1° 36'.

COQUETTE, a female character, no less contemptible than odious; against the iniquity of which Mr. G. Horne, in his excellent treatise, "On the Duties of the Female Sex," cautions his readers in the following decriptive and imprelve terms, "To delude a young man by encouraging his attentions for the pleasure of exhibiting him as a conquest, for the purpose of exciting the affections of another perfan, or from any motive except the impulse of mutual regard, is a proceeding too plainly repugnant to justice, and to delicacy of sentiment, to require much more

COQUILLADE, in Ornithology, the Alauda undata of Gmelin and undated lark of Latham.

COQUILLES, in Navigation, shells or moulds for bullets. They are made either of brass or iron. Two of them are required for the calling of a cannon-ball. And they never join or close so effectually, as to prevent the liquid metal when poured in from running somewhat out at the seam, where they join. This small part of the metal, or excellence of the bullet, is called the beard, which is broken or knocked off to make the ball perfectly round.

COQUIMBO, or VILLA SERENA, in Geography, one of the 13 provinces of Chili in South America. This is a rich, verdant fruitful valley, not far from the coast of the South Sea, producing corn sufficient for considerable exportation to Lima, and abounding with various mines. One mine of copper, situated about 5 leagues N. from the town of Coquimbo on mount Caro Verde, or Green Hill, rises to a considerable elevation in form of a sugar-loaf, and serves as a landmark to the port. The climate is singularly agreeable, being almost uniformly mild and serene.

COQUINO, or VILLA SERENA, the capital of the fore-mentioned province, was the second town built by Valdivia, in the kingdom of Chili, in 1544, for the purpose of maintaining an intercourse between Peru and Chili, in order to procure a regular supply, and to secure the fidelity of the Indians who lived in that valley. The town stands about 1/4 of a league from the sea in a most delightful situation, commanding an extensive prospect of the sea, a river of the same name, and the country, and presenting to view a charming variety of fields, with different kinds of grain and woods of a lively verdure. The town is large but not proportionably populous; the number of families not amounting to above four or five hundred, consisting of Spaniards, Mestizos, and a few Indians. The streets are conveniently wide, intersecting one another from north to east, and from east to west, as to form squares of buildings, with intervals for gardens. The houses are constructed with mud walls and covered with leaves, and each of them is provided with a large garden, planted with fruit trees and eucalyptus vegetables.
COR

vegetables. It has several parish churches, and three convents, and also a town-house, where the Alcaides and Regidores meet, who, with the corregidor, form the corporation. On the north side of the town runs the river; after flowing in various meanders through the whole valley of the same name; and, by canals cut from it, furnishes the town with water, which is principally applied to preserve the fertility and beauty of their gardens. The river at its mouth forms a very fine bay, where ships lie safely and commodiously, though the coast is rocky; some islands lying so as to keep off the winds. S. lat. 29° 52'. W. long. 71° 19'.

COR, in Geography, a town of Chiefne Tartary, in the desert of Cobi. N. lat. 44° 16'. E. long. 95° 29'.

COR, in Anatomy. See Heart.

COR, Fr. CORNO, Ital. in Moggio. A horn.

COR de Chaffe is a very long and instructive article in the Encycl. Metz; but the plates, to which the reader is frequently referred, not having yet published, the precepts for performing on the instrument, if translated, would not be intelligible.

COR, in Natural History. See Chama.

COR Caroli, in Afromony, an extra-conellated star of the second magnitude in the northern hemisphere, situated between the Coma Bremicenses and Ursa Major; so called by Sir Charles Scarborough, in honour of Charles I.

COR Hydra, a star of the second magnitude, in the heart of the constellation Hydra.

COR Leonis, or Regulus, a fixed star of the first magnitude, in the constellation Leo.

COR Sarp/li. See Antares.

COR Aquilum, in Natural History, a species of Echinus found only in a fossil slate.

COR Boeii. See Cardium Aculeatum.

COR Marinum, the name of one of the classes of the echini marini, the characters of which are, that the anus is placed in the side of that point of the shell which appears as if cut off; and the mouth has two lips, and is placed in the third region of the axis of the bale. Klein's Echin. p. 34.

COR Venus/is, Venus's heart. See Cardium Caridess.

CORA, in Ancient Geography, a town and Latin colony of Italy, in the country of the Volsci, according to Virgil, Silvius Italicus, and Livy; now Cori. This is a town of Latium on the left of the Appian way. S. E. of Velitrae. By its ruins we may conclude, that it was a place of importance; among these we discover a temple of Caior and Pollux, and an aqueduct for conducting water, &c. The ancient walls are still remaining. Allo, a town of Italy, situated in a promontory of Eturua. Justinus Liplius says, that in the passage of Tacitus which mentions it, we ought to read Cofa, which is not improbable.

CORAGE, Coragium, in our Old Customs, a kind of impostion extraordinary, growing upon some unusual occasion; and it seems to be of certain measures of corn; for corus tritici is a measure of wheat. Draccon, lib. ii. cap. 116. num. 6, who, in the same chapter, num. 8, has these words: "Sunt etiam quaedam communes prelaciones, quae servata non dicuntur, nec de confutatis ventunt, sed cum necessitas intervenerit, vel cum non venit; sicut non higidia, coragia, & caravagia, et alia plura de necessitate et ex contentu communi totius regni introducunt, &c."?

CORACA, or Corace, in Ancient Geography, a town of Arabia Petraea. Ptolemy.

CORACESIUM, a fortified place of Afa in Cilicia, according to Piny and Strabo; the latter of whom says, that it was situated on a rugged rock at the extremity of Cilicia.

CORACIAS, in Ornithology, a genus of the order, Pies, or Pies. The birds of this genus have the bill sharp at the edges, the tip incurvated, and the bare base of feathers; tongue cartilaginous and bifid; feet formed for walking.

The coracias genus comprehends only those birds which are known by English writers under the title of Roller, amounting altogether to between twenty and thirty species. In Latham's Synopsis it is observed, that the bill of the roller is straight, bending towards the tip, with the edges culvated; the nostrils narrow and naked; and the legs for the most part short, with the toes placed three before and one behind, the whole of which are divided to their origin. It differs from the corus, or crow tribe, chiefly in the nostrils being deftite of reflected bristles, and having the legs shorter. Brosson makes a particular genus of pies under the name of coracias, including those birds of the Indian genus corus which have the beak a little bent or arched. The coracies of the latest French writers, it may be likewise remarked, belongs to the corus genus both of Gmelin and Latham, as for example, the corus graculus (Corony chonh) and corus eremita (Hermis crow), &c.

Of the two last mentioned writers are referred to the coracias genus by the French.

The roller tribe is not confined to any particular part of the world like some other genera of birds, but the far greater number of its species are found in warm climates.

Only one species of the roller has been yet discovered in England, the garrulous roller, coracias garrula.

GARRULA. Blue, back r.d.; quill-feathers black. Linn. Fr. Sv. Common roller. Penn.—Donov. Brit. birds. Pica marina et garrulus argenteolus, Ray. Gallus, Brosson. Roller, Buffon. Gavia marina, Zimm. A beautiful bird, in size somewhat inferior to the common jay; the head, neck, breast, and belly are of a fine blueish-green, the back and scapulars reddish-brown; coverts on the sides of the wing rich blue; the tips of the quill feathers dusky above, beneath blue; the tail forked with the two middle feathers obscure green, the rest blue with the tip on the outer edge black; legs short and dirty yellow.

This species inhabits various parts of Africa, and Europe, but in greatest numbers in the warmer regions; in the north of Europe they are uncommon, in England very rare. It has obtained the name of garrulous roller in allusion to its chattering noise. The species is of the migratory kind, gregarious and timid, and builds in trees, particularly the beech. In the south of Germany it is seen in flocks in autumn, in company with the rooks and other birds feeding for worms, small seeds and roots, in tilled, or cultivated grounds.

Inhabits Bengal and the isle of Mindanao. Dr. Latham observes that it does not essentially differ from the following species, the chief difference being the fulvous violet colour on the breast, and the want of the long outer tail-feathers. The bengalensis, he thinks, may be perhaps the female or a young bird, as the long tail-feathers of coracias caudata do not appear till the second year. Lath. Gen. Syn.
In head claws down quills leffer back, rump, face exterior the legs the throat tail-feathers fcapulars, euus, Blue Blue-green Ceylon.

This is rather less than the common jay. The bill black; the whole space round the base of the bill white; head and under parts of the body, the upper parts of the wings, and tail, blue-green; shoulders and quills deep blue; the outer tail-feathers of great length as in the last species; hind part of the neck, and the back of a reddish-brown; the legs of a reddish-brown colour. It inhabits Ceylon and Senegal.

The bill of this bird is black; tip of the upper mandible much bent; sides of the head from the nostrils to a little beyond the eyes are white; the rest of the head, neck, and under parts of the body fine green; the two middle feathers of the tail are dull, with a gloss of blue, especially down the middle, the outer ones blue-green; the two exterior tail-feathers are six inches longer than the rest, and the end, beyond the extremity of the others, of a fine deep blue; the legs are red-brown. A native of Abyssinia.

A native of the East Indies. Its size is that of a jay, the length ten inches and a half; the bill yellowish, broader at the base, and more hooked than in any of the genus; the head and hind part of the neck brown; back, rump, and scapulars, with the wing and tail-coverts, green-brown; throat fine blue; down the shaft of each feather a pale line, the other parts beneath blue-green; quills blue and black, with a large pale blue spot. The wings are longer than in the other species of roller; the tail even at the end, the two middle feathers green at the base, with the other part black; legs yellowish with black claws.

The length of this bird is eleven inches. The bill is dull, an inch and a half in length; the crown of the head blue-green; throat, breast, neck, and back, reddish brown, with the sides of the head and throat darkred, streaked with white; rump and tail, with the under parts from the breast, fine cuneate blue; the middle feathers of the tail green, the outer ones blue at the bottoms and tips, in the middle sea-green; the wings green and blue. A native of Ceylon.

Ceylana. Blue, exterior edge of the quill-feathers pale yellow. Linn. Cape roller, Lath. Inhabits Ethiopia; an obscure species described on the authority of Linnaeus.

Length of this species eight inches; the bill dully. Native place unknown.

A beautiful species found in Madagascar. The length of this bird is ten inches; the bill is very stout at the bars, rather short and pointed. The yellow colour; the legs reddish-brown. Magicana. Reddish-grey; beneath and on the wings pale grey mixed with flame colour. Gmel. Galalgus magicanus, Buff. Merula magicana, Schb. Rollier des Magica, Buff. Mexican roller, Lath.

Larger than a thrush, and inhabits Mexico.

Pueila. Blue, collar in front, and at the side, with the breast, belly, quill-feathers, and greater wing-coverts black. Fairy roller, Lath.

Size of a blackbird, and inhabits India.

The length of this bird is eight inches. The female cerine-grey and not streaked like the male; quill-feathers black, edged with cerineus; iris pale red. A native of New Caledonia.

Inhabits China, and is called at Canton Sau-ta-hoang.

The size is that of a jay; the length eleven inches and a half; the bill and irs are red; head, and hind part of the neck, back, rump, and upper tail-coverts green; through the eyes on each side is a black stripe; the under parts from the chin to the vent yellowish-white tinged with green; wing-coverts olive-brown; quills the same with a mixture of chestnut in some, and others tipped with white; the tail resembles that of a magpie in form, and is marked at the tip of every feather with a white spot; the legs and claws are pale red, and longer than in other rollers.

Vagabunda. Head and neck black; body above ferruginous-brown, beneath cerineus; middle of the wing white; tail very long, wedge-shaped, greyish with the tip black. Lath. Grey-tailed roller, Lath.

This is a native of India; the length is seventeen inches; its bill black; legs cerineus; lesser wing-coverts rufit brown; greater and secondary quill-feathers white, the primary ones black.

Cayana. Tawny-green; beneath dirty white; eyelids white; chin with a black streak each side; tail cuneated. Gmel. Griviert, ou role de Cayanne, Buff. Cayanne roller, Lath.

Inhabits Cayenne, and measures about nine inches in length, the bill is reddish; legs long and grey.

Dociolis. White interpersed with reddish; beneath chestnut; legs pale yellow; tail-feathers black with the tips white. Gmel. Dociole roller.

Size of a blackbird, and inhabits the southern parts of Asia. The bill is yellow; the nine first quill-feathers white as far as the middle and from thence black, the rest entirely black; claws flesh colour.

Length sixteen inches; bill thick, and with the legs black; tail seven inches. Native country unknown.

Atra. Tesselaceous red; beneath reddish-purple; vent blue-green; wing and tail-feathers blue, with the tips blackish. Gmel. African roller, Lath.
Length eight inches and a half; the body stout, bill yellow; legs brown. A native of Africa.

Melanoccephala. Blue-purple; head and neck black; body beneath white; quill-feathers fuscous; tail emaciated and white at the tip. Gmel. Black-headed roller, Lath. Size of a crow, bill and legs red; nape pale grey; two middle tail-feathers blue, the rest purplish, and the whole white at the tip. Inhabits China.

Strepera. Black; foot on the wings, vent, base, and tip of the tail black. Lath. Noisy roller. This is an inhabitant of Norfolk island in the Pacific ocean, where it occurs in vast numbers; it has the reputation of being a sly bird, and is very noisy in the night. The length is nineteen inches, of which the bill is two inches and a half long, somewhat straight, black, dentinate, and horn-coloured near the tip; multiris naked, long, and placed near the base of the bill. The first six quill-feathers are white at the base; the tail long and rounded, the larger feathers white at the base, the lateral ones white at the tips within. When the wings are folded they reach as far as the middle of the tail. The legs are black, the outer toe connected at the base to the middle one.

Varia. Black; beneath, lower part of the back, rump, and upper tail coverts white; tail black, equal, with the tips of the feathers white. Gmel. Caucaecus de la Nouvelle Guinee. Buff. Pied roller, Lath. Length about thirteen inches; the bill two inches and a half long, and of a blueish colour with the tip dark; legs lead colour. A native of New Guinea. This bird partakes of characters common to the oriolus, coracias, and ramphastos genera, and might with some propriety be referred to either. In the index ornithologicus it is placed with the coracias tribe.

Coracinsil, in Ancient Geography, a people who inhabited the northern part of the island of Sardinia. Coracinsus, in Ichthyology, the name of a fish-fish caught in the Mediterranean, and called by some authors fesvum, and by Aldrovand and Salvian umbra. It is of the colour of the common tench, but in figure more approaches to the perch: its scales are small; its mouth not very large, but well furnished with teeth; and its tail is not forked, but when extended, seems of a roundish figure; the ends of the rays or nerves of the tail-fin are black, and the other fins are all black, and feen as if dyed with ink.

Coracinsus Brasiliensis, the Labrus Cromis of Gmelin, and Guatunca of Margrave. Found in Carolina.

Coracius Mons, in Ancient Geography, a mountain of Asia Minor in Jonia, situated near the town of Colophon. Strabo.

Coracle, a fishing boat of curious construction used in Wales for time almost immemorial. These boats afford a specimen of the earliest British navigation, and they are used at this time on many of the rivers in Wales, probably without any deviation from their original form. They are made with very strong basket-work, and covered with hides, or coarse canvas, with a thick coating of pitch. Their shape is oval and resembles the figure of a walnut-shell, their length is generally five feet, and their breadth seldom less than four. They contain only one person, who fits precisely in the middle, and by dextrous management maintains his just balance. The instrument with which he moves his boat is a paddle; one end of which rests upon his shoulder, and the other is employed by his right hand, in making a stroke alternately on each side. The left hand is, in the mean while, employed in conducting the net, and he holds the line between his teeth. These vessels were anciently used, as the means of intercourse between the inhabitants on the opposite banks of the rivers. They are now applied only to the purpose of fishing. So frail an invention would probably have been exceeded by something of greater strength and capacity, had not there been found a remarkable convenience in their lightness. The fisherman, when his labour is finished, flings his boat across his back, and marches homewards under the burden of his machine and booty. There is scarcely a cottage in the neighbourhood of the Tywi in South Wales, or several other rivers in those parts, abounding with fish, that has not its coracle hanging by the door. Such is the adroitness of those who use them, that they are very rarely overturned on lakes or rivers; and they sometimes even venture a little way out to sea, when the weather is perfectly calm. Similar to these in their nature are the Indian canoes; though they are constructed of different materials and forms, and applied to different purposes.

Coracobrachialis, in Mythology, a muscle of the shoulder-joint, arising by a tendinous and fleshy origin from the apex of the coracoid processes of the scapula, and connected for some extent with the short head of the biceps. It passes downwards and backwards, to be inserted into the inner side of the os humeri about the middle of the bone. The musculo-cutaneous nerve generally penetrates the fibres of the muscle; whence it has been called the musculus perforatus Caffrinii. It will move the os humeri towards the side; it will elevate the bone, and carry it obliquely forwards across the front of the chett. It may rotate the os humeri outwards, particularly if that bone has been previously turned inwards.

Coracodes, in Ancient Geography, a port of the W. coast of the island of Sardinia. Ptolemy.

Coracothyoides, in Mythology, a term applied to the omomydous muscle, for which see Larvix.

Coracoides, in Anatomy, a small sharp processes of the scapula; so called from its resembling a crow's bill.

The word comes from corax, corvus, and vertic, image.

The coracoides is placed in the upper part of the neck, and projects over the head of the bone of the arm. It serves to strengthen the articulation of the shoulder; and gives origin to one of the muscles of the arm.

Coracomantes, from corax, corvus, and nutus, divination, in Antiquity, a kind of diviners, who made their predictions by observing the crows.

Coraconesus, in Ancient Geography, an island of the Mediterranean sea, towards the coasts of Libya. Steph. Byz.—Alfo, a place of Peloponnesus, in Arcadia; situated, according to Pausanias, where the river Ladon discharged itself into the Alpheus.

Coracoradalisis, a name given by Winlow to the beices flexor cubiti. See Biceps.

Coradi, or Curadi, Ottavio, in Biography, a Bolognese painter, the scholar of Giacomo Cavedone. His principal excellence consisted in the boldness and truth with which he copied the works of his master. He flourished in 1670, and is said by Pilkington to have died in 1643. Malvatis, Orlandi.

Corah, or Corah Jensenabad, in Geography, a small city of Hindooistan, or capital of a province in the Doob, or country between the rivers Ganges and Jumna; subject to the nabob of Oude: 184 miles S.E. of Agra, and 67 S.S.W. of Lucknow. N. lat. 26° 10'. W. long. 80° 50'. When lord Clive assumed the government of Bengal, in 1765, he restored to Sujah Dowlah all the conquests that had been gained from him, except the provinces of Corah and Allhabad, which were reserved as part of an establishment for the emperor, or great Mogul. The Corah provinces were valued at 50 lacs. The emperor was to reside at Allhabad, under the protection of the English, to whom,

Vol. IX.
in reality, he owed all that he possessed, and a treaty offensive and defensive was entered into with Sushis Dowla, the nabob of Oude. The ambition of the emperor was not satisfied; but after about six years quiet residence at A lahabad, he put himself into the hands of the Maharrattas, who promised to set him on the throne of Delhi. The immediate consequence of this connexion was a cession of the Corah provinces to the Maharrattas, who, unlike the English had interposed, would have established themselves in that important angle of the Doab, which commands the navigation of the upper part of the river Ganges, and the whole course of the Jumna. On this occasion, the British government considered the Corah, &c. provinces, which, by right of conquest, were originally theirs, as having reverted to them again, when they were alienated from the purposes for which they had been originally granted to the emperor; and applied to the aggrandizement of a power irremediable to them and their allies. They, therefore, refusing the possession of these provinces, and immediately ceded them to the nabob of Oude, for a valuable consideration. See Oude.

CORAL, in Botany, arbor non spinosa; Pet. Rai. See Erythrina crista-galli.

Corallaria affinis; Sloam. See Sophora occidens- talis.

Corallus maritimus; Com. See Erythrina corallo- dendron.

Corallus sericea; Dill. See Erythrina herbacea.

Corallus polyphylla; Sloam. See Piscidia erythrina.

Corals in Zoology, a general English name for zoophytes of the lilius tribe, or those which animal resembles a plant, and have the plant form and articulate; with the joints longitudinally divided, united by spongy or conicous junctures, and covered by soft porous cellular flesh. About six species of this curious genus are at present known. See lis.

Corals, red, or true red coral, was considered by Linnaeus as an isis, and arranged as such in the Systema, though Linnaeus himself acknowledged to Mr. Ellis, the author of the Natural History of Zoophytes, that the latter had more properly classed it with the gorgonia, or sea-fan, the genus isis being sufficiently distinguished by its jointed item. In the last edition of the Systema, the coral is placed with the sea-fans, or gorgonia.

The red coral grows in an expanded and somewhat flattened form, with dichotomous branches, that lessen towards their extremities. The flesh is of the colour of red lead, or inclining to vermilion, soft, slippery, and full of minute vessels. The mouths are placed on the surface, and rise up in a conical form, confluent of eight valves, just opening, from whence proceed papules of a white colour, with eight claws, each of which has a double fibre at both edges. The bone itself, dissected of the flesh, is the true coral of the thinus, and which, in its natural state, is of a fleshy texture, and of bright red colour, with the outside marked with minute furrows, or irregular divisions, interspersed with a few slight depressions, corresponding with the situation of the shells, before the flesh be removed. For a further account of this curious article, see Gorgonia publilis.

Corals, black. In the Linean system, the true black coral is described as pertaining to the same genus of zoophytes as the red kind, under the specific name of antipathes. This fact is found on the shores of the Indian and Mediterranean seas, and grows in a shrubby form to the height of about two feet, with the branches erect, and alternately pinnate. The bone is of a black colour, marked on the outside with flaxen flax, and in its native state is covered with flesh of a grey colour. See Gorgonia antipathes.

The gorgonia antipathes, or true black coral, must not be confounded, from the similarity of names, with the antipathes genus, the latter being very distinct, although its species are not unfrequently denominated black corals, as well as the gorgonia before-mentioned. There is a great affinity between the antipathes and gorgonia genera; notwithstanding which they may be readily distinguished, the bony part of the antipathes being bexet with small spines, and covered with gelatious flesh, and numerous polyple-bearing tubercles, while the bone of the gorgonia is smooth, or delittle of spines, and the flesh cellular.

From the old botanical writers it appears, that many of the zoophytes were considered as genuine plants; and that in particular several sorts of black corals were formerly called antipathes. But as the characters of these marine bodies are better understood in the present age, only part of these have been retained in the genus antipathes, and some of the rest referred to the gorgonia. The antipathes of certain kinds were formerly used as feepes for princes, and likewise for divining rods, and other similar purposes, as in evident from the remarks of Salimania, addressed to Solinus, wherein he says, that antipathes denotes something proper to reflect incantations, and that they were in use for that purpose by several Indian nations.

There are a number of different species of this kind of black coral, which, not being sufficiently noticed under the article antipathes, it may be proper to describe in this place.

This kind inhabits the Indian, Mediterranean, and North seas. It is of a hard and honey black substance, extremely brittle, and varying in length and thickness; one described by Mr. Ellis measured two feet long, and was about the thickness of a writing-pen; another, not thicker than the bane of a quill's feather, was about seven feet in length. In its natural state this kind is variously twisted, or generally in a spiral manner; and the leaf which covers the spiny surface of the bone is full of little gelatinous warts.

A native of the Indian ocean. This kind is full of small short spines, the branches are loose and irregular, and the whole remarkably black. The specimeen brought from Batavis, and described by Mr. Ellis, had the surface marked with ovate cavities, differing about the branches, which were of a brownish-yellow colour, and supposed to be the ova-

Subpinnata. Branched and pinnate, rough with feta-

cuous alternate sub-divisiones, and a few others proceeding transversely from them. Soland. and Ellis.

Described by Gmelin as a native of the Mediterranean sea on the authority of Ellis, who, however, merely informs us his specimeen was brought from Gibraltar, and is supposed to be taken in the sea therabouts. The spines of this kind are long and small, and of an amber colour when magnified. The surface of the antipathes appears to be cinerenous.

Myriophylla. With numerous, incurved, pinnate branches, the subdivisions with long spines pinnules on the upper side. Soland. and Ellis. Myriophyllum indicum venetum, Petiv. Ericca marina, tenuis, Rumpf.

This is called by Ellis the yarrow-leaved antipathes; it is a beautiful shrub-like appearance, with many pinnated branches, bending downwards all round; the colour ye-

lowish-
Coral

lowish brown, and the surface rough, but considerably less so than the species subprimata. Found near the Spice islands.

*Allopecuroides.* With spinous, fetaceous, closely panicked branches. Soland. and Ellis. *Fox-tail antipathes.*

The trunk of this species rises from a broad spreading base, and divides immediately into several large branches, of about one-third of an inch in diameter. As they rise up, one side of them appears flat, with a groove or channel along the middle of it, where there are the remains of many little branches that have grown in rows on each side. It then divides into branches, and often into other branches, all which are in form of close panicles, not unlike the fox-tail graps. Thse panicles are composed of very rough thorny minute branches, which are twice as long on one side of the stem as the other. This rises to the height of two feet, and is of a greyish colour on the outside, the inside black and very brittle. A rare species, discovered on the coast of South Carolina.

The cyprès antipathes was erroneously called by Linnaeus with the gorgonia; Gmelin places it with the antipathes. The species inhabits the Indian ocean; it is about two feet in length, and is covered with a brownish-down, beneath which the colour is deep black.

*Dichotoma.* Very long, dichotomous, and upright. Pallas.

Inhabits the Mediterranean, is about two feet in height, round, and dusky.

*Oricalcea.* Brassy, smooth, with a simple, rigid, flexuous stem, and alternate, scattered, dichotomous branches. Pallas. *Gorgonia ena,* Linn. Twelve inches in length, and very rigid. A native of the Indian ocean.

*Clathrata.* Very much branched, intricate, with confused sub-divisions in every part coalescing, the younger ones fetaceous. Pallas.

Size of the leaf, and of a black colour within: this inhabits the Indian ocean.

*Flabellum.* Dilated, very ramose, and sub-divided, the sub-divisions branching both ways, and cohering together in a reticulated manner. Pallas. *Erica marina affinis,* Rumph. This kind inhabits the Indian sea, and is about six inches wide, black, rough, and uncuriously curved.

*Pennacea.* Branched, somewhat incurvated, the branches with fetaceous and very crowded rough sub-divisions. Pal. *Accabat ruturutura,* or *Erica marina crassa,* Rumph. *Fusilus pristus,* Adir.

Inhabits the Indian ocean, the outside grey and rough, within black.

*Poeniculacea.* Very much branched, with fetaceous decompound sub-divisions. Pallas. *Fenus marium,* Rumph. Twelve inches high, the colour black. A native of the Mediterranean.

*Coral, subtile.* See *Madrepora,* *Millepora,* and *Cellepora.*

Coral gives title to an official composition, called *jiyub of coral,* sometimes preferred by physicians; as is lik wise the powder of coral finely ground, and afterwards levedgated on a marble, and made up into a proper form. But there are few, except those who are fond of medicines with gems in them, that make use of it. By means of its exceeding hardness, it is supposed to take away with it a great deal of the levigating done.

Dispensary writers have given us receipts for a great many preparations of coral, as magisteries, tinctures, salts, &c. none of which enter the present practice.

Coral and coraline being the shells of marine animals of the polype kind, possess the same chemical properties as the fresh shells of oysters and other shellfish, i.e., they are calcareous earths impregnated with some animal principles. *Coral, artificial,* is made of cinnabar well battered; a layer whereof is applied on a piece of wood well dried, and polished, first moistened with size; the whole is then again polished; and for varnish, rubbed over with the white of an egg. See *Grotto.*

*Coral, filfery.* The time for fishing coral is from April to July; the places are the Persian gulf, the Red sea, coasts of Africa towards the ballion of France, the isles of Majorca and Corfica, and the coasts of Provence and Cata-

The method of fishing is nearly the same in all places: that used at the ballion of France, where there is an established fishery, under the direction of a company at Marseille, is as follows.

Seven or eight men go in a boat, commanded by the patron or proprietor; the caftle throws his net, if we may so call the machinery wherein he uses to tear up the coral from the bottom of the sea: and the other, as he manages the boat. The net is composed of two beams tied across, with a leaden weight to press them down; to the beams is fastened a great quantity of hemp loosely twisted round, among which they mix some flagon nets. In this condition the machine is let down into the sea; and when the coral is pretty strongly embarrassed in the hemp and the nets, they draw it out by a rope, which they unwind according to the depth, and which sometimes requires half a dozen boats to draw. If the rope happen to break, the fishermen are in great danger of drowning. They have two machines, one for fishing up the coral where the bottom is smooth; and the other, called in the Provençal language the *salabre,* so constructed as to be employed where the bottom of the sea is rocky and unequal.

Before the fishermen go out, they agree on the price of the coral, which is ordinarily at the rate of 4. 6 d. per pound.

When the fishery is over, which in a season usually amounts to twenty-five quintals of coral each boat, it is divided into thirteen parts; the patron whereabouts, or master coraller, has four, the enter two, and each of the six companions one: the thirteenth being reserved for the company, &c.

Spallanzani has particularly described the coral fishery in the isles of Minor. (Travel in the two Sicilies, &c. vol. iv, p. 519.) This, he says, is both a laborious and dangerous occupation. The instrument, with which they force the branches of coral from the rocks, is formed with two poles of wood, crossing each other at right angles, and having a piece of a net fastened on the under side to their extremities. A large stone is fixed where the parts cross each other, that the instrument may more readily sink to the bottom. A cord is strongly tied round the middle of it, one end of which the fisherman holds in his hand, guiding by it the net to those places where the coral is supposed to grow: and which is enclosed, in the pieces of the net, broken off, and drawn up. This fishery

4 X 2
is carried on from the entrance of the Faro to the part of
the strait opposite to the church of the grotto, or through
a tract six miles in length, and to the distance of three
miles from Messina. The rocks which produce the coral are
situated almost in the middle of the strait, at different
depths, from 330 to 650 feet. The bottom and caverns of
the rocks are the places from which they endeavour to
bring up the coral with their nets; and it is a constant
observation, that every branch is perpendicular to the plain
on which it grows, without ever turning on one side.
Coral, it is said, grows more plentifully in places situated
to the ca11 than in those to the south; it is rarely found to
the well, and never to the north. In the first situation it
is larger, and of a finer colour, than in the second and
third; which two valuable qualities are likewise found in
which is brought from a less depth, compared with
that which is grown at a greater. The greatest height to
which it grows is never a foot, and its usual thickness is
that of the little finger, and somewhat less than that of the
rocks of Trapani and Barbary; but the latter are exceeded
by the Mellinefe in vividness of colour. These differences,
according to the account of the fishermen, arise from their
oral being produced in a sea which is kept in continual
agitation, from the surface to the bottom, by the current
and the winds. With respect to colour, there are three
kinds; the red, the vermon, and the white coral. The
first is subdivided into the deep crimson-red, and the
lighter red. The vermon is extremely rare, but the
white common. In the white they include the clear white
and the dull white.
The coral fishermen have divided the whole tract in
which they fish into ten parts. Every year they fish only in
one of these parts, and do not fish in it again till ten years
are elapsed. This interval of ten years they think necessary
for the coral to acquire its full growth in height and
profusion. When they transgress this law, they find, in fact,
the coral smaller, and of less confidence, and the intensity
of the colour is always in proportion to the number of
years they have deferred from fishing. When the ten years
have elapsed, they believe that the coral no more increases
in height, but only in thickness, which, however, has its
limits. In fact, they have observed that the coral filled
up near San Stefano, a place where none had been fought
for in the memory of man, though it was of a very bright
colour, was not higher than the ordinary coral, though it
exceeded it by one-third in thickness.
The number of ships which usually go together in this
fishery is eighteen or twenty, each of which is usually
managed by eight men. The quantity of coral procured
may amount every year to twelve Sicilian quintals. The
quintal, as is well known, contains two hundred and fifty
pounds, and the pound twelve ounces. The gain acquired
is therefore adequate to the labour; yet may the fishery be
considered as a secondary occupation, since the fishermen
only follow it when they have no other employment by
which they can make a greater profit. Spallanzani exa-
nined the branches of coral, as they were taken out of
the nets, by putting them into glass vessels filled with sea-water.
It is well known that, in this cafe, the white polypi will
come out of their cells in the coral as soon as the water
is perfectly at rest. He examined and re-examined
these polypi, as it was the first time he had seen them;
but he discovered nothing which can make any addition to
the accurate observations of Peydelfon, Jullien, Guettard,
Donati, and the very recent remarks of the celebrated
Cavolini, which seem to leave nothing to be desired to
complete our knowledge of these animalcula, and their na-
tural habits. Having made some additions and correc-
tions to the observations of count Marigli, relative to this
subject, he proceeds to describe the principal of those
branches, which now make a valuable addition to the clas
of Zoonphyta in the imperial museum at Paris. He observes,
That the bark of this branch has the colour of sealing wax;
but the solid coral is purple, with some transparency at
the extremity of the branches.
2. The bark in colour resembles that of the foregoing;
but the included solid coral is of a less vivid red.
3. The bark is of a bluish grey; the solid coral grey,
with a slightly reddish tinge.
4. In this specimen four branches shoot from the same
item; two of a pale red in the bark, and a whitish red in
the solid coral. In the fourth the bark is of a whitish
colour, and the solid coral still whiter.
5. Three branches joining in one, the colour of
which, both in the bark and the solid coral, is a milky
white.
With respect to the structure of the cortical and solid parts
of the white corals, he observes that they are the orifices
of the cells in the bark of the white coral, which being oöter-
derated like those in the red, appears to be a proof that
the polypi in both are of the same structure, and conse-
quently of the same species; the polypi inhabiting the
red coral having likewise eight tentacles. That coral is
soft in the sea, but hardens when it comes in contact with
the air, was the opinion of the ancients; but has been
proved false by the observations of the moderns. The
coral-fishermen of Messina, who derive all their knowledge
from experience only, are convinced this opinion is erro-
nous; but they assert that coral which has not attained
maturity has not that degree of confidence it acquires
when it has arrived at its full growth. The truth of this
position Spallanzani was not able to ascertain, as, for that
purpose, it would have been necessary to call the net in
one of those ten parts of the strait in which it is pro-
hibited by the law to fish till the expiration of the ten
years prescribed. Yet the rules of analogy derived from
what is observed in all animals and vegetables, inclined him
to favour this opinion. It is agreed however by the fisher-
men on the coasts of Barbary, and also by those of Messina,
Sardinia, and Corfìca, that the deeper they descend into
the sea, the smaller is the coral. Donati observes, that
the broken and detached branches of coral will continue to
live and multiply in the sea; and this Spallanzani allows to
be the case, provided they meet with a firm point of sup-
port to which they can attach themselves with their various
humour. Otherwise, if they fall on the movable sand,
they become the sport of the waves, and he has no doubt
but they must perish. The fishermen, with whom Spallan-
zani conversed, appeared to be well acquainted with the
true generation of coral; as they told him that they had
frequently observed, on hard matter drawn from the bot-
tom of the sea, the first principles of coral beginning to
germinate, which they describe as having the appearance of
a red spot, with a button or bud implanted in those mat-
ters, sometimes tender and fragile, and sometimes hardened,
and of the colour and nature of ordinary coral.
They were likewise acquainted with those branches of
coral which, when filled up, are sometimes found perfor-
ated by lithophagous worms, and which are mentioned by
Vitaliani and Marigli. Their nets had frequently brought
them up, either from the bottom of the sea, from ca-
verns, or the sides of rocks; and these perforated corals
were found sometimes broken in the trunk, where the per-
forations
formations are most frequent; and at other times attached to some body which formed them as a vase. They were of opinion that these corals were thus perforated, because they were dry; and this dryness, they imagine, proceeds either from age, or their having been broken from their roots by some wind, or by a part of a rock falling on them; or possibly by the coral nets, which do not always bring up all the branches of coral they tear away from their roots.

_Coral islands_, in Geography, called by the Spaniards in their old charts _las corales_, or _jiles del coral_, three islands lying in the form of a triangle and situated S.W. of the Lazardron, in the East Indian ocean.

_Coral river_, a river of New Mexico which runs a W. by S. course and discharges itself into the head of the gulf of California, near the mouth of the Colamero river.

_Coral-tree_, in Botany. See _Erythrina Corallo-bendium_.

_Coral-curr._ See _Dentaria Bulbifera_.

_Coralaria_, _parvifolia_; Rumph. See _Adenanthera Pavonina_.

_CORALIS_, in _Ancient Geography_, a marsh of Asia, in Lycaonia, placed by Strabo in the vicinity of Galatia.

_CORALIUS_, a river of Greece, in Buxotia.

_CORALLA_, a place of Asia, in Cappadocia, on the Euxine sea, according to Arrian's Periplo.

_CORALLI_, a people of European Sarmatia, who inhabited the banks of the Euxine sea, towards the Danube.

_CORALLINA_, in _Zoology_, a genus of zoophytes, the animal of which is a plant-like form, with the stem fixed, and the branches subdivided, calcareous, and mossy joined.

The ancient naturalists millook corallines for a particular tribe of plants, and accordingly introduced them into their works under the title of marine mosses. Tournefort enumerates thirty-six species among his plants; and indeed certain kinds appear to be so nearly allied to the lichen family, that some continental botanists, even in the present day, are in doubt where to draw the exact limit between the cryptogamia and the corallina.

All the corallines adhere to rocks or other solid bodies, and are concretions formed by the polype animals which inhabit them, the coralline itself being only the habitation of these creatures. The branches are commonly elevated, of a shrub-like form, and exhibit an elegant appearance from the symmetry and general proportions of their respective articulations; the branches being composed of little joints, like beads strung in a necklace. The joints consist of a calcareous and gelatinous matter, and have the surface perforated, or full of minute pores, which in many species are so very small as to be visible only with the aid of glaesses. It is in these minute cells that the polyps reside, and through which they either protrude their limbs when they lie in wait for food; or draw their nourishment through the aperture. When a branch of coralline is immersed in vinegar the calcareous crust dissolves, and leaves the cartilaginous parts uninjured, and by that means enables us to examine its internal tubular structure. In point of colour the corallines differ very considerably, not only in different, but also in the same species, and without exception the whole become white on exposure to air.

The coralline tribe, possessing much elegance and beauty, are highly ornamental in a collection of natural history; one species only appears to be appropriated to an useful purpose, which is the corallina officinalis, vail quantities of which are gathered and employed in medicine as an abortive.

Among the older writers the word coralline had a very general acceptance, and seems to have comprehended every description of polype-bearing sublittines, in addition to the coralline genus of modern naturalists, such as the _tubipora, fragmentaria, cælata, fideola, alethium_, &c. Mr. Ellis, in his publications on corallines, adheres rather too closely to this idea, but still defines the several genera with so much accuracy as to render his works of the greatest value to future naturalists. His vesiculated, tubular, calciferous, and articulated corallines are referable to the different genera above-mentioned (which see respectively). He includes also among his corallines the _cæsia_, _gorgonia_, and _patch_. &c. in which he is certainly wrong. The species of the true corallina at present known are as follow.

Species.

_Tridens._ Trichotomous, with compressed three-lobed flat joints. Ellis.

Found on the coast of the North American islands, where it was first discovered by Mr. John Greg.

This kind grows on the coast of Jamaica, and other West India islands, and is found also in the Mediterranean sea. The colour is white, and the joints somewhat kidney-shaped.

_Monile._ Trichotomous, with the lower joints compressed, convex, cuneated, oblong, and with the upper ones sub-cylindrical. Soland. and Ellis. Flethy coralline.

_Incrassata._ Trichotomous, with compressed plano-convex wedge-shaped joints. Soland. and Ellis. Flethy coralline.

This kind is very frequently called up on the shores of the American islands, particularly Jamaica.

_Tuna._ Trichotomous, with compressed flat roundish joints. Soland. and Ellis. _Tuna corallina_. _Opuntia marina_. Park. Thesat.

_Found in the Mediterranean sea._

_Nodulata._ Trichotomous, and very much branched, with thick wedge-shaped joints, those at the divisions broadest, the terminal ones tricuspidate or ovate. Pallas. _Nodularia alba_. Imp. _Moseus corallides_. C. Bauh.

Inhabits the same seas as the preceding. Grows to the height of eighteen inches, and is very thick, strong and white.

_Squamata._ Trichotomous, the joints of the stem roundly compressed and wedge-shaped, those of the branches flatly compressed; terminal ones flattish and sharply two-edged. Ellis.

Inhabits European coasts, and is of a sea-green colour.

_Loricata._ Trichotomous, with compressed, sub-convex, wedge-shaped joints, angulated at the sides; the terminal ones with small obtuse lobes. Ellis.

A native of the Mediterranean sea.

_Palma._ Trichotomous, with compressed, sub-convex, wedge-shaped joints, slightly denticulated at the tip; the extreme joints broad, and often furnished with short finger-like lobes. Ellis.

This was found in the American seas, and is of a glossy white colour.

3

_ELONGATA._
ELONGATA. Trichotomous, with the joints of the stem roundish and cuneated; those of the branches cylindrical; the extreme joints a little obtuse, and some of them capitated. Ellis.

Varies in colour from red to purple. It inhabits the European coasts.

SUBULATA. Trichotomous, with the joints of the stem cuneated and two-edged, and projecting small pointed branches from the top of each of their sides, with round joints. Ellis.

The appearance of this coralline is very flat, white, slender, and small, and seems as if it were very closely pinnated or bifurcated with fine white fibres, projecting out on each side like the plume of a feather. This is the most delicate of the coralline tribe. Found in the West Indies.

Granitera. Trichotomous, with the joints of the stem compressed and wedge shaped; those of the branches roundish, and furnished with opposite ovate ovaries, seated on small pedicles. Ellis.

This differs from all the other kinds of trichotomous corallines, in having proliferous ovaries, or branches growing out of them, being other ovaries. It is of a fine slender texture, and of a sea-green colour. It was found on the coast of Africa, in the Mediterranean sea.

OFFICINALIS. Sub-bipinnate, and usually trichotomous, with the joints of the stem somewhat cuneated or turbinated; those of the branches round, and some of the terminal ones capitated. Ellis. Corallina officinalis, sub-bipinnata, articularis fusciturbinata, Linn. Fl. Suec. Corallina officinalis, Toberaen herb. Mysurus constrictus, Barrel.

Common on almost every shore, where it grows on the rocks in tufts of two, three, or four inches in length, and varying considerably in colour, being red, yellow, green, and white. This is the coralline of the shops, and is the kind used in powder as an abr.-rubent.

Pinnata. With pinnated branches without joints, and covered with a mealy substance. Ellis.

Found on the coast of the Bahama islands.

Ruby. Dichotomous, filiform, with the joints of the stem round; those supporting the divisions elavated, and some of the lower ones bicornuted. Ellis. Corallina rubens, Linn. Corallina filiformis dichotomata sufflata, articularis omnibus cylindris, Pallas.

Inhabits European seas; length two inches; colour red.

Crystata. Dichotomous, filiform, in crested clusters, with roundish joints; those supporting the leaf sub-divisions elavated. Pallas.

This kind inhabits the European and American seas. The colour, as in officinalis, varies from red to purple, green, yellow, and white.

Fractiissima. Dichotomous, with smooth, even, cylindrical joints; those at the extremity broadest at the tip. Linn. Corallina minimum capitaceum, Sloane.

This is found in the West Indian and Mediterranean seas, and is so extremely fragile, that perfect specimens are very rarely obtained; the colour is milk-white; length about two inches.

Spermophorus. Dichotomous, filiform, with roundish branches; those supporting the two last sub-divisions elavated. Linn., &c.

Inhabits European seas, is of a milk-white colour, and about an inch in length.

Corniculata. Dichotomous, with the joints of the stem and branches bicoromuted; those of the subdivisions roundish. Linn.

Inhabits the same seas as the preceding.

FRUTICULOSA. Dichotomous, with round branches tapering towards the extremities, without joints, and mealy. Ellis and Soland.

There are many varieties of this shrub-like coralline; the species occurs on the coast of the Bahama islands.

Indukata. Dichotomous, with smooth round spreading branches, freely jointed. Ellis and Soland.

Found on the same shores as the preceding species.

Lichenoides. Dichotomous, with the branches a little rugged and not jointed, the tips dilated and flattened. Ellis. Liverwort coralline.

This coralline is of a sea-green colour; it inhabits the Bahama islands.

Rugosa. Dichotomous, with cylindrical branches, hardly jointed, rough, with transverse wrinkles, and compressed at the tips. Ellis and Soland. Fucus Marinus, &c.

Found on the coast of Jamaica.

Marginalta. Dichotomous, with freely jointed smooth flat branches, and raised margin. Ellis.

This kind occurred on the shore of one of the Bahama islands. Mr. Ellis observes, that though this coralline is found, when dry, on the shore, more flat than the rest of this kind, it is very probable, when it is fresh taken out of the sea, it is much rounder, the fibres in the fibre being extremely delicate, which occasion its shrinking very much, when the gelatinous fluid is evaporated.

Cylindrica. Dichotomous, with cylindrical and nearly equal smooth joints. Ellis.

Mr. Ellis received this species of coralline preferred in spirits, from the West Indies, and observed by that means the internal parts appeared full of a clear gelatinous substance. Upon opening some of the joints, a number of minutely branched tubes were also discovered, and hence this writer concludes, that the tubular-hollow appearance described by authors, proceeds from their having diffused only dried specimens.

Obtusata. Dichotomous, with oval-oblong joints, a little compressed and rounded at the ends. Ellis.

Inhabits the shores of the Bahama islands.

 Oblongata. Dichotomous, with oblong cylindrical joints, a little compressed. Ellis

A species allied to the foregoing corallines, and found on the shores of the same islands.

Lapidescens. Dichotomous, with cylindrical downy branches. Ellis.

This kind is sometimes found trichotomous, or three-branched, instead of two. In specimens just received from the sea, the surface appears covered with short hair-like verticillate down, of a reddish colour, disposed in regular circles, one above another.

Barbata. Dichotomous, with short cylindrical joints; those at the extremity bearded at the tips. Linn.

Inhabits the shores of Jamaica, and measures about three inches in length. This is the bearded, or bead-coraline, of Ellis.

Rosarium. Dichotomous, with round bead-like joints, those of the stem longest and cylindrical. Ellis. Rosary coraline.

Nearly allied to the last, but specifically different. A native of the West Indies.

Cuspidata. Branches often dividing into four parts, and ending in sharp points; joints cylindrical, and united by a gluttonous teninous substance. Ellis.

Found in the West Indies; it is very brittle, white, and grows in tufts about three inches high.

Tribulus.
TRIBULUS. Branches often dividing into five; joints two-edged, and united by a glutinous tendinous sub stance. Linn.

A West Indian species, of a whitish colour, and rather larger than the lath.

Flagellum. Stem simple, incurred, with the branches sticking together, in a foliaceous fan-shaped manner, and somewhat waved. Linn.

This coralline is also found in the West Indies, and varies much in figure, being sometimes of a flat kidney shaped form, of about an inch in height, and sometimes expanding to a large subdivided, lobed, and undulated mass, from one to five inches broad, and as many in height. At the bottom of the stalk is a tuft of fine hair-like tubes. There are many kinds of this curious coralline found in the West Indies, which vary in colour from a greenish-brown to a milk white.

Conclutinata. Stem fiddle, slightly incurred, with the branches dichotomous, and agglutinated together, and forming a naked fan-shaped leaf. Linn.

Found on the coast of the Bahama islands; the colour sea-green, and the height an inch and a half.

Phoenix. Stem fiddle, incurred, terminating in an oblong frond, composed of distinct fasciculated branches, produced on all sides, the sub-divisions of which are united together, and appear quite flat. Linn.

This is the palm coralline of Ellis, a singular species found on the coast of the Bahama islands; it is of a milk' white colour, and about three inches and a half high.

This coralline varies in the thickenfs of its branches, as well as in size, being found from one to four inches long. In some the item is very short, in others four times the length of the head. The joints are easily distinguished where the branches divide; the item is composed of tubular filaments covered with calcareous crust; its general colour is white. This sort of coralline adheres to flakes by the base of its filaments, and is often found attached to such bodies, in large clusters, in the West Indian ocean.

This is one of the most singular of the coralline genus, and differs from the rest, among other particulars, in having the item regularly wrinkled. The item is small at the base, and grows wider as it rises, till it sends forth its branches at the top; it adheres at the base like the fuculare, being composed of ramose tubes, which tubes do not leffen as they extend or branch out, but have an equal diameter throughout their whole length. The species is found in clusters in the American seas, particularly near the Bahama islands.

We must lastly mention the corallina teretris of Linnaeus, a species, according to that writer, distinguished by having the branches placed opposite, and the joints cylindrical, with lateral peduncles, and transversely wrinkled fructifications; it is further added, that the species is a few lines high, and inhabits heaths in Friesland. Gmelin admits it as a species of coralline, with some doubt, and seems uncertain whether to consider it of the animal or vegetable kingdom, and undoubtedly not without reason, for it has been described by different writers, both as a plant and a coralline. Meele defines it to be a vegetable of the cryp-
close across, and crampcd together with iron. On each side lengthways of this bridge or flage, there was a parapet, which reached just above a soldier's knee. At the farthest end of this flage or ladder, there was a bar of iron in shape somewhat like a pellc, but sharpened at the bottom, or brought to a point at the lower end. And connected with the top or upper end of it, there was a ring. To the ring there was fixed a rope, by means of which, with the help of the pulley at the top of the pillar, the machine was hoisted up, and as an enemy's vessel approached let fall on it, sometimes on the prow, and sometimes on either side, as an opportunity presented itself. The farthest end of the machine falling with great force, struck into the deck of the enemy's vessel, and held it fast. In this situation, if the two vessels happened to be side by side, the Romans, who first made use of such means in the sea-fight between them, commanded by Diilius, and the Carthaginians, leaped on board the enemy's vessel from every part of the side of their own at once. But if the vessels were joined only by the prows, they then went two and two abreast along the machine, the two foremost extending their shields or bucklers right before them to ward off the brokes or blows that were aimed at them in front, whilst those that followed, refted each of them, the bofis of his buckler upon the top of the parapet on either side, and thus covered both their flanks. Such were the machines employed on that occasion by the Romans, to which they gave the name of Corvi, or Corbeaux.

Some French writers give the name of Corbeaux to the machines with long beams extending beyond the battlements and iron-stands bolpended to them by chains, with which Archimedes, at the siege of Syracaie, under Marcellus, raised the Roman vessels erect out of the water, and then, by lowering the chains from the beams, let them fall into the water sometimes on one side, and sometimes bottom uppono foot. But it is evident from Polybius's account of those machines, that they were quite different from the corvi of the Romans, which we have just given a description of. The corve was also very different from what these writers call the corve a later-coursants, the corve a griffets, the corve demgfiex, the corbeau tenaille, and the corbeau a fafe.

**Corbeil, in Natural History, the name of a curious species of Ochama.** It is of the larger kind, and is deeply frilated, both longitudinally and transversely; so that it has a fort of reticulated surface, like balst-work.

**Corbeil, in Latin Corbelin, in Geography, a town of France, in the department of the Loir, and district of Montargis; eight miles N.W. of Montargis.**

**Corbeil, in Architecture, the representation of a basilic, sometimes seen on the heads of carvairds.** The word is also used for the vate, or tambour, of the Corinthian column; so called from its resemblance to a basilic, or because it was first formed on the model of a basilic.

**Corbeil, or Corbul, is also used, in Buildings, for a short piece of timber placed in a wall, with its end sticking out six or eight inches, as occasion serves, in manner of a shouldering-piece. The under-part of the end, thus sticking out, is sometimes cut into the form of a boulte; sometimes of an ogee, and sometimes of a face, &c. according to the workman's fancy; the upper-side being plain and flat.**

Those corbels are usually placed for strength immediately under the semi-girders of a platform, and sometimes under the ends of chamber-beams: in which latter case they are commonly placed a foot or two below the beam, and have a piece of timber standing upright close to the wall from the corbel to the beam.

**Corbeil, is also used by some architects for a niche, or hollow, left in walls for images, figures, or statues to stand in.**

**Corbeilin, in Geography, a town of France, in the department of the Arve, and district of La Tour-du-Pin; 30 miles N.E. of Lyons.**

**Corbeny, or St. Markou, a small town of France, in the department of the Aisne, with a priory of Benedictines, where the kings of France used to pray for nine days, after having been anointed at Rheims.**

**Corbera, a town of Spain, in the province of Valencia; 20 miles N. of Valencia.**

**Corbett, in Architecture, is used by some, as Harris, in his Lexicon, for corbel.**

**Corbeuntos, in Ancient Geography, a town of Asia, in Gallia, assigned by Ptolemy to the Teutoburger.**

**Corbia, a town of the island of Sardinia, situated 25 miles from Bos, according to the Itinerary of Antonine.**

**Corbiana, or Corbiana, a province of Asia, between Hyrcania and Bactriana, according to Strabo, who lays that it was in the country of the Elymean.**

**Corbie, in Latin Corbela, a small town of France, in the department of the Somme, on the Somme, in N. lat. 5° 32' 32", one hundred miles north of Paris; it is the chief place and canton in the district of Amiens, and has 1941 inhabitants. The whole canton contains 11,626 inhabitants dispersed in 24 communes upon an extent of 175 kilometres and a half.**

**Corbien, in Ancient Geography, (Khorrom al-Ash) a place of Asia, on the banks of the Gyndes, S.S.W. of Ecbatana and N.N.W. of Susa.**

**Corbières, in Geography, a town of Southern France, and chief place of a bailiwick, in the canton of Carcassonne, 10 miles south of Carcassonne.**

**Corbières, a valley of France near the Pyrenees, celebrated on account of a victory which Charles the 22nd obtained over the Saracens.**
CORBIGNY, or ST. LEONARD, in Latin Corbiniacum, a small town of France, in the department of the Nievre, chief place of a canton in the district of Clamecy, has 2315, and the whole canton 11,221 inhabitants. The territorial extent of the latter is 307 kilometres and a half. It is composed of 17 communes.

CORBILLO, in Ancient Geography, (Cuoton) a port of Gaul, upon the Loire. M. D'Avrille places it at a little distance from Conthominum or Nantes to the west.

CORBIO, a town of Spain, belonging to the Suebittani.

CORBIBEAU, from Corbin, a raven, in Ornithology, an African bird, described by M. F. le Vaillant, in his "Histoire Naturelle des Oiseaux d'Afrique, &c." This bird is similar to the raven in the shape of his body, his feet, and his claws; his middle claw is united as far as the first articulation, by a membrane, to the inner one; and the feathers on the lower part of his back are turned upwards, and cover his nostrils; but he is unlike the raven in his back, in the length of his wings, and in his graduated (stage) tail. He appears, says the writer, to occupy in part the interval between the genus of the ravens and that of the vultures; though he resembles the former in a greater degree than the latter. He is similar to the African vulture in the size of his wings, which when spread are three inches longer than his tail; in his graduated tail, in the form of his beak, which is compressed side-ways, convex above, crooked and rounded. These particulars distinguish the corbeiba from all the species of ravens hitherto described; and this bird may be always ascertained by the white patch on the nape of his neck, which strongly contrasts with the glossy black that constitutes the rest of his plumage; except a white mark which separates the files of this white patch on the back of his neck, and encircles the neck. This bird has some resemblance, in point of form, to birds of prey; and his manners and mode of life confirm the resemblance. Corbin constitutes the chief part of his food; and these birds frequently assemble in large and noisy crowds. The appetite for flesh and blood leads him to kill lambs and young antelopes, and to pursue even the largest quadrupeds. He flies with great strength, and raises himself to a great height by his long wings. He constructs his nest, in October, amidst the trees; and lays four eggs greenish, spotted with brown. The corbeiba is not a bird of passage, but continues the whole year in the country where he was born. The female is less than the male, and the black less glossy.

CORBRENE, in Ancient Geography, a people of Afia, placed by Polybius in the valleys of Media, with the Cofianus and other barbarous nations.

CORBRIDGE, in Geography, a place of England in Northumberland formerly a borough, which sent members to parliament. In 1295 it was burned by the Scots, and in 1311 suffered severely from the same invaders; 4 miles east of Hexham.

CORBULO, Gna. Domitius, in Biography, a distinguished commander under some of the Roman emperors. By Tiberius he was made superintendent of the highways in Italy. His conduct in this situation was questioned by succeeding sovereigns. In the year 37, he engaged in military service, and had the command of an army in Lower Germany, among whom he maintained, though at the expense of his humanity, the strictest discipline. In this commission he was eminently successful over the enemies of the empire. By Nero, in 54, he was sent into Armenia, which was invaded by the Parthians. He employed all his efforts in restoring the discipline of the legions which had been encroaved by the luxury of Syria. A maxim by which his conduct was governed, was, "that an enemy might be conquered with a pick-axe," referring to the labours of entrenchment and fortification, for which the Roman armies were so much distinguished. No frequency, either of foment or climate, prevented him from keeping his troops in the field; and in suffering, as well as in exertion, he was an example to his men, going contantly in their clothing, and with his head bare. He never pardoned a defeter who was apprehended. His various successes were important to the government under which he was employed, and will be related under the article Rome. After he had forced the Parthians to an accommodation, he became, on account of the glory attached to his military reputation, an object of suspicion and jealousy with Nero, who resolved upon his death. He accordingly summoned him to his presence by a letter filled with the most flattering expressions of regard. The brave soldier scorned to suspect the integrity and honour of his infamous sovereign. He prepared to attend the court, but no sooner had he reached the port of Corinth, than he met an order to die. Reflecting for a moment upon his own want of prudence and foresight, he exclaimed, "I have merited my fate by trufling to the professions of the monfier," and instantly plunged his sword through his body. This was in the year 67. He left behind him memoirs of the severel wars in which he had been engaged.

CORBUT, Charles and Philip, two draftsmen and mezzotintoopers of London, by whom we have several portraits from different masters, as well as other prints from Vandyke, Ramsey, Titian, Oilade, Renolds, Wilton, &c. Charles Corbut, who was the elder, flourished about the year 1760. Heinecken, Surtt.

CORCANG, or Al. Ioraniyan, in Geography, a town of Afia, on the river Gihon.

CORCAS, or Grand Corcas, an island almost in the form of a crescent, N. of St. Domingo, in the windward passage, about seven leagues W. of Turk's island, and about twenty E. of Little Inagua, or Heneagua, N. lat. 21° 55'. W. long. 70° 55'.

CORCELET, in Natural History, that part of the fly cliffs which is analogous in its situation to the breast in other animals. Many have called it the breast in that also, but improperly; because the breast of other animals is the place of the lungs and trachea; but these organs are in the fly clafs distributed through the whole body. The wings are affixed to this part of the fly clafs; and there are some diffecrations of great consequence, in regard to the arrangement and distribution of those animals into genera. Rezurrer's Hist. Infest. tom. iv. p. 126.

CORCALLE, in Geography, a river of France, which runs into the Arroux near Autun.

Gen. Ch. Cal. Perianth five-leafed; leaves linear-lanceolate, acute, erect deciduous. Cor. Petals five, oblong, oblique, narrowed towards the base, erect, the length of the calyx. Stam. Filaments numerous, capillary, shorter than the corolla; anthers small. Fil. Germ superior, pyramidal, fiddle thick, very short; styles simple or bident. Peric. Capsule from two to five-celled, from two to five-valved. Seeds numerous, angular.

Eff. Ch. Corolla five-petalled. Calyx five-leafed, deciduous. Capsule from two to five-celled, from two to five-valved. Sp. 1. C. vilicosus, Iinn. vilicent-leaved corchorus, or common...
le-shaped." Root annual. Stem about two feet high, cy-
indrical, smooth, even-furnished, a little branched. Leaves alternate, some spear-shaped, some oval, some almost heart-shaped, serrated, with a bristle-like reflexed appendage on each side of the base, on long slender petioles; stipules simple, small, at the base. Flowers small, reddish-yellow; peduncles a line and half long; bracts three, awl-shaped. C. triflorus, somewhat cylindric or spindly-shaped, two inches long, obliquely pentagonal, attenuated into a beak at the tip, five-celled, five-valved; cells divided by incomplete transverse partitions. Seeds numerous, nearly pyramidal, dark brown, fixed in a double longitudinal row to the cen-
tral margin of the pericarps. A native of Asia, Africa, and America; cultivated as a pot-herb in Egypt, Syria, and other parts of the East, particularly by the Jews. It is said to poftice some medicinal qualities, and to be useful as an emulent, a sweetener, and a pectoral. 2. C. tri
queterous, three-celled, three-valved; angles bifid, flabrous; leaves oblong; lowest ferratures bristle-shaped." Root an-
ual. Stem a foot high, cret, cylindrical, even-furnished, green. Leaves alternate, petiolate, undulate-ferrated; fit-
pules bristle-shaped, small. Flowers yellow; peduncles nearly opposite to the leaves, short, two-flowered; calyxes angular, petals narrow. C. triflorus linear, trian-gularly primiti-
flaped, channelled at each angle, flabrous, obtuse and 
fimple at the tip. A native of Arabia. 3. C. trifida. Linn. Mant. 56.; Mart. 3. Lam. 3. (C. Americanus and: 
Linn. 6. Sept. 127. fig. 4.) 5. trilocu-
laris; Burm. ind. 2.32. tab. 37. fig. 2. "Capsules linear, nearly cylindrical, flabrous; lowest ferratures of the leaves bristle-shaped." Stem even-furnished, green. Leaves lanceo-
late, marked with lines, undulate-ferrated. Capsules termi-
nated by the three, much diverging, bifid styles. La Marck 
received from Sonnerat an East Indian Specimen, which, be-
seems to be C. trilocularis of Burman, and to be somewhat 
different from Plunet's plant. Its leaves are linear-lan-
colate, toothed, on short petioles; its capsules grow two 
or three together, on very short peduncles, and are termi-
nated by three diverging points, which do not appear bifid.
1. tab. 85. (C. americana carpini folio, fructu longiore; 
25. fig. 1.) "Capsules oblong, three-celled, three-valved, 
fix-furnished, fix-culpidate; leaves heart-shaped; lowest fer-
ratures bristle-shaped." Root perennial. Stem about a foot 
high, cylindrical, purplish, with divercating branches. 
Leaves petiolate, oval-heart-shaped or oblong, edged with 
sharp teeth, the two lowest sometimes, but not always, ex-
tended into a long awl-shaped appendage. Flowers yellow, 
small, lateral, two together, on short petioles. Capsules termi-
nated by three widely divericating bifid beaks; valves mark-
ed on the inside with obsolete transverse ferratures, instead of 
partitions; furnished with a double, crenulate, and some-
what undulated dorsal wing. A native of the Weft Indics. 
5. C. acutangulus. Lam. 5. Wil1l. 5. (Lyfimachia; Pluk. Phyt. 
tab. 44. fig. 1.) "Capsules prismatic-wedge-shaped, acutely 
angualr, three-toothed; leaves egg-shaped, sometimes with 
a single bifide at the base; petals hispid." Root perennial. 
Stem about a foot high, cylindrical, rather slender, hispid, 
branchcd. Leaves alternate, on long petioles; stipules five 
or fix lines long, narrow, bristle-shaped. Flowers yellow, 
small, lateral, in pairs, on short peduncles; petals oblong, 
rather narrow; bracts three, bristle-shaped, often longer 
than the flowers. C. trifidus long, narrowed towards the base, pentagonal, two of the angles more acute and more 
pronounced than the others, terminated by three biffid beaks.
Mart. 5. Lam. 5. Wil1l. 7. Gert. 
7. Lam. 179. fig. 6. Lam. Ill. Pl. 478. fig. 3. (Alcea fosa. 
corchorus; Pluk. aln. 18. tab. 257. fig. 4. Gemia favis; 
Rumph. amb. 5. 212. tab. 28. fig. 11.) "Capsules round-
ish, depreffed, wrinkled; lowest ferratures of the leaves 
bristle-shaped." Root annual. Stem five or six feet high, 
tete, cylindrical, smooth, branched. Leaves five or fix 
inches long, petiolate, oval-lanceolate, toothed, thin, pale 
green above, glaucous underneath. Flowers small, lateral, 
flgile; calyx-leaves conceave, incurred, shorter than the 
corolla; petals emarginate. C. trifidus short, flatid, wrinkled, 
five-celled, five-valved, (imperfectly ten-celled, ten-valved; 
with larger cells fertile; five smaller barren, placed between 
the others near the circumference of the capsule; Gert.) 
A native of China and the East Indies. A kind of 
broth is obtained from the macerated flms, which is much ued 
Wil1l. 6. Vahl. symb. 3. p. 69. (Euphrasia affinis; Pluk. ambl. 
85. tab. 439. fig. 6.) "Capsules consist, woolly, fidedeleed, 
nerly, flabrous; leaves oblong-elliptical, petiolate, withoout 
bristle-shaped appendages at the base." Lam. Root per-
ennial. Stem one or two feet high, slender, cylindrical, almost 
entirely smooth, a little branched. Leaves less than an 
indefinite, alternate, toothed, petals somewhat villous; 
slipules simple, narrow-lanceolate. Flowers yellowish, small, 
almoft sessile, lateral in fascicles opposite to the leaves. 
Capsules five or fix lines long, cret, three-celled, five-celled, 
furred. A native of the East Indies. 8. C. biflorus. 
Amer. 165. Hort. 3. 57. Plf. 81. tab. 157. (Guazuma; 
Plum. gen. 36. Burm. amer. tab. 104.) "Capsules round-
ish, woolly; leaves egg-shaped, obtuse, tomentous, equally 
furred." Linn. "Leaves elliptical, tomentous, crenate; 
capules ovate-oblong, downy, umbellett." Lam. A shrub 
three feet high, or more; branches alternate, cylindrical, 
clothed with a whitish cottony down. Leaves alternate, 
petiolated, near two inches long, and one broad. 
Flowers yellow; common peduncles opposite to the leaves, the length of the petals, foliaries, cottony, supporting five or fix pe-
decilled flowers; calyx cottony on the outside; petals scarcely the length of the calyx. C. trifida a little immersed, 
very woolly, obtuse, two-celled. A native of South Amer-
oblong, woolly; leaves tomentous." Thunb. Stem 
flabby, cylindrical, cret, two feet high, and more; 
smooth, purple, branched; branches alternate; at the bot-
top purple and smooth; at the top tomentous, cret, 
and like; branchlets filiform, spreading, tomentous. 
Leaves alternate, petiolated, armed, spreading; petiole very 
short, tomentous. Flowers orange-coloured, axillary and ter-
inal, generally solitary. C. trifida cylindrical, woolly. 
A native of Japan. La Marck afferts that it is different 
8. Lam. 9. Wil1l. 13. Jacq. Hort. 3. tab. 78. (C. folio 
ulmi major; Plum. Sp. 7. Burm. Amer. tab. 103. fig. 2.) 
"Capsules oblong, hairy; item hairy; leaves oblong, equally 
furred." Root annual. Stem about two feet high, cy-
indrical, rather slender, branched. Leaves alternate, un-
equal at the base, on short hispid petioles; stipules narrow, 
very
very hirsut. Flowers yellow; peduncles and calyces hirsutip; petals oblong, shorter than the calyx, obtuse, narrowed a little towards the base; stigmas yellow, the length of the petals; stem oblong, columnar, hirsut, with whitish hairs directed upwards; style biflorn, the length of the stigmas; filaments two, not spirading. Capsule near an inch long, two-furrowed, two-valved. Seeds small, black. A native of the West Indies, and South America. 11. C. japonicus. Linn. Sp. Pl. 1. Mart. 9. Lam. 18. Willd. 14. Jacq. Hort. 3. tab. 59. (C. folio linnii minor; Plum. Sp. 7. Birm. Amer. tab. 103. fig. 1. Corehora affinis; Siam. Jan. 50. huit. 1. 145. tab. 94. fig. 1. Corea folcis minoribus; Brown. Lam. 1. 147.) "Capsules linear, compressed, two-valved; leaves lanceolate, equally ferrated." Root perennial. Stem about two feet high, almost woody, erect, slender, cylindrical, panicked, somewhat pubescent. Leaves smaller than those of the preceding species, without awl-shaped appendages at the base, on rather long petioles, which are pubescent on one side. Flowers yellow, lateral, peduncled, solitary, or in pairs; germs cloathed with short hairs. Capsules nearly smooth, two-valved. According to Linnaeus, the spring flowers are without petals, tetradromous, with a four-leaved calyx; but those produced in autumn, correspond with the generic character. 7. C. japonicus, a native of the West Indies. 12. C. japonica. Mart. 7. Lam. 11. Willd. 14. (Aped. Fl. Jap. 227. (Toito, vulgo jambo baki; Kämpf. amen. 844.) "Capsules round, smooth; leaves doubly ferrated." Stem shrubby, two feet high or more, smooth; branches alternate, filiform, angular. Leaves several together from alternate buds, petioled, almost heart-shaped, ovate-acuminate; stigmas acute, almost pinnate, nerving, villous, and particularly so on the nerves underneath. Flowers yellow or orange-coloured, terminal, solitary, on short peduncles. A native of Japan, where it is cultivated on account of its beauty. There is a variety with double flowers. 13. C. tetragonum. Mil. Mart. 15. (C. flore flavo corynthus phyllido; Pluk.) "Capsules quadrangular, reflexed at the points; leaves ovate-heart-shaped, crenate." Stem about two feet high, with small branches. Flowers pale yellow, very small. Capsules swelling, rough, about an inch long, flattened at the top. A native of both Indies. 14. C. linealis. Mil. Mart. 11. "Capsules linear, compressed, two-valved; leaves lanceolate, ferrate toothed." Stem three feet high, with weak branches. Leaves about three inches long, and one broad, fitting close to the branches. Flowers pale yellow, very small, opposite to the leaves, solitary. Capsules two inches long, flat, two-celled. A native of New Spain, about Cartagena. 15. C. bifurcatus. Mil. Mart. 12. "Capsules linear, compressed, with two horns at the points; leaves heart-shaped, ferrated." Stem between three and four feet high, herbaceous, strong, with upright branches. Leaves on long slender petioles, and between them many smaller leaves, nearly of the same form, and fitting close to the branches. Flowers pale yellow, very small, lateral, on short peduncles. Capsules near three inches long, flat, ending in two horns, two-celled. A native of Jamaica; raised from seeds sent to Miller by Dr. Houlton. 16. C. flexuosus. Mart. 14. Willd. 12. Thumb. in Linnaeus. Trans. 2. 355. "Leaves doubly ferrated, cupuldate; stem zig-zag." Stem cylindrical, rendered somewhat angular by the deciduous leaves, two feet high, erect, smooth. Leaves two inches long, alternate, petioled, obliquely heart-shaped, villous, spreading. Flowers yellow, terminal. 17. C. ferratus. Mart. 15. Willd. 9. Thumb. ibid. "Leaves oblong, ferrated, cupuldate; branches smooth." Stem erect, smooth, branched; branches cylindrical, purple, erect. Leaves two inches long, alternate, petioled, spreading; stigmas large, bristle-shaped at the tip, slightly rough with hairs above, smooth underneath. 18. C. floridus. Mart. 16. Willd. 8. Thumb. ibid. "Leaves egg-shaped, bristle-ferrated, opposite; stem and branches zig-zag, climbing." Stem cylindrical, branched; branches opposite, divaricated. Leaves opposite, on short petioles, rounded at the base, acuminate, an inch long. Flowers yellow, terminal, solitary, foliar. The last three species are natives of Japan.

Propagation and Culture.—All the species may be raised from seeds sown in the spring in a hot-bed, protected by a glass frame. Soon after they come up, they should be transplanted into a fresh hot-bed; when they are grown strong, they should be removed into separate pots; and if gradually exposed to the open air, they may be shewn out of the pots in June, and set in an open border, where they will generally flower and ripen their seeds. C. hirsutus must be kept in a bark-bed in the hothouse during winter. Miller.

CORCIA, in Geography, a town of the island of Corfica; 14 miles N.N.W. of Corte.

CORCIEUX, a small town of France, in the department of the Vosges, chief place of a canton, in the district of St. Vincent, with a population of 1143 individuals; that of the canton amounts to 8351, upon 17724 hectares; and the number of its commune is 13.

CORCOBA, in Ancient Geography, a town situated on the south coast of the island of Tarrabona, according to Ptolemy.

CORCOMA, a town of Africa, in Mauritania Caesariensis, between Carepuna and Lagruntum. Ptolemy.

CORCONIANA MANSIO, a place of Sicily, on the route from Catana to Agrigentum, according to the Itinerary of Antonine.

CORCOPAS, a river of Pannonia, which, according to Strabo, passed before Naupontus, and discharged itself into the Savus.

CORCULUM, in Vegetable Physiology, is a term used by Linnaeus, after Cæsarianus, for the heart, or more properly embryo, of a seed; alluding to its shape, which, in the walnut, and many other seeds, resembles the animal heart in miniature. It is the most important and even essential part of a perfect seed, to which all the rest are subservient, being the point whence the future plant originates. In unpregnated seeds it is deficient, or rather abortive; in fertile ones it is closely connected with the cotyledons, on which it depends for the food supplies of nutriment, and other exciting causes of its evolution. The corculum consists of two parts: the radícula, or radicle, which, by an unerring law of nature, descends in order to become the root; and the plumula, or feather, which, as regularly accedes, and becomes the stem and leaves. Dr. Darwin ingeniously accounts for this diversity of direction in these two parts, from the former being mutable by moisture, the latter by air; and presumes that inarch extends itself accordingly where its vitality is most excited. Other philosophers have explained the same phenomenon, far less happily, on mechanical principles. See COTYLEON and EMBRYO. S.

CORCULUS, the little heart, in Natural History, a name given by authors to a small species of cordiformis, or heartbell, of a rose colour.

CORCURA, in Ancient Geography, a town of Asia, in Alyssia. Ptolemy.

CORCYPRA, (Corcyra) one of the Greek islands, situated in the Ionian sea, and called, in more ancient times, Drapane, Scheria, and Phoxaia. It is said to have taken its name from that of a nymph, whom Neptune ravihing in this
this island. It is about 45 miles in length, 21 in breadth, and 510 in compass. It was famous for the delightful gardens of King Alcimus, who courteously entertained Ulysses after his shipwreck. The southern parts of the island are barren, mountainous, and ill provided with water; but the northern coast is very fertile in all kinds of delicious fruit, excellent wines, olives, grain, &c.; whereas Homer has denounced it the fruitful Scheria. It had anciently two cities of no small note, viz. Coregyra and Saliopus: the former was the metropolis of the island, and once very powerful, as appears from Thucydides, and others; the latter is commenced by Pliny and Ptolemy as a wealthy and well-built city, but Ciceron calls it only a haven.

This island is said to have been first inhabited by the Phoenicians, whence it was called Phoenacia; but afterwards the Corinthians sent thither a numerous colony, B. C. 756. The Corecyrians were, for some time, masters of the isle. Their government was first monarchical; but afterwards they formed themselves into a republic, and made a very considerable figure in the flourishing times of Greece. Herodotus informs us (lib. vii. cap. 168.) that they were very powerful by land; but he much blames them for their deceitful conduct, with respect to the aliment they promised the Greeks against Xerxes: for, being invited by the Athenian and Lacedaemonian ambassadors to join them in the common cause, they readily engaged to send powerful succours, alleging that they would not neglect the safety of Greece in so imminent a danger; being well apprized, that if the enemy prevailed, they would soon be reduced to the condition of slaves. The ambassadors departed; and the Corecyrians, fitting out a squadron of 60 ships, sailed to the coast of Peloponnesus, and having anchored about Pylos and Tenarum, waited in that station to see the event of the war, being resolved to join the victorious party. When they heard that the Persians were defeated at Salamis, they left their station, and joined the rest of the Greeks, pretending that they had been prevented by the Eteocline winds from doubling the cape of Melos, and being present at the battle. The Corecyrians submitted to Alexander, and remained subject to the kings of Macedon, till they were delivered by the Romans, in the reign of Perseus; from which time they enjoyed their liberty, till the reign of Vespasian, when they underwent the common fate of the other Greek islands and states both in Europe and Asia. The Corecyrian felicitous were proverbial even among the Greeks. See COREY.

Corecyra Mebna, or Nigra, so called to distinguish it from the former, an island in the Adriatic sea, on the coast of Illyricum. The Cutilians built a town on this island. In the war of Illyricum, B. C. 229, the Romans, under the command of L. Postumius Albinus, and Cn. Fulvius Centimalus, landed in the island, and the Corecyrians delivered up the garrison of the Illyrians, who had taken possession of it under the command of Demetrius of Pharos; and the whole island submitted, conceiving that this was the only method of securing themselves for ever from the infatuation of the Illyrians. Upon the conclusion of peace, it was agreed, that Corecyra, as well as some other places, should continue in the possession of the Romans. This island is now called Corfoli.

Corezycz, in Geography, a town of Poland, in the palace of Volhynia; 40 miles N. of Conkiantown.

Corezy, or Kortkamin, a town of Poland, in the palatinate of Sandomierz, on the Vistula; 48 miles W. S. W. of Sando marz.

Cord, or Chord, an assemblage of several threads of hemp, cable or twisted together by means of a wheel.

The word comes from Ceypo, which properly signifies an interline, or gut. wherof cords may be made.

Cord of St. Francis, a kind of rope adorned with knots, worn by the brothers of the fraternity instituted in honour of the saint.

Some, as the Cordeliers, Capuchins, Minorites, and Recollects, wear it white; others, as the Pique, black. Its design is to commemorate the bonds wherewith Jesus Christ was bound.

Cord, the society of, includes a great number of people belonging to religious. To obtain indulgences, they are only obliged to lay five Pater, five Ave Maries and Gloria Patri, and to wear this rope, which must have been first blest by the superior of the order.

Cord of wood, a certain quantity of wood for burning; so called, because formerly measured with a cord.

It is now measured, particularly in Worcestershire, where the name has been regulated by statute, between two lakers of wood, four feet high, and eight feet apart; and is to be four feet broad and high, and eight feet long = 128 cubic feet = 4.74 cubic yards = 5.622 shells or cubic inches of France = 455.223 cubic links.

Cord wood is properly new wood; and such as, when brought by water, comes aboard a vessel; in opposition to that which is floated. All burning wood, not exceeding eighteen inches circumference, is deemed cord wood.

Cord, Magical, an instrument in great use among the Laplanders, and supposed to be of great virtues among them. It is a cord or rope, with three knots tied in it. They use many magical rites and ceremonies in the preparing and tying of this cord; and when thus prepared, it is supposed to have power over the winds; and they will fall, by means of it, a good wind, or at least a promise of one, to a ship. If they unite only one of these knots, a moderate gale is to succeed; if two, it is to be much stronger; and if three, there is to be a storm.

Cord, Unbleached. See Unbleached funiculus.

Cord-wood, in Rural Economy, a term applied to the small sorts of broken-up or other wood, which was formerly sold by the cord.

Corda, in Ancient Geography, a town of Albion, in the country of the Sigeone. As this place was situated farther to the N. W. than the other towns of the Sigeone, it is thought to have stood on the banks of Loch-Cure, out of which the river Neith springs.

Cordage, is used, in general, for all sorts of ropes and cords, great and small; and more particularly for those that are used in the rigging and fitting out of small vessels. The word is also used for the art of preparing andmanufacturing the ropes, &c. See Cable. See also Rope, and Rigging.

The naval cordage of different ages and nations has been formed of very different materials. Thee of the earlier ages were probably thongs of hide or leather; the use of which was retained by the Caledonians in the third century, and by the nations north of the Baltic in the ninth and tenth centuries. They are even now used as ropes in the windy isles of Scotland. They were superseded in the southern parts of Britain, and on the continent, at an early period, by iron chains. Accordingly we find, that in the maritime and commercial
commercial country of the Veneti, who were intimately connected with the Belgts of Britain. Iron chains were used for cables in the days of Caesar. However, in the more improved countries of the south, thongs of leather and chains of iron had long given place to the use of vegetable threads; and the art of combining them into strong cords was under-footed and practiced. In this manner the Greeks used the common rushes of their country, and the Carthaginians applied to the same purpose the spartium or broom of Spain. And as all the cordage of the Romans was formed of these materials, at their last defeat on our island, the art of manufacturing them would necessarily be introduced with the Roman settlements among the Britons. Under the direction of the Roman artists, their junct, or rushes, would be wrought into cordage. Accordingly the remains of old cables and ropes are still distinguished among the British sailors, by the name of "old junk." Moreover, the Roman fails, which, in the days of Agricola, were composed of flax, were afterwards made of hemp; and our own are therefore denominated "canabilis," or "canvas," by our present mariners.

About the same period, the same materials were substituted for the junk of the British cordage; for the use of hemp ropes upon land, and of hempen nets for hunting, was very common among the Romans in the first century. The Indians still make their cordage of the bark of cocoas, and other trees, and of strands of plants. The cordage of the British navy is made of the Riga or best Petersburg break hemp, and tarred with good Stockholm or Ruffia tar.

The cordage is said to be baked, when, having passed a fove, or other hot place, it is drained of all its moisture. White cordage is that not yet pitched. Cordage pitched in the fove, is that which is passed through hot pitch as it comes out of the fove. Each quintal of cordage may take up about twenty pounds of pitch. The cordage is sometimes pitched in the thread. For the method of making ropes and different sorts of cordage, see Rope-making.

By 25 Geo. III. c. 56, no person shall use, in the manufacture of any ropes for shipping, (or sell the fame,) hemp called sheet-chucking, half clean, whole line, or other topping, cordils, damaged hemp, or any hemp from which the flable part thereof shall have been taken away by the manufacturer, on pain of forfeiting, for the manufacturer, such rope, and treble the value of it; and for the vender, not being the manufacturer, a sum equal to treble its value. For the better distinguishing the quality of such ropes, that which is inferior to clean Petersburg hemp shall be deemed inferior cordage, and marked accordingly, by running from one end of it to the other three-tarred mark yarn, spun with turn contrary to that of rope yarn, and also one like tarred yarn in every other rope for the use of shipping; and the maker shall mark or write, on a tally to be affixed on it, the word "flable," or "inferior," (as the case shall be,) and also his name, signed by himself or his attorney, together with the name of the place where manufactured; and in default thereof, shall forfeit 15s. for every hundred-weight. And if any such rope-maker shall wilfully or knowingly permit his name to be put to any such ropes, not being of his own manufacture; or if the vender or proprietor, or any other person, mark upon the tally the name of any perfon, not being the manufacturer, he shall forfeit 20l. And if any person shall make any cables of any old or worn thuff, which shall contain above 7 inches in compass, he shall forfeit four times its value. Foreign-made cordage, for which no duties have been paid, belonging to a ship owned by any of his majesty's subjects, resident in Great Britain, or the British colonies, and entering any port in this kingdom, shall be duly entered on oath at the custom-house (standing and running rigging excepted); and before the ship be cleared inward, the master shall pay the duties, on pain of forfeiting the cordage, and 2s. for every cord of it. Upon the importation of cordage, tarred or untarred, there is a duty payable of 6s. 6d. per cord, and no drawback allowed upon exportation; and in the port of London, there is a further seaveage-rate of 14d. per cord, or 112 lbs. upon the importation of cables-ropes for cordage.

As to the strength of ropes, or cordage, M. Reaumur takes occasion, in the Memoirs of the Royal Academy, to consider the question, whether a rope composed of several twills, or strands, interwoven, e. g. ten, have more strength to fulfill a weight, than the ten twills would have separately, placed parallel over one another; or, which is the same thing, whether, if each twill be capable of fulfilling the weight of a pound, the whole cord be able to fulfill more than ten?

On the one hand, 1. By virtue of the twilling, the diameter of the rope is made larger than are those of the ten twills together; but it is apparently by its thickness that a rope fulfills a weight, or refills a fracture. 2. Twilled strands have not all, as when parallel; a vertical direction with regard to the weight; several of them, and even the greatest part, have oblique directions, and of consequence do not bear all the share of the burden they would otherwise bear. In effect, they are inclined planes that are only pressed with a part of the load.

Hence it would follow, that the surplus of the strength of the twills might be employed in raising a larger weight.

On the other hand, it is true, that, in twilling the strands, some are stretched, and others left more loose; and the new tension given the former, serves to weaken them, and has of itself the effect of a weight: thus they become less able to fulfill one so large. Tho le more lax, on the contrary, evade, in some measure, the action of weight; for the action is distributed equally on the ten supposed equal twills; and if some, by reason of their particular disposition, receive less than their quota, the weight will act more forcibly on the rest, and will break them, as being more tense; after which, it will easily dispatch the rest, as not being in sufficient number to oppose it.

This is the sum of what can be urged for and against the twilling; to decide between them, M. Reaumur had recourse to experiment. The result was, that, contrary to all expectation, he still found the twilling diminished the strength of the rope; whence it is easily inferred, that it diminishes it the more, as the rope is the thicker. For inasmuch as the twilling diminishes; the more twilling, the more diminution.

The refusal or friction of cordage is very considerable; and by all means to be considered in calculating the power of machines. M. Amontons observes, in the Memoirs of the Royal Academy, that a rope is so much the more difficult to bend, 1. As it is thinner, and more stretched by the weight it draws. 2. As it is thicker; and, 3. As it is to be more bent; i.e. as it is to be coiled, for instance, into a smaller ring.

The same author has thought of ways to prove, in what proportion these different refusals increase: that arising from the smallness of rigidity occasioned by the weight which draws the rope, increases in proportion to the weight; and that arising from its thickness, in proportion to the diameter. Lastly, That arising from the smallness of the gyres, or pulleys,
pulleys, about which it is to be wound, is indeed greater for smaller circumferences than large ones, but does not increase so much as in the proportion of those circumferences.

On this footing, the loss a machine suffers by the cordage, being estimated in pounds, becomes, as it were, a new weight, to be added to that which the machine is to raise. This augmentation of weight will render the cords still the more flint; which excess is to be computed as before.

Thus shall we have several sums still decreasing; which are to be added together, as in the article of friction; and it will be surprising to see what a sum they will amount to.

See Friction.

Where ropes are used in a machine, all the resistence resulting from their diffidence is to be put together; and all that occasioned by the friction; which will make so considerable an augmentation to the difficulty of the motion, that a power which to raise a weight of 3000 pounds, by means of a fixed and moveable pulley, needed only 1500 pounds, must, according to M. Amontons, have 3942 pounds, on account of the frictions, and the resistence of the cordage.

CORDAGE, twice-laid, is that which is made of caft rigging, as shrouds, stays, mooring and other cables, which, if not much worn, will make good ropes for wetting the sides of ships, worming and wooling for cables, spun-yarn for feizing, worming for large stays, feizing for lops of blocks, small cable-laid ropes for warping ships, rat-lines, scaffolding-rope for dock-yards, &c.

When the yarn of this old stuff is overhauled, a little thin tar should be poured on it, which will make it pliable and lie better. The yarn unfit for knotting will pick into oakum for caulking.

CORDA T D E L A F, in Botany. See Leaf.

CORDAX, in Antiquity, a gay sort of dance.

CORDE, MAURICE DE LA, in Biography, born at Reims, where he attained considerable eminence for his classical and critical learning, was made doctor of the faculty of medicine, at Paris, in the year 1559. In the course of an harangue, before his brethren of the faculty, having censured with apathy the manners of the Romish clergy, and some of their ceremonies, and spoken too favourably of the reformed religion, he was seized and thrown into prison. This happened in the year 1560. An edict of pacification being obtained the following year, he was released, and, with the rest of the Huguenots, allowed openly to profess his religion. He was also permitted to practice medicine; but the College, who were firm in the Catholic religion, took him from the place of reader or lecturer. De la Corde was one of the few Huguenots who escaped the massacre, which took place on the eve of St. Bartholomew, in the year 1572; and in 1574, he obtained an order from parliament, reinstating him in his rights in the faculty of medicine. He published, in 1574, "Hippocratis Libellus de his quae Virginibus accident," with Commentaries, 8vo. Paris; and in 1584, "Hippocratis de morbis Multicrura, Interpretatio," folio. Haller Bib. Med. Eloy Diit. Hist.

CORDAU, a feu, Fr. cord-match, or match of cord, fit for retaining a small quantity of fire for a long time, and of furnishing it, or being lighted up, when wanted.

CORDEAU, Fr. a cord made ufe of for measuring ground. That which engineers commonly made ufe of was divided into toises, feet, and inches, in order to have the exact openings or magnitudes of angles, and the lengths of lines, which they wished to trace or measure. But as cords shrink in moist or wet weather, and lengthen in dry, this in-
COR

toon; it has been more worthy appreciated; as well on account of the purity of its style, as from the depth of its researches. M. Cordemoy was elected a member of the French academy in 1755. Besides his History of France, we have a 4 vol. volume of his works, published in 1732. In the latter part of his life, he was afflicted in his literary labours by his son Lewis, who was born in 1651, and who became successively a licentiate of Sorbonne, and an abbot in the church of Clermont. He was a voluminous writer, chiefly on theological subjects; and was considered among the Catholics as an able advocate of their cause, against the attacks of the defenders of Protestantism. He was, however, of considerable service to his father, in the last part of his General History of France, and it is believed, wrote the whole of that part which extends from about the conclusion of the reign of Lewis V. to the end of the work. By order of Lewis XIV. he continued that history from the time of Hugh Capet until the year 1660, which he did not live to finish. He died at the age of 71, in the year 1722. Moreci.

CORDERIE, Fr. a rope-yard. A fort of work-houses or place convenient for making, both for the artillery and vessels, cords, cables, hawser, &c. In inland towns, the corderies are open and uncovered, and common on the rampart, along the walls; and in maritime towns, or for ports, where considerable armaments are made, they are usually low buildings, covered, long, and narrow, constructed near the arsenals and magazines. These last mentioned cordories have generally, in France, been called CORDERIES Royales, because the most of them were built and kept up at the expense of the king. CORDES, in Antiquity Geography, a river of Asia, in Mesopotamia, which, rising in the mountains, pursu'd its course to the south, and encompassing the town of Dara, was lost in a gulf near it.

Cordes, Balthasar, in Biography, born at Antwerp, in the year 1592, belonged to the society of Jesuits in the Low Countries, and was doctor of theology at Vienna, where he attained a considerable share of celebrity, as professor of that faculty. He was a man of great learning, particularly in Greek literature. His principal works, as editor and author, were, "S. Dionysii Areopagitae Opera omnia, Gr. et Lat., cum Scholia, &c." in 2 to. fol.; "Expositionis Patrum Graecorum in Psalmos," in 3 to. fol. He died at Rome, in the year 1650.

Cordes, John de, was born at Lymieux, in the year 1570, and at an early age discovered a considerable turn for literary pursuits, in which he would probably have been encouraged, but the death of his father obliged him to apply to trade. When he was about 50 years of age, a change of circumstances enabled him to relinquish business, and to indulge his original propensity. He entered himselt Into the society of Jesuits at Avignon; but a series of ill health obliged him to quit their seminary, and to pursue his studies privately. He afterwards became a canon of his native place, and a collector of rare and valuable books. He was himself an author and editor of considerable reputation; and after his death, which happened in 1642, his library was purchased by cardinal Mazarine. He was editor of the works of Hincmar, archbishop of Rheims; and of the works of George Cossander. He translated father Paul’s "History of the Differences between Pope Paul V. and the Republic of Venice," and likewise Camilo Portio’s "History of the Troubles in the Kingdom of Naples, under Ferdinando I." Moreci.

Cordes, in Geography, a small town of France, in the department of the Tarn, on the river Ceron; 12 miles N.W. of Alby. It is the chief place of a canton, in the district of Alby, and contains 2,552 inhabitants. The canton contains 24 communes, upon 185 square kilometres, with 8,019 inhabitants.

Cordes de Touffou, a town of France, in the department of the Upper Garonne; 20 miles N.W. of Thoule.

Cordesefagen, a town of Germany, in the circle of Upper Saxony, and district of Pomerania; 10 miles W. of Collins.

Cordes, in Geography, a small town of France, in the department of the Saone and Loire, and district of Autun; 2 leagues N. of Autun.

Cordonato, a town of Italy, belonging to the state of Venice, in the county of Pordenone; 5 miles N. of Concordia.

Cordon, a river of Italy, which runs into the Po, between Belluno and Feltri.

Cordia, in Botany, (named by Pluiter in honour of Eurius Cordus and his son Valeriaus, two German botanists of the sixteenth century, the former author of Botanologica, feu Collectum de varis Herbis; the latter of Annales on Dioscorides, and of a History of Plants in four books with figures.) Linn. Gen. 2, 16. Schrbr. 357. Fid. 36. Ann. Ill. 270. Fift. 2. 382. (Spelletina; Gart. 474.) Chois and order, pantalia mons. Nat. Ord. Acrie. Fifi. Linn. Borognies. Juf. Sebeto, Vent. Gen. Ch. Col. Perisanth one-leaved, tubular, or bell-shaped, toothed or deeply divided. Cor, monopetals, generally funnel-shaped, sometimes campanulate or wheel-shaped, tube, about the length of the calyx, often enlarging upwards; border cleft spreading; generally cut into five, sometimes four, five, seven, or eight obtuse divisions. Stam. generally five, sometimes four, five, seven, or eight, awl-shaped, inserted into the tube; anthers oblong, Tyl. Germ. inferior, roundish, acuminate; style twice bifid; stigma obtuse. Pet. Drape globular or egg-shaped, growing to the calyx; nut narrowed or pitted, two or four-celled; some of the cells frequently abortive. Seeds solitary, egg-shaped, acuminate at the summit.

confiding of lateral branches with a few short ramifications: calyx green, cylindrical, five-crested; divisions of the corolla five or six, open, a little reflexed. *Drupa* black, oval, acuminate, smooth, pulpy; not deeply furrowed, perforated; naturally four-crested, but two of the cells generally abortive or quite obliterated. a. a native of Egypt; b. of the East Indies. Poiret asserts that it is not easy to determine what was the myxa of Linnaeus, and thinks it probable that two species have been confounded, but though the African and the East Indian plants differ a little in habit, and in the form of their leaves, he has, for the present, considered them only as varieties. A more accurate knowledge of their flowers and fruit will be necessary before they can be pronounced to be absolutely distinct. The fruit has been esteemed a valuable medicine in disorders of the chest and urinary passages, but is now entirely out of use in England. The East Indians eat it macerated in salted vinegar, and reckon it serviceable in diarrhoea. An excellent glue is made of the pulp, which is more viscid than that of the *Jujube*. 2. C. indica. Lam. Iii. 1817. Poir. 15. "Leaves egg-shaped, obtuse, crenate near the summit; coriaceous and terminal; calyxes ten-crested." A shrub twelve or fifteen feet high; branches zig-zag, smooth, crenate, pubescent on their upper part. Leaves alternate, petioled, feathery on both sides, marked on the upper surface with small whitish joints, a little pubescent underneath when young; petioles pubescent, half the length of the leaves. Flowers yellowish; peduncles very short; calyces whitish, strongly ridged, four-toothed, a little scarious at the edges; tube of the corolla the length of the calyx; border open, with five, seven, or eight divisions; filaments eight; filaments erect, filiform, villous at the base; anthers oval, compressed; style the length of the filaments. *Drupa* whitish, egg-shaped; not terminated by a recurved point, four-crested, two of the cells frequently abortive. Found by Dombey at Huanza and in the neighbourhood of Lima, where it is very common. La Mareck enquires whether it may not be the *myxa* of Linnaeus, excluding all the synonyms; but there can be no ground for the conjecture, as *Linnaeus* certainly referred to a plant of the old continent. 3. C. philippina. Willd. 2. Phyt. 1. 4. tab. 4. fig. 1. (C. myxa. Poir.) "Leaves roundish, heart-shaped, nervet, veined, oblique. Nearly allied to *C. myxa*, but the leaves are quite entire and the calyxes not ridged. A native of the East Indies. 4. C. monoeica. Willd. 3. Roxb. Coromand. 1. 43. tab. 59. "Leaves roundish, egg-shaped, toothed, veined, pubescent; coriaceous axillary, monoeious." Leaves three inches long or more, two inches broad, alternate, very crenate, acute; petals about one-third of the length of the leaves. Flowers white, small, in axillary or terminal coriaceous, which are shorter than the leaves; corolla funnel-shaped, with five egg-shaped obtuse divisions; filaments within the tube of the corolla; filaments awl-shaped, enlarged at the base, anthers lanceolate. *Drupa* yellowish, globular, point-d, filled with a glutinous pulp. A native of forests on the coast of Coromandel. 5. C. sericifera. Juss. Poir. 3. "Leaves heart-shaped, acutely serrated; lanceolate terminal. Branches erect, cylindrical, smooth and even. Leaves about three inches long and two inches broad, alternate, petioled, egg-shaped, acute or somewhat acuminate, irregularly serrated, membranous, dark green above, yellowish-green underneath; nerves simple, alternate. Flowers in a close, few-flowered, axillary, paniculate, a little leafy at the base of its first branches, small, white; calyx and border of the corolla five-lobed; filaments five. A native of the East Indies; described from a dried specimen without fruit in the herbarium of Jullien. 6. C. rubrocordata. Lam. Iii. 1817. Poir. 4. (Novella nigra, feu amari; Rampf. Amb. 2. 226. tab. Vol. IX. 777.) "Leaves somewhat heart-shaped, entire, even on its upper surface; calyx cylindrical. A tree. *Drupa* spreading, tufted, smooth. Leaves from four to six inches long, or nearly as many broad, alternate, slightly pubescent underneath along the principal nerves. Flowers in short, bove terminal racemes, large, white with a reddish rind; calyx tubular, smooth, three-toothed; corolla funnel-shaped, wrinkled or plaited; tube at least twice the length of the calyx, much elongated near the top; border with six or seven rounded lobes; filaments fix or seven; anthers variable; style shorter than the filaments. *Drupa* the size of a hazel-nut, four-crested; some of them abortive. Discovered by Commodor in the Peralin Islands in the East Indies. 7. C. colletiaco. Lam. Sp. pl. 5. Mart. 6. Poir. 5. Willd. 14. (C. chretioides; Lam. Iii. 1817. Poir. 4. tab. 4. fig. 2. C. chretioda; Lam. Iii. 1817. Poir. 4. fig. 1.) "Leaves oblong-ovate (cordate-ovate; syyt. nat.) quite entire; flowers in coriaceous axillary; calyxes tomentose on the inner side." A middle-sized tree. *Trunk* divided near the top into spreading branches. Leaves alternate, petioled, acutet, wrinkled. *Flowers* yellowish-green, in loose somewhat-paciowed terminal coriaceous; peduncles branched, very unequal; corolla funnel-shaped, with five deep divisions. *Drupa* bright red, the size of a small cherry, with a sweetish clammy pulp. A native of the West Indies, where the fruit is a favourite food of turtles and other poultry. In Jamaica it is called clammy cherry, or turtle-berry tree. S. C. hispida. Willd. 15. (C. colletiaco; Aub. Guian. 1. 219. tab. 86. C. nodolba; Lam. Iii. 1817. Poir. 8.) "Leaves oblollow, alternately both ways, pubescent; flowers in terminal and axillary coriaceous; peduncles hispida. *Leaves* narrower than those of the preceding species. Stem and peduncles hispida. *Corymyx* denfe, somewhat umbellated, not dichotomous-divaricata. *Fruit* white, oblique, acuminate. A native of Cayenne and Guiana. 9. C. tetrandra. Lam. Iii. 1817. Poir. 11. Willd. 16. Aubl. Guian. 1. 222. tab. 87. "Leaves egg-shaped, somewhat heart-shaped, acute, feathery quinque-lobed; flowers in coriaceous terminal; flowers tetrandrous." A tree forty or fifty feet high, with spreading branches. Leaves eight or ten inches long, three or four broad, alternate, entire or slightly undulated, nervet; petals as inch long. *Flowers* greenish; common peduncle forked, dichotomous at the summit, and branched; calyx top-shaped, with four roundish acute lobes; corolla funnel-shaped; tube short, border expanding, four-lobed; filaments four. *Drupa* whitish, round; nuts three or four-crested; somewhat oval, wrinkled, enclosed in a white glutinous subflavus. A native of Cayenne and Guiana. 10. C. tetraphylla. Lam. Iii. 1817. Poir. 6. Willd. 18. Aubl. 1. 432. tab. 88. "Leaves four in a whorl, invariably egg-shaped, quite entire; peduncles lateral, many-flowered." A shrub fix or seven feet high, with knotty branches. Leaves nearly oblong, firm, nervet, a little reticulated, smooth on both sides. Flowers white, sliflie, on long common peduncles; calyx with five acute teeth; corolla funnel-shaped; tube narrow, at the base: border five-lobed; filaments longer than the corolla. *Drupa* yellowish, the form and size of an olive; not very hard, generally one-crested. A native of Guiana, on sandy soil near the sea. 11. Pseudo-ulmis. Lam. Sp. pl. 2. Mart. 4. Lam. Iii. 1817. tab. 96. fig. 2. Poir. 7. (fig. 3.) Amer. 43. tab. 175. fig. 16. Brown Jam 177. tab. 29. fig. 1. "Leaves lanceolate-egg-shaped, quite entire; lanceolate terminal; calyxes tomentose, ten-crested." A considerable tree. *Branches* spreading, cylindrical, clothed on the upper part with a thick covered crenate down. Leaves alternate, smooth, coriaceous, on short peduncle. Flowers large, white,
white, permanent, shrivelling: principal branches of the panicle furnished at the base with narrow sessile bractlets; pedicels short, unequal, three-flowered; calyx oblong, funnel-shaped, slightly toothed; corolla twice the size of the calyx, with four, five, or six almost oval oblong divisions; filaments fleshy to the tube of the corolla, from the base to the middle; anthers incumbent, yellow; germ oblong, filiform; style shorter than the filaments; stigmas thick, obtuse, yellow.

A native of Jamaica, where it is esteemed one of the best timber-trees. 12. C. flavescens. Poir. 9. Aubl. 1. 236. tab. 89. (C. farinosa; Linn. Ill. 1907.) “Leaves ovate-oblong, acuminate, smooth, quite entire; racemes lateral; drupes obtuse.” A shrub, producing from the roots several woody, farinaceous stems, eight or nine feet long, spreading upon the neighbouring plants and trees. Leaves alternate, petiolated, armed, reticulately veined, six or seven inches long, and three broad. Flowers yellowish, in lateral racemes, on a rather long common peduncle; calyx with five or six deep, round, acute divisions; corolla funnel-shaped; tube enlarged above the calyx; border with four or five round, spreading lobes; filaments five or six; anthers arrow-shaped; germ greenish. Drupes purplish; but not enveloped with a dry and firm membrane. Seeds affording a glutinous matter. A native of Cayenne and Guiana. 13. C. flavaefida. Linn. Mart. 256. Mart. 2. Lam. 1904. Poir. 10. Wild. 4. “Leaves egg-shaped, acute, serrated, februous; petioles becoming thorns.” Branches stiff, erect, tomentose, ferruginous. Leaves alternate, tomentose undercurrent; petioles very short, jointed, breaking off at the joint when the leaves fall, the part that remains sharpening into a thorn, as in volkameria. Flowers in axillary, simple, or bined racemes, equal in length to the leaf; calyx campanulate, with five obcure teeth; corolla campanulate, five-toothed, twice the length of the calyx; filaments acute. Drupes black, fleshy, about the size of gooseberries. 14. C. toquense. Lam. 1911. Poir. 12. Wildl. 10. Aubl. Guian. 1. 228. tab. 90. “Leaves cordate-ovate, acuminate, quite entire, villous; racemes compound.” A much-branched, spreading shrub, five or six feet high; branchlets brittle, villous, cullet. Leaves from four to six inches long; three or four broad, alternate, nearly sessile, rough and villous above, tomentose and pale green underneath. Flowers white, in axillary and terminal racemes; common peduncle long, villous leaves; calyx about tubular, five-toothed; tube of the corolla short; border spreading, with five roundish lobes; filaments five; filaments the length of the corolla; germ a little villous at the base. Drupes yellowish, fleshy, one-celled. A native of Guiana. 15. C. macropythia. Linn. Sp. Pl. 4. Mart. 5. Lam. 1901. Poir. 13. Redoute Pit. Mus. Par. Annals of Museum of Nat. Hist. vol. 1. Annals of Botany, 1. 127. (Colococoeus platyphyllus; Jam. Bot. 168. Prunus racemosa foliis maximis; Sloan. Jam. 184. Hist. 2. 130. tab. 221. fig. 1.) “Leaves ovate-oblong, villous, veined, very large; racemes forming a corymb; calyx cup-shaped.” A tree from forty-five to sixty feet high. Trunk never more than sixteen inches thick; branches cylindrical, villous while young, several times two or three forked, diverging, and declined towards the earth. Leaves from fix to thirty inches long, from three to seven broad, alternate, deflected, clothed with short rough scabrous hairs, entire, or edged with small sharp teeth; nerves obliquely transverse, prominent underneath; petiole short, cylindrical, channelled. Flowers white; calyx oval, villous, with five upright, straight, obtuse teeth; tube of the corolla cylindrical, entirely villous; segments of the corolla cylindrical, deflected, a little curled, rounded at the tip; filaments five, longer than the corolla; anthers velluteous, with two cells separated at the base, and attached to the filaments by their backs; germ oval, acute. Drupes red, fohbical, about the size of a pea, two-celled. A native of Jamaica. 16. C. jibic. Linn. Sp. Pl. 3. Mart. 3. Lam. 1898. tab. 96. fig. 1. Poir. 14. Wildl. 5. Bot Mag. 794. Bot. Rep. tab. 157. (C. folis fibre pandis; Jacq. Amer. 42. C. acaulis juglandis folio; Plum. Gen. Amer. 150. C. folis amphiobius; Brown Jam. 202. Sebeleinon scabria; Dill. Eth. 341. tab. 355. fig. 331. Caryophyllus sp. Lam. 1913. Hift. 2. 25. tab. 64. Catesb. Car. 2. 91. tab. 91. Novellia nigra; Kump. Amb. 2. 226. tab. 75. Brown Fl. Ind. 509.) “Leaves egg-shaped, somewhat repand, februous; calyx cylindrical.” A shrub from seven or eight feet high. Stems several, erect, smooth, cylindrical, branched. Leaves alternate, on short petioles, slightly repand when young, the older ones more or less repand, the upper ones entire. Flowers deep yellow or scarlet, in large terminal racemes; pedicels one, two, or three-flowered, calyx with three divisions near the top; corolla funnel-shaped; border with five oval, obtuse, crenulate divisions; filaments five; filaments recurved. Drupes inversely pear-shaped; nut deeply furrowed. A native of the East and West Indies. It is not improbable that the above quoted synonyms refer to more than one species; but no b-tamit has hitherto found sufficiently discriminating specific characters. The East Indian plants have yellow, the West Indian scarlet flowers. 17. C. aficonta. Lam. 1896. (C. sebeleinon 3; Poir. Wildl. Sebeleinon alpinus? Lam. Wanzey; Bruce’s Travels, 5. 57, with a figure.) “Leaves roundish-oval, entire; panicle terminal; calyxes top-shaped; nut of the drupe triquetrous.” A tree. Trunk dividing into four or five thick branches, about three feet and a half from the ground. Flowers snow-white, fleshy, entire, and folded back at the margin. A native of Abyssinia. 18. C. aficonta. Wildl. 6. Forst. Prod. 1909. “Leaves egg-shaped, acuminate, rough; flowers in cymes, wrinkled.” A native of the island of Tangatou. 19. C. dichotoma. Wildl. 7. Forst. 110. “Leaves oblong-egg-shaped, scarcely crenate; corymb dichotomus.” A native of New Caledonia. 20. C. fabrifolia. Poir. 16. “Leaves ovate lanceolate, obtuse, wrinkled, very rough, reticulately veined underneath; racemes lateral.” Branches smooth, fritated, cinereous, or yellowish, somewhat pubescent when young. Leaves two inches long, one inch broad, alternate, very firm, coriaceous; pedicels two or three links long, short, firm, rough. Racemes fleshy, villous, beset with whitish hairs. Native country unknown. (Described by Dupuis de Jussieu, and preferred in his Herbarium, 21. C. dingenieri.) “Leaves egg-shaped, entire, rough, whitish underneath; panicle terminal; calyxes cylindrical.” Branches dark brown, thick, angular, very rough. Leaves from fix to eight inches long, four or five broad, alternate, thick, coriaceous, cr日ted, reticulately veined; pedicels almo st cylindrical, short, thick, very rough. Flowers in panicked racemes, shorter than the leaves; racemes unequal, equal, cylindrical, fleshy, sebruous, a little pubescent; pedicels one-flowered. A native of St. Domingo. 22. C. levioca. Lam. Ill. 1912. Poir. 18. “Leaves egg-shaped, veined, shining; panicles lateral; filaments villous near the base.” Branches flender, filiform, cinereous, cylindrical, knotty. Leaves alternate, petiolated, rather small, quite entire, obtuse, or a little acute, narrowed at the base, coriaceous, smooth on both sides, reticulately veined. Pedicels short, but longer than the leaves, smooth, branched; calyces smooth, short, fritated; corolla open, somewhat campanulate; border five-lobed. A native of the West Indies. 23. C. sanguines. Jaff. MSS. Poir. 19. “Flowers tetrandrous; leaves membranous, egg-shaped, acute, smooth; racemes short.” A tree about twenty feet high. Branches dark brown, flender, cylindrical, quite smooth.
CORDIA.

Smooth. Leaves alternate, four or five inches long, about three inches broad, thin, nerved, and rectically veined; petals two in each, long and more, smooth, compressed. Flowers in panicled racemes, scarcely longer than the petals; pedicels very short, one-flowered; calyx with three divisions; corolla with four divisions half way down. Brought from Senegal by Adamson. 24. C. exalata. Lam. t. 190. Poir. 21. "Leaves egg-shaped, acute at the base, rough; corymb terminal; flowers quinquefoliata." A large tree. Branches smooth, fringed. Leaves about four inches long and two broad, alternate, quite entire, obtuse, somewhat acuminate, cuneate, almost shining; petals very short, fringed, lightly compressed. Corolla a little longer than the leaves; pedicels very short, thick, one-flowered, calyx short, smooth, campanulate, with five small acute teeth. Drupes globular, the size of a pea, two-celled. A native of Guiana. 25. C. nervosa. Lam. t. 1906. Poir. 23. "Leaves alternate and opposite, ovate-oblong, acuminate, nervet; petals short; bracts awl-shaped." A tree. Branches cinerifera, thick, angular, rough. Leaves from eight to ten inches long, four or more broad, alternate, entire, smooth, deep green and shining above, pale yellow underneath; nerves strong, oblique, parallel, a little branched or confluent towards the edges of the leaf; petals very short, thick, knotty at the base. First divisions of the panicle almost dichotomous; branches short, thick, almost woody, smooth; calyxes smooth, with five short oval divisions. A native of Guiana. 26. C. rotundifolia. Poir. 23. Ruiz. and Pav. Flor. Peruv. 2. 24. tab. 148. Prunas Sibilla; Piek. Almog. 306. Phytog. tab. 217. fig. 2. "Leaves roundish and oval, crenate, furrowed; peduncles corymbiform." A shrub about twelve feet high. Stems straight, often almost procumbent; cylindrical; branches numerous, very long, fleshy, 212-zag, villous when young. Leaves from two to three inches long, and two broad, alternate, petioled, wrinkled, veined, rough, rather hispid. Flowers yellow, large; calyx tubular, fringed, with five short acute teeth; corolla funnel-shaped; tube the length of the calyx, dilated at the orifice; border with five plaited, oval, acute divisions; filaments awl-shaped, villous at the base; anthers oval-oblong, concave; germ oval, acuminate; flyle the length of the flaments. Drupes whitish, half enveloped by the calyx and a viscid pulp; nut oval, acuminate, five-furrowed, two-celled. The fructification often varies from six to eight in the number of its parts. A native of Peru, in dry sandy ground, and by the sides of the roads. 27. C. dottata. Poir. 24. "Leaves egg-shaped, angularly-cut, toothed; pedicle dichotomous, large, divaricately, branches petioled, hispate." Branches a little zig-zag, brown or cinereous, cylindrical, rough, clothed with short fuscous hispate hairs. Leaves from three to five inches long, from two to four broad, alternate, rough with small whitish points and deep green above, paler and yellowish underneath; some feebly toothed, others moderately cut, a little angular, with short acute teeth; nerved and reticulately veined; petals about an inch long, slender, cylindrical, villous. Flowers white, almost campanulate; pedicle terminal; ramifications numerous, growing gradually shorter, fuscous, pubescent; pedicels very short, one-flowered; calyx short, almost campanulate; tube of the corolla short, dilated at the orifice; border large, very open, with five or fix small lobes. A native of Cuba. 28. C. micranthus. Mart. t. 11. Poir. 25. Wildl. 12. Swartz. Prod. 47. Flor. Ind. Occid. 1. 493. "Leaves elliptic, acute, entire, membranous, veined; racemes compound, loose." Branches corymbose, a little twilled, wrinkled, smooth. Leaves alternate, coria-
of polts, or an imaginary line of separation, between two
armies either in the field or in winter-quarters, or for cov-
ering a particular frontier or tract of country.

CORDON, in Geography, a small island in the Pacific
ocean, near the west coast of Nicaragua, at the entrance of
the bay of Rincão.

Cordon-Jaume; the order of, or of the yellow flaring, in
France, was instituted by the Duke de Nivers in 1606, and
abolished the same year by Henry IV. of France.

Cordina, in Ornithology, a name given by Buffon to the
Ampelis caudata of Gmelin, and the purple-breasted chas-
ter of Pennant and Latham.

Cordon, in Geography, a mountain of Valencia in Spain, is
competed entirely of rock salt, 4 or 500 feet high and about 3 miles in circumference: Mr. Bowles informs us, that there are no traces of gypsum near this mountain, as in most similar instances it is the case.

In the climate of Spain, this mass of salt remains undif-
folved by the rains, or the waters of a river which washes it. Mr. Trowedland carried a fragment of this salt with him through Spain, without the least sign of deliquescence, but on his return to England he soon found it surrounded by a pool of water, owing to the coldness and humidity of our atmosphere. In Spain this rock-salt, like the flour-
spars of Derbyshire, is employed to make flour-boxes, vases, and other ornaments and trinkets.

CORDOVA, ADRIANO OF, in Biography, is called from the
place of his nativity, a considerable town in Spain,
was a barefooted Carmelite who applied himself to horti-
cultural practice with success. It is regretted, however, that from a too great modesty or diffidence of his own powers, he was induced to debase so many of his pictures as soon as he had finished them. The few that remain are at Cordova, the most remarkable of which is a Crucifixion with St. John, Mary Magdalene, and other figures of half length, in the manner of Rafael Sadeler, in the convent of the Carmelites. This artist died at Cordova in the year 1630.

Cordoba, or Cordona, in Geography, a city of An-
dalusia in Spain, forming a kind of semi-circular amphitheat-
tre on the right bank of the Guadalquivir, in an exten-
sive and fertile plain at the foot of a range of mountains,
named the Sierra Morena, 84 miles N.E. of Seville; it is
N. of Malaga; 210 S.W. of Madrid, in N. lat. 37° 40'.

It is the ancient Cordoba, the first Roman colony in Spain, and probably on that account called Colonia Patricia, or simply Patricia, as appears from an inscription on an antique marble in the church of St. Marina:

D. M. S.

Pius in Suos. H. E. S.

Sit T. T. Levi.

Cordova has been styled the mother of men of genius.
From the very foundation of this city it was the fear of
learning and sciences. Strabo says, that the ancient books of the Tarde, their poetry, and their laws written in ver-
de, were preserved at Cordova. Its academy was celebrated
for rhetoric and philosophy; it had also a Greek profes-
sofficer. The elder Seneca, and Lucius Aemilius Seneca, pre-
ceptor to Nero, were born at Cordova, as well as Lucan
the poet, whose grandfather Aemius Lucas, celebrated for
his eloquence, flourished here. So did Gallo, another fa-
mous orator; Portius Lidura, of whose works there re-
 mains one harangue; and Maximus, master of the elider
Seneca. Tully, in his oration for the poet Archias, men-

tions several poets of Cordova who were established at Rome among others, Sextilius Henna, of whose writings there is only one elegy extant, in which he laments the death of the Roman orator.

After the fall of the Roman empire, Cordova was subject to the dominion of the Goths, until the Gothic monarchy of Spain was overthrown by the Saracens, under the command of Tarik. A Roman captive and profligate who had been enfranchised by the caliph of Damascus, assassinated Cordova with seven hundred horse. He surprised the town, and drove the Christians into the great church, where they defended themselves above three months; and of all the Spanish military chiefs the governor of Cordova is recorded as the only one, who fell, without conditions, a prisoner into the hands of the Saracens.

Abdelaziz, the son of Mulia, to whom the administration of Spain, under the caliph of Damascus, was confided, conceived the design of erecting an independent throne at Cordova; but no sooner was a suspicion of his intentions diffused than a powerful conspiracy was formed against him. As he was repairing alone to the mosque of Cordova, he was attacked and murdered by the conspirators.

On the assassination of Abdelaziz, Ayyub assumed the administration of Spain. He was soon removed by the superior favour or merit of Alahor, who, like Abderez, one of his succedors, vainly attempted the conquest of the west.

Under twenty successive lieutenants of the caliphs, Spain, imbued, in a few generations, the manners of the Arabs; and by assuming the name of Spaniards, the Arabs affected their original claim of conquest.

In the meantime the rival houses of Ommiiah and of Abbad, the uncle of Mahomet, contented the East by their pretensions, from the Indus to the Euphrates. Their contest was decided on the banks of the Zeb. Mervan XIV., and last caliph of the house of Ommiiah, was forced to yield to the enthusiasm of the Abbasides, conducted by Abdullah the uncle of his competitor. The vanquished caliph crossed the Euphrates, and without halting in Palestine, pitched his last camp on the banks of the Nile, where he was attacked by Abdullah, and the lance of an Abbasid terminated the reign and life of Mervan.

In the proscription of the Ommiades, a royal youth of the name of Abdallah was alone escaped from the rage of his enemies, and was received on the coast of Andalusia with open arms. The Arabian chiefs, who reverenced the memory of the immediate successors of Mahomet, drew their fables in his support. The defeat of the Zeb was avenged on the banks of the Guadalquivir; that river was fortiied with the bodies of the slaughtered Abbasides; and the throne of the victorious Abdallah was established at Cordova in the year 755 of our era.

During a prosperous reign of thirty years, Abdallah, encouraged agriculture, commerce, and the arts. Cordova became the centre of industry, of politeness, and of genius. His son Hassen, who succeeded him, not only patronized, but was even a proficient in the arts. He fulfilled the famous mosque, which had been begun by his father, and threw over the Guadalquivir a bridge which remains a lasting monument of his skill.

Under the second Abdallah a perpetual supply of pure water was conducted through pipes and aqueducts into the heart of Cordova, and numerous mosques augmented its magnificence.

Learning flourished under Alkaham the second. He founded the university of Cordova, and the birth-place of the Senecas, and the Lucans, asserted again its pretensions to literary fame. He collected so immense a quantity of manuscripts, that before the end of his reign the royal library is reported to have contained the almost incredible number of six hundred thousand volumes, of which the catalogue alone filled forty-four folio volumes.

But the pomp of the third Abdallah, who reigned from the year 912 till 961, appears still more incredible. His wives, concubines, and black eunuchs, amounted to fifteen thousand persons. He was attended to the field by a guard of twelve thousand horse, whose belts and feathers were studded with gold. To perpetuate the name of his favourite Sultana, he constructed, three miles from Cordova, the palace and gardens of Zebra or Arizapha. The edifice was supported by above a thousand columns of the finest marble; the walls of the hall of audience were incrusted with gold and pearls. A formidable army secured the prosperity which his dominions derived from his wife administration. The royal city of Cordova contained six hundred mosques, nine hundred baths, and two hundred thousand houses. Eighty large cities, three hundred towns, and twelve thousand villages obeyed his sway, and yet, in less than fifty years after his decease, the kingdom of Cordova was dissolved, and the house of Ommiiah overwhelmed.

His son, Alkaham the second, whom we have already mentioned as the founder of the university of Cordova, died in 976, and left the throne to Hassam his son, a feeble infant, and the reins of administration to the celebrated vizir Mahomet Abenamir, who from his valour acquired the surname of Almanzor or the Defender. He successfully struggled against civil and foreign commotion, and at his death, his renown was respected in his descendants. The office of vizir became hereditary in his family. His son ruled with a power as absolute as that of the caliphs; their insolence provoked the ambition of other chiefs; the exclusive pretensions of the house of Ommiiah were disregarded, the grandson of the great Abdallah was plunged into a dungeon, and the glory of the throne of Cordova, which under the Ommiades had shone with such a lustre, during a little more than two centuries, was overshadowed by a long night. The limits of the Saracen dominions gradually receded. Several petty principalities were formed on the ruins of their empire, which was at length confined within the boundaries of Granada.

In the mean time the university of Cordova preferred for a long period of years the reputation which it had acquired under Alkaham II. It was at Cordova that Avenpace and Algazel, two figures mentioned by St. Thomas, taught moral philosophy; that Alial Cohacen and Abeein Rezel acquired their profound erudition; and that Abouvaliz, the great astronomer and physician, furnished the Wise, received his education. Within its walls were formed those thirty philosophers and physicians, who arranged the works which, under the name of Avencana, were dedicated to prince Ga
dara, to whom they have been falsely attributed.

Among the learned Moors, to whom Cordova gave birth, are Abheimarac, Abramo, Mefulco, Rebez Almanzor, known by a number of curious works, and a history of the conquest of Spain, Aben Rezel who likewise wrote on the division and conquest of Spain, and Averroes, called, by way of eminence, the commentator.

Cordova has preserved nothing of its ancient grandeur, except a vast enclosure filled with houses half in ruins. Its population from 300,000, which it was in the time of the Moors, is reduced to 15,000. Its long, narrow, and illu

Cordova.
The bishop of Cordova is suffragan of the archbishop of Seville. His annual income exceeds 5000l. St. Raphael, the patron of Cordova, has a magnificent gilt statue at one of the gates, which forms a singular contrast with the wretchedness that reigns within the town.

The only remarkable edifice of Cordova is its famous cathedral, which formerly served as a mosque to the Moors, and still retains the name of Mezquita. It forms a long square of one hundred and fifty-eight paces by one hundred and thirty-eight, and is well lighted, but too low. About six hundred columns of blackish marble placed in Quemex are well preferred; but they do not reach the ceiling; they are made with the outlines in twelve feet high, and have neither base nor capital; they are joined to each other by two arches placed above the other, covered with plaster, and supported with stone work whitened over. The result of the whole is not altogether agreeable to the eye, and the cathedral is more remarkable for its oddity than for any very striking beauties, though nothing would equal its magnificence were the height proportioned to the extent. Its exterior presents only a minute and irregular edifice with enormous square pillars.

By the side of the cathedral is a small grove, the fascinating remains of the taftful luxury of the Moors. It is planted with orange-trees, the tufted foliage of which serves as a asylum to great numbers of birds, and hangs over several fountains which constantly cool the air.

The ancient palace of the Moors has been converted into stables, in which one hundred flailors are usually kept. Their genealogy is carefully preserved; the name and age of each are written over the stall in which they stand. The beautiful horse of Cordova is reckoned the most perfect. There is a curious manuscript in the Escorial marked D.CCC.XCVII on horses and horsemanship, written by a Moorish prince, and dedicated to the third king of the family of Benewfet, who reigned in the year 1501.

Archbishop Roderic Ximenes, in his "Historia Arabum," informs us, that Cordova was paved to early as the middle of the ninth century, or about the year 850, by Abdalrahan II. the 4th Spanish caliph. This prince, who knew the value of the arts and sciences, and who favoured trade so much, that in his reign abundance prevailed throughout the whole land, caused water to be conveyed into this city, which was then his capital, by leaden pipes, and ornamented it with a muque, and other elegant buildings.

Cordova, a province of South America, being, by the new division of 1782, an intendency of the viceroyalty of Buenos Ayres, about 100 leagues in length, and 70 in breadth, intersected by several chains of mountains, and watered by several rivers. This district is chiefly celebrated for woollen manufactures, being fostered on the eastern side of a grand and high branch of the Andes.

Cordova, a neat clean town, in the above-mentioned district, distant 150 miles from Buenos Ayres, and pleasantly located at the foot of a high and wooded ridge. The town was founded about the year 1550, by Juan Nunez de Prado; and in 1570 erected into an episcopal see. Its chapter consists of the bishop, dean, archdeacon, chapter, rectors, and treasurer; but it has neither canons nor prebendaries. Cordova is situated between the river Primero, so called because it is the first of five in the neighbourhood, which flow in the same direction, and a hill, on a level but sandy soil, so that the rains speedily pass, though the vaults be unwholesome. The city approaches a square form; but the cathedral is irregular, from the want of symmetry in the towers. There are many good and strong houses in the city, but seldom high, though the roofs be elevated; and there are three convents, and two colleges, one of which the Franciscans have absurdly filied the university. Few places of equal extent can display equal wealth; all the inhabitants, Spaniards as well as Creoles, being noted for activity and industry. The chief trade is in wools, which are brought from the southern provinces; and having fed them in the fields, they conduct them to the fair of Salta, where they are sold to merchants from Peru, at 8 or 10 dollars each; but some fend them, on their own account, to be sold in the Peruvian markets, the value being proportioned to the distance. The inhabitants may be 6000; and the houses, mostly of different mixtures, do not procure their freedom so easily as in other parts of America. As meat is very cheap, and the were weave and make their own clothes, they are at once cally maintained, and very useful; nor do they wish for freedom, being neither fatigued nor oppressed. The female faves are excellent washer-women, and go into the river with the water above their middle; nor are they deficient in other kinds of industry. The ladies of Cordova are neatly clothed, and careful observers of the customs of their ancestors; whence the faves are not permitted to wear any cloth but that manufactured in the country. The wine, and a considerable part of the grain, are procured from Mendoza; while brandy is brought, in leather bags or bottles, from S. Juan de la Frontera, 30 leagues to the N.W. of Mendoza, on the northern extremity of the province of Cuyo, N. lat. 31° 30'. W. long. 63° 15'.

Cordova, Mountains of, are a chain passing N. and S. on the W. of this province, regarded by some as a branch of the Andes, and said to be covered with perpetual snow. These mountains, according to Helms, sometimes present red and green granite, and gneiss, while the grand chain of the Andes consists of argilaceous schistus. As the ridge of mountains becomes gradually higher, the population increases; but at Ramonfs, 60 miles from Cordova, they again branch, and so far from one another, that from that place to Tucuman the traveller passes through a saline plain, 70 Spanish miles in length, and for the most part barren and defert, from which the mountains are seen at a distance. The whole ground is covered with a white incrustation of salt; and bears no plants except the "saldia salt," which grows here to the height of four Parian yards. The decayed town of "St. Jago de Eterno" is situated in this plain.

Cordova, a considerable town of North America, in Mexico, the whole district of the trade being fugar, for which it has 33 mills. Estalla says, there are 260 families of Spaniards, 126 of Melizos, and 273 of Mexican Indians. Thierry describes Cordova as a large town, with numerous domes, towers, and steeples, and a large square in the centre, with
with Gothic arcades on three sides, the cathedral filling the fourth, and a fountain of delicious water in the middle. The streets are wide, straight, and paved, and the houses mostly of stone; but the inhabitants are indolent. The situation is in a kind of natural passage towards the province of Mexico; the vegetation being rich and beautiful, on a soil of red clay, from 10 to 15 feet in depth, producing all the fruits of the two hemispheres. N. lat. 15° 15'. W. long. 97° 40'.

CORDOVA. See CORDUMA.

CORDOUAN, the Tower of, an extremely well-con- structed pharos or light-house, at the mouth of the river Gironde, in France; 66 miles N.W. of Bourdeaux, and 15 miles S.W. of La Rochefit. In N. lat. 45° 35' 15'. It was built by Louis XIV. in the year 1665. The formidable mats of rocks on which it stands is formed by the reefs that flit the shore. The tower itself is 100 feet high, the great lantern 15; and from 200 to 350 pounds of pitch are consumed in it every night. The watchmen are generally relieved every fortnight: they take care, however, to provide themselves with at least one month's provisions, because the boats cannot approach the reefs but when the sea is perfectly calm. F. A. Fisher's Travels in Spain, Letter vi.

CORDUBA, CAVR. FRANCESCO, in Biography, a painter and engraver of Italy, by whom we have a set of 44 etchings, medallion sized upright plates, from the fountains in the gardens about Rome, engraved by figures much in the style of Callot. He marks his plates thus: "Eques Franc. Corduba del et Sculp." Strutt. Heineckon.

CORDUBA, in Botany, Cluf. See Asparagus albus and Aphyllus.

CORDURA, now Cordova, in Ancient Geography, a town of Spain, S.E. of Mallaria, upon the river Buclus. It was in this town, as Strabo informs us, that the Romans fixed their habitation, when they first entered Spain. But if it be true that it was founded by Marcellus, as Strabo himself says, we are led to imagine, that from the time when the Romans first inhabited it to the period when Marcellus conducted a colony hither, it could not have been very considerable. However, Silius Italicus says, that it suffered from the time of the second Punic war. However this be, it was from the epoch of Marcellus that it bore the title of a patria colonia, from his having establish'd in its families of this order. Corduba was the first place which the Romans had in Spain, distinguished by the epithet of Cordubata, and with the privilege of coinage money. It afterwards became so considerable, that Strabo compares it with, regard to its commerce, with Gades; and he also extols the extent and fertility of the adjacent country. It was no les celebrated for its literary reputation, as it was the residence of the two Sene'ces, and of the poet Lucan. On some medals, bearing the name of Corduba, we see on one side a well-dressed female head, and on the other a winged figure, holding a cornucopia; but the greatest number of medals belonging to this city are inscribed with "Colonia Patricia." It is probable that it was called by the first name before the establishment of the colony, and afterwards by the other. See Cordova.

CORDUENA, a town of Armenia. See CORDESE.

CORDULA, or Cordyla, Portus, a port of Asia in Pontus, upon the Euxine sea, according to Arrian, who places it between mount Sacer and Hermaphassa, S.E. of Trapezus.

CORDUS, or Sordus, the name given to an ancient people of Gallia Tarragonensis, who dwelt in the vicinity of the Pyrenees, upon the coast of the Mediterranean sea.

CORDUS, Aulus Cornelius, in Biography, a senator and historian of Rome, during the reigns of its first two emperors. In his history of the civil wars, and of the reign of Augustus, he refers to C. Caius, and designates him "the last of the Romans." For this offence he was impeached, and put on his trial; during which he manfully vindicated his cause, and in his defence exclaimed, "Pettority will pay to every man his due honour, nor, if I am condemned, will there be wanting those who will cherish the memory, not only of Brutus and Caius, but of me also." This was not the effusion of an envious spirit, but the confidence to which his virtue and talents gave him a just claim. His prediction has been abundantly fulfilled; and it adds us pietate, at the distance of nearly two thousand years, to record the heroism of a man who disdained to fear the arm of power, and who held in contempt the tyrant Scipio, whose name has descended with so much infamy attached to it, as that of Cordus has with unfulfilled honour. For seeing that he should be condemned by the tribunal appointed to hear his cause, he resolved to put an end to his life, by abstaining from his daily food. On the fourth day, finding himself well naught animated by hunger and debility, he sent for his beloved daughter, Marcia, from whom he had conceal'd his intention, and, embracing her with tender affection, apologized for keeping this only secret from her, adding, "I am now half-way on the road, and you neither ought to call me back, nor can do it." She departed: and while his accusers and judges were debating what course to pursue, he breathed his last in peace. The senate ordered his books to be burnt; and though some copies were spared, which his daughter caus'd to be made as public as possible, yet nothing now remains except an epitome of Cicero, preferred in the Sabinia of M. Seneca. Of their value an estimat may be formed by the character given of them by Seneca. Speaking to Marcia, he says, "You have well deferred of Roman literature, and of piety, to whom will defend a faithful record of events, which cost the author so dear: you have well deferred of himself, whose memory will live and flourish, as long as it is thought worth while to know the history of Rome; as long as there shall remain any one, who shall wish to recur to the acts of his ancestors, any one who shall be defierous of knowing what a Roman once was: what, when all necks were bowed beneath the Spanian yoke, was the character of an unconquerable spirit, free in his head, his heart, his hands." Rom. Hist.

CORDUS, RURICUS, by Melchior Adam called Henry Urban, celebrated for his skill in medicine and in poetry, was a native of Simmerghays in Hesse. To attit himself in the profession of his studies, he employed some of his early years in instructing the sons of some of the neighbouring gentry. In performing this office, he had the good fortune to attract the notice of Eranus. In 1521 he went to Italy, where he attached himself in a particular manner to the study of botany; collecting and examining a number of rare plants, and diligently comparing them with the descriptions of them left by Dioscorides. At Ferrara he took the degree of doctor in medicine, which he afterwards taught at Erfurt and Marburg. In 1535 he went to Bremen, where he spent the small remainder of his life, which terminated, when he was only of a middling age, in the year 1538. He was author of several, and some very valuable, works. His "Treatise on the English Sweating Sickness" was published at Tifour, in 1529, 4to; and in 1532, he gave a Latin version
Cordula, in Ichthyology, an American fish, the Scooter cordula of Gmelin, the Gurna teres of Maregrasse, and the Trachurus brevifrons of Ray.

Cordylene, in Botany, a herb. See Dracena dress, and Yucco gloriosi et arizonis.

Gen. Ch. Cal. four-leaved, caduncous; leaves linear, nearly close. Cor. four-petalled, cruciform, open; style the length of the calyx; border ovate, quite entire. Stam. Filaments fex, erect, filiform; two lateral ones shorter; others almost erect, small, oval. Petic. Germ superior, cylindrical, smooth, ovate at the upper end; style very short; stigma obtuse. Pcrie. Silique jointed; the leaf joint dilated, globular, ovate, terminated by the permanent style. Seeds several, convex, somewhat compressed, oblong.

Eff. Ch. Calyx nearly close. Silique cylindrical, jointed; the leaf joint more distinctly separated.

Sp. 1. C. minuta, Point. in Encey. 1. Willd. 1. Des. Atl. 2. 72. tab. 152. "Silique one-celled, spreading; leaf joint muricate; leaves partly lyrate." Root annual. Stems about two feet high, erect, scabrous, hispid, especially on the lower part, slightly fruticose, branched; branches alternate, axillary. Leaves smooth, or clothed with a few dilatant hairs; lower ones oblong, or elliptical, decurrent; some quite entire, others lyrate; upper ones lanceolate, alternate, slightly fruticose, or a little toothed. Flowers alternate, almost sessile, in a terminal raceme; calyx smooth, or somewhat villous, coloured; corolla pale yellow. Silique smooth, or a little villous. Seeds four or five. Discovered by Desfontaines about Mayane, in the kingdom of Algiers. C. 2. levigata, Willd. 2. Pot. 2. (Smapi graciew; Tourn. Cor. 17. Lt. 1. 398. tab. 35.) Eucam. aleppica; Gent. 258. tab. 143. f. 9. Vent. Jard. de Cels. tab. 64.) "Silique two-celled, prefl; terminal joint smooth; leaves pinnatifid. Stems a foot high, erect, quite smooth; branches alternate, widely spreading. Leaves somewhat flat, alternate, smooth, peltate; segments linear, cutine, channelled. Flowers in terminal upright racemes; corolla purple, or pale red. A native of the island of the Archipelago.

Cordylus, in Anciout Geography, a town of Asia, placed by Step. Byz. in Pamphylia.

Cordylus, in Zoology, a species of lizard, the Lacerta cordylus of Gmelin and Linnaeus, with a short verticillated tail, dentilate scales, and a smooth body. It is found in Asia and Africa. Its body is livid or blackish.

Core, in Rural Economy, a name applied to a disorder incident to sheep, occasioned by the presence of small flat worms inserted in the liver. The greatest chance of removing this complaint is by changing the sheep into a more airy and dry pasture.—It also signifies the heart of the wood of trees, and likewise of some sorts of fruit, as the apple, pear, 

Core Bank, in Geography, a narrow island of America, on the coast of N. Carolina, about 40 miles long, and scarcely 2 broad. N lat. 34° 22' to 31° 55'. W. long. 75° 26' to 76° 50'.

Core Sound lies on the coast of N. Carolina, south of, and communicating with, Pamlico.

Corea, or Corea, in Ancient Geography, a place at which Pallas commenced on the northern side, according to
to Josephus; who says it was near Scythiopolis and a fortress named Alexandrium.

Corea, in Geography, called by the Chinese Kao-li, and by the Mantehew Tartars Solbo, a kingdom of Asia, in the form of a peninsula, extended between China and Japan, and every where surrounded by the sea, except towards the north, where it is connected with Chinese Tartary, which bounds it on the north; it is bounded on the east by the sea and islands of Japan; on the south by the straits of Corea, separating it from Japan, and by the ocean; and on the west by the Yellow sea, which parts it from China. This kingdom is commonly reckoned to be 200 leagues in length from N. to S. and 100 in breadth from E. to W. The great number of shoals and headlands which surround the coasts of this peninsula, render access to it by sea equally dangerous and difficult. Its least distance from Japan is only 25 leagues. The origin of the Coreans is very obscure. It appears, however, that this peninsula was at first inhabited by different tribes, which composed several states; and that, in course of time, they united under the same government, and formed one kingdom, which was called Kao-li. The Coreans were most probably of Tartar extraction. This kingdom is governed by a sovereign, who exercises absolute authority over his subjects, although he himself is a vassal and tributary of the emperor of China. On every succession to the crown, the prince receives on his knees the investiture of his flates, granted, or at least, confirmed by the emperor, and distributes among the emperor's envoys the sum of 800 tails, and several other customary presents. The minister of Corea afterwards repairs to Pe-king, to profest himself before the emperor, and present him the tribute. The princes, who has crowned the king, cannot assume the title of queen, until she has received it from the court of Pe-king.

The Japanese conquered this kingdom about the end of the 16th century; but the Coreans, assisted by the Tartars, who had subdued China, drove them from their country. The Mantchews, thus masters of Corea, endeavored to compel their new subjects to shave their heads, after their manner, and to adopt the Tartar dress. This innovation irritated their minds, and occasioned a general revolt throughout the kingdom of Corea, which was at length appeased by the prudent attention of the reigning family. The interior geography of this kingdom is little known: we are informed, however, that it is divided into eight provinces, containing 490 districts, 33 cities of the first class, 5% of the second, and 70% of the third. King-kita, or Kinko-tau, situated in the province of King-hi, is the capital of the whole kingdom, and the ordinary residence of the sovereign. This prince is absolute master of all the wealth of his subjects, which he inherits after their death. He is very rigid in the administration of justice; and particular punishments are appointed for murder, robbery, and adultery. Every seventh year all the freemen of the different provinces are obliged to go to court in rotation, and to keep guard round his person for two months; so that, during this year, the whole country is in motion and under arms.

The Coreans are well-formed, ingenious, brave, and tractable. They are fond of dancing and music, and particularly dote in acquiring the sciences, which they are said to study with ardor. Men of learning are distinguished from other classes of people by two plumes of feathers, which they wear in their caps. When merchants present any books for sale to the Coreans, they shew their respect by dressing in the richest attire, and burn perfumes before them to treat concerning the price. The northern Coreans are of a larger size, and more robust than those of the south; they are addicted to arms and become excellent soldiers; using, in combat, crossbows and very long fabrics. The Coreans do not inter their dead till three years after their decease; they wear mourning for a father or mother three years, and for a brother three months. When they perform the ceremony of interment, they place around the tomb the clothes, chalices, and horses of the deceased, and any thing else of which he was fond when alive; all which they have to be carried away by those who assisted at the funeral. Their houses consist only of one story, and are very ill built; in the country, they are of earth, in cities, generally of brick; but they are all tinctured with straw. The walls of their cities are constructed after the Chinese manner, with square turrets, battlements, and arched gates. These people have borrowed their writing, dress, religious worship, ceremonies, belief of the transmigration of souls, and the greater part of their customs, from the Chinese. Their language, however, is different. (See CHINA.) Their women are subject to less restrictions than those of China; and they also differ from the Chinese with regard to their marriage ceremonies. In China, fathers and mothers often marry their children without their consent, and even without their knowledge; but in Corea, the contracting parties choose for themselves, nor do they consult the inclinations of their parents, or allow them to interpose any objection in the way of their union. The principal productions of Corea are wheat, rice, and ginseng. This country also produces gold, silver, iron, fossil salt, eulor and fable's skin, a beautiful yellow varnish, the splendor of which is almost equal to gilding, and which diffuses from a tree resembling the palm tree, small horses about three feet high, and white paper. Small brushes for painting are made here of the hair of a wolf's tail, which are much esteemed in China. The paper of Corea, of which a considerable quantity is annually imported into China, is made of cotton; it is as strong as cloth, and those who write upon it make use of a small hair brush or pencil; without the precaution of rubbing it over gently with a little alum-water, it would not bear the ink of European pens. With this paper the Coreans partly pay the tribute due to the emperor, supplying the palace with it every year. The Chinese purchase it, not for the purpose of writing, but for filling up the figures of their fan-windows, because, when oiled, it resists the wind and rain much better than theirs; they also use it as wrapping-paper; and it is likewise serviceable to their tailors, who rub it between their hands till it becomes as soft and flexible as the finest cotton cloth, instead of which they often employ it in living clothes. If it be too thick for the purpose intended, it may be easily split into two or three leaves; and these leaves are even stronger, and less liable to be broken, than the best paper of China.

The sea-coasts of Corea abound with fish; many whales are found there every year towards the north-east, several of which, it is said, bear in their bodies the darts and harpoons of the French and Dutch, from whom they have escaped in the northern extremities of Europe. If this be true, it seems to indicate the existence of a passage from thence into the seas that lead to the north of America. We refer the reader for farther information with regard to this country to Du Halde and Groffer.

Corea. Strait of, that part of the sea which separates the southern part of the continent of Corea from the Japanese islands, between N. lat. 32° and 36°, and E. long. 130° and 132°. The channel, 735 Pereauce (Voyage, vol. n. p. 17, Eng. ed.), that separates the coast of Japan from the continent may be 15 leagues wide, but it is reduced to 10 leagues by rocks which interruptely border the southern coasts of Corea, from Quelpaert, and which continued, till we had doubled the S.E. point of that peninsula, to that we
were able to keep very close to the continent, distinguisht
the houses and towns on the coast, and reconnoitre the bays.
We law, says Perouze, on the summits of the mountains some fortifications exactly similar to European forts. It is highly
probable the principal means of defence, employed by the
Corcius, are directed against the Japanese. This part of
the coast is very favourable to navigation, for there appears
no caule of danger; and at 3 leagues in the offing the depth
of water is 60 fathoms over a muddy bottom; but the
country is mountainous, and appears very arid. The snow
was not entirely melted in some hollows (May, 1787); and
the soil seemed but little susceptible of cultivation. The
habitations, however, are very numerous. We counted a
dozcn lampanes, or junkas, failing along the coast, and seem-
ing in no respect to differ from those in China, their fairs
being also made of matting. See Dagelet, Island of
COREATIS, in Ancient Geography, a place of India,
near the mouth of the Indus, according to Arrian.
CORED, in Geography, a town of Egypt; 16 miles N.E.
of Belbeis.
CORED Herrings. See Herrings.
COREGGIO, in Biography. See Correggio.
COREGLIO, in Geography, a town of Italy, in the
state of Lucca; 15 miles N. of Lucca.
COREGONI, in Ichthyology, a division of the SALMO,
including those with fearlessly conspicuous teeth.
COREIA, in Antiquity, a festival in honour of Pro-
pine, named Core, Kote, which, in the Molossian dialect, sig-
nifies a beautiful woman.
CORELLA, in Geography, a town of Spain, in Na-
varre, on the Alhama; 6 leagues from Tudela.
CORELLI, Arcangelo, in Biography. The performance
and compositions of this admirable musician, form an
era in influential music, particularly for the violin, and
its kindred instruments, the tenor and violoncello, which he
made respectable, and fixed their use and reputation, in all
probability, as long as the present system of music shall
continue to delight the ears of mankind. Indeed, this moat
excellent master had the happiness of enjoying part of his
fame during mortality; for scarce a contemporary mu-
cial writer, historian, or poet, neglected to celebrate his ge-
nius and talents; and his productions have contributed long-
er to charm the lovers of music by the mere powers of the
bow, without the aidfulness of the human voice, than thone
of any composer that has yet existed. Haydn, indeed,
with more varied abilities, and a much more creative genius,
when instruments of all kinds are better understood, has
captivated the musical world in, perhaps, a still higher de-
gree; but whether the duration of his faviour will be equal
to that of Corelli, who reigned supreme in all concerts, and
excited undiminished rapture full half a century, must be left
to the determination of time, and the encreased rage of de-
praved appetites for novelty.
Corelli was born at Fugignano, near Imola, in the terri-
tory of Bologna, in February 1653. He is said by Adami
to have received his first instructions in counterpoint from
Matteo Simonelli of the Papal chapel; but the general opini-
on is, that his master on the violin was Giambattista Bai-
fan, of Bologna. It has been said (Life of Handel, 1762,
p. 46.) without authority, that Corelli went to Paris in the
year 1672, but was soon driven thence, by the jealousy and
violence of Lulli. That he returned Germany after he had
finished his studies, we are informed by Gaspar Prutz (Satzk.
Tomponii, &c.) that he was in the service of the duke of Bavari, in 1690. Soon
after this period, he seems to have returned to Italy, and
settled at Rome, where, about 1658, he published his first
"Twelve Sonatas." In 1683, the second set appeared,
under the title of "Balletti da Camera," which, the same
year, gave rise to a controversy between the author and
Paolo Colonna, concerning the diatonic succession of fifths,
between the first treble and the base of the allemand in the
second sonata. In 1699, Corelli published the third opera
of his sonatas; and in 1694, the fourth, which, confounding
of movements fit for dancing, like the second, he called
"Balletti da Camera."
In the works of the poet Guidi, published at Verona,
1727, it is recorded that, in 1686, when our king James
II. poulou sent an ambassador to pope Innocent XI. to
make a tender of his duty as a faithful son of the Romish
curch, at a grand academia which Christina queen of Swe-
den, then a profadyte, and resident in the Alma Città di
Roma, gave on the occasion, the music was composed by
Bernardo Paquin, and the band, amounting to one hundred
and fifty performers on bowed-instruments, instrumeni di
arco., led by Arcangelo Corelli.
About this time, when the opera was in a very flouri-
ishing state at Rome, Corelli led the band as principal violin.
But his folos. the work by which he acquired the great-
eflu reputation during his life time, did not appear till the
year 1700, when they were published at Rome, under the
following title: "Sonate à Violino, e Violone, à Cembalo,
Opera quinta, Parte prima, Parte seconda, Preludio, Alle-
amende, Corente, Gighe, Sarabande, Gavotte et Folhia."
This work was dedicated to Sophia Charlotte, electrefs of
Brandenburg. His great patron at Rome was cardinal
Ottoboni, the general encourager of polite arts and learning,
to whom, in 1694, he dedicates his "Opera Quinta," and
in whose palace he constantly refided, col petto to cará-
tere d' atuaile servitore of his eminence, as he expres-
s himself in the dedication.
Crescitumvini (Comment. della Volg. Poelia, vol. i. chap.
xi. Roma 1702.) speaking of the splendid and majestic acade-
ma, or concert, held at cardinal Ottoboni's every Mon-
day evening, says, that this performance was regulated by
Arcangelo Corelli, that most eminent professor of the violon:
famofissimo professore di violino.
In 1708, we have an honourable testimony of his high
rank in the profession, given at Venice in the first edition of
the "Armonico pratico al Cembalo," by Francesco Gai-
parini, who calls him, "virtuosifimo di violino, e vero Or-
feo di nostro tempo," (cap. vii.) And Adami, in speaking
of Simonelli, Corelli's first master in counterpoint, says,
that he made many scholars, "among whom, the most cele-
brated was the famous Corelli, the chief glory of the age,
with the fame of whose five works, already published, the
world is filled; and the sixth, confisting of concertos, which
he is now (1711) polishing for the prince, will complete his
immortality."
A very particular and intelligent friend, upon whose judge-
ment and probity we have a most perfect reliance, having
had a conversation with Geminiani about five or six years
before his death, and a friend of his at that time having
had in meditation the writing a history of music, he com-
mitted to paper, when he got home, the chief particulars
of his conversation, supposing they might be of some use
to his friend; but as the plan he had in view has been long
laid aside, we have been favoured with the anecdotes and
particulars that were obtained from Geminiani, which, as
they chiefly concern Corelli, and were communicted by one
of his most illustrious scholars, who heard and saw what he
relates; we shall insert them here.
"At the time that Corelli enjoyed the highest reputation,
...
his fame having reached the court of Naples, and excited a
defire in the king to hear him perform; he was invited, by
order of his majesty, to that capital. Corelli, with some
reluctance, was at length prevailed on to accept the invita-
tion; but, lest he should not be well accompanied, he took
with him his own second violin and violoncello. At Naples
he found Alessandro Scarlatti, and several other masters, who
entreated him to play some of his concertos before the king;
this he for some time declined, on account of his whole
band not being with him, and there was no time, he said,
for a rehearsal. At length, however, he consented; and in
great fear performed the first of his concertos. His allom-
ment was very great to find that the Neapolitan band ex-
cluded his concertos almost as accurately at light, as his own
band, after repeated rehearsals, when they had almost got
them by heart. Si facias, (says he to Matteo, his second
violin) a Napoli!

"After this, being again admitted into his majesty's
preference, and desired to perform one of his sonatas, the
king found one of the adagios so long and dry, that being
tired, he quitted the room, to the great mortification of
Corelli. Afterwards, he was desired to lead in the perfor-
amance of a masque composed by Scarlatti, which was to be
executed before the king; this he undertook, but from
Scarlatti's little knowledge of the violin, the part was some-
what awkward and difficult: in one place it went up to F;
and when they came to that passage, Corelli failed, and was
unable to execute it; but he was acquitted beyond measure
by the king, the Neapolitan leader, and the other vi-
olinists, perform which that had baffled his skill. A song
succeeded this in C minor, which Corelli led off in C major;
riconminicatam, said Scarlatti, good-naturedly. Still Corelli
performed in the major key, till Scarlatti was obliged to call
out to him, and let him right. So mortified was poor Cor-
relli with this disgrace, and the general had figure he imag-
ined he had made at Naples, that he fled back to Rome in
silence.

"It was soon after this, that a hautbois player, whose
name Geminiani could not recoleét, acquired such a prelau-
se at Rome, that Corelli, disgusted, would never play again
in public. All these mortifications, joined to the success
of Valentini, whose concertos and performances, though
infinately inferior to those of Corelli, were become fashion-
able, threw him into such a state of melancholy and cha-
bras, as was thought, said Geminiani, to have hastened his
death."

This account of Corelli's journey to Naples is not a
mere personal anecdote, as it throws a light upon the com-
parative state of music at Naples and at Rome, in Corelli's
time, and exhibits a curious contrast between the fiery genius
of the Neapolitans, and the meek, timid, and gen-

eral character of Corelli, so analogous to the fyle of his
music.

In 1712, his concertos were published in a beautiful
edition, engraved at Amsterdam, by Etienne Roger and
Michael Charles le Cerne, and dedicated to John Wil-
liam, prince palatine of the Rhine; but, alas! the au-
thor surived the publication of this admirable work but
six weeks; the dedication bearing date at Rome, the 3d
day of December 1712, and he died on the 18th of January
1713.

He was buried in the church of the Rotunda or Pantheon,
in the first chapel on the left hand of the entrance of that
beautiful temple, where a monument, with a marble bust
on it, was erected to his memory, near that of the great pain-
ter Raphael, by Philip William, count palatine of the Rhine,
der the care of Cardinal Ottoboni; on which is the fol-
lowing inscription:

D. O. M.

Vixit Annos LI X. Mens. X. Dies XX.
Obit. IV. Id. Januarii Anno Sal. MDCCXIII.

During many years after his decease, there was a kind of
commemoration of this admirable musician in the Pantheon,
by a solemn service, consisting of pieces selected from his own
works, and performed by a numerous band, on the anniver-
sary of his funeral. A solemnity which continued as long
as his immediate scholars survived, to conduct and perform
in it. The late Mr. Wifman, who arrived at Rome before
the discontinuance of this laudable custom, assured us that
his works used to be performed, on this occasion, in a flow-
ning, and distinct manner, just as they were written, without
changing the passages in the way of embellishment. And
this, it is probable, was the way in which Corelli himself
used to play them.

Of the private life and moral character of this composer,
little new information can now be acquired or expe-
cited; but if we may judge of his equanimity and natural dispo-
ition by the mildness, facetiousness, and even tenor of his musical ideas,
his temper must have endeared him to all his acquaintance, as
much as his talents.

Indeed, the account that is given of his dying worth
cooa.o. of a valuable collection of pictures, and
bequeathing them all to his patron Cardinal Ottoboni, does
more honour to his parsimony and gratitude, than judgment;
a musician leaving money to a cardinal, while he had a rela-
tion or neccessitous friend in the world, seems to favour more
of vanity, than true generosity. And the cardinal, himself,
manifested his opinion of this bequest, by keeping only the
pictures, and distributing the rest of Corelli's effects among
his poor relations, to whom they naturally appertained.

To attempt to give a character here of Corelli's composi-
tions, which have been so long heard and universally admis-
ted, may to many of our readers appear wholly useless; yet
as they are thrown aside as antiquated lumber by some, and
regarded as models of perfection by others, our wish is to rank
each musician in his true place, with equity and faireness,
inclines us to make a few reflections on the genius and works of
this master, before we quit the subject.

As Corelli originally titled the second and fourth opera of
his sonatas, "Balletti da Camera," from the dancing and fa-
miliar movements contained in them; the first and third, from
their gravity of style and movement, may be called
"Sonate da Chiesa." The name distinction may be made
with propriety in his concertos, and even sonatas; the first

5 A 2 eight
eight of the former, and six of the latter, being much more solemn and ecclesiastical than the rest.

With regard to the intrinsic worth of his four books of sonatas at present, notwithstanding the exquisite pleasure they may have afforded ourselves and others, during youth, it is very much diminished by the general improvement of melody, knowledge of the bow, and boldness of modulation, which have freed invention from former fancies, and generated new ideas and effects. Indeed, during the time of Corelli, and long after, every one who knew the mechanical laws of harmony, however ignorant of the violin, let about composing sonatas, solos, and concertos, for it; but the great masters of that instrument, whose genius and invention have kept pace with their hand, have now nearly crushed all such impudent and impudent attempts.

Corelli’s sonatas, as a classical book for forming the hand of a young practitioner on the violin, has ever been regarded as a most useful and valuable work, by the greatest masters of that instrument. We were told by Mr. Wiseman at Rome, that when he first arrived in that city, about twenty years after Corelli’s decease, he was informed by several persons who had been acquainted with him, that his “Opus Quinta,” on which all good schools for the violin have been since founded, cost him three years to refine and correct. Tartini formed all the scholars on these solos; and Signor Giardini has told us, that of any two pupils of equal age and disposition, if the one was to begin his studies by Corelli, and the other by Geminiani, or any other eminent master whatever, he is sure that the first would become the best performer.

The concertos of Corelli seem to have withstood all the attacks of time and fashion with more firmness than any of his other works. The harmony is so pure, so rich, and so grateful; the parts are so clearly, judiciously, and ingeniously disposed; and the effect of the whole, from a large band, to a majestic, solemn, and sublime, that they preclude all criticism, and make us forget that there is any other music of the same kind existing.

Geminiani, according to our friend’s memorandums, whence an extract has already been given, affirms that Corelli rivalled himself much of the compositions of other masters, particularly of the sonatas in which he played at Rome; that he acquired much from Lulli, particularly the method of modulating in the legatura, and from Bononcini’s famous Camilla.” This was not very intelligible; nor does the charge appear well founded; as Lulli has made but little use of the legatura. With these maestros we are acquainted; but we find frequent imitations of the more natural passages of Scarlatti, particularly in the beautiful adagio of his eighth concerto, in which there is a great resemblance to a movement in a cantata which was set by Scarlatti in 1704, eight years prior to the publication of Corelli’s concertos.

There was little or no melody in instrumental music before Corelli’s time. And though he has much more grace and elegance in his cantilena than his predecessors, and flow and solemn movements abound in his works; yet true pathetic and impassioned melody and modulation seem wanting in them all. He appears to have been gifted with no uncommon powers of execution; yet, with all his purity and simplicity, he condescended to aim at difficulty, and manifestly did all he could in rapidity of finger and bow, in the long unmeaning allegros of his first, third, and sixth solos; where, for two whole pages together, common chords are broken into common divisions, all of one kind and colour, which nothing but the playing with great velocity and neatness could ever render tolerable. But like some characters and indecorous scenes in our best old plays, these have been long omitted in performance.

Indeed his knowledge of the power of the bow, in varying the expression of the same notes, was very much limited. Veracini and Tartini greatly extended these powers; and we well remember our pleasure and astonishment in hearing Giardini, in a solo that he performed at the oratorio, 1709,
COR

play an air at the end of it with variations, in which, by repeating each strain with different bowing, without changing a single note in the melody, he gave it all the effect and novelty of a new variation of the passages.

However, if we recollect that some of Corelli's works are now more than a hundred years old, we shall wonder at their grace and elegance which can only be accounted for on the principle of ease and simplicity. Purcell, who composed for ignorant and clumsy performers, was obliged to write down all the fashionable graces and embellishments of the times, on which account his music soon became obsolete and old-fashioned; whereas the plainsness and simplicity of Corelli have given longevity to his works, which can always be modernized by a judicious performer, with very few changes or embellishments. And, indeed, Corelli's productions continued longer in unfading favour in England than in his own country, or in any other part of Europe; and have hence only given way to the more fanciful compositions of the two Mantins, Zanelli, Camponi, Giardini, Bach, Abel, Schwindi, Baccherini, Stamitz, Haydn, Mozart, and Pleyel.

After the publication of Corelli's works, the violin seems to have increased in favour all over Europe.

Coren delini, in Geography, a town of Swiffzerland, in the canton of Solothurn, to 9m. N. of Solareum.

Corentin, a considerate river of South America, in Dutch Guiana.

This genus differs from bidens in having a ray, and from verbena in having the florets of the ray barren.

Sp. 1. Coreopsis fulva. Wild. 1. Jacq. Hort. Schen. 1705. tab. 373. "Leaves bipinnatit; pinnule linear-lanceolate, with ribs half their breadth." Root perennial; outer-leaves of the calyx numeros, reflexed. A native of Mexico. 2. Coreopsis verticillata. Linn. Sp. Pl. 1. Mart. 1. Wild. 2. Bot. Mag. 156. (Coreopsis verticillata; Gr. Virg. 151. Chrysanthemum; Flk. Mant. 48. tab. 544. fig. 4.) "Leaves decomposed-pinnate; segments filiform." Root biennial. Stem from a foot and half to three feet high, erect, fringed. Leaves fcfille, opposite, but often appearing to grow in whorls in consequence of being cut off at the base into linear segments, which are curved in various directions. Flowers terminal; florets of the disk brown; of the ray yellow; calyx short; outer leaves narrow, loofy, shorter than the others. A native of Virginia and Louisiana. 3. Coreopsis californica. Linn. 2. (Coreopsis fulva; Gr. Virg. 151. Chrysanthemum; Plk. Mant. 48. tab. 544. fig. 4.) "Leaves triplicate-pinnate; segments linear, candelabred on the upper surface." Nearly allied to the preceding, but constantly distinguished from it by its foliage and habit. Root perennial. Stem a foot and half high, erect, smooth, fringed. Leaves opposite, connate, fcfille, divided at the base into three pinnate segments. Flowers terminal; florets of the disk brown; on a somewhat prominent receptacle; of the ray yellow, acute, entire, or bifid; outer scales of the calyx narrow, loofy, obtuse. A native of Virginia. It may perhaps be doubted which of the last two is the verticillata of Linnaeus. 4. Coreopsis tinctoria. Wild. 3. Ehret. Brit. 1719. "Leaves pinnatit; pinnae linear, three-parted or undivided; disk the same colour with the ray." Root perennial. A native of Carolina. Wild登now supposes this species to be the verticillata of La Marek; but he cannot be right, if it have the disk and ray of the same colour; for La Marek, who described from a living plant, expressly says, that the disk of his verticillata is brown, and its ray yellow. It is on this circumstance alone, that the separate existance of tenuifolia seems to depend. 5. Coreopsis coronata. Linn. Sp. Pl. 2. Mart. 2. Wild. 4. (Coreopsis coronata; Plk. Mant. 48. tab. 544. fig. 4.) "Leaves pinnate, serrate, marked with lines; smooth." Root annual. The plant is altogether that of Bidens frondosa; but it has the flowers of Coreopsis, with a large ray of eight fringed, oval florets. A native of Virginia. 6. Coreopsis triestifolia. Wild. 5. Mich. am. 2. 139. "Leaves pinnate, lanceolate, serrate, smooth; scales of the outer calyx ciliate-serrate." A native of Upper Carolina, in moist ground. 7. Coreopsis virgata. Wild. 5. (Coreopsis virgata; Mich. am. 2. 140.) "Leaves pinnate, serrate, pube-vent; horns of the seed very long, divaricated." A native of North America in the country of Illinois. 8. Coreopsis aequiflora. Mart. 188. Jaff. 140. "Leaves pinnate; pinnule five, serrate-glaber; ray six-flowered; seed three-horned." Root spindly-flushed, fleshy, white. Stem a foot and half high, herbaceous, erect, quadrangular, grooved. Leaves quinate, lanceolate. Flowers entirely fuscous-coloured, few together, on terminal peduncles; florets of the ray six; eggl-shaped, quite entire; horns of the seed brittle and divided; calyx erect, many-leaved. A native of China. 9. Coreopsis nitida. Wild. 7. Mich. sper. 2. 140. "Lower leaves bipinnatifid; upper ones linear, three-parted; seeds naked." Calyxes generally simple, sometimes somewhat ciliated. A native of marshes in Carolina. 10. Coreopsis leucantha. Linn. Sp. Pl. 6. Mart. 3. Lam. 6. (Bidens leucantha; Wild.) "Leaves pinnate, serrate; florets of the ray of a different colour from those of the disk." Root annual. Stem three or four feet high, quadrangular, smoothish; the opposite sides channelled; branches opposite. Pinnule five, seldom three, eggl-shaped, undivided, smooth, equal, even; the three outer often confluent, almost decurrent by the outer side, quite entire at the tip; petalschannelled, connected on both sides by villous hairs. Flowers terminal, alternate, two or three, on long peduncles; inner scales of the calyx five; outer five, smaller, more distinctly separated; florets of the ray five; eggl-shaped, three-toothed, three-nerved underneath; disk small, convex, yellow. Seeds three-horned, hump'd backwards. Linn. A native of Virginia. La Marek thinks it not distinct from C. coronata. 11. Coreopsis auriculata. Lam. 7. (Coreopsis virgata; Linn. Sp. Pl. 6. Mart. 2. Lam.) Wild. 7. Bidens americana triumpha; Plk. Mant. 48. tab. 544. fig. 4.) "Leaves serrate, serrate, smooth; florets of the ray of a different colour." Root sweet-scented, whitish, fibrous. Stem about three feet high, quadrangular, smooth, sweet-scented. Leaves opposite; generally composed of three eggl-shaped, acute, smooth, toothed-leaves. Flowers terminal, solitary; florets of the ray yellow, resembling the common cow-wheat. Seeds three-horned; receptacle almost hemispherical. Plk. Mss. A native of the West Indies, and South America. Linnaeus, in his specific character, describes the ray as similar in colour to the disk, and if he had not quoted Plummer as his

C O R

C O R
tioled, veined, decurrent; lower ones whorled; upper ones alternate. Root perennial. A native of North America, flowering in September and October. Professor Martyn conjectures that this is the alternifolia of Linnaeus, and that the alternifolia of Hortus Kewensis is a different plant. 30. C. radiata. Mill. Mart. 17. "Leaves linear-lanceolate, sharply serrated, opposite; ray of the flower large, entire." Root annual. Stems four feet high, creet. Leaves from three to four inches long, three quarters of an inch broad, acuminate, or short petioles. Flowers two from each of the upper joints of the stem, opposite; peduncles, long; flinders, bearing two or three pairs of small leaves or bracts, one-flowered; flowers of the ray five, oval, entire; of the disk numerous, dark-coloured. A native of South Carolina, flowering in August, raised by Miller from seeds lent by Dr. Dale.

Propagation and Culture. Most of the perennial species are hardly and may be readily increased by parting the roots. The second and fourteenth require a light loamy earth and sunny exposure. The geographical should be sown in a hot-bed and afterwards transplanted into a warm border.

Coreopsis, in Gardening, contains plants of the flowering herbaceous perennial kind; of which the species cultivated are the whole leaved coreopsis, or tick feed flower. (C. verticillata.) The three leaved coreopsis. (C. trilobata.) The alternate leaved coreopsis. (C. alternifolia.) The four leaved coreopsis. (C. lanceolata.)

Method of Cultivation. The mode of propagation in these plants is easily effected, either by crumbling or dividing the roots in autumn when the bracts decay, planting them where they are to remain, keeping them clean from weeds, and cutting down the bracts annually in autumn when they begin to decay. The third and fourth months may be rendered more favorable by the use of a hot-bed. All these plants are well calculated for the more large borders and chums, introducing them in the vacant spaces between shrubs, as they exhibit a plentiful bloom till late in the autumnal months.

Coreesium, in Ancient Geography, a lake or marsh in the island of Crete. Steph. Byz.

Coressus, one of the four towns of the island of Cossus, according to Strabo and Ptolemy. Coreesium, or Corecis, a name given by Xenophon, Diodorus Siculus, Sec. to a high mountain of Asi Minor in Ionia, about 40 stadia from the city of Ephesus. At the foot of this mountain was a town of the same name, called by Steph. Byz. Coremis, which he represents to be a town of Ephesus, because of its dependence upon it. He says that it derived its name from the following circumstance. Diana, having been delivered of Lenata, and having brought her band ashore of the people of the country to whom this place belonged? they replied "Kep, os!" Virgin, it is yours. In this fable is traced the etymology of the name.

Coreta, in Botany, Brown. See Corchorus silique-fus.

Coretta, in Ichthyology, the name of a large East Indian fish of the tunny kind, and figulated to be no other than the common tunny, or Scornax Thunnus. It grows to fix or even feet long. Its eyes are large, and its irises yellow; its tail is broad and forked, and in colour of a yellowish green; its belly-fins are yellowish, and its belly of a fine bright glossy blue, with a silvery cast. It is generally caught with hooks, and is a very fine tailed fish. Ray.

Coretum, in Ancient Geography, a gulf of Palm- Mazots, according to Pliny; who says that a mountain of rocks separated this gulf from the lake of Buge, into which the river Hysanas discharged itself.

Coreva, or Corelia, a place of Africa propria, on the route from Turbarua to Tacape, between Valla and Mufi, according to Antonine.

Coreur, a town of Syria on this side of the Ganges, according to Ptolemy. It is thought to be the same with Coreera.

Corfe Castle, in Geography, is an ancient market-town, situated near the centre of the Isle of Purbeck in Dorsetshire, England; at the foot of a range of hills, on a rising ground, declining to the sea. Its origin must undoubtedly be attributed to the castle, which existed previous to the year 982: though the town itself does not appear to have been of any importance till after the conquest, it being wholly unnoticed in Domesday book. The manor and castle seem always to have defended together. Though this is an ancient borough by prescription, it was not incorporated till 18th Eliz., when Earl Christopher Hatton obtained a charter, inwelling the inhabitants with liberties similar to those of the Cinque-ports, with various other privileges; these were confirmed by James I. and Charles I. The government of the town is vested in a mayor, and eight barons who have served the office of mayor. The earliest return to parliament was in 14 Eliz.; the right of election is possessed by all persons within the borough who are feized in fee, in possession, or reversion, of any freehold, in tenants for years, determinable on any life or lives, paying foot and lot. The town consists chiefly of two streets of stone buildings. The church, a large ancient fabric, comprises a nave, chancel, two aisles, and a large embattled tower: twelve arched arches support the roof, and four pillars, in the Saxon style, but all different, are connected with the porch. The number of houses in the late return was 152; and of inhabitants 741; many of whom find employment in the adjoining clay-works and flint quarries; and a few in knitting stockings. A weekly market is held on Thursdays. This town is 116 miles S.W. from London. The district which includes Corfe castle, and is about ten miles in length and eight in breadth, contains twelve or thirteen Sunday schools, distributed through the different parishes; each being governed by a committee of the principal inhabitants, subject to the inspection of a general committee who meet at Corfe castle as occasion may require. The average number of children who attend these schools is about 450. Dorsetshire was one of the first counties in which Sunday schools were established. Some excellent regulations, relative to the general management of these institutions, may be seen in Hutchison's Dorset, vol. i. p. 328, 2d edit.

The castle at Corfe "stands a little north of the town, opposite to the church, on a very steep rocky hill, mingled with hard, roughly chalk-stone, in the opening of those ranges of hills that incline to the east part of the site. Its situation between the ends of these hills deprives it of much of its natural and artificial strength, being too much commanded by them, that they overlook the tops of the highest towers; yet its flintwork is so strong, the ascent of the hill on all sides but the fourth to steep, and the walls so many and thick, that it must have been one of the most impregnable fortresses in the kingdom before the invention of artillery. It was of great importance in respect to its command over the whole site; whence our Saxons flours pleasantly did it Corfe gate, being the pafs and avenue into the belt part of the site." (Hutchinson's Dorset, i. 280.) The castle is separated from the
the town by a strong bridge, of four very high, narrow, semi-circular arches, crossing a deep moat, now dry. The bridge leads to the gate of the first tier, which remains nearly entire, probably from the thickness of the walls, which, from the outward to the inner bridge, is in some parts still nine yards. On the higher part of the hill, at some distance from the centre of the fortress, there is the keep or citadel, which still retains nearly its original height, and commands a very extensive prospect to the north and west.

The precise period when this castle was built is uncertain; but from concurrent circumstances its erection is ascribed to King Edgar. That it did not exist previously to the year 887, when the munition at Shaftesbury was established, is certain, from an inquisition taken 54 Hen. III.; whereas the jurors returned, "that the abbeys and mansions at Shafton (Shaftesbury) had, without molestation, before the foundation of the castle at Corfe, all works within their manor of Kingston, in the isle of Purbeck."

Between two and three miles eastward of Corfe, is Nine Barrow Down, an eminence to named from nine large barrows situated on it in a line, supposed to be of British construction. The whole number of barrows on this downs are sixteen of various dimensions; most of them circular, and very regularly shaped. A shallow trench surrounds eight or ten; and near them is a hollow or cavity. The highest part of the downs rises 642 feet above low water mark.

At a small distance, north west of Corfe, is Grange or Grece Groane, the seat of John Bond, esq.; it anciently was part of the possessions of the abbey of Blandon, and the occasional residence of the Abbot. Hutchins's History of Dorsetshire.

CORFINIUM (S. Pelino), in Ancient Geography, a town of Italy, the capital of the Peligni, situated at a small distance from the Aternum, on a delightful plain surrounded by mountains. In the time of the Social war, A. D. 662, the allies fortified it, and made it a place of arms. During the civil wars, Caesar obliged Domition to retire hither, befleged him there, and took the place.

CORFU, in Geography, the ancient CORCIRA (which fre), an island of the Mediterranean, at the mouth of the Adriatic, near the coast of Albania, about 15 leagues long and 8 wide. In ancient times the inhabitants of this island formed a powerful republic; in succeeding times it belonged to the king of Naples; and it was afterwards sold for 30,000 ducats to the Venetians, who maintained a fleet of galleys in the port, and a strong garrison to defend this and the neighbouring islands. It was seized by the French in 1797; and by an article in the treaty of Campo Formio, in 1797, the French republic was allowed by his majesty, the emperor, king of Hungary and Bohemia, to polleds, in full sovereignty, the cit-devant Venetian fylaps of the Levant, viz. Corfu, Zante, Cephalonia, St. Muree, Corigo, and other islands dependent on them, together with all the cit-devant establishments in Albania, which are situated lower down than the gulf of Dodino. In 1799 this island was taken by the Russians, and, together with Cephalonia and Zante, &c. constitute an independent republic under the protection of Russia.

This island is said to contain about 50,000 persons, and is divided into four bailiwicks or governments. The religion of Corin is partly that of the Latin and partly that of the Greek church. The latter has for its chief a proto-papa, or head-priest, elected in an assembly of the clergy and nobility; he is immediately dependent on the patriarch of Constantinople, and pollethes all the episcopal powers. His office lasts five years, and he then returns to the chief of ordinary paps, with the privilege of wearing a crimson girdle. His revenue is confined to the prebendes of his office, the amount of which he continues to increase, as an indemnity for the expense he incurred in procuring his nomination. To the cathedral there are canons attached, as to that of the Latina church; but they have no fixed pretend. The only advantage accruing from their canonicate is that of being at the head of the clergy, together with the honour of wearing a violet girdle, and a small tassal of the same colour to their hats. The number of churches in Corfu is very considerable. Each officiating priest is annually elected by the assembled parishioners; but he has no fixed salary. Most of the churches, especially those in the country, have been built by private persons, who, as proprietors, nominate the papa. The richest of these churches is that in which are deposited the relics of St. Spiridion, to whom the Greeks pay a peculiar devotion; and the festival of this saint is celebrated with the greatest pomp. The night between Holy Thursday and Good Friday is remarkable for the number of processions which perambulate the city.

In the isle of Corfu are several convents of men and women, which tend very much to oppress the inhabitants. The ignorance of the Greek clergy, especially in the rural parts, is so great as to be proverbial; the most learned among them being hardly capable of writing and reading their own language.

The air of this island is healthy, the land fertile, and the fruit excellent. Oranges, citrons, the most delicious grapes, honey, wax, and oil are very abundant. Some places are mountainous and barren, and good water is scarce. Salt forms a great part of its riches.

CORFU, the capital of the fore-mentioned island, the seat of a bailiff, a provost, a captain, &c. and the see of an archbishop. It is fortified, and defended by two fortresses; the town has a good harbour and a considerable trade. N. lat. 36° 43'. E. long. 20° 2'.

CORGAL, a country of India, near the coast of Malabar, bounded on the N. and E. by the Myfore country, on the S. by the country of the Nayrs, and on the W. by the sea.

CORGATHA, in Ancient Geography, a town of India, according to Ptolemy.

CORGOLIN, in Geography, a town of France, in the department of the Côte d'Or, and district of Beaune; 5 miles N. of Beaune.

COR, anciently Coria, a town of Italy, in the Campagna di Roma; 10 miles S. of Palestrino.

CORIA, or CORICA, in Ancient Geography, a town of the isle of Albion, in the country of the Damni, according to Ptolemy. The conjectures about the situation of this place are various and doubtful; but, upon the whole, that of Mr. Baxter seems to be the most probable, who places it at Kirkintilloch, a place of great antiquity, upon the wall, about 6 miles from Glasgow.—Alto, a town of Albion, belonging to the Otadesi, and supposed to be Corbridge in Northumberland by Camden and Baxter; but Hulsey imagines it to have been situated much farther north, probably at Jedburgh, and supposes it to have belonged to the Gadeni.—Allo, a place of Greece, in the Peloponnesus; near the town of Helice, according to Ælian.—Allo, a town of Italy, near Rome. See Cori.

CORIA, in Geography, a town of Spain, in the province of Estremadura, the see of a bishop. It contains two churches, two convents, and two hospitales; near it are medicinal springs; 90 miles E. of Toledo, and 110 E.S.E. of Madrid. N. lat. 39° 36'. Long. 16° 38' E. of Peak of Tenerife.—Allo,
COR

Alfo, a town of Spain, in the county of Seville, on the Guadalquivir: 7 miles from Seville.

CORIACO, a town of S. America, in the province of Cumana, on a gulf to which it gives name; 40 miles E. of New Cordova. It contains about 6,500 persons.

CORIALLUM, in Ancient Geography, a place of Gaul, in the Lyonnensis secunda; near the cape de la Hogue, according to d’Anville.

CORIANDER, in Agriculture, the name of a plant which is cultivated in the field by the farmer in some districts, though not to any very great extent. In both Effex and Kent it is, however, occasionally met with as a field crop.

In its culture it is advised, that the seed should be sown in the autumnal season, on rich, friable land, which has been well prepared by tillage; and that when the plants have risen above the surface of the ground, they should be hoed out to the distance of about four inches every way, clearing them well from all sorts of weeds. It is supposed that by this management they will become strong, and produce a greater quantity of good seed.

The advantages of cultivating this sort of crop are thus stated in the fourth volume of the Letters and Papers of the Bath Society.

Sowed ten perches of land with coriander seed, the foil a good sandy loam.

Expences.

or 15 l. 18s. 4d. per acre.

The author of the paper observes, that he has since made several larger experiments in this article, but that none has proved so good a crop as the preceding, yet all of them such as to afford a good profit. There is a ready sale for the seed with the druggists, druggists, and confectioners. The former purchase very large quantities: the price varies from 15s. to 42s.

According to Mr. Vancouver, in his Account of Effex Husbandry, the mode of cultivation is thus performed.

"The culture of coriander, which has been much attended to in the neighbourhood of Tolhurst Darcey, is, he says, thus managed: old lay-ground is ploughed in the beginning of March, and after the surface is completely pulverized, the seed is sown fourteen pounds to the acre; three hoeing and letting out the plants four inches square will cost one guinea per acre. Average produce, 10 cwt. per acre, 12s. per cwt. This is considered to be a very good preparation, after once ploughing, for wheat; and as the land is generally ploughed in two yard ridges, or fitches of eight furrows wide, a row of beans is generally planted with the coriander, on each side of the open furrows between the fitches, and are usually harvested at the same time.

"It is frequently the case in this district to cultivate a triple sort of crop, consisting of coriander, caraway, and teasel.

"When (says the above writer) caraway is sown with the coriander, from the care and attention necessarily bestowed on differenting the plants, the hoeing seldom costs less than one guinea and a half per acre; but the caraway is not regularly set out for a crop till after the coriander is harvested, at which time a very expensive hoing becomes indispensably necessary.

"Teasel is sometimes cultivated in the same field, the feed being sown with the coriander and caraway; but as neither the caraway nor teasel come completely and regularly the second year, both crops are usually allowed to stand for the third summer. This is esteemed good management for old coarse pasture grounds, which, after three ploughings, are commonly sown with wheat, and then cleans chalked."

The following directions are given for this culture, by Mr. Sewell of Maplestead: "About the beginning of March, plough some old pasture land; if it has been ploughed for a century, the better; and the soil should be a very strong clayey loam. Mix 12 lbs. of caraway, 10 lbs. of coriander, and 12 lbs. of teasel seeds together, which is sufficient for one acre; sow directly after the plough and dries (he supposes harrow) the land well. When the plants appear of sufficient strength to bear the hoe (which will not be until about ten weeks after sowing), it must not be omitted, and in the course of the summer it will require three hoeings, and one at Michaelmas; each will be about 8s. per acre. The coriander is annual, and is fit to cut about the beginning of July; it should be left in the field after cutting, and throned on a cloth, in the same manner as rape feed.

"About April following, your teasel and caraway will want a good hoing, done deep and well, and another hoing about the beginning of June; these two hoings are to be done at 7s. per acre each. The caraway will be cut to the beginning of July, and must be throned in the same manner as coriander. The teasel will not be ready till the middle of September, when those heads which are beginning to turn brown are cut off the stem, with a flax a foot long, and 25 of them are tied in a bunch, 24 of the bunches are fixed on a small flax, and called a row, 24 of which make a load in bulk, equal to a ton of hay from the meadow. The work of cutting and bunching the teasel can only be done by those who have been well acquainted with and learned the mode; it must be looked over, and the heads cut at several times, as they ripen. The teasel and caraway are perennial, and some of the plants do not perfect their seeds till the third or fourth year, though in general you have a crop the second year, and the seeds that are scattered from the crop the second year often come to perfection the fourth year; he has known instances of this being continued for seven years. The usual way is to plough directly after the crop is gathered the third year, and for which, of which commonly a good crop is obtained, the land being in fine order, from the turf being rotten, and the repeated hoings. See Tassel.

"The first appearance of teasel, after it is sown, is much like a lettuce, coriander like a parsnip, and caraway like carrots. The produce of caraway has often been, on the very rich old lays in the hundreds or low lands of the county, 20 cwt. per acre. There is always a demand for it in the London market, sometimes to low 45s. per cwt., and it has been up to 50s. per cwt.; mostly on an average at 21s.
Coriander is also very productive on good land, often producing 24 cwt. per acre, sometimes not more than 6 or 7 cwt., the price being sometimes 36s. per Cwt., often so low as 10s., average in general about 12s., London market. Teasels are used only amongst the manufacturers of ordinary cloth and baizes, to raise the wool on them that covers the thread. As we have a large business of that kind carried on in this part of the country, we have a regular demand for teasel; the average price 12s. per load, the produce sometimes a load per acre, often not more than one-fourth of a load. The land can only be filled with plants, and the more one kind predominates, the less malt reasonably be expected of the crop that succeeds. It is mowly fown on land so strong, as to require being a little exhausted to bring it fit for bearing corn. In drill of the land fown with caraway and coriander the teasel is omitted, as being a more troublesome and uncertain crop, and generally the product of car-raway is much greater without than with teasel.

In many parts of this district there are gardening-farmers who travel about and contract for breaking up old grafs land, in order to sow caraway. The farmer ploughs to a great depth, and does whatever horse-work is wanted, finding the land also at a rent of 15s. per acre on some farms, and the produce is divided. It is reckoned a more profitable way of breaking up grafs than for common crops; but, much depending on a variable price, is reckoned hazardous; though the caraway men have intelligence enough among themselves to aim at not overflockelting the market.

It is observed, that the coriander is always the first crop, the caraway being fown with it as clover is with barley to succeed it; and it is left from three to six years, according to the success; great hoeing is bestowed on it to keep the land clean: when it returns to the farmer, if there be noch he falls, if not, he fows wheat. With some farmers their half receipt from 50 acres has varied from 150l. to 200l. a year.

Coriander, in Botany. See Coriandrum.

Eff. Ch. Petals infulced, emarginate. General involucel one-leaved or none; partial, going half way round, or none. Fruit sphericel, or serotiform.

Sp. 1. C. foetuosa. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Gært. tab. 22. fig. 2. Linn. Illuat. Pl. 105. fig. 1. Woodv. Med. Bot. tab. 181. Eng. Bot. Pl. 67. Bauh. Pin. "Fruit globular," Root annual, strong-fencel. Stam. about a foot and half high, erect, smooth, slightly fristed, cylindrical, generally branched and divericated. Leaves compound; lower ones pinnated; leaflets roundish-ovate, lobed, and toothed; upper ones twice-ternate; segments linear. General and partial umbel many-rcved. General involuce of one linear leaf; partial involuce from three to five-leaved, going half way round; leaves lanceolate. Flowers white, tinged with red; proper calyx very conspicuous; outer petals of the outer flowers large, forming a kind of ray round the umbel. Fruit oblongely ribbed, aromatic. A native of the southern parts of Europe and of China; naturalized in Suffolk about Ipswich, and in some parts of Essex. Every part of the plant, when fresh, has a very offensive smell; but the dried seeds have a tolerably grateful smell, with a moderately warm and slightly pungent taste. They are diaphoretic and carminative, and are commonly sold by the confectioners encrusted with sugar. When taken in large quantities they are said to be delerious, but Dr. Withering affirms that he has known six glasses of tea taken down at once, without any remarkable effect. They give out their virtue totally to refined spirits, but only partially to water. The Edinburgh college use them in the bitter infusion and the preparations of ferns, to cover the disagreeable taste, and prevent the gripping tendency of those medicines. 2. C. telescicultural. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Ill. Pl. 196. fig. 2. Willd. 2. (C. minus telescicultural; Bauh. Pin. 156. Pluk. aln. 120. tab. 169. fig. 2.) C. fylvestrae fuscitidisumum; Bauh. Pin. 158. "Fruit diodeous." Root annual. Stem scarcely a foot and half high, angular, branched. Leaves once or twice pinnated; leaflets deeply cut into narrow acute segments. Umbel small, often simple. Partial involucel none, outer petals not forming a ray. Seeds separating below, almost cohering above, a little wrinkled, but not inflated. A native of the south of Europe.

Propagation and Culture.—Both species are raised from seeds sown in the autumn, in an open situation, on a bed of good fresh earth. When the plants are come up, nothing farther is necessary but to hoe them to about four inches distance every way, and to keep them clear from weeds. The first species is cultivated in Essex, mingled with carum carvi, or caraway; both foiey for the sake of the seeds. See Carum Carvi. To prevent the large and bulk part of the seed being lost, women and children are employed to cut every plant separately, and to put it immediately into a cloth, in which it is carried to some convenient part of the field, and there thrust upon a fail-cloth. The produce of an acre is from ten to fourteen hundred weight. See Coriander, in Agriculture.

Gen. Ch. Flowers dioecous, sometimes monoecious or polygamous. Male. Cal. Perianth very short, five-leafed; leaves somewhat egg-shaped, concave. Cor. Petals (Gland. Juss.) five, very small, placed on a disk on the outside of the flaments. Stam. Filaments ten, very short; anthers erec; oblong, with two cells separate at the base. Female Cal. like the male. Cor. Petals, as in the males, converging. Stam. as in the males, but abortive. Pyy. Germs five, compressed, united; stylos long, bristle-shaped; stigma filip. Peric. none. Seeds five, kidney-shaped, covered by the succulent petals which take the appearance of a berry. Linn. (Peric. Capsules five, connivent, small, one-seeded, not delicient, covered on the side by the enlarged and thickened glands, making the fruit look like half a berry.) Juss.

Eff. Ch. Calyx five-leaved; corollae five-petalied; anthers ten, almost filide. Styles five. Seeds five, covered by the succulent petals.

Lam. III. Pl. 822. (Rhus myrtifolia monspeliaca; 
Buch. Pin. p. 414.) "Leaves almost sessile, ovate-ob-
long, flowers in racemes." A shrub four or five feet high. 
Stems smooth, cincereous; branches opposite, lute, flexible; 
young ones quadrangular. Leaves opposite, entire, smooth, 
acute, green on both sides, nerved, smaller on the flower-
ing branches. *Racemes* simple, terminating the young la-
ter branches; bracteas foliarly, small, awl-shaped; pedun-
cles twice the length of the bracteas; calyx and corolla 
pale green; flowers sometimes monoecious, and sometimes 
hermaphrodite. A native of the south of France, and of 
*"Leaves cordate egg-shaped, sessile." A tree from twenty 
to twenty-five feet high. Trunk the thickness of a man, 
branched from the bottom. Leaves an inch and half long, 
an inch broad. Leaves opposite, nerved on the young 
branches, almost embracing the stem. Flowers as in the 
preceding species. A native of Chili. 3. C. microphylla. 
Poir. 3. *"Leaves very small, egg-shaped, obtuse, nearly 
seisile; flowers spikes, lateral." A shrub. Stems quadrangu-
lar; branches numerous, crowded, filiform, flexible, 
short. Leaves four or five lines long, three broad, opposite, 
firm, entire, slightly heart-shaped, green above, paler un-
derneath, nerved. Flowers on small filiform peduncles, 
with foliarly acute bracteas. A native of Peru. 4. C. far-
cordate egg-shaped, on short pedicles; stem procumbent, 
diffuse. A native of New Zealand.*

CORIDORGIS, in Ancient Geography, a town of Ger-
many, situated on the Danube, between Medoitanum and 
Prumbellus. Ptolemy.

CORIENTES, in Geography, a cape of Mexico, or New 
Spain, on the N. Pacific ocean. N. lat. 25° 50'. W. long. 105° 
30'.-Allo, a cape of South America, on the coast of Peru, 
in the Pacific Ocean. N. lat. 4° 50'.-Allo, a cape of Af-
ear, on the eastern coast of the Indian Sea. S. lat. 24° 
15'. E. long. 33° 31'.-Allo, the name of the fourth-west-
ernmost point of the island of Cuba. N. lat. 21° 58'. W. 
long. 84° 30'.

CORIENTES, Los. See Corrientes.

CORILLA, in Biography, the Arcadian name given to 
the celebrated Improvisatrice, Maria Maddalena Morelli 
Fernandez, of Pilion; honoured at Rome with the laurel 
crown, 16 Feb. 1776, in the same manner as Petrarcha, 
Tasso, and Perfetto, had been before. An account of 
this translation, beautifully printed at Parma, by Bodoni, 
in 1779, contains her diploma and all the discourses, poems, 
sonnets, &c. written on the occasion, with the examination 
which she underwent, concerning her knowledge of the 
most important subjects upon which she was required to 
improvet on, or treat extempore, in verse publicly at the 
Campidaglio in Rome. The Italian title of this narra-
tive is, "Atti della solenne coroneazione fatta in Campido-
glio della insignepoetisa D-na. Maria Maddalena Morelli 
Fernandez Pilione. Tragali Arcadi Corilla Olimpie." Twelve 
members of the Arcadian academy were selected out of 50, 
publidy to examine this new edition of a Tenth Muse, 
which has been so often dedicated to ladies of poetical and 
literary talents. Three several days were allotted for this 
pubic exhibition of poetical powers on the following sub-
jects: sacred history, revealed religion, moral philosophy, 
natural history, metaphysics, epic poetry, legislation, elo-
quence, mythology, fine arts, and pastoral poetry.

In the list of examiners there appear a prince, an arch-
bishop, three monsignors, the pope's physician, abaci, avo-
cati, all of high rank in literate and criticism. These, 
severally, gave her subjects, which, besides a reading 
at verification in all the matters of Italian poetry, requir-
ed science, reading, and knowledge of every kind. In all 
these severe trials, she acquitted herself to the satis-
faction and astonishment of all the principal performances, 
clergy, literati, and foreigners then resident at Rome; among 
the latter was our foreigner's brother, the duke of Gloucester.

Near 50 sonnets by different poets, with odes, canzoni, 
terze rime, ottave, canzonette, &c. produced on the sub-
ject of this event, are inserted at the end of this narrative and 
description of the order and ceremonies of this splendid, 
honourable, and enthusiastic homage, paid to poetry, clas-
tical tale, talents, literature, and the fine arts.

This renowned lady merits no notice as a musician, as 
well as poet; as she sung her own verses to simple 
tunes with a sweet voice, and in good taste. She likewise 
played on the violin; but at Florence, where we saw and 
heard her, in 1779, she was accompanied on the violin by 
the celebrated and worthy pupil of Tartini, Nardini. At 
this time she was not more than 35; and had a pleasing, 
dignified, and intelligent countenance. See in the music 
pl. No. the two airs to which she sung at Florence, ex-
tempore verses on subjects given.

CORIM. See Hast-militaris.

CORINÆUM, in Ancient Geography, a promontory of 
Minor in Ionia; part of Mount Munar.

CORINDIUR, a town of India, on this side of the 
Ganges. Ptolemy.

CORINDUM, in Botany. Tourne. See Carundii-

CORINE, in Zoology, the Antelope Corine of Gmel-
in, has very slender, short, smooth, ilarepilous horns, bent 
slightly into the form of a lyre; the upper parts of the body 
are yellowish-tawny, the under parts white, with a dark 
stripe along the sides, and two lines on each side of the face, 
the upper one white and the other black. This animal, 
which inhabits Senegal, is less than a roe; the neck, body, 
and flanks are of a tawny-yellow colour, the insides of the 
thighs and belly are white, and a dark line, along the sides, 
divides the two colours; the knees are tufted with hair; 

35 B 2
the ears are large; the horns are about six inches long, almost upright, bending a little outwards in the middle, and somewhat approaching at the tips, the lower parts being surounded with circular wrinkles. This species resembles the heave in colour, face, softness, and mufky odour; but differ very much from it in the figure of the horns; though Gmelin, after Pallas, suppose that it is the female of that species.

CORINEA, in Ancient Geography, a country of Asia, in Armenia Major. Ptolemy places it between the sources of the Tigris and Euphrates, and to the south of Thespis.

CORINEUM, a town situated on the southern coast of the isle of Cyprus, between Citium and Salamis. It was episcopal, and called by Hercules, in his Notitia, Corinth.

CORINUM, a town of Albani, belonging to the Dobunii, and allowed to be Greccefer in Gloucestershire—also, an ancient town of Illyria on the Adriatic gulf; supposed to be the present Cori.

CORINTH, Corinthus, a city of Greece in the Peloponnesus, upon a gulf of the same name. This city was the capital of a small state, situated on the isthmus of Corinth, having the bay of that name, now called the Gulf of Lepanto, and the isthmus or neck of land, which joins Peloponnesus to the continent, on the north; Scyuan, on the west; the gulf of Saron, on the east; and the kingdom of Argos, on the south. Its utmost extent from east to west was about half a degree, and from north to south, about half that space. It had no rivers of any note; but abounded with mountains, the chief of which was called Acrabornthium, at the foot of which the city of Corinth was built, and on the gulf stood the citadel. It was also famed for the fountain Pyrene, furred to the muses; though others place this fountain on the hill Helicon, and most others again, on that of Parnassus.

Corinth is said to have been founded by Sisyphus, the son of Aeusus, and grandfather of Ulysses, about the year of the world 2560, as some say; or according to others 2700; B.C. 1307, and about six years before DSenioron's flood, B.C. 1530. The ancient name of this city is said to have been Epiura, which it took from a nymph of that name, reported to have been the daughter of Oceanus and Tethys; or, according to others, of Meryss, the wife of Epimetheus, the son of Iapetus, and brother of Prometheus. At this time it was but an inconsiderable town, though it rose afterwards to be the metropolis of the kingdom, and one of the noblest and most opulent cities in Greece.

Corinth, the new name of this city, has been variously derived; some have deduced it from the Greek εομενος, fatis or abundance, implying the opulence of the place; but the ancient inhabitants trace the origin of the appellation to Corinthus, the son, as some have said, of Jupiter, or, according to others, of Marthon, and brother of Sicyon. However, most authors aterne the name, as well as the building, or rebuilding of it, to Corinthus, the son of Pelops. Corinth was also called Helipolus, or the city of the Sun, probably, as Gronovius conjectures, from the ruggedness and barrenness of its situation and territory, for such, as Strabo tells us, it really was.

Corinth, besides the citadel already mentioned, had two port-towns, viz. Lecheum situate on the bay of Corinth, and Cenehrea on that of Samos; and connected with the city by a double wall of about 12 stadia or half a league in length, different from the city by 70 stadia or about 3 leagues. There were the only two havens; and, indeed, the only two cities of any note, next to Corinth, that belonged to this territory. These were so well situate for naval commerce, and so near the metropolis, that they made ample compensation for the barrenness of the soil. These two naval roads which opened a way into the Ionian and Egean seas, might easily have gained for them a superiority, if not a command, over all Greece, if this advantageous situation had not inclined them more to commerce than war. For their citadel being almost impregnable by nature, and commanding both seas, they could easily cut off all communication between one half of Greece and the other; so that it was not without reason called one of the letters of Greece. But being led by their genius and disposition to improve their advantages more for navigation and commerce than for military exploits, they became in process of time so exceedingly opulent, that the little influence they had over the other states was owing rather to their wealth than their valour. By the gradual increase of their opulence, partly from commerce, and partly from the influx of strangers that flocked hither from Europe and Asia, their city became at length one of the most considerable and splendid in Greece; being adorned with a great variety of sumptuous buildings, such as temples, palaces, theatres, porticoes, cenotaphs, baths, and other edifices; all enriched with a beautiful kind of columns, capitals, and bafes, from which the Corinthian order took its name, together with numerous statues executed by the most famous artists. Such indeed were its wealth, magnificence, and excellent situation, that it was thought by the Romans equally worthy of empire with Carthage and Carpus. It would carry us far beyond our limits minutely to describe even the principal edifices that adorned this famous city; but in order to enable the reader to form some judgment of its extent and magnificence, we shall recite some few particulars, referring to Paunanius in cor. for a more ample account.

We have already observed that this city was seated at the foot of a high hill, on which stood the citadel. To the south it was defended by the hill itself, which is there extremely steep. Very strong and lofty ramparts protected it on the other sides. Its circumference was 49 stadia, or about 1 1/2 leagues; but as the walls extended along the sides of the hill, and surrounded the citadel, it might be reckoned upon the whole at 83 stadia or near 3 leagues. The road to the citadel had so many windings, that the summits could not be attained, without passing through an interval of 30 stadia. The situation of the citadel and its ramparts rendered it so strong, that it could only be taken by treachery or famine. At the entrance was the temple of Venus, with the statues of the goddess clad in brilliant armour, and accompanied by another of the god of love, and a third of the fun, who was adored in this place before the worship of Venus was introduced. In the way to the citadel was a chapel dedicated to the Egyptian Isis, and another to the Pelagian Isis. Two others were dedicated: one to Serapis of Canopus, and the other to another Serapis. The spring Pyrene, where Bellerophon is said to have found the horse Pegues, was ornamented with sumptuous embellishments, consisting of several caves in form of grottoes, all covered with white marble, from which the cold and limpid water of that fountain fell into a large basin. The forum was decorated with temples and statues; the theatre was a grand and beautiful edifice of white marble, in which the assembly of the people deliberated on affairs of state, and the musical contests and other entertainments were exhibited at the festivals. The Isthmian, or course, was also constructed of white marble. The temple of Neptune was a grand building; its avenue was lined on one side with the statues of all those athletes who had won the prize at the Isthmian games (which fee), and on the
the other with slaty pines planted in regular rows. The temple itself, though not very spacious, was adorned with a multitude of bronze Tritons, or sea-gods. Here were also the chariots of Neptune and of his wife Amphitrite, drawn by horses covered all over with gold, except their hoofs, which were of ivory. The two deities were carved in a standing posture, and Neptune had young Palaemon riding on a dolphin by his side. The bases of the chariots were likewise adorned with curious baso-relieves, and the temple itself with a multitude of other embellishments. Diana of Ephesus was also exhibited in a public place together with two gilt wooden statues of Bacchus. Fortune also had a temple, and her statue was made of Perian marble; and near this temple was that which was dedicated to the mother of all the gods. There were several other statues; among which we may select an Apollo, furnamed Clistus, in bronze; a Venus by Hermogenes of Cythera, two Mercuries, three statues of Jupiter, a Minerva in bronze, mounted on a pedestal, the baso-relieves of which represented the Muses. The city of Corinth abounded with public baths, the number of which was augmented by the emperor Adrian; but those of Neptune, constructed by Eurykles of Sparta, were the most famous. The temple of Venus at Corinth is said by Strabo to have been rich, that it maintained more than 1000 corsettants, who were devoted to her service, and which drew hither a multitude of strangers. The festivals of the Aphrodides were celebrated in this city by harlots, as we learn from Athenaeus (Deip. nos. i. xiii. c. 6); who also informs us, that they who supped with the goddess Venus, promised to dedicate some females to her rites, and they obtained what they required.

At first the commerce of Greece was carried on by land, and entered or left the Peloponnese by the road of the isthmus. The Corinthians took occasion to impose a duty on the transit of all commodities, and derived from this duty a certain degree of opulence. In order to avoid the dangers of the sea, proverbially stormy, between the ille of Crete and Cape Malea in Laconia, merchants chose to transport their goods to the seas terminating at the isthmus. Thus, the merchandise of Italy, Sicily, and the western nations, was landed at the harbour of Lechium; and that from the islands of the Aegean sea, the coasts of Asia Minor, and of the Phoenicians, at the port of Cenchrea. In process of time, commodities were conveyed by land from one harbour to the other, and means contrived for transporting even the velums. Corinth, having thus become the mart of Asia and Europe, continued to collect duties on foreign merchandise, covered the sea with ships, and formed a navy to protect her commerce. Her industry was excited and encouraged by success; the built ships of a new form, and first produced (triremes) galleys, with three branches of oars. Her naval force procured her respect; all nations poured their productions into her emporium. The sea was covered with rafts of paper, and failcloth, brought from Egypt, ivory from Libya, the leather of Cyrene, incense from Syria, Phoenician dates, Carthaginian carpets, corn and cheese from Syracuse, pears and apples from Euboea, Phrygian and Thessalian flaves, together with a multitude of other articles which were continually brought into the ports of Greece, and particularly into those of Corinth. The games of the isthmus also drew together to this city a prodigious number of spectators. These resources increasing the wealth of the state, workmen of every kind were protected, and exerted themselves with new emulation.

Corinth abounded not only with warehouses, but with manufactories of her own. Among other articles, the inhabitants made coverlets for beds, which were much sought after by foreign countries; she also collected a great number of the pictures and statues of the bell maidens. Her manufactories of brass and earthen ware were held in great estimation. Although Corinth possessed no copper mines, her workmen contrived, by mixing that which she received from foreign countries, with a small quantity of gold and silver, to compose a metal extremely brilliant, and almost proof against rust. (See $23.) Of this they made cuirasses, helmets, small figures, cups, and vellips; no less esteemed for the workmanship than for the material, which were enriched with foliage and other chased ornaments. Thoie on their pottery were equally beautiful.

The women of Corinth were admired for their beauty, and the men were distinguished by their love of gain, and of licentious pleasure. Venus was their principal deity; and the courtesans consecrated to her service, attended, in the time of public calamities and imminent danger, at the sacrifices, and walked in procession with the other citizens, singing facing hymns. The Corinthians, indeed, were so much devoted to traffic and luxury, that they very much neglected the encouragement of the liberal arts and sciences, and also of that spirit of glory and conquest, Torridized by their neighbours. Nevertheless, they cultivated a good discipline, both in peace and in war; and this their opulence, with its effects on their disposition and conduct, rendered absolutely necessary. Though they seldom, if ever, engaged in war, with a view of enlarging, but chiefly for the purpose of defending their territories, protecting some neighbouring state, or maintaining the liberty of Greece; yet this small kingdom furnished many brave and experienced officers to the other Grecian cities, who were frequently preferred to their own generals. The Corinthians were, in reality, the greatest protectors of liberty; and though they remained for some centuries under a monarchical government, yet they always manifested an aversion from tyranny, and an inclination to assist those who were opprefed.

We have already observed, that Sicyon was supposed to be the founder of the Corinthian monarchy; which is said to have continued in the lineal succession of his family, for seven or eight generations; till it became extinct, or till it was expelled the kingdom by Acilias, one of the Seven Rivals, about thirty years subsequent to their return, about B. C. 1074; in which family the kingdom of Corinth remained for a long interval, between three and four hundred years. Royalty was at last abolished, and the sovereign power was intrusted to 200 citizens, one of whom presided over the rest under the appellation of "Prytanis," about the year B. C. 779. About the year 659 B. C., Cypselus terminated this aristocracy, by usurping the sole government, and restored the monarchy, which he retained for about thirty years. He was succeeded by his son Periander, who held the government for 44 years. Having banished his son Lycophon to the island of Corcyra, the capital of which had been built by the Corinthians, in the year B. C. 763, Periander was reduced to the necessity of recalling him, but his proposals were received by the exiled son with indignation. He finally, however, resolved to abdicate the crown, and confine himself to Corcyra, whilst his son, quitting that island, assumed the reins of government at Corinth. But the Corcyreans, dreading the arrival of Periander, defeated this project by putting Lycophon to death, sentenced by an impartial judge. Periander died at 80 years of age, after a reign of 44 years. As soon as he had closed his eyes, the Corinthians destroyed every monument, and even the sight-
 Celt traces of tyranny. His successor reigned only three years; and after this short interval, the Corinthians, joining their troops to those of Sparta, established a government which, subsisting for a long period, and which approached nearer to an oligarchy than a democracy, no affairs were submitted to the arbitrary decision of the multitude. In the year 439 B.C. a war commenced between Corinth and Corcyra; and in the year 343 B.C. the Corinthians were defeated at sea by the Corcyreans, aided by the Athenians. And this contest between Corinth and Coreya, brought on the Peloponnesian war. In the year 395 B.C. the Athenians, Thebans, Argives, and Corinthians, formed an alliance against the Lacedaemonians, and this gave occasion to the Corinthian war. For an account of the alliance which Corinth afforded to the Syracusans, see the article TIMoleon. By the peace of Antalcidas B.C. 387, the Corinthians were obliged to withdraw their garrison from Argos, which then became free and independent. When Alexander entered Babylon, the Corinthians sent ambassadors to offer him the freedom of their city; and after a short stay in the city, the Persians were induced to accept it with joy, when he was told, that this honour had been conferred only on Hercules. When Aratus of Sicyon, prator of the Achaeans, had taken possession of the citadel of Corinth, B.C. 243, the Corinthians were prevailed upon to enter into the Achaean league; and about the same time they yielded a decree, that the Romans should be admitted to celebrate the Isthmian games, with the same privileges as the Greeks. At a subsequent period, B.C. 146, they inflicted the Roman deputies, commissioned by Lentulus to appease the troubles occasioned in Peloponnesus by the Achaean league; but upon the arrival of the consul Mummius, Corinth was besieged; and after the defeat at the battle of Lepanota, the consul entered the city, and abandoned it to be plundered by the soldiery. All the men who were left in it were put to the sword, and the women and slaves sold; and after the statues, paintings, and rich vestments were removed, in order to their being carried to Rome, the houses were set on fire, and the whole city was consumed. From that time the Corinthian braes, which was in reputation long before, became yet more famous; for it is pretended, that the gold, silver, and braes, which were melted, and which ran together in this conflagration, formed a new and precious metal. The walls were afterwards demolished, and raised to their very foundations. This dreadful calamity was inflicted by order of the senate, for punising the inofence of the Corinthians, who had violated the law of nations, in their treatment of the ambassadors sent to them by Rome. The booty taken at Corinth was sold, and it produced a considerable sum; no part of which Mammius retained for himself, but confounded the whole to Rome, for the purpose of being laid out in adorning the city. Among the paintings, which it is said there was a piece drawn by Anticles, the most celebrated painter in Greece, which represented Bacchus; the beauty of which was not known to the Romans, for Polybius had the mortification to see it used by the soldiery as a table, upon which they played at dice. In the sale of the booty, it was adjudged to Attalus for 600,000 solidi, or about 3625l. sterling. Many other statues and paintings of the most excellent matters, preferred in the wreck of Corinth, were transported to Rome. Upon Polybius's return into Peloponnesus, he had the painful and mortifying sight of the destruction and burning of Corinth, and the affliction of finding his country reduced into a province of the Roman empire. Corinth remained in a ruined and desolate state for many years. At length Caesar, after he had subdued Africa, and whilst his fleet lay at anchor at Utica, gave orders for rebuilding Carthage; and soon after his return to Italy, he likewise caused Corinth to be rebuilt. Strabo and Plutarch agree in describing the rebuilding of Carthage and Corinth at the instance of Julius Caesar; and Plutarch remarks this singular circumstance with regard to these two cities, that as they were taken and destroyed in the same year, they were rebuilt and repeopled at the same time. Under the eastern emperors, Corinth was the scene of an archbishop, subject to the patriarch of Constantinople. Roger, king of Naples, obtained possession of it under the empire of Emanuel. It had afterwards its own sovereign, who ceded it to the Venetians, from whom it was taken by Manomet II., in the year 1458. The Venetians retook it in 1667, and held it till the year 1715, when they lost it to the Turks, in whose possession it has remained ever since.

Corinth, in Modern Geography, Corinto, or Corinto, a town of Greece, in the Morea, situated near a narrow isthmus of the same name, which joins the Morea to the reil of Greece, between the gulf of Lepanto and that of Engin. It was formerly, as we have seen in the preceding article, a very rich and powerful city. At present it contains about 13 or 14 hundred inhabitants; each house has a garden, planted with orange and other fruit trees. It is 46 miles E. of Athens or Atti, and 342 S.W. of Constantinople. N. lat. 38° 5', E. long. 22° 55'.

Corinth, a township of America, in Orange county, in Vermont, W. of Braddock, containing 575 inhabitants.

Corinth, Isthmus of, in Ancient Geography, the neck of land which joins Peloponnesus (the present Morea) to the upper part of Greece, and which is computed to be about six miles wide. As this forms an obstacle to the passage from the Ionian to the Ægean sea, it has been frequently proposed to dig a canal through it, forming a juncture between these seas, and thus preventing the circumnavigation of the Peloponnesus. Pliny, who mentions this project, and who, without being superfluous, represents it as a rash attempt, alleges the unhappy end of four princes who lived about it, viz. D. Memmius of Philaea, Julius Caesar, Caligula, and Nero. When Nero undertook this business, superfluous discouraging the attempt; and it was said, that, at the first stroke into the earth, blood gushed out, that groans issued from the subterranean caverns, and that phantoms had appeared to the inhabitants of those parts. Nero, however, directed these idle tales, and determined to proceed. He encouraged the Pretorian soldiery in their work by perfiling allistance, and flattering hopes of success. The number of workmen whom he collected from all parts, and from all the gaols in the empire, was immense; and Vespasian, as Josephus informs us, furnished him with 6000 Jews, selected from a much greater number whom he had imprisoned. The work was begun on the side next the Ionian sea, at the port called Lechaion, and in 73 days an interval of four stadia was dug; and this was about the tenth part of the breadth of the isthmus. On the last of these days, Nero sent an order to discontinue the work. Two reasons were assigned for this change of opinion and purpose. By some it was said, that certain Egyptian mathematicians, whom the emperor had consulted, having taken the level of the two seas, east and west of Peloponnesus, found the waters of the Ionian higher than those of the Ægean sea; so that there was ground for apprehending that, if a communication were opened by a canal across the isthmus, the island of Ægina, and the low lands on the side of the Ægean sea, would be overflowed and destroyed. But this allegation is a mere pretence;
pretence; because these two seas do actually communicate southe of Peloponnesus, and therefore their waters must be on a level. Considering the pertinacious temper and extreme vanity of Nero, it is very probable that he would have perished, notwithstanding every objection of mathematicians, if he had not been alarmed by reports from Italy, where disturbances arose in consequence of his absence, and which made it necessary for him to return, so that he abandoned his enterprise. The news of a conspiracy at Rome terrified him exceedingly, and hastened his return. For an account of the games celebrated on this occasion, see *Eusthian Games*.

**Corinth.** Gulf of, now the gulf of Lepanto, commencing, as some of the ancients have said, at the isles called Oasis, having to the N. the mouth of the river Achelous and the Echimades, and to the S. the promontory called “Araxum Promontorium”; but, according to others, the gulf of Corinth denotes that portion of water forming a strait to the S. by the point called “Rhium,” and to the N. by that called “Anti-Rhimus.” This gulf extends eastward as far as Esotia. In the interior part, it forms two small gulfs; the one, advancing to the N., between parts of the Locride and Phocide territories, called, after the town of Crippa to the N.E., “Crisius Sinus;” the other was formed by the most eastern part of the gulf, and was called “Alcyonium Mare.”

**Corinthian brass.** See *Æs Corinthium.*

**Corinthian Order, in Architecture.** This is generally enumerated as the third of the Grecian orders, and forms the ultimate term of richness and elegance proper to that style of architecture.

The Corinthian order is principally distinguished by its capital, which may be described as consisting of a bell-shaped body, covered with an abacus of a quadrilateral plan, with convex sides; two tiers of leaves surrounding the lower part of the capital, between which little flanks or caulicoli rise up to the corners of the abacus, and those bending over form four volutes, and other volutes or ornaments occupy the centre of each side. Considerable varieties occur in ancient buildings; but this may be taken as a general analysis, which will include all Corinthian capitals.

The account, given by Vitruvius, of the origin of this order, has been already detailed in the article *Graec Architecture.* It must, however, be observed, that the Egyptian buildings present many capitals of a bell-form, decorated with leaves, which bear a sufficient resemblance to the Corinthian capital, to justify a supposition that this composition may have been derived from the imitation of an Egyptian model.

Callimachus, to whom the invention of the Corinthian capital is attributed, is supposed to have lived about the 6th Olympiad, or 540 years before the Christian era, which would give a very high antiquity to this order; but the first distinct account we have been able to find of its introduction in any building, is the following from Paulinus, l. viii. The ancient temple of Minerva at Tegea, in Arcadia, having been destroyed, a second edifice was erected, under the direction of Scopas, far exceeding in splendour and magnificence every building of the kind in the Peloponnesus. In this structure the three orders of Architecture were employed. Within the enclofure were galleries supported by Doric and Corinthian columns, surrounding the hypaethes or open area of the cella; and on the outside of the temple were porticoes of the Ionic order. This building may be dated in the fourth century B.C. To judge from the extant remains of this order in Greece, which are comparatively neither numerous nor important, we should say, that it had never obtained a degree of favour equal to the other two orders; but in the buildings of Rome, and in works in other countries under Roman influence and direction, quite the contrary is the case; and it is to these sources that we are to look for the best examples of the Corinthian order.

Vitruvius, l. 3. c. 1. in treating of this order, observes that Corinthian columns, excepting in their capitals, have their symmetry the same as the Ionic; but the height of the capital renders them proportionally taller, and more graceful: for the height of the Ionic capital is only a third part of the thickness of the column, whereas that of the Corinthian is the whole diameter of the shaft. The other members, which are placed above the column, are taken from the Doric or Ionic orders; for the Corinthian has no entablature peculiar to itself, but has either triglyphs, mutules in the cornice, and guttae in the epistylem, as in the Doric manner; or else, according to the Ionic disposition, the frieze is ornamented, and dentils are placed in the cornice: so that by these two orders, joined with a different capital, a third order is produced.

The preceding observation of Vitruvius, that the Doric entablature was sometimes applied to Corinthian columns, is in itself very extraordinary, and is not supported by any antique examples; but the remark respecting the Ionic entablature is found to be strictly true in a number of instances, as we shall proceed to shew by the description of the following examples:

The arch of Adrian at Athens. A cornice, with dentils, a plain frieze, an architrave, with three plain facias, and an Attic base.

The arch of Adrian at Rome. A cornice, with uncut dentil-band, a plain frieze, an architrave, with two plain facias, and an Attic base.

A building called the Incantades at Salonicha, the ancient Thessalonica. A cornice, with dentils, a swelled frieze, ornamented with flutings, an architrave, with three plain facias, an Attic base.

The temple of Vesta at Tivoli. A plain cornice, with uncut dentil-band, an ornamented frieze, an architrave, with two plain facias, and an Attic base.

The temple of Antonius and Paulina at Rome. A plain cornice, with uncut dentil-band, ornamented frieze, an architrave of two facias, divided by an Adragal, and an Attic base.

The portico of Septimus Severus at Rome. A plain cornice, with a small uncut dentil-band, a plain frieze, an architrave of three facias, divided by mouldings.

In all these instances, the entablature and base are entirely similar to those commonly observed in the Ionic order, from which those Corinthian examples only differ in the form of the capital; but in the examples which remain to be cited, it will appear that the Romans attempted to give to the Corinthian order a more distinct character, by appropriating to it a peculiar entablature and base, and thus made a complete order of what might be previously regarded, as Vitruvius appears to consider it, in the light of a complete invention.

The Portico of the Pantheon. A cornice, with modillons, and an uncut dentil-band, a plain frieze, an architrave of two facias, divided by mouldings, and a Corinthian base.

The temple of Peace at Rome. A cornice, with modillons and dentils, a plain frieze, and an architrave of three facias, divided by mouldings.

The three columns of the Campo Vaccino, supposed to belong
belong to a temple of Jupiter Stator. A cornice, with modillons and dentils, a straight frieze, an architrave of three facias, divided by mouldings, and a Corinthian base.

The temple of Jupiter Tonans at Rome. A cornice, with modillons and dentils, a straight frieze, and an architrave of three facias, divided by mouldings.

The arch of Constantine. A cornice, with modillons and dentils, a plain frieze, an architrave of three plain facias, and an Attic base.

A temple at Ephesus, supposed by Chandler to be the temple erected, by permission of Augustus, to the god Jupiter. A cornice, with modillons and dentils, a swell ed and ornamented frieze, an architrave of three facias, divided by mouldings, and an Attic base.

The temple at Nîmes called the Maison Quarré. A cornice, with modillons and dentils, a straight frieze, an architrave of three facias, divided by mouldings, and an Attic base.

To render this account of the progressive improvement in the Corinthian order more complete and satisfactory, some instances may be given, in which the alteration remains imperfect, having only taken place partially, with a great resemblance to Ionic forms.

A portico at Athens, supposed by Stuart to be the ancient Poikile. This building presents a cornice, with mutules of two square facias, an architrave, with two plain facias, and an Attic base.

The frontispiece of Nero at Rome. A cornice, with mutules of the same form as the half mentioned, an ornamented frieze, and an architrave of two facias, divided by an ogive.

In these two instances, there are no dentils or dentil-bands in the cornices; and the mutules, by their situation and shape, appear rather to be a variation from the proper Ionic dentil than a new member.

Considering the Corinthian order in its most complete state, we find it possessed of a peculiar entablature distinguished from that of the other orders by a cornice with modillons and dentils, a straight frieze, and an architrave of three facias divided by mouldings. The column is marked by its capital, and also by a peculiar base called the Corinthian base. This description is wholly applicable to the three columns of the campo Vaccino, which are probably the most complete and beautiful examples of the order existing. See Plate 29.

Of the modern architects, who have treated of this order, Palladio makes the column 91 diameters high, and gives only one-fifth part of this altitude to the entablature, which consists of a cornice with modillion and dentils, a straight frieze, and an architrave of three facias divided by Atralgals. The base is Attic. Scamozzi's design bears a great general resemblance to Palladio's, but he gives ten diameters to the column. The entablature is one-fifth of this height, the cornice has modillons, only the architrave consists of three facias divided by Atralgals, and the base is Attic. Serlio, in his Corinthian order, has followed Vitruvius in giving it an Ionic entablature with dentils, and in the proportion of the capital. The column is nine diameters high, and has a Corinthian base. Vignola's is a grand and beautiful composition in which he has chiefly imitated the three columns. He gives the column ten diameters in height with a Corinthian base. The entablature is one-fourth of the height of the column, the cornice has modillons and dentils; a plain frieze, and an architrave of three facias divided by mouldings.

The following Table will exhibit the proportions of some of the principal examples of the Corinthian order, premising that the different members are measured by the diameter at the bottom of the shaft, which is divided into sixty minutes.

"The Corinthian order," says Sir William Chambers, "is proper for all buildings where elegance, gaiety, and magnificence are required. The ancients employed it in temples, dedicated to Venus, to Flora, Proserpine, and the nymphs of fountains; because the flowers, foliage, and volutes with which it is adorned, seemed well adapted to the delicacy and elegance of such deities." This account, though plausible in theory, is wholly unfounded, and is, in fact, a mere modern refinement. The Romans, in borrowing their architecture from Greece, appear to have particularly appropriated the Corinthian order, they found it possessed of an ornamental character adapted to the splendour and magnificence of their taste, and used it indiscriminately on all occasions, and in the temple of any deity in the same manner that the early Greeks used the Doric, and the Ionians the Ionic order. Thus the Romans erected Corinthian temples to Jupiter, Neptune, and Mars; and the Greeks built the temples of the same deities of the Doric order. The temples of Minerva at Athens and at Siutium are Doric; the temple of Minerva at Frigie is Ionic. The temple of Jupiter Olympus at Elia, was of the Doric order; the temple of the same god, erected by Adrian at Athens, is Corinthian. The orders of architecture are national. Thus the numerous temples of the Grecian colonies in Sicily and Italy are uniformly Doric, marked by the most severe and maify simplicity. The cities of Jonia present the best examples of a chaste and elegant Ionic; while the magnificent structures of Balbec and Palmyra, are wholly of the Corinthian order, and in the most florid style of ornament.

CORINTHIANS, Epistle to the, in Biblical History, are two letters, addressed by the apostle Paul to the inhabitants of Corinth,
Corinth, including both Gentile and Jewish converts, and comprehended in the sacred canon of the New Testament.

Some have inferred from 1 Cor. v. 9, that the apostle had written another epistle to the church at Corinth; but Dr. Whitby (in loc.) observes, that no fathers ever ascribed to St. Paul more than 14 epistles, including that to the Hebrews; nor does Eusebius mention any third epistle to the Corinthians, amongst the true, controverted, or spurious writings which pass under his name. Moreover, no Christian writer ever cited any thing from this supposed epistle; and all the Greek scholiasts declare, that the apostle speaks in these words, "not of another, but of this very epistle," which, says Dr. Whitby, "is sufficient to justify the version I have given of these words. I had written, or was writing, in this epistle." Besides, his supposed epistle to Laodicea is cited as a book expounded by St. Jerom; his epistles to Seneca are in like manner cited by St. Jerom and St. Auftin; the acts of Paul are cited, and rejected from Origen and Eusebius; but none of them make any mention of more than two epistles to the church of Corinth.

The first epistle was written about three years after the apostle had left Corinth, to preach the gospel in other parts of Greece; and it was written at Ephesus, as appears from ch. xvi. 8, 9, 19, and Acts xviii. 18, 19, according to Pearson and Mill in the year 57, the third of the emperor Nero; but, according to Lardner's computation of St. Paul's times and travels, in the spring of the year 56, and this was also the opinion of Lennart and Beaufraire. This epistle was written in answer to some important inquiries proposed by the Corinthians, and for the purpose of correcting the various irregularities and disorders, of which they were guilty. The first article under the head of abuses, with which they were chargeable, related to the parties and factions into which they had fallen, and the opposition which was made by some of them to St. Paul's apostolical mission. The first four chapters comprehend this first head. The second topic which the apostle confines was the case of a notorious offender in the Corinthian church, who had been guilty of most scandalous incest with his father's wife. (See chap. v.) The third article which the apostle exhibits against the Corinthians is, that by a covetous and litigious temper they were led, in violation of the rules of Christian prudence and charity, and sometimes in opposition to the principles of justice, to persecute their brethren in the heathen courts. (Chap. vi. 1—11.) In the fourth place, the apostle cautions them against the sin of fornication, to which, in their Gentile state, they had been much addicted, and which some seem to have reckoned among things that were indifferent, or to consider as of inferior enormity; introducing useful reflections on matters of indifference, and illustrating the heinous evil of fornication from views peculiar to the Christian religion. (Chap. vi. 12 to the end.) As Corinth was conveniently situated for commerce, it abounded in riches, and was furnished with all the accomodations, elegancies, and splendours of life. Hence, by too natural a consequence, the inhabitants were led into luxury, lewdness, and all manner of vice; so that they became infamous even to a proverb. Thus, Kegiain 6wiv, a Corinthian woman, is, in the language of the ancients, a lewd prostitute, according to the proverb (cited in Erafm. Adag. Cest. 7. p. 633. 720.) & καθαρὴ ἡπετὶ κατεργασάμενη, at Corinthi eideris corpore qualem factura. And Kegiain 6wiv, Kegiain 6wivs, is ιδιονς, φαντασίων indiculare. (Hefych. Phavor.) We have already observed (from Strabo) that there was in it a temple dedicated to Venus, which πάοκες κατά τοῦ Χριστοῦ καικαί ονομάσει. See CORINTH.

Having thus largely, and with great fidelity and plainness, corrected some lamentable disorders which prevailed among the Corinthians; the apostle proceeds to the other principal object of his epistle, which was to answer certain questions which they had proposed to him. Here he determines, 1st, those which related to the marriage state; rating, that in some circumstances this state should be entered into, and continued in; but in others, forebore, particularly at that time; and enjoining wives not to depart from their husbands, and husbands not to dismiss their wives. (Ch. vii. 1—11.) He then shews, that marriages were not to be dissolved, as some thought they might, on account of a difference in religion; and he urges contentment with the divisions, in which they were called, whether they were married or single, bond or free. (v. 12—14.) And with regard to single persons, he affords the inexpediency of their marrying in the peculiar circumstances of the church at that juncture. (v. 25, to the end.) To the second query proposed, viz. how far they might comply with their heathen neighbours in "eating things sacrificed to idols," he replies, by reminding them that though all Christians might well be contented to know the vanity of those imaginary deities, to which the sacrifices were offered, yet it might prove an occasion of grief and scandal to some, if the profaners of Christianity should partake of those sacrifices in their temples; which, therefore, Christians would require them by all means to avoid. (Ch. viii.) He then, after waving, for his own part, the expectation of a maintenance from the Corinthians, states the right, which, as a minister of the gospel, he really had to be supported by those among whom he laboured; and this he argues both from natural equity, and scriptural principles. (Ch. ix. 1, to the end.) He next refutes the argument against partaking of entertainments upon "things offered to idols" in the heathen temples. (Ch. x. 1—13.) He proceeds to caution them against all approaches to idolatry. (v. 14, to the end, ch. xi. 1.) In reply to a third query, concerning the manner in which women should deliver anything in public, when urged to it by a divine impulse, he first settles this point; he then considers various circumstances relating to public worship and guards against abuses in the celebration of the Lord's supper, and also in the exercise of spiritual gifts; concluding with a recommendation and description of mutual charity. (Ch. xi. 2, to the end, ch. xii. ch. xiii. ch. xiv.) As some of the Corinthians doubted, and others denied, the resurrection of the dead, the apostle establishes this great and peculiar article of the Christian faith. (Ch. xiv.) He then closes the whole with some necessary counsels to the Corinthian churches and exhortations to fortitude and charity. (Ch. xvi.)

The second epistle of St. Paul to the Corinthians was written during his stay in Macedonia, whither he had gone from Ephesus, somewhat more than a year after his former epistle; according to Pearson in the year 57, and as Mill supposes near the end of that year; or, as Dr. Lardner conjectures, in September or October. (Ch. xi. 1—5, ch. xiii. ch. xiv. ch. xiii. 1.) It was conveyed by Titus, who was returning to Corinth in order to forward the collection intended for the poor Christians in Judea. Its evident design, in general, is to illustrate some of the same points upon which he had discoursed in the former, according to the information which the apostle had received from Titus concerning the circumstances and temper of the Corinthian church; and the writer interposes and enforces some occasional reflections and advice upon various subjects, which he thought most conducive to their instruction and edification. From a view of the epistle it is evident, that a great part of it is employed in reclaiming the Corinthian church from their undue attachment.
touching to judging teachers, and from that party-spirit, which they had indulged, and in recognising proper regards to the undiluted doctrine of the gospel, and to his own aposthecal counsel5. - This leading design of the epistle is interrupted by the occasional introduction of other matters, which can form no reasonable objection to the accuracy and beauty of this excellent composition; for the transitions arise from some obvious and important sentiments, which render them natural and just. In these digressions there is an admirable wisdom; because they relieve the minds of the Corinthians from that unsteadiness, which they must have felt from a constant attention to so disagreeable a subject as their unprofitable conduct towards the apostle himself.

It is in the same kind of propriety and sagacity, that the several intimations, which the dignity of the apostolic character obliged St. Paul to drop against those, who might perhaps in their opposition, are referred to the close of the epistle; as they would feel with additional weight, in all probability, after their minds had been softened with the reiterated expressions of his tender affection to the Corinthians in general, and the innocence and amiable features of his character had been represented in such a variety of views. See Doddridge's Exposition, vol. iv. Whitby's Comment. vol. ii.

We cannot close this article, without referring to some pertinent and judicious remarks, made by archdeacon Paley, in his "Horæ Paulinae," (an excellent work of original criticism and reasoning,) on the undesignated agreement or conformity that is manifest between these letters of St. Paul to the Corinthians, and the history of his life and travels in the book of Acts.

As it appears, from chap. vii. v. 1. that the first epistle was written to the Corinthians, in answer to one which he had received from them, this alone is a circumstance that favours the authenticity of the epistle: for it must have been a far-fetched contrivance in a forgery, first to have feigned the receipt of a letter from the church of Corinth, which letter does not appear; and then to have drawn up a fictitious answer to it, relative to a great variety of doubts and inquiries, purely economical and domestic; and which, though likely enough to have occurred in an infant society, in a situation and under an institution so novel as that of a Christian church then was, it must have very much excerted the author's invention, and could have answered no imaginable purpose of forgery, to introduce the mention of at all. Particulars of this kind are such as follow:—the rule of duty and prudence relative to entering into marriage, as applicable to virgins, to widows—the cafe of husbands married to unmarried wives, of wives having unmarried husbands—the cafe where the unmarried party choses to separate, when he choses to continue the union—the effect which their conversion produced upon their prior state, of circumcision, of slavery—the eating of things offered to idols, as it was in itself, as others were affected by it—the joining in idolatrous sacrifices—the decorum to be observed in their religious assemblies, the order of speaking, the silence of women, the covering or uncovering of the head, as it became men, as it became women. These subjects, with their several subdivisions, are so particular, minute, and numerous, that though they be exactly agreeable to the circumstances of the persons to whom the letter was written, nothing but the existence and reality of these circumstances could have suggested to the writer's thoughts. Another particular deferring of notice is, that in this correspondence the Corinthians did not say one syllable about the enormities and disorders which had crept in among them, and in the blame of which they all shared; but that the apostle's information, concerning the irregularities then prevailing at Corinth, had come round to him from other quarters. (Ch. 1. 11, 12, v. 1, 2.) That the Corinthians, in their own letter, exhibit the fair side of their conduct to the apostle, and conceal from him the faults of their behaviour, was extremely natural, and extremely probable; but it was a distinction which would not have easily occurred to the author of a forgery; and much less likely is it, that it should have entered into his thoughts to make the distinction appear in the way in which it does appear, viz. not by the original letter, not by any express obligation upon it in the answer, but diffusely by marks perceptible in the manner, or in the order, in which St. Paul takes notice of their faults. For the particular traces of unintended and seemingly accidental coincidence between the facts that are recited in the two epistles, and those that may be collected from the history, and which is altogether irreconcilable with a premeditated imposture or forgery, we must refer the reader, conversant with subjects of this kind, and desirous of farther information, to the work already cited, p. 72—151.

We may here observe, that there is another epistle of St. Paul to the Corinthians, besides the two above mentioned, purporting to be an answer to an epistle from the Corinthians to him. This was translated by Crisdenus, from a copy in the Armenian language, which had been sent to Mr. Whiston, and was afterwards, from a more perfect copy procured at Aleppo, published by his son, as an appendix to their edition of Mose Choremenes. No Greek copy exists of this epistle: it is not only unsupported by ancient testimony, but negative and excluded; as it has never found admission into any catalogue of apocryphal writings, acknowledged by, or known to, the early ages of Christianity. This epistle is an artful and specious forgery, introduced with a list of names of persons who wrote to St. Paul from Corinth, and preceded by an account, sufficiently particular, of the manner in which the epistle was sent from Corinth to St. Paul, and the answer returned. But they are names which no one ever heard of, and the account it is impossible to combine with anything found in the Acts, or in the other epistles.

CORINTUS, in Ancient Geography, a town of Greece, in Thessaly.—Alfeo, a town of Greece, in Epirus.

CORIO, in Geography, formerly a town of Piedmont, in Italy, belonging to the king of Savoy, is now a town of France, in the department of the Po, chief place of a canton, in the district of Turin, containing 5152 inhabitants. The canton is composed of 5 communes, and reckons in all 6764 inhabitants.

Cioriiana, Christofano, in Biography, a designer and engraver in wood, who is said to have been a native of Nuremberg, but who afterwards established himself at Venice. Heemskerck conjectures that his real name was that of Lederer, a family full existing in Saxony, and which Christofano might translate into Coriiana, according to the custom of those times.

Vafari informs us, in his Life of More Antonio, that Christofano engraved, from the designs of himself and his scholars, all the portraits prefixed to the lives of the different painters, sculptors, and architects in his extensive work; and that he continued to enjoy the reputation of an excellent artist at Venice, where he was established. If so, Christofano Coriiana cannot have been born to late as 1628, which Mr. Huber supposes. Besides the prints for Vafari, many of those in the Ars Gymnastica Harerogmi Mercudiana, the work of Ulysses Aldrovandini, are attributed to this master. But it is probable there were two artists of the same name. Huber.

Coriiana, Cav. Bartolomeo, supposed the son of the
the preceding artist, was born at Bologna, about 1599, and
is said to have parted himself in design by studying in the
academy of Caracci. Guido, however, seems to have been
the painter he most admired; and we are indebted to Bar-
tolommeo for several excellent engravings in chiaro-furo,
from the drawings of that graceful painter. These prints
were produced, like those of Ugo de' Carpi and Andrea
Andrea, by means of three blocks of wood; one of which
gave the outlines and the greatest depths of shadow, as if
liacated with a pen; the second, the middle tints; and the
third, the darker masses. He flourished from 1630 to 1670.
His prints are generally signed with his name, or with his
initials, viz., B. C. Eques.

Amongst his best prints are the following: "St. Jerome
before a Crucifix," a half length figure, dated 1649, after
Guido; "the Daughter of Herodias, with the Head of
John the Baptist," from the same; "the Fall of the Giants," a
large upright print on four sheets, from the same printer,
dated 1647; and considered the chef d'œuvre of Coriolano.

Henckien. Huber.

Coriolano, Gio. Batista, the younger brother of Bar-
tolommeo, was born at Bologna, about 1596, and studied
painting and design under Gio. Luigi. Valdevo. Some of the
tales of Gio. Batista exist in the churches of St. Anna and
the Annunziata, at Bologna. He is better known by his
numerous engravings in wood and copper, the former of
which are preferred by the connoisseurs.

We shall only notice the following prints by this artist,
who is said to have died in 1649: "the Portrait of Fortuna-
tus Licecutus," 1639, in 4to; "Chrift crowned with Thorns," a
middle-sized upright plate, boldly etched from Lod. Caracci. Huber.

Coriolo, Teresa Maria, filter to the two preceding
artists, after having acquired sufficient knowledge of design
from the instructions of her father, studied painting under
Elisabetta Sirani. She also amused herself with etching,
as appears by a small print representing the Virgin and Child.

Huber.

Coriolanus, Caius Marcus, celebrated in roman
history, was descended from the family of the Marci,
and in his early years he displayed uncommon courage and
nobleness of mind, united with strong passion and the pride
of high birth. He first distinguished himself in the war
against Tarquin, who was expelled; and obtained a civic
crown, for having preserved the life of a fellow-citizen.
For his successes over the Volscians, he was presented with
a fine horse richly caparisoned, and a tenth part of the spoil.
The former he accepted, but declined a greater share of the
booty than fell to his lot in common with others of the same
rank. As a further favour, he demanded the release of a
Volscian prisoner, who had been connected with him by the
tie of friendship, which was immediately granted; and the
name of Corioli was unanimously conferred upon him,
on account of his great services in the capture of Corioli,
the capital of the Volscians, which happened in the year 493
B.C. About this time dissensions prevailed between the
patricians and plebeians: Corioli sided with the former,
and was exceedingly fevere against the plebeians. For some
of his measures he was haimoned before the tribunal, to
which he paid no attention, till he conceived the safety of the
date required him to come forward in his own justification.
Indeed, however, of softening the resentment of the
people by submission, he aggravated their displeasure by the
heartiness of his behaviour. He was now conducted to
be thrown from the Tarpeian rock; but from this severe
punishment he was saved by the courage of the patricians, in
whose cause he had embarked. He was at length tried by
the people, to whom he appealed by the favour he had re-
cived in fighting for his country, and by the lives he had
saved in battle; but the tribunes succeeded in obtaining
against him a sentence of perpetual banishment. He heard
the decree without emotion, and with a calm countenance
took leave of his mother, his wife, and children; but the
ingratitude of his country made an indelible impression on
his mind. He was bent on revenge: he joined with the
enemies of Rome, took many of the towns, and encamped
within five miles of the city itself. The people now saw
their error, and a deputation was sent out to treat with him:
he received them with haughtiness, but would give them no
hopes of a reconciliation. To a second and third melleage of
the same kind he shewed himself inexorable. At length,
his mother, wife, and children, came out to plead their
country's cause. To their entreaties he could no longer re-
fuse his ear. Raising his venerable parent from the ground,
on which he had prostrated himself, he exclaimed, "You
have saved Rome, my mother, but you have destroyed your
son." He retired to his tent, and soon after took measures
for a retreat. When he had brought back the troops to the
Volscian country, he divided all the booty among the fol-
diers; on which account he is ingratiated himself with the
men, that his own want of resolution was forgotten. By
some of the historians we are told he lived to a great age;
though others maintain that he was slain in a tumult, excited
against him for yielding to the prayers of his country. Plu-
tarch.

Corioli, in Ancient Geography, a town of
Italy, situated in the country of the Volsci, of which it
was the metropolis. From this town, which no longer sub-
fited in the time of Pliny, Marcus took the name of Corio-
lanus.

Corios, a river of Asia, towards Carmania.

Coriophagematoedendorf, in Botany, Pluk.

See Myrica querisfola.

Coriovalium, in Ancient Geography, a town of
Belgie Gaul, on the route from Colonia Trajana, between
Tendurum and Jalucum. Anton. Itin.

Coris, in Botany, &c. (Diele.) Tourn. 652. Ap-
Lam. iii. 292. Juss. 2. 288. Class and order:
maeae, Vent.

Gen. Ch. Cal. one-leaved, ventricose, five-toothed, crown-
ed externally with strong sharp bristles. Cor. monopetalous,
irregular; tube the length of the calyx, cylindrical; border
flat, five-parted; segments obtuse, cuneate, entire, unequal.
Stam. five, bristle-shaped, shorter than the corolla,
decurrent; anthers roundish. Fil. Germ superior, round-
ifi; style filiform, the length of the stamina; stigma simple.
Peric. Capsule globular, placed at the bottom of the calyx,
one-celled, five-valved. Seeds numeros, somewhat egg-
shaped, small.

Efl. Ch. Calyx ventricose, with thorn-like teeth. Cor-
iosi monopetalous, irregular. Capsule five-valved, included in
the calyx.

Seeds several, about six inches high. more or less erect, cy-
lindrical, branched, cuneate, or oblong. Leaves scattered,
numerous, small, linear; the upper ones in the wild plant
edged with sharp prickly teeth. Flowers red or

5 C 2

white,
white, in dense, egg-shaped, terminal spikes. A native of
sandy shores in the south of Europe.

**Coris lutra**; C. Bauh. See Hypericum coris.

**Coris** is also used in the East Indies for a kind of shell
which packs for money. See Bia and Cowry.

**Corisco**, in Geography, two islands of that name
on the coast of Guinea, belonging to Benin.

**Corispernum**, in Botany. (from κορής, a bug, and
Claws and order, monandria digynia. Nat. Ord. Oleracese,

Gen. Ch. Cult. nonn; Linn. Schreb. Willd. (two-leaved;
leaves opposite, compred, acuminate, incurved; Lam.
Juss. Vent. Gen. t.) Cor. dipetalon; Linn. (none, Lam.)
Stem. Filament one, but in the lower flowers often from
two to five, filiform; anther roundish. **Fijil.** Cern superior,
egg-shaped, compred; styles two, capillary (one;
Gæst.) frigmas acute. Pers. nonn. Seed single, oval,
compred, flat or a little concave on one side, convex
on the other, with an acute margin.

Eff. Ch. Calyx or corolla two-leaved, or two-petalled,
one of them wanting. Seed single, elliptical, plano-convex,
with an acute margin.

1. Willd. 1. Lam. Illus. Pl. 5. "Flowers lateral; bracte
like the leaves, linear, smooth underneath." Root annual.
Stem scarcely a foot high, pubescent towards the top, red-
dish beneath, furfited, branched. Leaves alternate, entire,
with a white longitudinal nerve, and somewhat membran-
ous edges; lower ones two inches long, about a line
broad, ending in a long point, diminishing gradually to-
towards the top of the item, without affumig the form of
bracte. Flowers axillary within the upper leaves, sessile.
**Seeds** emarginate. A native of Russia and the south of France.

2. "Spikes lateral and terminal, squarrous; bracte
egg-shaped, short, mucronate, somewhat villous." Root annual.
Stem a foot high or more, much branched, panicled, zig-
zag, cylindrical, almost smooth, greenish, with pur-
ple stria; lower branches almost decumbent. Leaves about
two inches long, alternate, linear, smooth, nearly
equally distant from each other. Spikes an inch long or
more; bracte very different from the leaves, with white
membranous edges; flowers sessile. Seeds not emarginate.
A native of Tartary and Siberia. There is a variety, per-
haps a distinct species, found in the south of France, with
weaker items and more slender generally terminal spikes.

3. C. orientale. Lam. 3. "Leaves long, narrow, linear;
flowers somewhat panicled, growing only at the ends of
the branches." Root annual. Stems about a foot high, flender,
reddish at the base, branched. Leaves narrowing towards the

triche.

CORITA, in Geography, a town of Spain, in the prov-
ince of Leon; 17 miles S.S.W. of Leon.

CORITANI, or Coricenti, inhabitants of ancient Al-
bion, were situated to the W. and N. of the Iceni, and,
according to Camden, were the ancient inhabitants of the
country, which is now divided into Northamptonshire,
Leicestershire, Rutlandshire, Lincolnshire, Nottingham-
shire, and Derbyshire. Other antiquaries, however, are of
opinion that their territory was not so extensive.
The name of the Coricenti plainly indicates that there was some
kind of affinity or connexion between them and their neigh-
bours, the Iceni. Some think they were two tribes of the
same nation, and that Cor-Iceni denotes the lesser Iceni,
from Carr, a dwarf, and Iceni. Others imagine that both
these British tribes derived their name from the different
kinds of animals which constituted their chief riches, and
the tending of which was their chief employment; the
Iceni from Uthesh, oxen; and the Cor-Iceni, from Corr, a
sheep. However this be, if the two tribes did not form
one nation, they were in very strict alliance, and shared
the same fate; having been both reduced to some degree of
subjection to the Romans by Oltorius Scapula, and totally
fudged by Sustonius Paulinus. The Romans made great
changes in the country of the Cor-Iceni, by introducing
agriculture, and by building many forts and stations in it
to keep them in subjection. Lindum, now Lincoln, the
ancient capital of the Cor-Iceni, became the seat of a
Roman colony, and one of the most considerable cities which
these people had in Britain; and it is mentioned both by
Ptolomy and by Antoninus in both his journals. By fol-
lowing the course of the 6th journey of Antoninus, from
London to Lincoln, we meet with a considerable number
of Roman towns and stations within the territories of the
Cor-Iceni; as Venonze, now Clayce; Ratz, now Le-
celler; Virometum, now Willoughby; Margidunum, now
East-Bridgeford; Ad-Pontem, now Southwell; and Cro-
coiana, now Brugh, near Cottingham. The extensive coun-
try of the Cor-Iceni was included in the Romae province
called Britannia Prima.

CORITHUS, or Corythus, a town and mountain of
Italy, in Etruria, according to Servius on Virgil; but
Cluver thinks that Servius is mistaken; and that if such
a place existed, it must have been in the country since
called Cortona.

CORITIM, a town of Asia, towards Syria; placed
near the Euphrates by William of Tyre.

CORITUS, a mountain of Italy in Umbria; now Monte
Corvo.

CORIUM, a place in the isle of Crete, near the lake or
marsh called Coreium.

CORIUNDI, a people of Hibernia, according to
Ptolemy.

CORIUS, a river of Carmania.

CORIZENSIS, an episcopal see of Asia, in the pa-
triarchate of Antioch.

CORIZIOLA, in the Materia Medica, is a name given
by some authors, particularly by Rhus, to the scam-
mony.

CORK, the exterior bark of a tree belonging to the
genus of oak (Quercus Saber), which grows wild in the
southern parts of Europe, particularly France, Spain, Por-
tugal, and Tucany. When the tree is about 15 years
old, it is fit to be barked, and this can be done successively
for eight years. The bark always grows up again; and
its quality improves as the age of the tree increases.
If care is not taken to strip the bark, it splits and peels
off by itself, being pushed up by a second growth forming
under that of the preceding year.

**Stripping and preparing the Bark.**—The bark is taken
off by the Portuguese in sheets or tables, by cutting it with
knives having two handles, similar to those which the tanners
or flinders use at their beam, or horse, slitting it down after
the circular incision is made, from top to bottom; to effec
this incision they ascend the tree by a ladder to the part
where the branches spring from the top; they then make
a slice or flipo; the filaments connecting the bark with the
trunk are next cut down, or through, by a knife formed
like our hay-fade, and which they use in nearly the same
manner: the bark is frequently, through hale, broken off
at
C O R K.

at the root, in which case the two ends are distinguished by the appellations of "cut end" and "fall end," the first is that which had been at the top of the tree, where the circular cut was first made, and the second is that which had been next the ground.

Another mode of accomplishing the artificial stripping of the tree, is thus performed: several incisions are made from the top of the trunk to the bottom, and at each extremity of these incisions a circular cut is effected; by this operation the bark is cut off from the tree with either the lower or higher parts of the tree; consequently it is entirely deprived of support, in a little time it loofens, and its separation is completely accomplished by the hand; thus the progress of nature is expedited by very simple means. Before the operation of barking is again performed upon the same tree, should it be a young one, it ought to stand three years; it is not however unfrequently cut within the period; when it is cut too young, it is generally preferred by the English cork-cutter in his cellar till it alters from green to the colour proper for its purpose, which is effected merely from the time he keeps it in that state, though after all, it is still much inferior to that taken when the tree has arrived at maturity.

After being detached from the tree, the Portuguese "burn it," laying the convex side of the bark to the fire; in this operation they are careful to cover all the blemishes they possibly can, holes are filled up in an insufficient manner either by the swelling and straightening of the wood upon the fire, or by the artful introduction of foot and dirt. When the judgment of the burner is sufficiently exercised in straightening the bark, and artificially repairing its defects, it is laid into the farm yard for sale, in sacks, and bought by the merchants from thence for exportation.

Another method used in straightening the bark, is to pile it up in pits, loaded with heavy stones, by which method it becomes flat, this is afterwards more completely effected in a damp cellar, and is called "laying the cork." When this operation is finished, it is dried over a strong fire in what is called "a burning yard." From negligence in this process it receives too much of that black colour which is so frequently discovered in articles made of cork; when sufficiently dried it is ready for flacking.

The cork is not burnt, but only charred on each surface; previous to this operation the pores of the bark are open, and its consequent porosity of texture would make it not only give too much way to the knife; but particularly in the case of "taps" and "bungs" would render it a filter, rather than a preferer, of liquids. It shrinks with the application of moderate heat, and thereby closes the pores, by which any filtration might be effected. If "burning" ever be used as a cover for defects, it is not an original design but an accidental advantage, which is taken of a necessary procès; "bungs" and "taps" are always charred on both surfaces; good bottle corks, though the bark of which they are made is likewise subjected to the operation of fire, do not after they are cut exhibit any marks of that element, being cut in the length way of the wood, the pores lie in a contrary direction, and the charring consequently is taken off by the process of rounding them.

The tree cork as well as the ufe to which the bark is applied, &c.—This tree, as well as its ufe, was known to both the Greeks and Romans. By the former it was called phellos. Theophrastus reckons it among the oaks, and says, that it has a thick flaky bark, which must be stripped off every three years to prevent it from periling. He adds, that it was so light as never to sink in water, and on that account might be used with great advantage for a variety of purposes. That the fiber of the Romans was our cork-tree is generally and justly admitted. Pliny relates of it every thing said by Theophrastus of the phellos; and from his account we learn, that at the period when he wrote, cork was applied to as many purposes as at present. At that time fishermen made floats to their nets of cork; that is, they affixed pieces of cork to the rope which formed the upper edge of the net, in order to keep it at the surface of the water. Another ufe to which cork was applied, according to Pliny, was for anchor-buoys. "Ulus ejus ad corollum maxime navium," that is, as this passage may be interpreted, it was ufed for making buoys, called "Ancoralia," which were fixed to the cable, to prevent it from floating on the surface of the water, over the anchor, pointed out the place where it lay. Our navigators ufe for that purpose a large but light block of wood, which, in order that it may float better, is often made hollow. See Buoy.

Another ufe of cork among the Romans was for being made into soles, which were put into their shoes, in order to secure their feet from water, especially in winter; and, as high heels were not then introduced, they served the purpose of elevating ladies and making them appear taller than they naturally seemed. The practice of employing cork for jackets to affiff in swimming is also very ancient; for we are informed, that the Roman whom Camillus sent to the capital when befleged by the Gauls, put on a light drefs, and took cork with him under it, because, to avoid being taken by the enemy, it was necessary that he should swim through the Tiber. When he arrived at the river, he bound his clothes upon his head, and placing the cork under him, was so fortunate as to succeed in his attempt. The most extensive and principal ufe of cork at present is for flappers to bottles. To this purpose it is excellently adapted; because it is very light, may be easily comprized, and expands again by its elasticity as soon as the pressure upon it is removed, and, therefore, it fills and stops up very closely the space into which it has been driven by force. Besides, it may be easily cut into all forms; and though it abounds with pores, which are the cause of its lightness, it suffers neither water, beer, nor any common liquid to escape through it, and it is but slowly and after a considerable interval that it can be penetrat ed even by spirits; its numerous pores seem to be too small to afford a passage to the finest particles of water and wine, which can with greater facility coze through more compact wood that has larger or wider pores. This ufe of corks was not altogether unknown to the Romans; for Pliny expressly says, that it served to stop vessels of every kind, and influences of its being employed for that purpose may be seen in Cato (De Re Rustica, cap. 120.) and Horace (lib. iii. ed. 8. 10.) its application to this ufe does not cease, however, to have been very common as other substances have been generally employed for this purpose. Stoppers of cork seem to have been first introduced after the invention of glass bottles, of which no mention occurs before the 15th century. See Bottles.

This wood is still formed into soles for shoes, into corks and bungs for stopping bottles, &c. into a floatage for the nets of fishermen; it is employed generally, though perhaps with a considerable degree of error in teaching the art of swimming; it is also ingeniously ufed on account of its lightness, when an amputation of the human leg has been necessary, to supply the deficiency; the Spaniards line stone walls with it, which not only renders their houses very warm but corrects the moisture of the air; the Egyptians made coffins of it, which being covered in the inside with a redous composition
position preferred their deal boat. It is burnt to make that light black substance, called Spanish black, from its having been first made in Spain.

Cork bark has not only been applied as above, but also in the preservation of life, when endangered by shipwreck; the most conspicuous exhibition of its advantages is in the application of it in the construction of the "life boat" or "cork boat," as it was originally called. We have under the article boat, life boat," given our readers a short account of that invaluable invention; since which we have procured a very valuable account by the principal secretary of the meeting who first advertised the reward; we have also obtained from the liberality of Mr. Greathead, and the interpell of the gentleman alluded to, a plan or section of the boat, drawn by the original inventor, which will be given under the article Life Boat.

A cork jacket too has been revived from an old German discovery, by Mr. Dubourg; to preserve the lives of persons in danger of drowning, which is constructed as follows. Pieces of cork about three inches long, by two wide, and the usual thickness of the bark, are inclosed between two pieces of strong cloth or canvas and formed like a jacket without sleeves; the pieces of cloth are fastened together round each piece of cork, to keep them in their proper situations; the lower part of the jacket about the lips is made like the same part of women's flanks, to give freedom to the thighs in swimming; it is made sufficiently large to fit a robust man, and is fastened to the body by two or three strong tapes fastened far back on each side, and tied before; the strings are thus placed to enable any wearer to tighten it to his own convenience.

Cork in its action has the elasticity of a spring, and when pressed into any aperture, it exerts a force acting outwardly on all sides from the centre. It is this quality that makes it valuable in flushing out the external air from fissures, and elastic fluids; and it is fitted for this purpose in a degree proportioned to the impermeability of its pores. The elasticity of cork has also been employed for many other purposes in the arts; it forms the spring of the lighter in ordinary candlesticks, and where the frame is not heavy, it can be made into a good substitute for the pulleys and weights of the sashes of windows. See Candlestick and Windowsash.

Other vegetable productions have likewise been occasion-
ally employed possessing qualities similar to cork. The spon-
dias lutis, a native of South America, which flourishes in moist situations, and which is there called monibon or mon-
bun, is sometimes brought to England, as a substitute for cork. The roots of liquorice are applied to the same use, and on this account, as well as its medicinal properties, is much cultivated in Schelovia, and exported to different countries. The tree called myrtif, which is found in North America, has also been applied to similar purposes.

Cork-cutting, or the Manufacturing of Corks. This business, though it is thought one of the most dirty, is not one of the least profitable; it is likewise easy in the acquire-
ment. The cork, after being pressed into square pieces, as above noted in the treatment of the bark, is received by the cork-cutters, and if not sufficiently flat for their purpose, they "lay" it again over a fire in their "burning yard," turning the convex part to the flame; the heat by twisting the edges of the bark, counteracts the natural bend, and compels it to receive a flat form. During this operation, a considerable degree of attention is paid to smoothing it, and particularly again to cover its defects. It is next cut into lrips, narrow or wide, according to the intended cork, long, or tap, for such are the names of the general divisions in this business. The use of the two former is well known, the latter is used for stopping the top-holes of barrels, as the name implies. These strips are again cut into squares, of a length proportioned to the use they are intended for. This operation is performed by one man, from whom they are handed forward to several others. A further division of corks takes place, of these different sorts according to their lengths, and are denominated "short," "short long," and "for longs.

The cork maker places himself before the table or plunk, on which is fastened a board about three inches thick, four broad, and twelve long; immediately on a line with his left hand is a piece of wood, rising about four inches from the board, and fixed about the middle of it, on which the cork is laid, after being cut as above. This wood not only supports the cork, and is as a guide to the workman, but by its elevation above the board, gives room for the knife to cut a part of the cork in a smooth and circular manner, without slanting on the table below. The piece is then turned to where the left cut ceases, and this is continued until the knife has gone completely round; the top and bottom are then pared level, and the cork thrown into a box or basket, with the rest of the same length. As the bark is not of the same quality throughout each piece, the corks are sorted by a boy into four kinds, "superfine," "fine," "common," and "coarse," and are sold accordingly.

The only tool employed by the cork-cutter is a knife about three inches broad in the blade, and about six inches long, very thin and sharp, and equal in breadth from the handle nearly to the end, which is finished by a gentle curve. This knife be sharpened upon the board where the guard is placed, by one whet or fiddle on each side, after every cut, and now and then upon a common whetstone.

From the foregoing it is evident, that the art of a cork cutter is principally to obtain a regular, round, and quick turn of the wirh, in guiding the knife so as to complete a pretty correct circle, and to make a smooth surface; it is on this account that the knife will be particularly sharp, to enable the workman to turn it with ease.

The parings of the cork are carefully kept, and sold to the dry colour makers, to be burnt into Spanish black.

It may be supposed that those who give the detail of any manufacture would be the best able to point out improvements in it, though this is not always the case; yet one improvement in the "laying" of the cork wood, appears of great importance to the writer of this. In the present mode, a great deal of time is lost in placing and removing the flumes used to flatten the cork; and though the weight may be moderated or introduced by degrees, yet it cannot be done in that regular manner which appears the most likely to effect the purpose. In addition to which it may be observed, that in proportion as the weight is carefully applied, will be the risk of breaking those pieces which must partake of the circular bend of the tree. To remove this inconvenience, and to do away the c'd, grief, and cumbrous method, a few might be used, such as that employed by the printers in mending their work; by its operation a gradual inclination would be given, the former objections done away, and a much nearer and workman-like method adopted.

Cutting the cork into strips might also be accomplished with much greater facility; the whole breadth of the cork might be cut by one stroke, by means of semi-circular knives, like small shee knives, at certain distances, in a frame, which, by being affixed to a pole, with a cross bar as a handle, might be driven through the whole breadth in the
the same time that a single flip is cut by the present method.

**Cork.** Acid of, in Chemistry, a yellowish thick acid matter obtained by distilling four times its weight of nitrous acid from cork. This is soluble in water and has an acrid bitterish taste. It does not crystallize, but becomes a certain like wax by evaporation; it is soluble in ardent spirit; forms deliquescent salts with the earths and alkalis; and has as strong an attraction for lime as the acid of sugar.

**Cork. Mountain, Suaber montanum, or Corium montanum, in Mineralogy,** a species of the vivistic genus of earths and stones, according to the arrangement of Kirwan (Mineral. vol. i.) Its colour is white, or reddish-white, or yellowish-grey, or ishlera, or ochre-yellow, or yellowish-brown. It is found either in thick compact pieces, and then called "mountain cork;" or in thin flat pieces, then called "mountain leather or paper;" or cellular, and then called "Caro montanis, &c." The luidre is o., rarely 1., and transparency 5. Its fracture presents fibres confusedly intersected with each other, sometimes so subtle as to be dissimilar with difficulty, and thus they give the fracture a compact earthy appearance. (Bergman, vol. 3.) It takes an impression, or yields like cork to the finger, and is somewhat elastic. Sp. gr. before it is penetrated by water, 9.068 to 9.093; and after admission of water, from 1.4292 to 1.4342. (Drifton.) It perfectly dry, and sufficiently thick, it gives a found when struck. It finishes meagre. Bergmann and Saussure find it soluble, though with difficulty, by the blow-pipe. By Mr. Bergmann's analysis it contains from 56 to 62 per cent. of fixed, 22 to 26 of aërated magnesia, from 2.5 to 12.7 of argill, about 3 of calx of iron, and from 10 to 12 of aërated calx.

**Cork-paper, in Mechanics.** Fig. 1. Plate XVII. Mechanics, is a simple cork-screw, consisting of a screw, A, turning in a female screw attached by two small rods to the collar B, which receives the neck of the bottle from which the cork is to be extracted; the two rods have a groove in them to receive the eads of a cross-piece, connected with the cork-screw, and prevent its turning round with the screw A.

**Fig. 2.** is nearly the same, except that the nut, B, is turned instead of the screw.

**Fig. 3.** is called the neo-pler-alera cork-screw; it consists of two cork-screws A, B, one within the other; the screw which enters the cork is fixed to the innermost one. In using this instrument both screws are screwed up to their shoulders, and the whole is turned round together without permitting the frame to turn, till the cork is drawn. The handle is then turned the contrary way, and the screw drawn out of the cork by means of the small screw B.

**Fig. 4.** is a screw of nearly the same kind, a rack and pinion being substituted for the screw B.

A cork-making machine is represented in fig. 5; in which A is a tredle to be worked by the foot; it is connected by a rod d, with an iron-roller D; the bottle to be corked is placed in a heathen cæf E, fastened to a board finding in a groove; the cork is inserted, and the bottle slid under the lever D, the foot is then placed on the tredle, and the cork forced in; the corks are ferr pinched by placing them under the lever at d, to make them enter easily.

**Cork-tree, in Botany.** See Quercus Sylvis.

**Cork.** in Geography, a county of Ireland, in the province of Munster, lying in the south-western extremity of the island, and by far the greatest in extent and population. It has the Atlantic ocean on the south and south-west; the county of Kerry on the west: those of Limerick and Tipperary on the north, and that of Waterford on the east. Its greatest breadth 50 miles (71|₂ English); and its greatest extent 98 miles (71|₂ English), containing 1,048,800 plantation acres (1,658,920 Eng.); and being about 16,5 (or 2,653 English) square miles. The number of houses, according to an official return made to parliament in 1791, was 75,739, and they must have since considerably increased. From this population has been estimated at 416,000, which is allowing 9.6 to a house in the city of Cork, and 5.6 to a house in other parts of the county, which those who are acquainted with the many populous towns in this country, and with the manner in which the cottages are crowded, must admit to be a very moderate computation. According to this statement, which is taken from Dr. Beaufort, the county of Cork contains very nearly a tenth-part of the number of acres in all Ireland, and above a tenth-part of the whole population. For not only its absolute population is the greatest, but its relative population is amongst the most considerable, being nearly the same as that of Antrim and Londonderry, and exceeded only by the very populous districts of Armagh, Monaghan, Down, Louth, and Dublin. It cannot therefore be wondered at, that it has three militia regiments to keep up. The number of parishes is 269, in which there are 105 churches. The bishopric of Cork, Ross, and Cloyne lie entirely within the county, and all the above parishes belong to them except five. Cork returns eight members to the imperial parliament, viz., two knights of the shire, two for the city of Cork, and one each for the boroughs of Kinsale, Youghal, Bandon, and Mallow. In so large a district there must be a great variety of soil. It contains more good land than bad, and some parts of the county are highly cultivated, especially the neighbourhood of the Blackwater, and the barony of Imnlhale, which is the seat of the baronies of Cork and Kerry, in which are the Shiel mountain, which are the poorest and the best improved. The whole county is hilly, and, a few places excepted, very defatted of trees, which is the consequence of the small number consumed in the iron-works in the 17th century, without new ones being planted. There are however some flats which are richly wooded. The Gaetees and the Waterford mountains bound it on the north-north. The Nagle mountains and the Bogre which run through the heart of the county, though separated from each other by a long valley, may be considered as part of a range, that is continued with few interruptions from Helwick Leed in Waterford, across the counties of Cork and Kerry to the ocean. On the north of this range lies a narrow plain, which extends from the bounds of Tipperary to Dingle-bay. The rocks most common in this country are argillaceous. A coarse red or grey sandstone, often varying to a coarser and more flaty fracture, forms the greater part of the coal and the hills near it. There are in this very strata of slate, some of good quality for roofing houses. A large vein of limestone intersects the red argillite, commencing in the peninsula of Corhse and the islands in Cork harbour, and extending on the south side of the river Lee to its junction with the Bride, and thence through a valley adjoining this latter river to the distance of about 12 miles from the city of Cork. This limestone, in an evident secondary as it contains a variety of petrified shells, and much of it on scaping has that disagreeable fœst which characterizes Silex flint. This district contains some marbles which admit a good polish. In some of the limestone quarries near the city of Cork, there are not only very transparent quartz crytals, but also large amethysts which are
are much esteemed by the jewellers. The bottom of Bantry bay is entirely composed of broken pieces of coral, called coral sand, which is found to be an excellent manure. In Carbery there is a magnesian limestone. On the Cork side of the Galtree there is abundance of fine limestone, and this useful article may be procured on moderate terms in every part of the county. The Galtree mountains themselves consist of a very coarse pudding stone, in which is much iron shot quartz. Near Galway, on the estate of the countess of Kingsfort, is the remarkable cave of Skheenrinky, which is deemed by Mr. A. Young superior to the peak. (See Michelstown.) The county of Cork abounds in fine rivers, and good harbours. The Blackwater rises in the mountains between Limerick and Kerry, and flows eastward through this county, receiving the Awbeg, the Funchem, the Bride, and many smaller streams in a course of 80 miles. The Awbeg is the Mulla of Spenfer, who resided at Kilcooleem-castle, not far from its banks, and the Blackwater is the Awednoff of the same poet. On the banks of the Blackwater are many fine orchards remarkable for the cider procured from them; and several handsome seats. It is navigable from Cappoquin in the county of Waterford, where it turns to the southward, and disembogues itself in the harbour of Youghal. The Lee issues from a lake called Gougane-Barr; which is, according to Smith, a most elegant and romantic spot, and has by some been preferred even to the lake of Killarney. This lake is well of Inchigelech, by which town the river paifes, and thence to the city of Cork, above which it divides into two branches which unite below the city; and it contributes much to the wealth and prosperity of that great commercial town. The passage down the river from Cork to the outer harbour consists of a succession of varied and beautiful scenery, which can scarcely be surpassed. The Bandon is another fine river, which, after watering the large and thriving town of Bandon-bridge, and the village of Inishman falls into the harbour of Kinsale: it is navigable for large vessels as far as Inishman, between winding banks which still decorare the character given them by Spenfer; "the pleasant Bandon crowned with many a wood." The whole coast of Cork is broken into creeks and bays. The harbour of Corkhaven, near Mizen-head, the south-west point of Ireland, is often referred to, when the easterly winds prevent vessels from gaining the harbour of Cork. Bantry-bay, a little to the north of this cape, is, at least, 30 miles long, and from three to five miles wide, with deep, sheltered, and free from rocks. For particulars of these harbours, and of the many towns which this county contains, the reader must be referred to their respective articles. At Dromagh and Dromana, in the barony of Duhallow are coal-pits, which are worked, but not in a judicious manner, or to much advantage. There is much ironstone, and there were many furnaces; but the dearness of fuel is a great check. Much linen is woven about Dunmanway, which is purchased by merchants in Bandon, and shipped from Cork. Near Bandon is a very extensive cotton mill, which gives employment to great numbers. There are some other manufactures, but none of much consequence, except those which belong more properly to the account of the city of Cork. The peastans in the county are very thickly distributed. In many parts they are very dependent on their landlords, working for them at a low price in payment of the rent of their cottages, and the small lot of ground adjoining them. This has been called the Cottar system. The cottages in general, though bad, are not so wretched in appearance as in some other counties, and with scarcely a single exception have a small garden for cabbages, as well as a field for potatoes, attached to them. The last supplies them with the principal article of their food. They all have a pig, and some of them several, in which last case they generally kill one for themselves at Christmas. This animal, as well as some poultry, often inhabits the same dwelling with its owner, though, of late, pig-fyres are becoming more common. There is a dachshund formed before the door of every cottage, which has a disagreeable appearance; but it is often the only place the owners have for laying up manure for their potato gardens. Shooting is the general business of the women, and notwithstanding the severe remarks that have been made on the laziness of the lower Irish, they are seldom seen idle. They spin more wool than flax. The middling and lower farmers have, of late years, improved much, both in their wealth and manner of living, and there is reason to expect further improvement, if the encouragement to agriculture continues, and the peace of the country be undisturbed. The system of agriculture, however, in life, is very bad, and much praise cannot be bestowed on the great landholders for their exertions to improve it. Cork partakes, with other counties of Ireland, the evils arising from abentees, some of the greatest proprietors being of this class; yet few counties have so great a proportion of respectable residents. With respect to the history of this county, we may observe that it was a kingdom of itself before the arrival of the English, and was governed by the McCarts. A descendant of that family, on resigning his Irish title of M'Cartmore, was made by queen Elizabeth, earl of Clancarty, a title which was attainted soon after the revolution, in consequence of the attachment of the evil to the dethroned monarch. Henry II. granted the whole kingdom of Cork by charter to Robert Fitz Stephen and Milo de Cogan, about the year 1177; but they were able to get possession only of a small part of it. It is unnecessary to trace the various changes of property which took place from forfeitures and intermarriages. It may be right however to mention that queen Elizabeth divided a great number of acres, which had been forfeited, among various undertakers, who agreed to introduce English tenants. Sir Walter Raleigh had three seigneuries and a half given to him on this occasion, which he sold, in 1603, to Sir R. Boyle, afterwards the first earl of Cork, who was a great improver, and founded several towns. This property now chiefly belongs to the duke of Devonshire, who is the representative of the elder branch of the McCarts family. Many of Cromwell's officers afterwards obtained settlements in this county. Beaumont's Memoir. Young, &c. &c.

Cork, the second city of Ireland, and capital of the county of the same name, was originally built on a low marshy island, formed by the branches of the river Lee, from which circumstance its name is said to be derived, corcaigh, in Irish, signifying a moor or marsh. It appears, from the imperfect account we have of the early periods of Irish history, that in the 5th, or, as Ware says, in the 7th century, there lived a pious hermit called Barroc, or Fin Barroc, and in after ages, St. Fin Barry, who founded a monastery for regular canons of St. Augustine, and a school on the south side of the river Lee, near the place where the present cathedral stands; and that his name drew such numbers to it, that to use the words of Colgan, "it changed a desert into a city." In the 9th and 10th centuries, this monastery and town were often plundered by the Danes, who then infested Ireland; but, at the beginning of the 11th century, they founded the present town in an island of the river, of an oval shape; and called it either from the name of the town they had burned, or the marshy situation, Cor-...
CORK.

252. It was, however, very small, and probably did not contain above 1000 inhabitants; but the creeks which interfered it, were convenient for mooring the Danish vessels, and thus their merchandise and plunder were secured. On the arrival of the English in 1172, Cork became an English colony, and a royal garrison. King John ordered the fortifications to be repaired; a stone wall was built; castles were erected at the north and south gates; and bridges were made with portcullises for maintaining communication with the little towns adjoining the abbeys that had been founded on the north, as well as on the south side of the river, and which are now the north and south suburbs. Cork, however, was not fo early a place of the first importance in the island. Stanhurff speaks of it as inferior to Limerick and Waterford; and Boate, who wrote near a century later, in the time of Cromwell, as inferior to the same towns, and Galway. Camden, who wrote in the time of Queen Elizabeth, thus describes it: "It is of an oval form, enclosed with walls, and encompassed with the channel of the river, which also crosses it, and is not accessible but by bridges lying along, as it were, in one direct street, with a bridge over it. It is a populous little trading town, and much reforted to; but is beset with rebel enemies on all sides, that they are obliged to keep constant watch, as if the town was continually besieged, and dare not marry out their daughters into the country, but contract one with another among themselves, whereby all the citizens are related in some degree or other." But though the town of Cork was confined to the small island now occupied by the main street and the numerous lanes which intersect it; yet the suburbs were considerable, and were protected by several castles.

The trade of Cork, in these periods, was not extensive, and the principal support of the inhabitants was the consumption of the monasteries, of which there were several. A haven, Kinlale was in greater estimation. Since the commencement of the 13th century, the town has been gradually enlarged, by taking in and building upon the several marshy islands which lay near the principal one. The channels which were between these, served the purpose of canals, and were convenient in some respects, by enabling the merchants to load and unload their vessels at their respective warehouses, which often joined their dwelling-houses. In this, it resembled a Dutch town, and such is the description given of it in "the Traveller's Guide through Ireland," published in 1806. It is now, however, more than twenty years since the plan was adopted, of filling up these canals; and there is at present (1807) not a single one in the city, which appears as one island, lying between the north and south branches of the river. By this means, there are several wide pleasant streets, which want only regularity in the buildings, to enable them to vie with those of the capital. The health of the city has also been promoted, for putrid exhalations arose from these canals, which were a receptacle for filth of all kinds; and, when the tide was out, had both a disagreeable smell and appearance. Many houses have been rebuilt, and in consequence of a new bridge thrown over the north channel, the city is increasing rapidly on the northern bank of the river. So long ago as 1788, the houses were 8003 in number; since which time, there has been a considerable increase. The number of inhabitants in several of the old houses is very great, in some cafes above 50; and from the account Dr. Whitehall has given of the population of Dublin, we may safely reckon ten to a house. We shall then be within bounds in stating the population of Cork at 80,000. It may serve to strengthen this opinion, that in the year 1801, when, in consequence Vol. IX.
mills, with large stores, at a place called Ballincollig, belonging to government. The public-market, nearly in the centre of the town, is very neat and convenient. The meat-market consists of three rows, on each side of which the butchers have stalls. The whole is well flagged, covered in, and lighted from above. Adjoining are the fish, poultry, and root markets. These markets are open, and supplied on every day, except Sunday; but on Wednesdays and Saturdays, which are reckoned market days, the supply is abundant, and of the best quality. There are some inferior markets, but they do not deserve notice. The county jail is a handsome new structure, built at a short distance from the city, which will enable the grand jury to take down the south gate at one end of the main street; on, and adjoining which, was the old county jail. As a new city jail is shortly to be erected, the north gate may also be taken down, which will be a material improvement to that part of the city. The bridewell is a plain building, suitable to its purpose. The county court-house has been lately new-modelled, and an elegant entrance to it built, so as to be more worthy of the extensive and opulent county, the benefits of which are transmitted there.

There are a great number of charitable institutions, but the buildings are not remarkable. Where the funds, indeed, depend on voluntary contributions, it cannot be expected that there should be money to expend on ornaments. If, however, they cannot be spoken of as contributing to the beauty of the city, they undoubtedly do honour to the feelings of the inhabitants. There are two infirmaries, containing upwards of 50 beds; a house of industry, with commodious cells for lunatics adjoining it; a house of recovery, for the reception of fever patients; a lying-in hospital; a foundling hospital, which receives about 200 children, besides those at nurse; a blue-coat hospital for 24 boys; a school of industry for 100 children of both sexes, with several almshouses and parish school-houses. There are, besides, a general dispensary, which is provided with every thing necessary for relieving the sick, and for lending small sums of money to poor tradesmen; a society for relieving persons confined for small debts, and for lending small sums of money to poor tradesmen; a society for relieving the poor, in time of sickness; and a society for assisting strangers, and enabling them to return to their respective homes. Except the foundling hospital, which is supported by a tax on coal; and the house of industry, which receives grants from the county and city grand juries; all of them chiefly depend on voluntary contributions, or on public amusements, which are made in a great degree conducive to charitable purposes. The consequent difficulty of procuring funds for their support, obliges the conductors of these institutions to use rigid economy; yet it may be questioned, whether the time now spent in providing necessaries might not be better employed in preventing the internal regulations; and whether a permanent support for every useful institution would not, on that account, be desirable. Cork has also a society for letting the condition and increasing the comforts of the poor, which maintains a correspondence with the similar societies in London and Dublin, and has suggested many useful plans, some of which are performed in with success. Though the citizens of Cork have been distinguished by some liberal travellers, as neglectful of the sciences and fine arts; yet there seems to be no just ground for this censure. The public library, supported by annual subscriptions, contains a large and well chosen collection of books, which is rapidly increasing. The institution already referred to, which also originated in private subscriptions, has a scientific library, a large collection of minerals, and the necessary apparatus for giving lectures in natural philosophy and chemistry. The managers of it, having received the countenance and support of government, are now adding a botanical garden, and extending their plan in many respects. The proprietors of the institution, with some other gentlemen, form a literary and philosophical society, which meets on two evenings in every month. With respect to the fine arts, music is a favourite amusement; and there are many excellent performers, both professors and amateurs. The highly celebrated Barry, who was a native of Cork, was first brought into notice by an ingenious townsmen, Dr. Keigh; and there are not wanting, at the present time, men who have talent to discern, and liberality to encourage, rising merit; though a place to remote from the capital cannot be expected to afford scope for eminent talents. The environs of Cork, towards Passage and Glanmire, are extremely beautiful: the lands rise in gentle hills, ornamented with many country houses, gardens, and plantations, and with woods and fields of variegated verdure. On an island between the two branches of the Lee, above the city, is a walk of an English mile in length, planted with trees; from which there is a pleasant view of part of the city, and of the suburb of Sunday's Well. It is called the Mardyke, and is a fashionable walk. But whatever advantages its environs may possess, or whatever improvements may take place in this city, the source of all must be sought in its safe and capacious harbour, which has now become a regular station for an admiral, and which is the place of rendezvous for fleets failing to the West Indies. The principal export from Cork has long been provisions, including beef, pork, and butter, made up either for the West Indies, or for the supply of the British fleet. The average exportation of beef, in the years 1743-1755, was 62,950 barrels; the average of butter, in the same years, was 84,105 cwt. and Smith says, it was ascertained that the average number of bullocks and cows slaughtered in Cork, from August to Christmas in each year, was near 100,000. The export of butter began about the year 1623; and about the same time the merchants began to barter up their beef and butter with hoops bound about with twigs, after the English manner; and at present they are also iron-hooped. The average of beef for 19 years, ending in 1773, had increased to 291,750 barrels; and that of butter to 120,000 cwt. The export of pork was at that time inconsiderable. The average value of the whole exports was 1,100,190l. sterling. The other articles of export were hides, bary and woollen yarn, cambrics, serges, candles, soap, tallow, herrings, glue, wool, and some small articles. Of late years, the export of beef, and of all the articles connected with it, has decreased; and that of yarn, cambrics, and serges, has almost entirely ceased: but the export of pickled pork and bacon, of corn, of porter, spirits, &c. has become considerable. The quantity of butter exported in 1806 was 160,000 cwt.; the number of black cattle, on the average of the three last years, was only 18,000; the number of calf-fkins, on an average of the same years, about 50,000. The imports are chiefly for the supply of the city, and the adjoining district. The breweries and distilleries of Cork are a great source of wealth. There are five porter breweries, besides many of ale and small beer. That distinguished by the name of the Cork porter brewery is the most extensive, not only in Cork, but in Ireland, and is probably surpassed only in London. There are four large distilleries, each of which pays 2100l. duty per week. At one of these is a steam-engine, of Boulton and Watt's latest construction: it is of 40 horse power, and no expense has been spared in the erection of it. The manufacture of clothing for the army is also very extensively carried on; and there are many kiler factories for coarse cloth, large, &c.

The
The manufactories of sail-cloth, sheeting, paper, leather, glue, glass, &c. are also considerable. The corporation consists of a mayor, two sheriffs, a recorder, and several aldermen. The charter was given by Charles I. The sheriffs are chosen by the freemen at large; and, after having served the office, are called burgesses. On the day of election, the names of all these burgesses are put into a box or hat, and five names are drawn out: of these five the freemen are to choose one to be mayor for the ensuing year. By an agreement, however, which has been entered into by a great number of freemen, who form a club, the tenor burgesses, if willing to serve, is always elected. The same club has also assumed to itself the choice of sheriffs, so as to render the public election a mere farce, or rather a ratification, according to form, of what has been previously determined at a meeting of the club. Cork, as well as Dublin, retains the privilege of sending two members to the imperial parliament. The electors consist of about 1500 freemen, and a number of freemen in the county of the city, which is very extensive. The eldest sons of freemen are entitled to their freedom, as well as those who serve a regular apprenticeship to freemen. Many also obtain this privilege by favour every year; for as the number of voters is too great to admit of any attempt to dictate to them at elections, so there is little inducement to throw difficulties in the way of obtaining freedom. The income of the corporation, which arises chiefly from duties paid by those not free on articles of trade brought into the city, is so small as to be scarcely sufficient for the current expenses. In history Cork has not been remarkable. Like most other parts of Ireland, it engaged in the interest of the impotors, Perkins Warbeck, which brought the citizens into some difficulty. In 1690 it was besieged by King William's forces, under the earl (afterwards duke) of Marlborough, and taken after a short resistance. The duke of Grafton, a natural son of Charles II., was killed at this siege.

Cork is 126 Irish miles S.W. from Dublin. The latitude of the observatory of the Cork Institution is 51° 53' 54" N. Longitude W. from Greenwich, in time, 33° 50'; in degrees, 8° 29'. Smith, Young, &c. &c.

Cork, Bishopsrick of, is supposed to have been founded in the fourth century. It was united with Rosc by queen Elizabeth, in 1586; and they are both contained in the county of Cork, as is also the adjoining one of Clare. The Union is, in Irish miles, about 65 by 17; and in English, 83 by 23. The number of acres is 480,300, which are divided into 127 parishes, of which only 54 have churches: Beaufort.

Cork-bay, a bay on the east side of Newfoundland island.

Cork, or Corking of a fiddle, are pieces of wood upon which the bootles are made fast.

This part of the fiddle was formerly made of cork, whence it still retains the name.

CORKAY, in Geography, a small town of France, in the department of the Côtes du Nord; is the chief place of a canton, in the district of Loundéc. The town contains 1483, and the canton 6481, inhabitants, dispersed in five communes, upon a territorial extent of 117½ kilometres.

CORLI, in Ornithology, the name given by Albinus to the Scopolarix tetanus, the spotted red-flank of Pennant, and spotted faipe of Latham.

CORKIN, in Geography, a small town of Prussian Pomernia, on the river Parnice; 12 miles S.E. of Cölberg. It has a few woollen manufactures.

CORLIS, in Ornithology, the common curlew, or Scolopax rusticus.
COROMOLAIN, in Geography, a town of France, in the department of the Calvados; 10 miles S.S.W. of Barneux.

CORMONS, a town of Germany, in the county of Goritz; 7 miles S.W. of Goritz.

CORMONANT, in Ornithology. See Pelecanus carbo, and Corvus aquaticus.

CORMOS, or CORMON, in Ancient Geography, a town of Arcadia, on the frontier of Lacania, near the source of the river Careianus, S.E. of Megalopolis. In the time of Pausanias, its ruins only were to be seen.

CORN, in Agriculture, a term applied to all sorts of grain fit for food; particularly wheat, rye, &c. The farmers, indeed, reckon under the denomination of corn several other grains; as barley, oats, and even pulse; as peas, vetches, &c., which, however, they sometimes distinguish by the denomination, fooler corn.

Europe, in every part of it; Egypt, and some other counties of Africa, particularly the coasts of Barbary, and some parts of America, cultivated by the Europeans, and the Armenians themselves, produce corn. Other countries have maize and rice, in lieu of it, and some parts of America, both in the islands and continents, simple roots, such as potatoes, and manioc.

Egypt was anciently the most fertile of all countries in corn; as appears both from sacred and profane history. It furnished a good part of the people subject to the Roman empire, and was called the storehouse of Rome and Italy. England, France, and Poland, seem now to have supplied the place of Egypt, and with their superfluities support a good part of Europe.

For the first discovery and culture of corn, authors are much divided: the common opinion is, that in the first ages men lived on the spontaneous fruits of the earth; as acorns, and the nut, or mall, produced by the beech; which, they say, took its name, linnus, from the Greek ἕλιον, I eat. It is added, that they had not either the use of corn, nor the art of preparing, or making it eatable. See Baking.

Ceres has the credit of being the first that shewed the use of corn, on which account she was placed among the gods; others give the honour to Triptolemus; others share it between the two, making Ceres the first discoverer, and Triptolemus the first planter and cultivator of corn.

Diodorus Siculus ascribes the whole to Isis; in which Polydore Virgil oberves, he does not differ from the rest; Isis and Ceres being, in reality, the same. The Athenians pretend, it was among them the art began; and the Cretoans, or Candiaots, Sicilians, and Egyptians, lay claim to the same. Some think the title of the Sicilians best supported, that being the country of Ceres; and authors add, she did not teach the secret to the Athenians, till she had first instructed her own countrymen. Others say, Ceres passed first into Attica, thence into Crete, and, last of all, into Sicily; many of the learned, however, maintain, it was in Egypt the art of cultivating corn first began; and it is certain, there was corn in Egypt and the East, long before the time of Ceres. For the various modes of producing corn, and preparing it for use; see Husbandry; and other articles appropriate to each kind of grain in this dictionary.

For the best method of preferring corn, see Granary.

Corn Laws, in Rural and Commercial Economy, are those laws and regulations which relate to the importation and exportation, as well as general trade in grain. They are a set of rules and regulations which have undergone much change and alteration at different periods, but which still seem far from having attained that degree of perfection which is essential in so important an article of commerce. It has been remarked by an able writer, that "almost every other manufacture may be admitted to a free trade; but as the trade of corn must at all times be limited by, and subservient to, the necessities of the state, it requires the attention of a careful and fostering parent."

It is therefore contended, that the agriculture of the nation "ought to be guarded by the wise and the strictest execution of them, as the only certain means of employing the greatest number of people, and consequent on increasing the population; and that it is the better entitled to this attention, that the farmer and the landholder pay a full proportion of all taxes imposed for promoting and protecting the fate of our other manufactures, both at home and abroad, as well as for the growth of corn alone.

Though very different principles have been laid down as the basis of these laws at different times, it seems evident that, as the strength and power of a nation must be proportioned to the extent and industry of its population, the chief attention of the framers of them should be directed to such measures as have an immediate tendency to encourage and promote the improvement of agriculture. It has indeed been contended, on the ground of long experience, that the foundation of such regulations should always be such as is calculated to induce the inhabitants to improve their grounds in such a manner as to raise the largest proportion of grain, the particular soil and climate is capable of permitting. And that this is "an object which can only be attained by securing a certain and steady market to the farmer for his produce; not only by preventing importation, but also, whenever it shall appear, from the moderate price of grain at home, that a greater quantity has been raised than is required for the annual supply of the inhabitants, by giving such a bounty on exportation, as shall ensure a ready vent for the excrecent flock in foreign countries. It is not enough, says the able writer, that a nation raises, in general, a sufficiency of corn for the consumption of its inhabitants: it must be accustomed to raise considerably more, in order to afford plenty in bad years; and its annals ought to be distinguished by a greater or lesser exportation; but on no occasion ought it to be reduced to the necessity of importation, and having recourse to foreign countries for an expensive and precarious relief."

Mr. Young in his "Political Arithmetic" likewise remarks, in speaking of the obstacles which bad corn laws threw in the way of good husbandry, and of the want of permission to export grain in Spain, Portugal, and some parts of Italy, that he does not conceive it possible, "under such a system, to have a flourishing corn husbandry—prices will be too fluctuating—some years will be so cheap that the farmers will be ruined, and others so dear that the people will be starved. Long experience must convince us, continues he, that this is not only reasoning but fact. Famines never appear in countries that admit a free exportation; but in all above named, where a contrary policy has been pursued, they have appeared frequently and severely." And he farther observes that "the variations in the earth's produce, owing to faticans, though not so great as some have imagined, where the husbandry is good, just where it is indifferent, must necessarily be considerable." He thinks that one maxim may be laid down on this subject which can hardly be contradicted, which is, that "the good of husbandry requires that the price of corn should be proportioned to the product. Let us then add, supposing the common consumption of a nation to be 5,000,000 of quarters of bread corn: the proportion between the consumption and the annual consumption must vibrate according to various circumstances. Suppose a crop, of 6,000,000 of quarters, and no exportation, what
CORN.

what, he asks, must be the consequence? There is the surplus of a sixth in the markets, consequently the price is brought down much lower than that proportion. Here, says he, lies the misfortune. If corn in such a year yielded a price proportioned only to the plenty, the misfortune would not be great; but the addition in the markets of a sixth sinks the price probably a third, and perhaps more. And further, supposing "another good crop, with a new surplus of a sixth or seventh; this coming upon granaries full of a part of the former surplus, sinks the price yet lower; and then the farmers are not only discouraged, as, he says, several writers have observed, from sowing another crop, but what is as bad, they are impoverished so much that they cannot plough, harrow, dung, drain, ditch, fence, or do any thing with proper spirit. These two circumstances, inability in future to act well, and discouragement from sowing again, can hardly fail, he thinks, of occasioning in future years a scarcity, or probably a famine. Then the farmers resp of course a thin crop, from their former inability, and that too over only part of the land usually tilled; in such a cafe, corn, he contends, must be very high to recompose the farmer; probably so high, that the government of the country is alarmed, and imports corn from wherever they can get it; then the price falls, when he again fullers. Thus a great crop or a bad one operates equally against him, and nothing can support him at all but such a product, as pretty exactly answers the annual consumption. There is no balance preferred in the measures, exportation is prohibited, yet importation is allowed; so that it is impossible the price should with any regularity be such as can encourage good husbandry."

"On the contrary, if the policy of the state admits exportation, the surplus of a large crop being sent away, keeps the price at home, he maintains, from falling too low; this is an encouragement to the farmer acting two ways; first, by enriching him, he is able the better to improve all his culture; secondly, he is induced to sow as much corn as possible, for every man, whatever be his trade, is desirous of increasing that commodity which sells best at market."

The bounty on exportation, which was formerly given in this country, is considered as a refinement on this policy, and which, though given originally with the view of raising the price of grain, as an encouragement to the country gentlemen, yet it had the contrary effect, having rendered corn much more cheap, by becoming so great an inducement to the cultivation of it.

It is, in short, strongly contended, that "in such countries as will adhere to so destructive a system as that of restraining the export of corn, it is not of much consequence whatever advantages are given to husbandry, since all others united, that can be named, or thought of, will not make amends to the farmer for the want of a market: it is of no consequence to enable him to raise noble crops, if when he has got them, he cannot sell at a proper price; his plentiful harvests tend only to his ruin." From the fullest consideration of the subject in various points of view, an able writer conceives it obvious, "that agriculture and manufactures are established on very different principles, and that whilst wealth and population raise considerably the money price of corn, and other rude produce of the soil, they have not an equal effect in advancing the price of manufactures." Hence, contrary to the opinion of the celebrated author of the Wealth of Nations, it is supposed the following political maxim may be fairly deduced: "that agriculture in rich and populous countries, stands more in need of a monopoly for its support than manufactures; and that the farther a nation advances in prosperity, it becomes the more necessary to secure its agriculture, not only by restraining the importation of foreign corn, but also by removing every impediment which may prevent, and by giving every encouragement which may promote, the extension of cultivation and improvement over the whole face of the country."

Consequently, that, if this country with "to preserve her present superiority in wealth and resources over the surrounding nations, agriculture must be protected by allowing to the husbandmen prices for their produce proportioned to the internal wealth and prosperity of the country; and that, if at any time, the bringing in of foreign corn tends to sink the money price of British grain below the corresponding value of labour and other commodities, the importation must be checked by judicious laws, altered from time to time, at different periods, to correspond with the prosperous or declining state of the country."

The principles on which the corn laws have been constructed at different times, so far as they can be traced and recognized, appear to have been these.

1. That of cutting off the importation of corn from foreign countries, except when the price at home was very high.

2d. That of granting a bounty on the exportation of it, when it does not exceed certain prices.

3d. That of having recourse to both these measures according to circumstances; or what may be termed a fort of mixed or shifting policy, without any thing being permanent, without any regular law, or due arrangements of prices at which export should be allowed, or import be prohibited.

4th. That of lowering the import rates and duties, as well as that of the bounty, on exportation in a considerable degree, in order to reduce the prices of corn in the home market, to the state of former periods, and thus to introduce a permanent law in respect to corn by which the inconveniences of a varying policy may be remedied. And,

Lastly, That of regulating the import and export of corn, and the bounties and duties upon them, by the particular circumstances of the period, so that the farmer may obtain a fair and reasonable profit in the home market.

Having now considered the different objects which should be particularly attended to in constructing laws for the regulation of the commerce in grain, and shewn the principles on which they seem to have been in general founded, it may not be improper to trace thecauses from which they proceeded, and the effects which they have produced at different times.

In regard to the corn laws of this country, as they existed previous to the revolution in 1688, it may be observed, that in order to "preserve the laws of the kingdom in force, it was considered necessary, for several centuries after the conquest, to renew or confirm them upon the accentions of new soveraigns, a practice which explains the reason of the various confirmations of the great charter, and the frequent re-enactments of the same laws, on this subject, as well as others, without any new meaning appearing on the statute-book."

At this period, the rents of lands, held by farmers or tenants, were for the most part payable in produce, as in corn, cattle, or some other product afforded by the soil. And the rules by which the rents were received were extremely indefinite and irregular; the measures of grain being various, and taken heaped, nine bushels generally constituting the quarter. For though by the great charters of king John and Henry III., which had been often confirmed by succeeding kings and their parliaments, one weight and
and measure had been directed to be made use of over all England, yet it was far from being the case, as is shown by an act of 1360, the 25th of Edward III., in which the weights and measures are again attempted to be regulated; and in which it is directed, that eight bushels sliver and no more, shall be received as the quarter of grain, "but faving the rents and farms, and all manner of franchises of the lords."

On which Mr. Dirom remarks, that, "with such refractions, it is not to be expected that the law could have any effect." And he adds, that, "under such impositions with the opprobrium of purveyance, and the depressed situation in life wherein the farmers were placed, it is not to be wondered that agriculture languished, and that a numerous community depended upon foreign provisions for their subsistence."

In tracing the progressive advances of agriculture from this depressed situation, it may be necessary to observe, that, at these periods, most of the business of the dealer or trader was carried on in the different markets and fairs of the kingdom, and that a large proportion of the revenue of the crown was drawn from the duties payable to the king, on the goods brought to them in order to be sold. And the barons had likewise, within their respective jurisdictions, tolls at the fairs. Hence it not unfrequently happened, that as the farmers and other dealers were conveying their corn and other necessaries to the markets and fairs to be disposed of, they were met by perons on the road, in order to purchase them for the purpose of retailing them at a higher price, in consequence of which, the king and the lords of the manors were deprived of the different duties payable upon them, and at the same time the price was enhanced on the people, in consequence of the diminished quantity brought to market. It of course became necessary, both on the score of public and private interest, to prevent the practice as much as possible, by the infliction of severe penalties; and various laws were enacted for the purpose at different times, the offenders being termed forellers, regators, and ingroffers.

Hitherto, as various laws had been formed with the view of inviting the importation of foreign articles of necessity, while the exportation of the superabundant flock of British grain had been prohibited, it cannot be supposod that agriculture had been encouraged as an object of national importance. About this period, 1393, however, a law was made, the 17th Richard II. c. 7, which authorized all the king's subjects to carry corn out of the kingdom, upon the payment of the customs and subsidies. And which was confirmed in 1425, referring to the king and council, power to restrain the exportation when they should judge it necessary.

However, from this reservation being confirmed into a prohibition to export grain without a licence, or from the difficulty of procuring the licence, the beneficial con-sequences to be derived from it were prevented; and from the check which was thus given to the art of cultivation, much inconvenience and diftrefs experienced in the country, as is fully shown by the preamble to the law of 1436, the 15th Henry VI. c. 2, by which it was followed, and in which liberty was given to perons to transport grain, without a licence to wherever they chose, except to the enemies of the king, when wheat was at 6s. and 8d. and barley at 5s. the quarter; which were fums rather above the medium prices, being in the proportion of the present money of 2l. 4s. for the quarter of the former, and 19s. 10d. for that of the latter.

The advantage of this law had been found so beneficial to the country in restoring abundance of grain, that it was in 1442 and 1444, confirmed and continued for ten year as well as soon afterwards made perpetual, by the acts of 20 Henry VI. c. 6, and 23 Henry VI. c. 5: and the effects of which, so far as they can now be discerned, were those of a very moderate and more steady, or less fluctuating, price of corn for forty years.

However, notwithstanding this, the laws favouring the importation of foreign grain still continued in force; and the trade was in the hands of foreign merchants or dealers, who conveyed their corn or other articles from one port to another, so as to anticipate the English farmers in the sale and disposal of their grain or other produce. And it is suggested by Mr. Dirom in his "Inquiry into the Corn Laws and Corn Trade," that "although those merchants may have loft upon the grain which they imported into England at this time, they gained upon the general course of the trade; because they received in return, wool, unfinished woollen cloth, and ready money, upon which they made great profit in their own countries, and thus were enabled to underfet the produce of our fields at home."

Further, "this appears to have been the case, even after this period, from two restrictive and regulating laws of Richard III. 1, c. 8, 13, by the lal of which it appears, that the foreign merchants who imported wines into England, had not only taken their payment two-thirds in woollen cloth, and one-third in ready money, but had considerably lefsered the contents of their wine casks, although fold under the former titles and contents."

The inconvenience and consequent diftress to which the business of cultivation was exposed, by the conftant importation of foreign grain, at length awakened the attention of the legislature, and in 1463, a preventive law was made, 3 Edward IV. c. 2; some of the caufes of which feem to have been, that the labourers or cultivators and occupiers of land, had been grievously injured by the importation of foreign grain, when corn at home was at a low price; by which the importation of foreign grain was prohibited, until the prices at home should exceed 6s. 8d. the quarter for wheat, 4s. for rye, and 3s. for barley; which is in the proportion of 1l. 15s. 2d. 1l. 1s. and 15s. 10d. of the present money.

The able author quoted above, considers thee as the laws to which the agriculture of this country owes its origin; and that notwithstanding their object have frequently been defeated by others, they are the basis or foundation which will remain; and on which a great fabric, now out of repair, has been erected; but which, by "moderate attention, may long continue to be the chief ornament and support" of the kingdom. It was on these laws, he adds, that the agriculture of the country refted for nearly a century; though the want of their being duly executed, rendered them in a considerable degree nugatory. For as the prohibition of the importation of foreign grain, was never sufficiently regarded; the occupiers of land had still to contend with the competition of grain from abroad as well as other oppressions and grievances at home; as is fully shown by an act made in the year 1552 against regators, forellers, and ingroffers, the 5 ar d of Edw. VI. c. 14; "by which the crime of forellalling is extended to perons buying victuals coming in ships from beyond the seas, to be sold in any market or fair, city, port, haven, creek, or road, as if no laws had been enacted by which such importation had been prohibited." And after observing that although the "repression of the practices of forellallling and regating might have been neceffary," it is not easy to discover any caufe "for the enactment of ingroffing" at a period so late as this when commerce had made such considerable advances; and further that, "by the same law, no peron
per son at home could transport corn from one port to an- 
other without a licence; neither could they purchase corn 
to be laid up in their granaries for home sale, until the 
quar ter of wheat was at, or under, 6s. 8d. (equal to 10s. 6d. 
of present money): malt and barley at 3s. 4d. (8s. 3d.); 
oats at 2s. 4½d.; peas and beans at 4s. (9s. 11d.); and 
rye at 5s. (12s. 5d.) per quarter.*

By these means it is contended that the former system of 
corn laws was wholly subverted, for that, "although these 
were the prices to which exportation was limited by the act 
of Edward IV. in 1463, the value of money was materially 
changed; for, at the former period, there were only 57s. 
6d. in the pound of silver, and now there were 60s. 4d. and at 
the former period, money bore a very high and unlimited 
interest, and now, it yielded only about 12 per cent. per annum; 
so that 6s. 8d. for a quarter of wheat, in 1463, was equal to 
1l. 15s. 2d. and in the year 1552, it was only equal to 
16s. 6d." as has been noticed above. And further that the 
prohibition to the purchasing of grain for storing up or con-
veying coast-ways, till the price should sink beneath the ex-
istence of raising it, must have necessarily put a total stop to 
all dealings in grain and of course ruin the farmers; all of 
which was done at a period when the price of corn had been 
invariably at a low rate. It is supposed not to have oc-
curred to the legislature at this period, that by keeping 
the grain at home in feasons of great plenty the price must be 
steadfastly enhanced, as the farmers would not be capable of continuing 
their trade of raising grain under such disadvantageous cir-
cumstances; of course, that as soon as the stock on hand 
was consumed, scarcity if not famine must be the con-
sequence; nor that by permitting an exportation of the ex-
creant stock, plenty would be ensured, by preferring an 
open market to the farmers, and in that way enabling them to 
carry on their business, and raise more grain than was in 
general necessary for the home consumption; nor was the 
benefit that would arise to the nation, from the increased 
number of persons who might be engaged in raising and ex-
porting the quantity of corn that could be spared, or the 
sums of money which would be brought into the country as 
the price of it, in the least attended to.

It seemed to have proceeded on the idea that the only 
mode of preferring plenty, was that of keeping the whole 
of the corn and other provisions at home, and importing as 
much as possible from abroad, which appears from experi-
ence to be far from having any foundation in truth.

However, the same system was farther enforced and 
followed out by the enacting of another law this year 1554. 
1 & 2 Phill. & Mary, c. 5. under the imposition of injury 
from the exportation of corn and other victuals; by which 
it was provided that "no manner of person or persons should 
export any wheat, rye, barley, or other sort of grain, grow-
ing within England; or any malt made within the same; or 
any butter, cheese, herring, or wood, without having licence 
fo to do, under severe penalties; except when the common 
price of corn, within England, should not exceed for wheat 
6s. 8d. (equal to 10s. 6d. of present money): rye 4s. (9s. 
11d.) and barley 3s. 4½d. (7s. 5d.) per quarter.*

Such was the policy of Edward IV. as well as of Philip 
and Mary, notwithstanding the price of wheat this and several 
years before, had been only 8s. the quarter (equal to 19s. 
10d. of present money); and the export prices below the 
medium ones in times of ordinary plenty; and in Scotland 
it was soon afterwards followed by laws expressly prohibitory 
under very severe penalties of the exportation of all sorts of 
victuals, tallow, and fleeth. Mary par. 6. c. 40. Jaa. par. 11. 
c. 55.

After the enacting of this law, from the seafsons being 
favourable and the importation of foreign grain being con-
tinued, the price of wheat remained about 8s. the 
quarter; the farmers became ruined, and the businessmen 
of cultivation much relinquished; which strongly marks the 
aburdity of directing persons to labour in occupations in 
which they cannot procure a reasonable subsistence. The ex-
cellent laws of Henry VI. and Edw. IV. had continued with-
out respite throughout the reigns of Henry VII. and VIII. 
without, however, being countenanced or having any execu-
tion, yet these sovereigns, as well as Edw. VI. and Philip 
and Mary, made repeated laws to enforce the people to 
cultivate and flow their grounds, 4 Hen. VII. c. 19. 7 Hen. 
VIII. c. 27. Hen. VIIII. c. 22; 3 and 6 Edw. VI. c. 15. 
2 and 3 Phill. and Mary c. 2. thofe of the latter being parti-
cularly prejudicial in repressing the spirit of husbandry.

Thefe inconsistencies did not however escape the attention 
of Elizabith, as almost immediately upon her accession she 
not only renewed the laws which formerly existed for rebuilding 
farm houses, and tilling the land formerly in cultivation with greater vigour, 5 Eliz. c. 2. but by another law 5 Eliz. 
c. 5. § 26. permitted farmers to export their corn as merchant-
dize, when the price was not high at home, as when wheat 
did not exceed 10s. the quarter, equal to 1l. 8s. of present 
money, rye, peas or beans, 8s. (16s. 7d.) barley and malt 
6s. 8d. (13s. 10d.) And as in the former of these laws, 
the penalties had been given to the king, they were now 
given to the next heir, &c. of the person offending. By this 
means a considerable extenion of the exportation prices took 
place, which is remarked by the bent writers of that period 
to have had a direct and immediate effect in the increase of 
tillage and the reduction of importation, though it had been 
observed by one of them that for several years preceding that 
time, "the importation of grain had exceeded forty-five 
millions of livres." Thofe are probably the first traces of the 
navigation laws.

Not long after this, in 1570, a still more rigorous effort 
was made to restore the agriculture of the country, in a law 
enacted for the better increase of tillage, &c. 13 Eliz. c. 13. 
by which exportation was permitted, without limitation of 
prices, from such ports and creeks, in which a customer or 
collector of the subsidy of tonnage and poundage, had been 
placed, to any part beyond the seas in amity with England, 
when not restrained by proclamation, provided such exporta-
tions were made in ships belonging to English born subjects 
refiding within the dominions; at such times as the several 
prices of grain should be so reasonable and moderate, when 
such exportations were intended, as that no prohibition 
should be made by the queen's proclamation, or by the 
presidents of the North, or of Wales, within their several 
juridictions; or of the justices of assize at their seessions, 
in other threes out of the jurisdiction of the said two presidents 
and councils; or by the major part of the justices of peace 
of the county at their seassions. Thus, thefe different 
magistrates were to annually confer and deliberate with 
the inhabitants of the county concerning the prices of the 
different sorts of corn within their juridictions, in regard to 
it's cheapness or dearth, and by their discretion decide 
whether it would be meet, at any time, to prevent any grain 
from being carried out of the realm, by any port within their 
juridictions or limits, and by a writing under their hands 
and seals, make a determination, either for permission or 
prohibition, and cause the same to be published by the 
sheriffs of the several counties; which was to continue in 
force until the same should be altered, by the said pre-
sidents and councils, or other powers respectively, except 
the same should, in the mean time, be countermanded by 
the queen, her heirs or successors; or by some order of the 
justices
judges of peace, in the counties situated out of the jurisdiction of the said two counties, in their quarter sessions to be held in the mean time, or the greatest part of them, should have the determination of the justices of assize to be hurtful to the country, in consequence of the dearth, or a great hindrance to tillage, in consequence of the great cheepness; which determination was in like manner to be published, and continued in force until a new regulation should be made; except the same should in the mean time be altered by the queen, her heirs or successors: provided always, that these precedents, &c., should not publish their determinations, until the same was first notified to, and approved by, the queen, or her privy council: and that the custom or poundage be paid upon exportation: provided likewise, that the queen, her heirs and successors, might at all times by proclamation, prohibit exportation, either generally from all the parts of the realm, or particular parts only.

Mr. Dirom supposes the corn trade, in this case, to have been considered in a scientific manner; and that if the plan marked out had been properly digested and modified, as well as the duties upon exportation removed, there could have been no doubt of the act producing the most beneficial consequences to the kingdom; but the judges, to whom this important business was intrusted, had no certain rule by which to direct their proceedings, not being permitted to determine, by the price of grain at the time of their annual inquiry, the only certain index of plenty or deficiency, but simply upon a conference with the people of the country, to decide whether it would be hurtful to the kingdom, from the dearth, or a great hindrance to tillage, from the too great cheepness, to admit the exportation of corn, than which, he thinks, nothing could be more vague and uncertain. But further that, "whatever consideration might have been given to the framing of this act, the laying a duty of twenty per cent. ad valorem upon grain to be exported by licence, and ten per cent. upon grain to be exported by the statute, was equal to prohibition, and gave full scope to the importation of foreign grain, which was still (he says) received without the payment of any duty."

However, "in Scotland, the prohibition to export grain to foreign parts was continued under severer penalties," as by Jas. 6. par. 11. c. 55.

Judging concerning the effects of the preceding law of England, from the prices of grain immediately subsequent to it; they do not seem to have been favourable, as the price of the quarter of wheat in 1574 was 2l. 16s. equal to 5l. 15s. 8d. of present money; and in 1597 not lower than 3l. 4s. equal to 6l. 12s. 8d.

In 1593, the corn laws seem to have again undergone a fort of revision, though the reason is not by any means explained; but they are taken notice of in an act, the 35 Eliz. c. 7, made for the adjusting of other acts, and which is entitled, "An Act for reviving, continuance, explanation, and perfecting of divers Statutes," by which it would seem, that the absurd and impracticable scheme of forcing the people to labour or cultivate their land, whether they could live by such means or not, had been given up; as the act passed in the 5th of the present reign was now repealed, and the plan laid down by that of the 13th appears likewise, from other circumstances, to have been relinquished, though the act itself is neither mentioned nor repealed, as the resolutions of the legislature are found to be changed by the 23d section of the present act: by which exportation was permitted, when wheat was at 20s. the quarter (equal to 2l. 1s. 4d. of present money); rye, peas, & beans, at 13s. 4d. (1l. 7s. 8d.); and barley and malt at 12s. (1l. 4s. 10d.); which are exactly double the prices at which exportation was permitted by the former law of the 5th. However, at the same time, the duties payable upon corn, exported by force of the statute, were doubled; which, together with an unlimited importation, without the payment of any duty whatever, amounted to a prohibition, and consequently rendered the act nugatory, keeping the price of grain at an extravagant height; as, in 1594, the quarter of wheat sold at 2l. 16s., equal to 5l. 15s. 8d.; in 1595, at 2l. 13s. 4d., equal to 5l. 10s. 2d.; in 1596, at 4l., equal to 8l. 15s. 4d.; and in 1597, at 4l. 12s., equal to 9l. 10s. of present money.

The laws concerning grain continued, however, in this situation till 1604, when, on the accession of James I. to the crown, various statutes were revived; some continued, and others repealed, without any specific reason being given; and one was enacted in respect to grain, the 2 Ja. I. c. 25. § 26. 27. by which the exportation prices were considerably increased; namely, when the quarter of wheat was at 26s. 8d. (equal to 2l. 13s. 4d. of present money); the quarter of rye, peas, and beans, 15s. (1l. 10s.); the quarter of barley and malt, 14s. (1l. 8s.); provided the grain was carried abroad in ships belonging to English born subjects; referring to the king, his heirs, and successors, the power to restrain, by proclamation, the exportation from the realm in general, or from particular places. But from exportation being full, under this act, encumbered with duties, it is obvious that the complete operation of it must have been greatly retarded or prevented.

And in another reviving act of the same reign, 21 Ja. I. c. 28. § 3. 4. in the sections relating to grain, the exportation prices were still further extended, under similar terms with the former act; namely, the quarter of wheat at 32s., the quarter of rye at 20s., the quarter of peas and beans at 16s., and the quarter of barley and malt at 16s., of current English money. This extent of 32s. for wheat was equal to 3l. 4s. of present money; 20s. for rye, to 2l.; and 16s. for barley and malt, peas and beans, to 1l. 12s.: which different sums are nearly double the medium prices of the present time, consequently very great, having obviously the extension of revenue in view. Besides this, the penalties for ingrossing were obviated by this act, while the prices of grain did not exceed those stated in it, which was become essentially necessary, in order to restore the internal as well as external trade in corn, which they had nearly kept up a flnop to.

But the duties upon exportation having still been kept up, the proper effects of the law could not be produced.

In 1627, not long after the accession of Charles I., it was again renewed in exactly the fame terms. 3 Cha. I. c. 5. § 24. 25. It is, however, remarked by Mr. Dirom, that "although the export prices were literally the same, they were very different in fact; for, in the year 1624, the yearly interest of money having been reduced from 10 to 8 per cent., 32s. for a quarter of wheat, which, in 1623, was equal to 3l. 4s., was, in 1627, equal to only 2l. 11s. 2d. of present money," and so in proportion, in respect to the prices of other grain. It is conceived that the long interval of parliament, after the feSSION in which this act passed, and the confusion which quickly succeeded the proceeding of the following parliament, in 1640, were probably the causes of no farther attention having been had to the business during the remainder of the reign.

Though, from the unfortunate circumstance of connecting the corn laws with the revenue, the excellent inquisitions of the reign of Elizabeth, and those of her two immediate succe:sors, had in a great degree been frustrated, agriculture had, in other respects, been treated by the laws as an object of much importance; not merely in the view of the numbers employed
employed in it, or the intrinsic value of the produce which it afforded, but likewise in consequence of the support which would be given to the navy, from the export trade, arising from it. On the reformation of Charles II., however, it was inconsiderately abandoned, being treated merely as an object of revenue.

In the year 1660, without the least reason being stated for any alteration in the corn laws, in a fiction of the act of tonnage and poundage, 12 Ch. 11. c. 4. § 11, corn is considered in the same list or roll with other articles, on which duties are made payable. The exportation prices of grain were still more extended; but the duties were raised so high, as to be equal to a prohibition. Importation was also permitted; but the duties here likewise operated as a prohibition. The prices set for the exportation of wheat being 40s., equal to 2l. 8s. of present money; 23s. for the quarter of rye, peafe, and beans, equal to 1l. 6s. 10d.; 20s. for the quarter of barley and malt, equal to 1l. 4s. 1d. and 16s. for the quarter of oats, equal to 16s. 2d. And further by this act, the duties payable on exportation were 20s. for the quarter of wheat, equal to 1l. 4s.; 10s. for the quarter of rye, peafe, beans, barley, malt, and buck wheat, equal to 1l. 2s.; and 6s. 8d. for the quarter of oats, equal to 8s. And by the same act, the rates inward, on duties on importation, were thus regulated: for the quarter of wheat, when the price, at the place of importation, did not exceed 4l., equal to 2l. 10s. 10d., the sum of 2l., equal to 2l. 8s.; and when it exceeded that price, 6s. 8d., equal to 8s. of present money. For the quarter of rye, when not exceeding in price as above, 36s., equal to 2l. 3s. 2d., the sum of 1l. 6s. 8d., equal to 1l. 12s.; and when it exceeded that price, 5s., equal to 6s. of present money. For the quarter of peafe, beans, barley, and malt, not exceeding in price as above, 1l. 6s. 8d., equal to 1l. 12s., the sum of 1l. 6s. 8d., equal to 1l. 12s.; and when it exceeded that price, 5s., equal to 6s. of present money. Consequently, Mr. Dirom observes, that until the price of wheat for quarter was higher than 2l. 12s. 10d. of present money, and that of other grain in proportion, from the importation high duties acting as a prohibition, and exportation, being in fact prohibited, prices would quickly rise, and bring the country to import at the low duties; a circumstance which, he says, accordingly happened: "for, in 1660, the quarter of wheat sold at 2l. 16s. 6d., equal to 3l. 7s. 6d. of present money;" "in 1661, it rose to 3l. 10s., equal to 4l. 4s. 1d.; and in 1662, to 3l. 14s., equal to 4l. 8s. 10d. of present money." He adds, that these laws, in addition to their having raised the price of grain to an "extravagant height, had ruined many of the farmers," and that agriculture declined, a great part of the lands lying without tillage or cultivation.

In consequence of this, the corn laws were again taken into consideration in 1663, the preamble to the act concerning which, 15 Ch. 11. c. 5. § 1, 2, 3, 4, sufficiently shews the deplorable state into which husbandry had fallen; and it would seem that the legislature was now seriously anxious to afford it encouragement. By this law, the exportation prices were extended beyond their former limits: that of the quarter of wheat being fixed at 43s., equal to 2l. 17s. 7d. of present money; the quarter of buck wheat, barley, or malt, 28s., equal to 1l. 13s. 7d.; the quarter of oats, 17s. 4d., equal to 16s.; the quarter of rye, peafe, and beans, 32s., equal to 1l. 18s. 5d. current English money: but the exported grain being still suffered to continue loaded with nearly 50 per cent. of duties, it operated as a prohibition.

Vol. IX.
paffed, entitled, "An Act for Improvement of Tillage, and the Breed of Cattle, for the common Good and Welfare of the Kingdom," it was enacted as lawful for every person, native or foreigner, to transport, at any time, as merchantize, all sorts of corn, although the prices exceeded the rates in the act of the 15th of the present reign; paying for the same the rates expressed in the act of tonnage and poundage. And that in cases where the prices of grain, at the places of importation, should not exceed the rates, as follows; there should be paid for custom these rates, namely, for every quarter of wheat, when the same should not exceed 53s. 4d., equal to 5l. 4s. of present money, the sum of 16s., equal to 1g. 2d.; when the same should exceed 53s. 4d., and not exceed 4l., equal to 4l. 16s., there should be paid 8s., equal to 9s. 7d.; for every quarter of rye, when the same did not exceed 40l., equal to 2l. 8s., the sum of 16s., equal to 1g. 2d.; for every quarter of barley, malt, or buck wheat, when the same did not exceed 32s., equal to 1l. 8s. 5d., the sum of 16s., equal to 1g. 2d.; and for every quarter of oats, when the same did not exceed 16s., equal to 1g. 2d., the sum of 5s. 4d., equal to 6s. 5d., and for every quarter of pease and beans, when the same did not exceed 40l., equal to 2l. 8s., the sum of 16s., equal to 1g. 2d. And that when the prices of corn should exceed the aforesaid rates, there should be paid the former custom and poundage: imagined to have been intended to be, by the act of 1663; 5s. 4d., equal to 6s. 5d., for wheat; 4s. 10d., equal to 4s. 10d., for rye, pease, and beans; 2s. 8d., equal to 3s. 2d., for barley and malt; and 1s. 4d., equal to 1s. 6d., for oats. 2 Charles II. c. 13. § 1. 2.

The above mentioned writer supposes that this law was without doubt designed to promote the exportation of English corn, and to restrain, if not prohibit, the importation of grain from abroad; but that the former was completely prevented, from the high duties continued upon it; and that the latter was rendered nugatory, in consequence of no rule being laid down for ascertaining the price of grain, at the time or place of importation: of course the trade continued to be carried on, on the payment of the low duties; agriculture languished; the dealers finding their account in feeding the populace with foreign grain, the prices of course keeping high: the average price of the quarter of wheat, for the ten years preceding this period, having been 2l. 8s. 10d., equal to 2l. 18s. 8d. of present money. It is suggested that by these laws the poorer sort of farmers became ruined, and the richer were weakened, being necessitated to turn their attention from corn to live stock, or any other objects by which they could support their families: the price of corn consequently rose on the manufacturer and labourer; and the importer of foreign grain became an important man, upon the ruins of the landholders, farmers, and others.

Notwithstanding this, the rest of this thoughtless and inattentive reign passed away without any alteration being made, though it continued for a period of fifteen years afterwards. Grain, of course, kept high in price: the average of the quarter of wheat, for the twenty years, from 1660 to 1680, having been 2l. 9s. 6d., equal to 2l. 19s. 9d. of the present money.

In 1685, on the accession of James II., the evasion of the duties payable on imported corn, and the distress caused by the vast importation of grain from abroad, were brought under the consideration of the legislature; and another act for the improvement of tillage passed; 1 Ja. II. c. 19, by which the defect of the above law was endeavoured to be obviated: it being there referred to the justices of the peace, in the several counties of England, where foreign grain might be imported, at their quarter sessions, after Michaelmas and Easter, on the oaths of two or more substantial persons, neither being merchants nor factors for the importation of corn, nor anywise concerned or interested in the corn to be imported, and each having a free estate of 20l. per annum, or a leafhold of 50l. per annum, to determine the prices of the several kinds of grain, which they were to certify to the principal officer of the customs in the several counties, for his rule and regulation.

The importation of victual from Ireland had been prohibited in Scotland, under very severe penalties, Char. II. par. 2. sess. 3. c. 3; only referring to the lords of the privy council power to admit of it, for such times as they should think proper, when the price within the kingdom should be at or above 8l. Scots, equal to 16s. of present money, for bear and meal; and 10l., equal to 20s., for wheat per boll. But in this year, 1686, by the act of Ja. VII. par. 1. sess. 3. c. 14, a total prohibition was enforced; all victual which should then be imported, being directed to be sunk or destroyed.

It is remarked by the writer we have quoted above, that for the ten years from 1650 to 1660, the average price of the quarter of wheat in this country had been 2l. 9s. 6d., equal to 2l. 19s. 5d. of present money; that from the latter period to 1670, it had been 2l. 8s. 10d., equal to 2l. 18s. 8d.; from this last period to 1685, it had been 2l. 10s. 8d., equal to 3l. 3s. 10d.; and that from 1683 to 1685 inclusive, it had been 2l. 4s. 3d., equal to 2l. 13s. 1d.

But the unfavourable tendency of the above system of corn laws is more fully shewn by the scale of prices, fixed by them for the exportation and importation of wheat, in the following tables, from 1560 to 1688, as taken from the above excellent work.

</table>

It is considered by Mr. Dirom as extraordinary, that the advantage which must necessarily accrue to a nation from raising the utmost possible quantity of corn, and exporting such portions of it as the consumption at home does not demand, should, for such a great length of time, have been misunderstood in this country; especially since the example of the neighbouring states, constantly bartering their excessive stock of this article for the raw materials and money of the kingdom, could scarcely have escaped notice for such a number of centuries. The importation trade is considered as operating, in various ways, in direct opposition to the benefit of the country; in consequence of which, agriculture became in a declining state; much of the ground was without cultivation; there was a decrease in the population, a proportionate reduction in the public revenue necessarily took place; and the number of remaining manufacturers were of course fed at an exorbitant price, by the products of foreign lands, the inhabitants of which were not unfrequently at enmity with us, but who drew vast sums from the country, and thus robbed it of its riches.

But we now approach a period in which a different system was acted upon, and in which a very material change took place in the laws respecting corn; but which was not accomplished by simply revising or amending the old acts, or by merely reducing the duties upon exported grain, but by at once giving up every idea of revenue from grain raised at home; and thus hesitating a new system which should invigorate and encourage the cultivation of the soil, while it afforded a new stimulus to the trade and navigation of the country.

In 1688, not long after the accession of William and Mary to the crown, the subsequent important act for encouraging the exportation of corn was passed, 1 Will. & Mary, c. 12, and ibid. c. 24, § 18, by which exportation was permitted from
CORN.

from England, when the prices at home did not exceed the following rates: malt or barley, 2s. 4d. the quarter, Winchester measure, equal to 28s. 10d. of present money; rye, 3s. 2d., equal to 38s. 5d. per quarter; and wheat, 4s., equal to 2l. 17s. 7d. the quarter; provided it was made in English shipping, and the master and two-thirds of the mariners, at half, being subjects of that state, and the exporter producing a certificate under his hand, of the quantity of grain shipped, to the collector of the customs at the port where the grain had been shipped, and proving the said certificate by the oaths of one or more credible persons; and upon bond, of at least 200l. for every 100 tons of corn, that the said grain should be exported to parts beyond the seas, and not again re-landed, the exporter should receive the following bounties: for every quarter of barley or malt, ground or unground, 2s. 6d., equal to 5s. of present money; for every quarter of rye, ground or unground, 2s. 6d., equal to 4s. 2d.; for every quarter of wheat, ground or unground, 5s., equal to 6s., and on producing a certificate, under the common seal of the chief magistrate in any places beyond the seas, or under the hands and seals of two known English merchants, that such corn had been actually landed; or upon proof, by credible persons, that such corn had been taken by enemies, or perished on the seas, the exporter's bond was to be given up; and the money, paid by the collector or commissioner of the customs, to pass in his account.

And the same system of policy was adopted soon afterwards in Scotland in 1695, by an act Will. par. r. c. 32, in which all export duties were taken off, and a bounty of eight marks granted upon ilk chalder of corn exported, when the prices did not exceed the following: wheat twelve pounds the boll equal to 1l. 42s. 4d.; bear, barley, or malt, eight pounds, equal to 16s. the boll; peas, oats, and meal, six pounds, equal to 12s. the boll; the whole being of Linlithgow measure, provided that the exportation was made in Scotch ships and by Scotchmen, the malt or ground three-fourths of the leamen being Scotchmen, power however being referred to the lords of the secret council, when the prices exceeded the fixed rates, to discharge and discontinue exportation.

The duties and subsidies payable upon exported corn from England, not having been given up by the former act, they were now, 1700, finally removed and taken away by another act, 11 and 12 Will. III. c. 20. § 4., whether upon ground or unground grain.

By this means what has been termed a new system of corn laws, was finally established in both this country and Scotland, and the act of Union taking place soon afterwards, 1706, their laws concerning grain were made alike. That when oats shall be sold at 1l. 12s. 6d. per running hundred, or for the average of the oatmeal within the last quarter, the grain or malt, at the rate of 1s. for every quarter of the oatmeal, to long as a duty is not paid, or as a bounty is not granted for exportation of other grains; and that the barley of Scotland have the same reward as barley.

It has already been seen that the prices and duties of corn imported, had been determined by the act of 1690, that for want of a new act for ascertaining the prices at the times and places of importation, the duties were evaded. The act of 1688, was to supply this defect; it enjoined and required the justices of peace of the several counties, at their respective quarter sessions, to inquire into and determine the prices of grain at fixed periods, and to send certificates thereof to the several customs houses within their jurisdiction, to be there hung up in a public place for the rule and direction of the parties concerned. But in consequence of neither the trouble of its execution being compensated, nor the neglect of it punished, it was in many places unattended to; and from no mode or rule having been substituted, in such an event, the defect was laid hold of by the importer, and much foreign grain was imported without payment of the duties during 1728 and 1729. And difficulties had likewise been met with from the modes employed in ascertaining the prices and quantities of grain exported.

There being, therefore, in different places a great neglect in the justices of peace, to determine the prices of grain, by which the duties on imported corn were to be regulated, the matter was now, 1729, taken up, and they were directed to do it in future, in their respective counties, at their next quarter sessions, or any adjournment, according to the act of 1670, and that on their omitting or neglecting to do it, and to certify the same, the collectors of the customs at the respective places of importation, were empowered to demand and receive the duties according to the lowest price of the several ports of corn mentioned in the last named act.

And to ascertain the quantity of grain shipped, for which a bounty was to be paid, in a better manner, the proper officers of the customs were directed to admeasure the same, by a tub, or measure, containing four Winchester bushels; and when such corn to be exported was brought to be shipped off in facks, they were empowered to make choice of any two of them out of twenty, and in that way compute the quantity to be shipped, on which the bounty was to be paid. And that the same powers should be employed in ascertaining the prices and quantity of bear, biggs, oatmeal, and malt, made from wheat or wheat malt, for being exported, s Geo. ii. c. 18. § 1, 2, 3, 4, 5. That in all such cases, as where any corn or grain had been imported since the first day of the Michaelmas quarter session, then last past, where the importers or proprietors had omitted to pay the respective duties on the same, they should forfeit and lose such grain, or the value of it.

Notwithstanding this, neglects still frequently occurred in determining the prices of grain, according to which the duties payable on importation were to be levied, and of course the means were afforded of much foreign grain being brought in, though the prices at home were very low; consequently another act was now, 1733, passed, for the better ascertaining the same, and preventing fraudulent importation, in which it was again recommended to the justices of peace, at their quarter sessions, in the several counties where foreign grain should or might be imported, to give in charge, to the grand jury, in the open court, to make inquiry and preferment, upon their oaths, of the common corn market prices, of middling English corn and grain, of the respective ports and quantities mentioned in the act, made in the 21st year of the reign of king Charles ii., as the same should be commonly bought and sold, in every such county, which preference should be certified by the said parties, in writing, to his majesty's chief officer and collector of the customs for the time being, at every such port, place, or haven, where importation should be made, and which should be hung up in some public place in the custom house, for general information and instruction: and that the custom duty upon foreign grain imported, as directed by the above act of Charles ii., should be collected and paid, according to the prices contained in such certificate. But that after importation, no foreign corn or grain was to be exported, or in any manner or shape laden on ship board, or put to sea, for carrying, conveying, or transporting it from one part or port of the kingdom to another, either by itself or in mixture with English corn, under the very severe penalties and forfeitures therein mentioned.

5 Geo. ii. c. 12.
CORN.

It is rated by Mr. Diron, in his very able "Inquiry into the Corn Laws and Corn Trade," that at this period agriculture had considerably recovered its strength, and that the exertions of the farmers had become vigorous and constant. That the prices of corn for several years preceding it had been very reasonable, and that a great export trade in corn had been carried on from this country; proper attention having been paid to the execution of these laws which were made to guard against fraudulent importations: the average price of the quarter of wheat, for the five years from 1731 to 1735 inclusive, being only 34s.; in 1736, 40s.; in 1737, 38s.; and in this year 1738, only 35s. 6d. Yet under these plentiful circumstances, the lower orders of the populace were excited to commit various outrages, by which the corn was destroyed. Therefore, in order to repress such disorders, an act was passed, 11 Geo. c. 23, by which such offenders were severely punished, and the inhabitants of the hundreds, in which such outrages should be committed, subjected to the payment of the damages.

The power of suspending the laws, in Scotland, which were made to prohibit the importation of foreign grain, or to buy, sell, or retail the same, which had rested on the act of 1703, and the two preceding ones therein referred to, having been formerly vested in the privy council of that kingdom; in consequence of the prices of grain having risen in 1740, from the severity of the winter, and some importation of foreign grain made contrary to law, from there existing no power of suspending the prohibitory acts there, on account of the act of the fifth Anne, c. 6, having done away the privy council, a temporary expedient without any new plan was now, 1741, had recourse to, and a law made, which transferred such power to the courts of Fustian, judiciary, and exchequer; the judges in these courts being required to determine on the necessity of exportation or importation, from the prices of grain in the county of Edinburgh. The duties payable in England by the act of the 22 Charles II. being required by the same law to be paid on the importation of grain into Scotland; the whole of the clauses and provisions of that act, as well as of that of the 2 George II., termed "An act to ascertain the custom payable on corn imported, being extended to Scotland."

Difficulties having arisen concerning the computation and measurement of wheat, meal, and other ground corn, on which a bounty was payable upon exportation, in order to adjust all differences arising thereon, by a law now (1751) made, the officers of the customs were empowered to allow the same bounty on the exportation of 234 pounds weight of wheat meal, or other ground corn or grain, as was allowed upon the exportation of four bushels of wheat, or other corn or grain, unground; and for the more effectually expediting the business, they were permitted to make choice of any two sacks out of twenty, from which to compute the weight.

24 Geo. II. c. 56. § 1.

These laws had greatly contributed to the extention of the export trade in grain, while plenty continued at home, with moderate prices. It is stated, that the average exportation of four years, from 1748 to 1751 inclusive, was 1,212,686 quarters annually; and that the average price of wheat, for the same four years, was 36s. 3d. the quarter.

From the money, applicable to the payment of the bounty, becoming inadequate to the discharge of the sums due on such extensive exportations, an act was now (1753) passed, 26 Geo. II. c. 15, by which the debentures, for the bounties on exported corn, were to carry an interest, when not paid within six months, at the rate of 3 per cent. per annum, according to the regulations of the act of the 12 and 13 of King William.

The crop of 1756 being defective and the prices of coarse rising, the populace from being long in the habits of plenty, mistaking the cause, committed various outrages in different places. And a law was brought forward in 1757; 30 Geo. II. c. 1, by which all sorts of corn, meal, malt, flour, bread, biscuit, or flarch, were prohibited exportation, before the 21st December 1757, except malt made to be exported, and declared to be to before the 21st December 1756, ships cleared out with it before the 25th being sufferd to proceed on their voyages: power was however referred to the king to remove the prohibition by proclamation, and to admit all persons, natives as well as foreigners, but no particular person or persons, to export grain. All duties, customes, rates, and impositions of every kind, on corn or flour, imported, or taken from the enemy and brought into the kingdom, were discontinued until the 24th of August 1757; and the same might be married coalways free of duty, 30 Geo. II. c. 7, and importation without duty was permitted also in ships of other friendly nations from any port or place whatever, 30 Geo. II. c. 9. § 14. After 11th March 1757, the distillation of low wines and spirits from any wheat, barley, malt, or any other sort of grain, or from any meal or flour, was prohibited during the space of two months, 30 Geo. II. c. 10; and it was afterwards continued to the 11th December in the same year; but with power to the king to suspend the act and permit it, by proclamation or an order of council, 30 Geo. II. c. 11.

By these laws and regulations, the exportation of corn is flated to have been completely checked, the quantity of about 80,000 quarters having been exported, previously to the prohibition, and about 150,000 quarters of foreign grain brought in.

There was however a restoration of the exportation trade in 1759, it proceeding as usual, with but little importation of foreign corn, but in consequence of the crop of 1762, being a little defective, importation took place from the rise of prices, which at the low duties was capable of being done, and of course was considerable, during that and the three years which followed it. During the last, from some cause of fear, an embargo was laid upon all ships laden with corn for exportation, the 26th of September, but which having been done contrary to law, it was necessary to pass an act of indemnity for it in the following year 1766, the 7 Geo. III. c. 7. On this is it remarked by the writer quoted above that there does not now seem to have been any sufficient ground for those measures; as in the year flated there were more than 300,000 quarters of grain exported, and under 250,000 imported.

In 1767, prohibitory laws were passed for a limited period, for the prevention of the exportation of corn, grain, meal, flour, bread, biscuit, and flarch, as well as the extraction of low wines, and spirits from wheat and wheat flour. Also a law for permitting, for a limited time, the importation of wheat and wheat flour, oats, and oatmeal, rye, and ryemeal without duty. 7 Geo. III. c. 3. 4. 5. 8. And in 1768 the same laws were renewed, having some additions made to them; it being now enacted that they should continue in force until twenty days after the beginning of the next session of parliament, or the exportation of the above different articles, as well as their distillation and preparation from wheat or wheat flour, was prohibited, except to particular British dependencies. And the importation both of wheat, wheat flour, barley, barleymeal, pulse, oats, oatmeal, rye, ryemeal, from any part of Europe, and maize or Indian corn and rice from North America, as well as wheat and wheat flour from Africa, were allowed without any duty. 8 Geo. III. c. 1, 2, 3. And in 1769, the prohibition was
CORN.

was continued until twenty days after the meeting of the next session of parliament, but the importation of rice from North America permitted duty free.

But in 1770 the former law of the preceding year, prohibiting the exportation of corn, grain, meal, malt, flour, bread, biscuit, and flax, and also the exportation of low wines and spirits from wheat or wheat flour, was continued in force until twenty days after the commencement of the ensuing session of parliament, provided that the said continuation might be abridged, and this act, or any part of it, altered and varied by any other act or acts to be enacted in the present session. 10 Geo. III. c. 1. Consequently by another law of this session, those parts of the former act, which prohibited the exportation of malt, were repealed. 10 Geo. III. c. 10. And an act was likewise passed for registering the prices at which corn was sold in the several counties of Great Britain, as well as the quantity exported and imported. 10 Geo. III. c. 39. And in 1771 prohibitory laws against the exportation and extraction of the above different articles were again passed, 11 Geo. III. c. 1. (with the exception of virtualing ships, on their being sent to British dependencies) to be in force till the twentieth day after the meeting of the next session of parliament. On the meeting of the session of parliament in the following year (1772), a prohibitory law was again passed, against the exportation and extraction of the above articles, to be in force till the twentieth day after the meeting of the next session of parliament. Afterwards an act was likewise passed, permitting the importation of wheat, wheat flour, rye, rye meal, and Indian corn, without duty, until the first day of December in the same year.

It is considered by the able inquirer into the corn laws and corn trade mentioned above, that all this would seem to have been recourrece to without any sufficient grounds, as the price of grain was not by any means very high, and the quantity exported from the year 1760 to 1770 greatly exceeded that which was imported.

On the meeting of parliament in 1773, an act was, however, passed, by which a free importation was permitted before the first day of January in the following year, for any wheat, wheat flour, rye, rye meal, barley, barley meal, oats, oat flours, peas, beans, tares, and all other sorts of pulse, from any part of Europe or Africa; and permission to carry the same coastways, under similar regulations to those of wheat or wheat flour the growth of this country, provided due entries were made according to the previous practice of the kingdom; and likewise for the free importation of wheat, wheat flour, Indian corn and meal, biscuit, pease, beans, tares, and all other sorts of pulse, from North America, under the same regulations. And another prohibitory law was enacted, 13 Geo. III. c. 3, 25, preventing the exportation and extraction of all the above named articles, wines and spirits, except for virtualing ships, or to British dependencies, until the first day of January 1774.

These laws, though radically injurious to the agriculture of the country, are conceived by Mr. Dirom, from their not trenching on the general system, as only productive of a temporary effect which might have been overcome.

By another law of the same year 1773, the 13 Geo. III. c. 40, such alterations and changes were however made, by the reduction of the export and import prices, and the rendering the duties on importation a mere tax, that a new system seems to have been introduced and established in the corn laws, destructive of the old code by which such benefits had accrued to the agriculture and commercial industry of the country; and by which, besides producing plenty and reasonable prices at home, by the disposal of the excescent flock in foreign markets, vast sums of money had been brought into the kingdom. The manner in which that useful code had been gradually raised, formed, and matured by experience, through a vast length of time, and finally established by the laws of 1670, 1688, and 1706, has been amply shown in the preceding part. But in order to place the different systems in a better point of contrast, and thereby afford a more distinct notion of their nature and principles, the excellent comparative tables introduced below, have been drawn from Mr. Dirom's "Inquiry into the Corn Laws, &c."

It is remarked by the able writer, in respect to these tables, that, according to the old laws, but especially that of 1670, importation was not allowed till the prices at home were very high, and then even the duties were great, in consequence of which, foreign corn could be only introduced for the supply of times of scarcity, never being able to come in competition with the home produce. That, the law of 1688 did not even notice importation; it being solely enacted for the purpose of promoting and encouraging the agriculture of the country, by affording a new market for the superabundant grain, and in that way giving a new stimulus to the exertion of the people, to bring the waste and barren lands into a state of profitable cultivation: The buñifers of importation being left to the laws which previously existed, by which it was supposed to be sufficiently restricted, if not wholly prohibited.

It is further, that at the time those laws were passed, and till 1714, the interest, borne by money, was 6 per centum per annum, being of course proportionally of greater value than at present, when the interest is only 5 per cent per annum. Besides, the old acts did not, in fact, admit the importation of flour or ground corn at any period; only the grain at certain places, where the prices should happen to be very high. Neither did they allow the carrying of imported grain by sea, coastways, or the transporting of it to any other place, except that to which necessity had brought it; restrictions which seemed so essential as to require being enforced, under very severe penalties, by the act of the 5th of George II.

But that the new law, or that of 1773, commences with importation, and directs that, at any time when the price of the middling sort of British grain shall be at the prices stated in the above tables, at the several ports and places where the same should be imported; then all corns and duties, formerly payable on wheat, wheat flour, rye, peas, beans, barley, bear, bigg, and oats, imported into the kingdom, should cease; and be no longer payable, while these prices continued. That, instead of the former duties, those stated in the above table, should only be paid. It was likewise enacted, that the importation of oatmeal from Ireland, or any other part beyond the seas, into any port or place in Scotland, should be lawful, where the price of oatmeal exceeds 13s. the boll of 8 stone, troy weight.

Further, that by the new law importation is admitted, when the prices of grain at home are at such a reduced rate, as that foreign corn may always come in competition with the home produce in the markets, an evil that has constantly existed since the passing of the act; besides, by this law, wheat and other grain imported, may be conveyed coastways, and entered and landed in any other parts of the kingdom, at which the prices of middling British corn, grain, or flour, are at or above the respective rates stated in the table given above, under such regulations as wheat, wheat flour, rye, peas, beans, barley, bear, bigg, or oats, the growth of this kingdom, are permitted to be conveyed coastwise. Also, that on importing corn, grain, or flour, and paying the duties, where the same shall be again exported within six months, the duties were to be drawn back and repaid.

<td></td>
<td>2 s. 2 d.</td>
</tr>
</tbody>
</table>

The provisions of the old laws of 1688 and 1706, have been already so fully stated and considered, that nothing further than what is contained in the above table seems requisite here.

Under the new law it was enacted, that, when the price of the quarter of wheat was at, or above, 44s.; rye, peas, and beans, 28s.; barley, bear, and bigg, 22s.; and oats, 14s., no such corn or grain should be transported or conveyed out of the kingdom, under severe penalties. That after the 1st day of January 1774, the bounties formerly allowed by law upon grain exported, should cease and determine; and that, in the place thereof, when the prices of it should be under the rates listed below, at the ports and places, whence the same should be shipped, there should be allowed, on the exportation of such grain, either ground or unground, being the growth of this kingdom, and shipped in British ships, the matter, and at least two-thirds of the mariners of such ships being subjects of his majesty, these bounties; that is to say, when the price of middling British wheat is per quarter under 44s., a bounty for every quarter of wheat, or malt made from it, 5s.; when the quarter of rye was under 28s., a bounty of 3s.; when the quarter of barley, bear, or bigg, was under 22s., a bounty of 2s. 6d. for every quarter of them, or of malt made from them, and when the quarter of oats was under 14s., a bounty of 2s. on every quarter, and 2s. 6d. upon every quarter of oatmeal, containing of 276 pounds avoidups weight.

Further, that, by the old laws, the justices of peace were to ascertain the prices at their quarter sessions, which, by the new law, was continued the same for England; but for Scotland it was transferred to the sheriffs of the different counties to be ascertained four times in every year, certificates of which were to be sent to the customs-houses within their jurisdiction respectively, so as to regulate the payment of the export and import bounties and duties.

However, so far as exportation was concerned, those rules were, in 1774, wholly altered, it being enacted, that the prices of exported corn, grain, and oatmeal should be regulated and directed according to the average prices, at which they should be respectively sold in the public market at or near to the port or place whence they should be intended to be exported, on the market day preceding that of their being shipped, and the bounties to be payable accordingly.

From the comparative statements given in the above tables, the difference in the principles and operations of these different systems of laws, will be easily understood, the former being calculated for the promotion of cultivation at home, and preventing the importation of foreign corn, unfees called for by necessity; while the latter is formed for the purpose of promoting the importation of grain from abroad, whether there may be any necessity for it or not. Thus the foreign cultivator is allowed the liberty of importing his corn into the country almost free from duty, while the bounty upon flour or meal produced from wheat is taken off.

But in order to expedite and render the conception of the various laws, which have been detailed above, more easy and familiar, we shall here introduce the tabular view of them given by the author of the " Inquiry into the Corn Laws and Corn Trade," as brought down to the year 1773.

As it would appear from what has been advanced in the preceding pages, that on the experience of a great length of time, it would seem that the laws and regulations in respect to grain, which were brought forward under the acts of 1670, 1688, 1706, and 1732, had considerable influence and effect in promoting the improvement of agriculture, increasing the quantity of corn, and thereby preventing the necessity of having recourse to importation for a precarious and uncertain supply; it may not only be proper to afford the following tabular view from the valuable work quoted above, of the prices, bounties, and duties, as laid down by them, by which their principles and objects may be more clearly comprehended, but also to contrast them with the regulations concerning those which have been enacted by the law of 1791.

N. B.—Flour, meal, and malt, are regulated in proportion to the several sorts of grain. The importation of malt is at all times prohibited.

* The bounty, by the tables in the act of parliament, appears to be given only upon rye, and not also upon the exportation of peas and beans.
CORN.

It has been observed on these tables, by Mr. Mackie, that though the import prices and duties are higher in a small degree in the latter, than was the case in the act of 1773, which is so far returning to the old system, yet that the encouragement held out to the husbandman is considerably less, than was the case under the ancient regulations. Without considering the difference in the value of money between the periods, it may be noticed, he says, that the bounty of 2s. on wheat, is now withdrawn when it reaches 42s., and exportation flopped when it advances to 46s. the quarter; while, by the old laws, exportation, with the bounty, was continued till the price reached 45s.

And importation, by this act, is permitted on low duties, when the price of wheat advances to 36s. 10d.; while, by the old acts, the duties were equal to a prohibition, until the price reached 4½, and even then, the duty was high, instead of being reduced to almost nothing, as is now the case, before wheat reaches a price capable of repaying the farmer in an unfavourable season. In fact, it is contended, that agriculture has derived little protection or support from the late laws, its continued prosperity depending rather on the impossibility of procuring adequate supplies of grain from abroad, by which the farmers in this country have, in a great degree, retained the monopoly of the markets, than the countenance it has received from the legislature.

Since the period already noticed, however, the above plan has been relinquished, and different changes and alterations have been made in the corn laws, by which it would seem that some parts of the old system have been again in some measure reverted to.

The act of 1773, by so greatly lowering the rates and duties on the importation of foreign grain, had contributed to fix and establish the import system, and speculation in corn, under the direction of the merchants, by which, from the prices of grain in the markets abroad, being commonly so much below those of this country, they were contantly ready, by some contrivance or other, to open the ports, before the price of the home grain in the markets, came to the rate at which foreign grain was permitted to be imported. It consequently became necessary, from time to time, to pass acts, in order to counteract such designs, and render the general law more efficient.

Accordingly, in 1781, an act was made, 21 Geo. III. c. 50, by which so much of the acts of the 7 Ja. II. 5 Geo. II. 6 Geo. III. and 14 Geo. III. as related to the ascertaining of the prices of medium English wheat, and other grain, in the port of London, and counties of Kent and Effex, was repealed; and, in the place of which, an inspector was appointed, to fix the weekly average prices, from the actual sales in the said port; by which exportation, and the bounties paid thereon, were to be regulated. But besides this, an average price is directed to be made up from the weekly returns of each three months, on the first day of the fictions held in London, in January, April, July, and September, for the purpose of regulating importation for three months, and the duty payable thereon, in the port of London, and the above-mentioned counties. And, in 1783, the law respecting corn was lupended, importation being permitted at law duties, and exportation prohibited, till the 27th August of the same year, in England, and the 25th of September in Scotland. 25 Geo. III. c. 1. 53. 81.

In 1789, an act was passed, 29 Geo. III. c. 38, for improving and extending the act of the 21 Geo. III. c. 50, by which every corn-factor in London, and the luburbs, was necessitated to give in weekly returns of his sales to the inspectors; and importation was permitted into London, Kent, and Effex, when the prices of middling British grain reached the rates fixed in the act of 1773, as formed from the six last weekly returns in the port of London, immediately preceding the quarterly sessions, with the exception of oats, which were formerly directed to be regulated by twelve weekly returns; the act being extended to the maritime counties of England, which were divided into eleven districts. The inspectors of corn returns, were to be appointed by the judges of peace in each county, and directed to make weekly returns of the prices of grain, from not more than twelve, or less than eight market towns in each county, the average prices, made from the weekly returns, being directed to be sent to the collectors of the ports in the district, for regulating exportation; and the average prices for the whole district, formed from the six weekly returns, immediately preceding the first day of February, of May, of August, and of November, were to regulate the importation of foreign grain and the duties paid thereon.

In 1790, an act of indemnity, 30 Geo. III. c. 1, was passed, for abrogating the corn laws, in pursuance of orders from the privy council of the 11th and 18th of November, 23d of December 1789, 2d and 5th of January 1790, by which the above orders are confirmed, and the laws respecting corn suspended; no fort of British grain being permitted to be exported, except the particular specified quantities for the use of the sugar colonies; but all kinds of foreign grain permitted to be brought freely into every port in the kingdom at the low duties; the act being to continue in full force, until the 29th of September in this year.

And, by the 30 Geo. III. c. 43, the execution of these laws was further suspended, until the 28th February 1791, full powers however being given to the privy council, to admit the exportation of all kinds of British grain, whenever it judged it necessary. Further, by the 31 Geo. III. c. 4, the two preceding acts were amended; and, by the introduction of a clause in the general corn law, passed this session, they were continued in full force until its commencement on the 15th of November 1791.

It is remarked by Mr. Mackie, in his "Letters on the Corn Laws," that none of these acts for rendering the law of 1773 more efficient, were extended to Scotland, the consequence of which was, that from the average prices not being fixed and determined by the actual sales, whenever the ports were opened for the importation of grain from abroad into it, it contently took place, when the current price of produce there was greatly under the reduced rates at which that act even admitted the importation of foreign corn; namely, wheat at 48s. the quarter, Winchester measure, &c. And that, on the contrary, when the overplus quantity of corn was in such abundance, as to permit exportation, the ports there were constantly shut, before the price of the home produce reached the limit at which exportation ceases; both of which causes operate unfavourably for the agriculture of the country.

In 1791, an act for a new general corn law was passed, 31 Geo. III. c. 38, commencing on the 15th of November of the same year, by which the 1 Ja. II. c. 19. 7 Geo. II. c. 12. 7 Geo. III. c. 39.; 13 Geo. III. c. 43.; 21 Geo. III. c. 50. and 79 Geo. III. c. 58.; and so much of the 15 Cha. II. c. 7, as prohibits the buying of corn to fell again, and laying it up in granaries, when above certain prices, were repealed. By
By this act, the maritime counties of England are divided into twelve districts, and Scotland into four districts, making sixteen in the whole. The prices of grain at the corn exchange in London, being made to regulate the exports and imports of the first district, which comprehends the ports of that city, together with the counties of Kent, Essex, and Suffolk. And, in the other districts, the particular market towns, at which the prices and quantities of grain actually sold are collected, are stated in the act. The dealers in grain are directed to give in, on oath, weekly accounts of their actual sales for that time, to the officer termed the inspector of returns, who, from such returns, is to make out an account of the general weekly average price of the whole district, which is to be transmitted to the collectors of the counties at the different ports within the said district, by which the bounties payable on exportation are to be regulated.

And, at four different times in the year, as within the space of seven days after the 1st of February, 15th of May, 15th of August, and the 15th of November, the receivers of corn returns in each district, are to make up the average prices of corn within the same, from the last six weekly returns thereof, with the exception of oats, which is to be made up from twelve weekly returns, this quarterly average being sent to the collectors of the counties at the different ports within the said district, at such periods as mentioned above, by which importation, and the duties payable thereon, are to be regulated for the following quarter.

But, in Scotland, the average prices of grain are not ascertained for the same purposes. The sheriffs of the different counties, once in the month, convene juries for fixing the average price at which it is usually selling, but the witnesses brought forward produce no account of their actual purchases or sales, only depending on what they believe from their own experience, and the opinion of others, to be the current prices. Monthly accounts of the average prices of grain within each county, are made from the sheriffs, by the sheriffs of the different counties, which are sent up to the receiver of corn returns in the port of London, from which the receiver is to make up an average account for each district, and transmit it to the collectors of the ports within the same, which is to regulate the bounties upon exportation; and, at the above-named quarterly periods, he is to make up the average prices from the last six monthly returns, which are to regulate the duties payable upon importation for the following quarter.

But corn from abroad may be imported and landed at any time without payment of duties, provided it be warehoused under certain regulations, but cannot be taken out of the warehouse for home consumption, until the low duties are paid, and such other duties as are payable at the time, in the district where intended to be used; nor can corn of either foreign or home produce be conveyed coasts away from the port of any district, where exportation is not permitted, at the time of shipping, to the ports of any district in which exportation is permitted.

And when the general average of the whole country exceeds the rates of import at the low duties, his majesty, in such case, the parliament not being sitting, can, with the consent of the privy council, suspend the execution of the act so far as to prohibit exportation wholly, and permit importation at the low duties, such permission continuing in force three months; but this power does not extend to prohibiting the exportation of foreign grain warehoused before.

Since the above act, other laws have been made for the further regulation of the trade in grain. In 1793, an act of indemnity was passed, the 35 Geo. III. c. 3, for putting a stop to the execution of the general corn law, by an order of council of the 5th of November 1792, prohibiting the exportation of home produce, and granting liberty to import corn from abroad, until the 1st of March 1793; and for further suspending the said law, by granting power to his majesty and council at any time during the sitting of the parliament, to permit importation and prohibit exportation.

And by the 33 Geo. III. c. 63, the general corn law of 1791 was altered, by the repeal of the clauses for ascertaining the average prices of corn in England, and substituting others of a similar tendency in their stead. And further, by granting liberty to his majesty and council, when parliament is not sitting, to permit the importation of grain, and prohibit the exportation of home produce, when the general average of the whole kingdom exceeds the prices at which grain can be imported at the low duties from Ireland and the colonies of North America, namely, wheat, 49s. rye, 32s. barley, 21s. oats, 15s. Likewise, by allowing exportation with a bounty of 1s. 6d. when oatmeal is under 17s. per holl; prohibiting exportation to foreign countries, when above 14s. the holl.

The law of 1795, the 35 Geo. III. c. 4, passed the 17th February, suspends the general corn law of 1791, by giving power to his majesty, with the consent of the privy council, to prohibit the exportation and permit the importation of all sorts of grain from abroad, without the payment of any duties whatsoever. The act to be in force until six weeks after the next parliament has met.

In consequence of a report of a committee of the house of commons, made in 1804, on which it appeared, that the price of corn from 1791 to the 1st of 1803, though very irregular, and increased on the average greatly by the years of scarcity, has in common afforded a fair profit to the grower; but that, from the diminution of the usual high prices having increased industry, by which large tracts of waste land have been brought into cultivation, which, joined to the two last productive seasons, and other causes, have occasioned such a depression in the value of corn, as may tend to the discouragement of agriculture, unless supported by the aid of the legislature. Accordingly an act was this year passed the 44th Geo. III. c. 199, for the purpose of regulating the importation and exportation of corn, and the bounties and duties payable on the same; and by which it was enacted, that from and after the 15th of November, 1804, so much of the act of the 51 Geo. III. c. 32, as regulates the prices at which British corn, grain, malt, meal, flour, and biscuit, may be exported, except to Ireland, and at which corn from abroad, grain, meal, and flour may be imported, except from Ireland, and as fixes the duties and bounties payable thereon, be repealed. Further, that, by this act, the importation and exportation of grain, into and from England and Wales, be regulated by the average price of the twelve maritime districts, and into or from Scotland, by the average price of the four districts of it; and that the bounties and duties be regulated by schedules annexed to the act; that whenever the average shall be under the prices, at which corn may be importable into Great Britain and Ireland, from abroad, on the low duties, exportation shall be prohibited by the act, and that the importation and exportation of corn into and from Ireland shall be regulated by schedules annexed to the act. The first schedule shows the prices, to which the scale of bounty is to attach on the export of corn, &c., and the prices at which the exportation is prohibited. According to which when may be exported.
CORN.

when at or under 48s. the quarter, with a bounty of 3s.; rye at or under 32s. with a bounty of 3s.; peas and beans are exportable without a bounty, until at or under 35s.; barley, bear, or bigg, or malt made of barley, bear, or bigg, may be exported at or under 28s. with a bounty of 2s. 6d.; oats at or under 16s. with a bounty of 2s.; wheat, flour, biefinn, &c. with a bounty of 1s. 6d. per cwt.; wheat meal, with a bounty of 1s. 3d. per cwt.; barley, bear, or bigg meal, with a bounty of 1od. per cwt.; and oatmeal, with a bounty of 1s. per cwt. But that when the price of wheat exceeds 5s. that of rye 3s. that of peas and beans 3s. that of barley, bear, or bigg, or malt made of them, 3s. and that of oats 19s. no export is to be allowed.

The second schedule shews the prices, according to which high or low duties are to take place on importation. When imported from the province of Quebec, or the other colonies or plantations in North America, wheat under 55s. the quarter, is subject to the high duty of 24s. 3d. the quarter; at or above 55s. but under 56s., to the first duty of 24s. 6d.; and at or above 56s., to the second low duty of 6d.; rye, peas, and beans, under 35s. are subject to the high duty of 22s.; at or above 35s. but under 37s., to the first low duty of 11s. 6d.; at or above 37s., to the second low duty of 2d.; barley, bear, or bigg, under 26s. are subject to the high duty of 22s.; at or above 26s. but under 28s., to the first low duty of 1s. 3d.; and at or above 28s., to the second low duty of 3d.; oats under 17s. are subject to pay the duty of 6s. 7d.; at or above 17s. but under 18s., the first low duty of 1s.; and at or above 18s. the second low duty of 2d.; oatmeal, if under 16s. 6d. the bolt of 130 lbs. avoid duty, or 125 lbs. Scotch troy, subject to every bolt to the high duty of 8s.; at or above 16s. 6d. the bolt, but under 17s. 4d. to the first low duty of 1s.; and at or above 17s. 4d. the bolt, to the second low duty of 2d. When imported from any other country abroad, wheat under 63s. the quarter, is subject to pay the high duty of 24s. 3d.; at or above 63s. but under 66s. the bolt of 120 lbs. avoid duty, or 128 lbs. Scotch troy, subject to every bolt to the high duty of 8s.; at or above 16s. 6d. the bolt, but under 17s. 4d. to the first low duty of 1s.; and at or above 17s. 4d. the bolt, to the second low duty of 2d. When imported from Ireland, the high duty is fixed at 10s.; and in or under 13s. 6d. the bolt of 120 lbs. avoid duty, or 128 lbs. Scotch troy, subject to every bolt to the high duty of 8s.; at or above 16s. 6d. the bolt, but under 17s. 4d. to the first low duty of 1s.; and at or above 17s. 4d. the bolt, to the second low duty of 2d. When imported from any other country abroad, wheat under 63s. the quarter, is subject to pay the high duty of 24s. 3d.; at or above 63s. but under 66s. the bolts of 120 lbs. avoid duty, or 128 lbs. Scotch troy, subject to every bolt to the high duty of 8s.; at or above 16s. 6d. the bolt, but under 17s. 4d. to the first low duty of 1s.; and at or above 17s. 4d. the bolt, to the second low duty of 2d. When imported from Ireland, the high duty is fixed at 10s.; and in or under 13s. 6d. the bolt of 120 lbs. avoid duty, or 128 lbs. Scotch troy, subject to every bolt to the high duty of 8s.; at or above 16s. 6d. the bolt, but under 17s. 4d. to the first low duty of 1s.; and at or above 17s. 4d. the bolt, to the second low duty of 2d.

The third schedule shews the prices to which the scale of bounty attaches on the export of corn, ground corn, flour, or meal, malt, &c. from Ireland, and the prices at which the exportation is prohibited. When exported to any country abroad, wheat at or under 29s. 5d. the barrel British, is allowed a bounty of 3s.; rye, and likewise peas and beans, at or under 29s. 4d., a bounty of 11s. 10d.; barley, bear, or bigg, or malt made from them, at or under 15s., a bounty of 1s. 5d.; oats, at or under 10s. 2d., a bounty of 12s. 3d.; wheat flour, biefinn, &c. a bounty of 1s. 6d. the cwt.; wheat meal, 1s. 3d. the cwt.; rye meal, or flour, 9d. the cwt.; barley, bear, or bigg flour, 10d. the cwt.; and oatmeal 1s. the cwt. The price of the wheat exceeds 3s. 1d. the barrel, British; of rye, peas, and beans 22s. 3d.; of barley, bear, or bigg, or malt made from them, 17s. 8d.; and of oats 12s. 3d.; no exportation is permitted.

The fourth schedule shews the prices according to which high or low duties are to take place on importation into Ireland.

By the act of the 45 Geo. III. c. 26. sect. 1, passed in 1805, for much of the act of the 41 Geo. III. c. 36, as may enable the lord lieutenant of Ireland to prohibit the exportation from it for a limited time, to as not to endure longer than the expiration of six weeks, after the commencement of the next session of parliament, corn, potatoes, and all other the provisions whatever, and to permit the importation of corn, &c. for such limited time, without the payment of duty, and the said act to be further continued in force until the 25th day of March 1806.

The act of the 16th July 1806, 46 Geo. III. c. 97. which is intituled, "An Act to permit the free interchange of every species of Corn between Great Britain and Ireland," enables the bounty and duties payable on exportation and importation of all corn and grain, meal, flour, bread, or biscuit, from Great Britain into any port or place of Ireland, or from Ireland, into any port or place of Great Britain, shall cease and determine. Provided always that the person exporting such articles declare before the chief officer of the customs that the corn, &c. is really intended to be exported to Great Britain or Ireland, as the case may be, on which certificates, &c. are to be given to the exporter as in other cases of transmigrant goods coastways, without any fee or perquisite.

And by an act of the 15th February, 1807, the 47 Geo. III. c. 7. the above recited act is amended, it being enacted that the said act, and the several clauses and provisions therein mentioned, concerning the exportation and importation of any sort of grain or corn, meal, flour, bread, or biscuit, from Great Britain to Ireland, or from Ireland to Great Britain was intended to extend, and is hereby declared to extend only to such corn or grain, meal, flour, bread, or biscuit, as is the growth, produce, or manufacture of Great Britain or Ireland respectively, and not to such being the growth, produce, or manufacture of any other country or place.

It is observed by Mr. Mackie, in his excellent "Letters on the Corn Laws," after quoting many judicious amendments in the act of 1791, that the power of the crown in suspending these laws without the consent of parliament is a highly dangerous power, which renders them in some measure of no effect. He conceives that in all free countries agriculture, which is an object of the greatest national importance, should constantly be under the sacred protection of standing laws, left the cultivators of the soil should not have their industry sufficiently encouraged. And that at present, however deficient the cultivation of corn had formerly been, when capitalists were always ready and on the watch to open the ports, and speculate in the introduction of grain from abroad, importation should never be permitted but with the greatest precaution, nor exportation put a stop to contrary to the established laws, except in cases of absolute necessity, when indemnity would be readily granted. Some method of counteracting this and other inconveniences of a similar kind he conceives to be essential. From the barriers which had been formerly set up, as a preventative of the importation of corn from abroad, being destroyed, by the repeal of the old laws and reducing the import duties, a change made by the law of the year 1773, has arisen, he conceives, the inability of Great Britain to supply herself with corn the produce of her own soil.

"In proportion," says he, "as the country advanced in prosperity,
CORN.

prosperity, the surplus quantity, after supplying the inhabitants, which used formerly to be exported, was gradually absorbed by the increasing population and luxury of the nation; and the law in question, among other causes, giving a check to the further extension of agriculture, necessary to counterbalance the additional consumption, the tide at last turned against the country, and a regular influx of foreign grain became expedient to supply the growing wants of the inhabitants."

The differences which took place in this way, are strikingly thrown in the statement given below from Mr. D'rom, who remarks that no accounts have been preferred concerning the exports and imports of corn, previously to 1697, or that, from the high duties, little trade of this nature was carried on; but that in the years from that period to 1700 inclusive, the amount of the exportation of the different sorts of grain was 331,223 quarters; while the importation was only 8,048 quarters; that, in the course of the ten years from the last of the above periods to 1710, the amount of the annual exportation was 24,945 quarters; while the average of the importation only came to 442 quarters. That in one of these years (1709) more than half a million of quarters, and in the course of the whole, not less than 2,849,446 quarters were exported, while only 4,442 quarters were imported.

In the next ten years, from 1711 to 1720 inclusive, the average yearly exportation increased to 449,193 quarters; the average annual importation being only 71 quarters. The amount of the exportation of these ten years being nearly in a double proportion to that of the preceding ten, amounting to 4,491,933 quarters; while the import was only 714 quarters.

In the subsequent ten years, from 1721 to 1730 inclusive, though from different circumstances, much foreign grain was introduced in some of the years, the exports kept nearly up to the preceding equal period; the amount of the whole of them for these ten years being 4,479,683 quarters; the imports of the different kinds of grain being 733,592 quarters.

For the ten years, from 1731 to 1740 inclusive, the act of 1729 having given a check to foreign importation and promoted cultivation, the average annual exportation was 549,447 quarters; while the amount of the average importation was only 4,690; the whole export of the ten years being 5,494,471 quarters; and the whole import only 46,889 quarters.

For the ten years from 1741 to 1750 inclusive, on account of the great industry and exertion of the farmers, in consequence of being released from prohibitory and injudicious laws, the annual average amount of exportation rose to the extraordinary height of 8,486,662 quarters; while the imports amounted only to 15,193 quarters. The exports in 1748 were 1,123,653 quarters, in 1749, 1,250,366 quarters, and in the following year the amazing amount of 1,697,778 quarters; the whole for the ten years being 8,486,662 quarters; while the imports of the several sorts of grain were only 159,437 quarters.

But for the ten years from 1751 to 1760 inclusive, the exports declined, on the average, to 582,837 quarters; the imports, on the average, being 37,357 quarters. This reduction in the exports is supposed to have depended on the deficient crops of 1756 and that of the following year.

From about this period the commencement of the import system seems to have taken its rise, which has since been carried to such an amazing extent.

The imports of the years 1763 and 1764 chiefly consisted of oats; but in 1765 they were different sorts of foreign grain, chiefly wheat, amounting to 218,031 quarters; while the exports of the several sorts of corn amounted to the extent of 457,730 quarters. In 1767 the vast amount of 927,420 quarters was imported, 500,000 of which were wheat; and on the average of the twelve years, from 1761 to 1772 inclusive, the annual exportation had sunk to 370,703, the yearly importation having increased to 231,279 quarters.

Under the sanction of the act of 1773, in 1774 the large amount of 926,174 quarters of grain were imported from abroad, one third being wheat or wheat flour; while the quantity exported was not more than 51,269. In 1775 the immense quantity of 1,151,457 quarters of foreign corn was imported, half of which being wheat and wheat flour, while the exportation only rose to 150,007 quarters. On the whole, for the twelve years from 1773 to 1784 inclusive, the annual average importation came up to 578,358 quarters; while the exportation decreased to 267,152 quarters. The whole importation of this period being not less than 6,486,293 quarters of foreign grain; while only 3,206,184 quarters of grain of home growth were exported.

This reverie of our corn trade, with the vast advantages which are afterwards by it to the nation, are still further shown by Mr. M'Kie in the table of the exports and imports of all sorts of grain, sent from or brought into Great Britain, from the conclusion of the above period to the year 1793.

ACCOUNT
## ACCOUNT of Exports and Imports of Corn into Great Britain, from 5th January 1785, to 5th January 1793.

</table>
The same writer, after observing that the act of 1791 in some degree discouraged the importation of corn from abroad, by increasing the rates or duties on it, which was a defect in the old laws, yet still that statute is far from a state of perfection. A radical error had, he conceives, been committed in the outfit of the corn laws, which has never been removed, which is that of the relative regulating rates of exportation and importation for the different kinds of grain, not having been fixed for such, proportionately to their real values, the labour and expense they stand the farmer in raising and bringing to market, as in such instances he would be under the necessity of relinquishing the cultivation of any particular fort of grain, fo rated from the corn dealer, in consequence being able to have almost a complete command of the home market, from his being capable of supplying it from abroad. This he contends is the case at present in regard to oats, as from various statements he shews, that if the rate of importation for that fort of grain had been regulated originally, "in proportion to the current values in 1670 and 1688, when the present sytem of corn laws was firstrafted," it should have been in the following proportion. "As 25s., the average price of wheat is to 83s. 4d., the import rate of wheat including the duty, fo is 12s., the average price of oats, to 30s. 6d., being the relative import rate at which oats ought to have been imported, including the duty; whereas the law allowed foreign oats to be imported at 17s. 4d. including the duty. This he shews to have continued till the cale with this fort of grain, from which the culture has been greatly abandoned by our farmers; and a large importation of that fort of corn, though much inferior to our own, rendered necessary, 5,362,921 quarters having been imported from 1785 to 1791 at the value of 4,985,399l. 6s. 4d.

It is concluded on the whole, that as the "wealth of nations varies considerably at different times, so ought the rates which regulate the export and import of foreign corn; if these affect the money price of our own produce in the home market, and tend to sink its relative value below the present price of labour, with which it must always bear a just and necessary proportion, the rates must consequently be raised in order to preserve agriculture, the only solid basis on which the real wealth and lalling prosperity of a state can be founded." Should our industry and capital continue to increase for thirty years, in the same ratio it has done since the peace of 1783, the money in circulation, the price of labour, and the expense of cultivation may be double what it now is; and the price of corn will naturally increase in the same degree: should the rates, at which corn from abroad is then permitted to be imported, have a tendency to obstruct such a rise, he contends, that they must either be heightened or this country will lose its agriculture, as has already happened in the case of oats; but that, on the other hand, should the prosperity of the country decline, fo as to lessen the demand for labour, or the floating capital to one-half, the price of corn should sink in the same proportion, to the diminished price of labour, and the import rates be lowered, if the means of preventing such a necessary diminution. Consequently, that, if these principles be well founded, a permanent law for the regulation of the export and import of grain, is inconsistent with fair policy; it should be such as to expire regularly at fixed periods, according to the wisdom of the legislature, on taking the situation of the country into full consideration, so as to regulate it in conformity to the price of labour, which is "the most certain index of the growing prosperity, stationary situation, or declining state of the nation."

In support of which Mr. Malpue, in his late work Vol. IX.

CORN.

in order "to reforge our independence, and build our national greatness and commercial prosperity on the sure foundation of agriculture, it is evidently not sufficient to propose premiums for tillage, to cultivate this or that waste, or even to pass a general inclosure bill, though these are all excellent as far as they go. If the increase of the commercial population keep pace with these efforts, we shall only be where we were before, with regard to the necessity of importation. The object required is, to alter the relative proportion between the commercial and the agricultural population of the country, which, he thinks, can only be done by force of syll:n, that will determine a greater proportion of the national capital to the national land." And he "fees no other way at present of effecting this object, but by corn laws adapted to the peculiar circumstances of the country, and the rate of foreign markets." These are stated as the leading principles and circumstances which are necessary to be particularly had in view in the framing of laws for the regulation of the trade in corn.

CORN, in Surgery, is a hard, dry, cuticular, warty, or horny induration in the skin, and sometimes also in the subjacent cellular membrane. In the former case, the induration may be moved backwards and forwards; but in the latter, it is immovable. Corns are in general not larger than about the size of a small pea, and are produced in consequence of external pressure, especially in such parts as are exposed to much friction, and where the skin is very near to the bone. They are, therefore, most generally found in the toes, or the soles of the feet; but sometimes also in other parts, as on the upper ridge of the hip bone, where they are produced by the pressure of women's stays. Sometimes also similar induations are formed in the ears of women, who wear heavy ear-rings. When they are formed in the feet, they generally arise from the use of too narrow or high-heeled shoes, and sometimes merely by wearing the stockings too tight. Frequently they produce no inconvenience; but sometimes they become so painful as to render the patient entirely lame. The pain is increased by wearing warm stockings, tight shoes, violent motion of the body, itching or walking too long, drinking spirituous liquors, and during variable weather. They are generally painful in hot weather, but rarely so in cold.

With respect to the cure, the surgeon may either endeavour to remove the pain for a time, or radically to free the patient from the disease. The violence of the pain may be immediately relieved, by the patient's sitting down, taking off his narrow shoes, placing his foot in a horizontal position, and cooling it a little. A more permanent relief may be obtained, by having off the prominent part of the corn with a knife, as far as it can conveniently be got at, without, however, exciting any hemorrhage, and by the use of emollient warm fomentations. The patient cannot be radically freed from his corn, unless he resolves, during the progress of the cure, to wear no other than wide, soft, and low-heeled shoes, and to walk and stand as little as possible. If this is out of his power, and he is under the necessity of frequently walking or standing for a considerable time, the pressure may be prevented in the following manner: Take a piece of linen spread with some emollient plaster; lay one piece over another, from eight to twelve times together, and cut a hole in the middle of them, exactly the same size and circumference as the corn; then apply it in such a manner that the corn enters the hole in the plaster, and is thus defended against the contact of the stockings and shoes. When such a plaster has been worn for the space of some weeks, the corn, if recent, generally disappears without requiring any other
other remedy. When the corn is situated in the sole of the foot, we need only cut a hole into a felt-sole, so as to fit the corn, and introduce it into the shoe.

By the following treatment, corns may be removed with certainty, radically, and speedily, especially if we employ at the same time the perforated sole or plater: Rub two or three times a day an emollient liniment, such as the ointment of althea, or, which is still better, the volatile liniment, upon the corn, and keep it covered during the intervals with an emollient plaster. Every morning and evening let the foot be kept for half an hour in warm water, and the corn well rubbed with soap. Let the external part of the corn, which will have become perfectly white, soft, and pulpy, be then scraped with a blunt knife, till all the soft part is removed, and till the operation begins to give pain to the patient; upon which, we must immediately desist. This treatment is to be continued till the corn is entirely extirpated; for if we deal from it earlier, the corn will grow again. However, we must take care not to cut the part with the knife, so as to make it give pain or bleed.

Amongst a variety of remedies that have been recommended for corns, the following are the principal: green wax, soap plater, diacition, or hemlock plater, a piece of bacon, the juicy pulp of a fresh lemon, and even a piece of green oil-cloth, &c. which are to be changed as often as may be necessary. The following remedies have also been recommended as infallible: R Gummi, ammoniac. Cen.citri. aa 3 j Aeg. aeris 5 j. M. F. Empl. S. To be spread upon linen and applied to the corn. Or. R Empl. de gabano, de ammoniac, diacition, comp. aa 3 j. Camph. 3 j. M. F. Empl. D. S. To be spread upon linen, and applied to the corn, in pieces just sufficiently large to cover it. In order to aid the operation of the remedy, we may previously soften the corn in warm water, and scrape off as much of it as we are able. The following platter has been laid to produce the lepuration of the corn within three or four days: R Gummi, galban. 3 j in acetoe diffluent, & ad fpfliudinem evaporat. Add. Picae navic 3 j. Empl. diach. flmpl. 5 j. In fine, Sni. ammon, virid. Aeris pulvertis. aa 3 j. M. F. Empl. The excision of the corn is not to be recommended as a radical method of cure, both on account of the difficulty and danger with which it is attended, and because it sometimes proves unsuccessfull. When the patient has got rid of his corns, he must avoid all the above-mentioned causes which tend to produce them, or they will again return.

Corns, in Veterinary Science, a troublesome disease in the feet of horses, most generally occurring in the fore feet, and in the inside heel, within the angle or union of the quarter with the bar; though these bruises are sometimes found in both quarters or sides of the foot.

Terms improperly used in any art or science render its access more difficult, obscure our views of it, and retard its advancement: To the term corns is, in this case, a gross misapplication of words, creating perplexity and misconception, and which actual experience in the disease is hardly sufficient to do away.

When the skin of the human foot is gradually compressed or rubbed, without any sudden and violent irritation that shall raise the cuticle or create a force, it thickens first, then becomes horny, and is rightly enough termed a corn, from cornus. Lat. or cornus. Fr. horn.

In the horse, on the contrary, whose foot is everywhere thickly clothed with natural horn, such an occurrence, if it were possible, could not be a disease; but if a bruise takes place in the foot, at the point above described, it is also called a corn, though agreeing in nothing with the former disease, but in the common circumstance of its affecting the foot with pain and lameness.

Where a corn, as it is called, exists in the foot, it is known by a redness, more or less intense, in the angle formed by the union of the bar with the sides of the foot, and is most generally observed, as we have already stated, in the inner quarter: it is tender, if pressed upon, producing lameness; and if the irritation is carried far enough, it betters, and the pus, being prevented escaping below by the sole, forms a purulence inside the hoof upwards, through the foliated fibritian or chalic processes, to the coronary; and if a shoe, pressing too hard upon the part, continues to be used, the irritation being kept up for a long time, the part becomes weakened in its function, not forming good found horn, and a painful disease is created, which is eradicated with difficulty, and is liable to recur, after relief has been obtained, by the slightest renewal of this permanent pressure, or of irritation of any kind.

Having briefly described the disease, as it commonly appears, we proceed to consider its cause, and the cure.

As it is unequal pressure that produces corns, even in strong feet, from the shoe bearing too hard upon the point of the foot above indicated; so, in fact naturally weak, a slighter degree of pressure, if the pressure be permanent, shall be sufficient to induce it: so that the disease may be observed in all sorts of feet, but far more frequently in weak ones, as in low heeled feet, or where the heels project very much, and the horn turns under, and is thin.

The horse's foot, we may remark, by being continually bound by the nails which attach the shoe to the foot, is ever hardening and diminishing in its volume, under their influence and pressure, and especially all the elastic parts of the foot, which, not being then called into much action, become inert and rigid, or are absorbed; the posterior parts of the foot, in particular, are damaged by it, and, in its contracting the foot, often forms waving lines of horn, which turn under at the heels, so that the shoe will take its bearing on the parts so disposed, in a direction tending inwards, and bring on bruises and weaknesses, or corns, as the smiths have been pleased to call them.

The inflammation induced by the bruise or pressure occasions an increase, or sometimes rupture, of the blood-veins of the part pressed on, so that instead of lymph, the red parts of the blood flow into them: and hence that redness in the horn of the bruised part, the external indication of this disease.

If the pressure be speedily and effectually removed, and all external irritation be kept away, healthy horn forms again, and the disease disappears; but if the irritation be kept up for any length of time, or has been attended with much violence, the vascular parts go on to suppurate; and the pus, as we have observed, forces its way with great pain to the coronary. Its frequent recurrence leaves the parts very weak, and the smiths are then apt to imagine it is natural to them, and convey this idea to others, and seldom admit the real cause of the disease.

One circumstance, we believe not much understood, it is of importance to dispele here, reflecting the production of this disorder, and which cannot be too generally known and considered, as it may be the means of warning those whose experience has not yet informed them of the danger: it is this, that if we make a perpendicular section of the horse's foot, across the two points of the heel, where the corns usually are found, it will be observed that the outside and inside heels exhibit different appearances: the vascular parts lying much lower on the inside than on the outside quarter; so much so, that any one holding the foot from the ground, and
and levelling the sole to his eye with his drawing-knife or butter, he would meet with the blood of the infinite quarter before he had brought it to what he would conceive the proper level of the outer, and before he had made the foot. For the horse's foot, no doubt for the wickett purposes, is not made a regular cone, as a care's inspection should apprehend it to be, but is placed inclining on the ground, with the inside the highest, forming a species of rhomb or lunezour: the inner parts being thinner in horn, more elastic, and flity; while the outer are flouter in horn, and with less vascular matter, and more adapted for receiving the wear, which, we may observe, takes place primarily on the outer side of the toe or piece, as may be seen by looking at the shoes when taken off, or observing the wear of the natural foot methods; and thus compression and uneasiness are prevented by the greater yielding and elasticity of the inner quarter and the heels: for had the foot been on every side equally unwielding, reflection, compression, and pain, under heavy burdens, or great or long continued exertions of the animal, would have been produced.

It is this difference which may deceive the smith, and make him bring the shoe nearer the quick on this quarter than he intends; and it is the superior elasticity and vascularity of his fore feet that occasions them to be more the subjects of this disease than the hind, where horns rarely occur, and which we have heard the smiths attribute to the.caufe of their flaring with their hind feet in the dung of the stable.

The position, also, in which the smith is obliged to hold the foot between his thighs, turned upwards, and drawn away from the horse outwards, will tend to increase his deception, in regard to these circumstances of the apparent levelling of the hoof; and where there is a weak, low, flitty heel, as it is termed, a slight mistake is sufficient to produce a bruised heel, or corn, which in flouter feet it would be more difficult to do; though in these we sometimes find it has been done.

A shoe too narrow for the foot, or with the heel made very sloping inwards, would also induce a bruise of these parts; for we see, by the brightness of the shoe at this part, after it has been on some time and removed, that the nails do not entirely prevent the motion of the heels on this surface.

Finally, a shoe not equally fitted to bear alike on all the parts of the foot, but bearing on the toe and heels only, especially the inner heel, and not taking sufficient pressure at the quarters, would, by this partiality of pressure, induce inflammation and pain. Clenching the nails too forcibly near the heel, so as to induce more pressure there than at the toe, would also do the same thing. Under the article Farriery, we propose considering some other parts of this subject, having barely infected enough of that branch of the business here as may be laid particularly to belong to this subject.

If this reasoning, therefore, be true, the corn arises from the weakness and insufficiency of the foot to bear the pressure of a nailed shoe, or from partial and ill disposed pressure in the strong feet, or improper pairing: therefore the ancients, who, we believe, knew nothing of this nail shoeing, had not their horses subject to this disease; and such, on examining their writings, turns out to be the fact: for though they have described, and often most truly, the diseaees of the horse, they have not described this disease, so as for us to conclude on its identity. The "Pulmiculmus ad apertum" of Vegetius, lib. ii. cap. 56. has some of the characters of the corn; but it is not clear whether oxen or horses were the objects of it, and he recommends uns-of

ing for it: whatever it is, it was probably a disease arising from a weak heel, which, by long journeys or rough roads, might be so bruised as to bring on similar consequences.

Having treated of the appearance of the corn and its causes, we have now to consider the remedy, first observing that prevention from it is ever the wickett line of conduct, especially in a disease where the mechanical causes of it are obvious, and can be prevented. Where the corn or bruised heel has taken place, the name and molt is general fogestion is to remove the shoe, and take away all the tissue escaped horn with the drawing knife, so as, on the re-application of the shoe, to remove all pressure from the part, and thus admit a new growth of horn not subject to external pressure. For this purpose, the horse may be turned to graze during its growth, when in general it will grow down apparently perfect: it is, however, if the disease has been of any duration, too apt to return, if the smith brings only the ordinary pressure of a shoe upon it; though this takes place by degrees, and not at the first shoeing; the parts weakened by the disease become unable to sustain even this pressure, and first become tender, and afterwards lame; or the parts feter, according to the degree of it. The barred shoe, on this account, is often had recourse to by the smiths with good success; the pressure to the corn being done away by the parts of the shoe opposite: it being bent out of the line of plane of the shoe, and then to the foot, a light floating of turpentine dailings on sawd is applied, and boxed in with tar clove. The continuance of this, which is seldom prilled in long enough, Religion the horn to progress, which being then left off, and the ordinary shoe applied, induces again the consequences, sooner or later, that we have described.

A shoe may be beat or filed out with a space opposite the corn; but we have found it more easy and certain, when the parts are arrived at this state, to make a shoe rather thicker than the ordinary shoe, and to cut off entirely that extremity of it that comes opposite the corn, to a short distance from it, so as to be affluce no pressure can arise from the shoe itself; for if the shoe be left long, however managed, by long wear it is apt to play and become relaxed, from the parts both of the hoof and shoe giving way to each other, and thus creating a degree of looseness, when the heel of the shoe, coming upon the part, reproduces the disease. It will be objected to this proposal, that the corn is left unprotected, and at first it will be a little tender, but this will speedily go off, and at each shaving will become of less consequence; and it is better of the two evils to contend with the occurrence of accidental pressure from irregularities in the rand, than the perpetual pressure of the shoe. In flight cases, after the shoe has been nailed on pretty firmly, we have taken a small saw, and sawed away the horn rolling on the shoe at this part, so as to make it press less there than on any other part of the foot; but if the shoe be allowed to play on too long, the nails, as we before stated, become relaxed, by the horn giving way, and pressure will occasionally take place on the corn.

Of late we have had several opportunities of using the shoe above described, and have found it in practice beyond our expectation; nor have we found it, though awkwardly imperfect, produce any of the evils we had apprehended it would be subject to. There are other methods than those we have described, but we do not mention them, from finding them insufficient. Where pus has formed, the horn covering it being effectively removed, digestive of turpentine are used, as in any other wound, till the healing of the sore takes place, when the cause that originally produced it must be carefully avoided.

> 5

Corn.
COR

Corn-Bottle, in Agriculture. See Centaury and Weed.

Corn-Butterfly, in Entomology. See Papilio.

Corn-Crowfoot, in Agriculture, is the common name of a plant of the weed kind, often found among corn crops, and which is very troublesome to the farmer. It has an upright stem, with pale green leaves, cut into long narrow acute segments; the flowers are of a pale colour. It is extremely difficult to eradicate from places where it is established. See Weed.

Corn, Ear of, in Natural History. Under this name different authors have described a variety of organic remains found in the strata of the earth. M. Schleicher, in particular, gives the figure of a foil, which he describes as an ear of corn, and from its figure, and suppos'd fulness, he argues, that the Mosaic deluge took place in the month of May! But Mr. Walsh considers this body rather as a zoo-phyle, the rays of which are divided by transverse lines, marking their separation into distinct vertebrae.

The Spica fœcalina, and granimis panicul of Dr. Richardson, the ear of barley which Mylius has figured, are of like doubtful origin; the latter, in particular, does not bear the proportions of an ear of barley.

The flange-gruppen of the German mineralogists more nearly resemble ears of corn, than the above. These are flat, oblong, blackish, and sometimes greenish bodies; but, becoming white, and acquiring a metallic lustre on their prominent parts by friction. Many have supposed these to be mineral substances, to which mere accident has given their present form; but they seem to be real vegetable substances, impregnated with metallic particles. They vary considerably in form, but are in general flattened, and are fluted with little round prominences, bearing very much the appearance of corn. They are found but very rarely, and perhaps only in the copper mines of Frankenburg in Hesse. M. Lihman, who has written expressly on these substances, does not consider them as changed vegetable substances, but as being of mineral origin; he found them to consist of copper, arsenic, sulphur, and iron, with a small quantity of silver in their composition. Wolfart, who has delineated and described these substances, calls them frumenti metallica, acknowledging that he cannot refer them to any particular species of grain. Mr. Parkinson gives two figures of these substances, but concludes his description thus: "I am therefore of opinion, that we must be satisfied with considering them as foils, whose origin must be referred to some hitherto unknown subject of the vegetable kingdom." M. Whitechurch, "Theory of the Earth," p. 169 mentions corn among the vegetable impressions found in the coal measures of Derbyshire; but this is doubtful as it was founded as any of the foregoing; and we have the best reason to suppose, that minute and scientific examinations will place all these among the incognata of a former state of aquatic existence.

Corn-Brush, in Agriculture, is that sort of brush which is principally cultivated and conducted under the system of corn, or the chief produce of which is grain. All the more dry sorts of land are adapted to this purpose. See Corn and Farm.

Corn-Flag, in Botany. See Gladiolus.

Corn-Flag, in Agriculture, is the name of a troublesome plant of the weed kind, which increases greatly by the root; when established in the field, it is with difficulty extinguished, as it is capable of sending up new plants from every part of its roots. See Weed.

Corn, Indian. See Indian Corn and Maize.

Corn Land, that kind of land which is adapted to the growth of grain. See Farm.

Corn, Lent, is a term applied to that sort of grain which is usually sown, or put into the soil about that season.

Corn, Marygold, is the name of a plant of the weed kind, of which there are two species, one found commonly in arable land, and the other in the fatness of the more moist kind. It is a great enemy to all sorts of corn crops. It is estimated with much difficulty, as it multiplies both by its roots and seeds. Deep and effective hoeings, frequently repeated, are of course requisite, before it runs up to seed. See Weed.

Corn Measure, in Rural Economy, that sort of measure which is used for grain. See Measure, and Weights and Measures.

Corn Mill, that sort of mill which is employed in the grinding of corn. See Mill.

Corn Parsley, in Agriculture, is the name of a low branching plant of the weed kind, often met with among corn crops. See Weed.

Corn Rent, that sort of rent which is regulated by the price of grain. See Rent.

Corn-Rent, in Law, denote those third parts of the old rents on college legacies, which are to be reserved by the legatees. Stat. 18 Eliz. cap. 6. These were the invention of lord-treasurer Burlig, and Sir Thomas Smith, then principal secretary of state, for upholing the revenues of colleges.

These great statesmen, observing how much the value of money had fell, and the price of all provisions risen, by the quantity of bullion imported from the new-found Indies, which effects were likely further to increase, devised this method. Their foresight and penetration have in this respect been very apparent; for though the rent so reserved in corn was at first but one-third of the old rent, or half of what was still reserved in money, yet now the proportion is nearly inverted; and the money arising from corn rents is, communis annis, almost double to the rents reserved in money.

Corn-Rocket, in Botany. See Bunias.

Corn-Sallad, in Agriculture, a species of the Valerian. See Valerian.

Corn-Sharpen. See Sharpening.

Corn, Spring, a term signifying such sorts of grain as are put into the earth in the spring season.

Corn-Stand. See Stand.

Corn-Stubble, that sort of fluff which remains after reaping or cutting any sort of grain crop. It should constantly be collected for the purpose of litter. See Stubble.

Corn-Stubble Rake, is a large kind of horse-rake, employed in some counties with much benefit. See Rake.

Corn-Straw. See True-corn.

Corn-violet. See Weed.

Corn, white, a general term used to signify all sorts of grain.

Corn-Weed, a sort of insect of the caterpillar kind, which is said to be very detrimental to corn.

CORNA, in Ancient Geography, an episcopal town of Asia, in Lycaonia, mentioned in the Acts of the council of Chalcedon, held in 451.

CORNA, in Geography, a town of Arafian Turkey, in the Arabian Irak, on the Euphrates; 6 miles N. W. of Baffor.

CORNACHINE Powder, in Pharmacy, a purging powder,
COR

oder, called also 'evil of Warwick's powder, and pulvis de tribus. It is composed of equal parts of antimonium diatomicum, digrydium, and cream of tartar.

CORNACHINI, Thomas, in Biography, born at Aries, in Tuscany, about the middle of the 16th century, obtained considerable celebrity, as professor of medicine at Pisa, where he lectured to large audiences several years. He died in 1555, and was succeeded in the professorship by his son Mark, who published at Venice, in 1607, in fol. "Tabulae Medicæ," the only work left by his father, in which he has collected the descriptions and accounts of diseases left by the Greek and Arabian physicians, with commentaries upon them. His son had the credit of giving his name to a purging powder, Pulvis Cornachini, consisting of calomel, a SS. Members, and burnt hairhorn, which still retains its credit, for its efficacy in destroying the atherides, a small worm, infecting the bowels of children. Mark also published, "De Homini GENERATIONE, de Vino, et Aqua, balneaticis Pufianis," Frankfort, 1667, fol. and a "Discovery on the Method of Curing, tuto, et juvando," he says, all those diseases, which are said to be derived from peccant humour. Haller Bib. Med. Elov. Diet. Hist.

CORNACUM, in Ancient Geography, a town of Lower Pannonia, according to Ptolemy and Antonine's Itinerary. CORNAGNE, an ancient tenure, the service whereof was to blow a horn, when any invasion of the Scots was perceived.

This tenure, which was a species of grand fealty, was very frequent in the northern counties, near the Picts and the Roman walls; but by lat. 12 Car. II. all tenures are converted into free, and common foggage.

An old rental calls cornage, newgold, q. d. new gold. Lord Coke says, in old books, it is called homedelg.

CORNARISTI, in Ecclesiastical History, the disciples of Theodore Cornert, an enthusiastic secretary of the states of Holland. He went at the same time against the Catholics, Lutherans, and Calvinists. He maintained that every religious communion needed reformation; but he added, that no person had a right to engage in accomplishing it, without a million supported by privacies. He was also of opinion, that a person might be a good Christian, without being a member of any visible church.

CORNARIUS, John, in Biography, a physician of great eminence, and author of numerous treatises on the theory and practice of medicine, was born at Zwickau, in Upper Saxony, in the year 1500. Haller says, his proper name was Hagenenbot or Hambut, but that following the custom of the time, he took the name of Cornarius, which he affixed to all his publications. He is said to have attached himself to the study of medicine, in the hope of discovering some method, or medicine, capable of restoring, or invigorating his constitution, naturally feeble and delicate. With this view, he resided in succession, at several German universities, and at length at Basle, in Switzerland, where he met with copies of Hippocrates, Aetius, and other of the Greek fathers, in their own language, which he had not before been able to procure. Returning with this treasure to his own country, having previously taken the degree of doctor in medicine at Padua, he set himself down to translate first the works of Hippocrates into Latin, which he completed in five years, and published at Basle, in folio, in 1543; then Aetius, and Paul of Aegina. He had before published, viz. in 1529, "De generi medicé, epigraphico et enumeratione," which has been several times reprinted. "De rebus medicinis literatis ampléctens," "De conviviorum veterum Graecorum," "De pecto libri duo; de Podagrae lusibus," in 1553, with various other dissertations. While thus employed, he did not neglect the practice of medicine, of which he is said to have had a considerable portion. His translations of Hippocrates, having been rudely attacked by Fuchhus, he answered it by a factual effusion, which he called, "Vulpeculae excoriata." This was printed at Frankfort in 1543, in 4to. Fuchhus answered this by a similar piece of satire, Cornarius furious. The translation of Hippocrates has long since been superseded by those of Vander Linden, and Teius, and those of Aetius, and Paulus Ezineta, were not much longer lived. They were however works of great labour, and contributed to lessen the difficulties of the task to those that followed.

Cornarius died at Jena, March 15th, 1558. His son, Diesmede, succeeded to his practice. He was appointed professor of medicine, in the university of Vienna, and physician to the emperor Maximilian II. He published at Leipzic, in 1595, in 4to. "Confiliorum medicinæ tractatus," also "Historia admiranda rariorum medicinarum." Haller Bib. Elov. Diet. Hist.

CORNARO, Francis, cardinal and bishop of Padua, in the sixteenth century, began his career as a military man, during the contests in Italy excited by the rival intertells of Charles V. and Francis I. in which the Venetian republic was involved. Upon a general pacification, he quitted the army and devoted himself to the perusing of literature and the study of politics. He was afterwards fixed upon as ambassador from the republic to the emperor Charles V. In 1547 he was raised to the dignity of cardinal by pope Clement VII. and after his admission into the college, he confined his labours to the deliberations of that body, where his learning and experience were highly appreciated. He died in his sixty-fifth year, A. D. 1543, of the gout, with which he had been long afflicted. Moreri.

CORNARO, George Basil, cardinal and bishop of Padua, was born in 1568. He also began life in the army, which he left for the church. He was member of the order of Malta, and grand prior of Cyprus, an office which was hereditary in his family. His application to literature, and his acquirements by foreign travel, painted him out as a person well and highly qualified to fill offices of great responsibility in the republic. He was first appointed to the superintendancy of the marine, and would have been sent as ambassador to France, had not his preference led him to embrace an ecclesiastical life. He accordingly went to Rome, where he was entrapped with certain commissioins which led him to high preferment and great dignities in the church.

In 1602 he was appointed ambassador to the court of Portugal, and was made titular archbishop of Rhodes. On his return, he was created cardinal by Innocent XII. and nominated to the bishopric of Padua. He died in the year 1722. Moreri.

CORNARO, Lewis, of a noble Venetian family, though from his not enjoying the honors attached to it, he should not to have been legitimate, was born in 1467. He lived to a great age, which he attributed, and probably with justice, to a strict, abstinent regimen, adapted by him, on his recovering from a severe illness, when he was more than forty years of age. His health had been declining several years, prior to this attack, owing as he acknowledges to his living a debauched and voluptuous life. In entering on his new regimen, he took care to avoid, he says, the extremes of heat, or cold, together with all violent exercise, and to live in a moderate dry air; all which, he contended, were equally important in attaining the end proposed, the restitution of a decayed constitution, as temperance and diet. During the remainder of his life, he only took twelve ounces of solid food,
food, wine, bread, fowry, rooks of eggs, and meat, and fourteen ounces of wine in the day. This portion, as he grew old, he rather diminished than increased, observing that the power of conversation is then less vigorous, and, as that weakness, the mind should be inclined. He married a lady of the house of Spillmberg, at Udina, by whom he had an only child, a daughter, when they were both advanced in years. At the age of 83, he wrote his "Siccorti della vita fabria;" a short treatise on the advantages of temperance, from which this account is principally taken. The work has been repeatedly translated, and printed in every country in Europe. He was then, he says, so brisk, lively, and active, that he could mount his horse, without assistance from any rising ground. Sometimes he retired to his villa, seated in a valley, watered by the Brenta, enclosed with large, well-cultivated fields, and a considerable number of buildings, made habitable by his own industry. "It had been full of fens and bugs; he says, a habituation, more fit for flies, toads, and tarantels, than for man." He had the pleasure of enjoying the society of his daughter and eleven grandchildren she had produced; who amused him with their musical exhibitions, in which science as well as in that of architecture, he had no inconsiderable skill. He died at Padua, April 26th, 1566, at the age of 98. His wife, who survived him, lived also to nearly the same age. Sir John Sinclair, in his "Code of health and longevity," mentions the elation of 1779 as the best English translation of Cornaro's works. There are four discourses on one subject, penned at different times; the first, which he wrote at the age of 63, is intituled "A treatise on a sober life," in which he declares war against every kind of intemperance. The second was composed three years after, and contains directions for repairing a bad constitution. The third he wrote when he was 91, intituled "An earnest exhortation to a sober life;" and the last is a letter to Barbaro, patriarch of Aquileia, written when he was 95, which contains a lively description of the health, vigour, and perfect use of all his faculties, which he had the happiness of enjoying at that advanced period of life. Eloy, Dct. Hist. Gen. Biog.

CORNARO-PISCORIA, LUCRETTA HELENA, an illustrious Venetic lady, was born at Venice in 1646. At the age of eleven having imbibed a devotional temper, and an ardent love of literature, she took a vow of chastity, which she maintained through life, though a dispensation was obtained from it, without her knowledge. She was an excellent linguist, being thoroughly conversant with several of the modern languages and with the Latin, the Greek, Hebrew, and Arabic. She had a taste for poetry and music, and composed verses which she sung to her instrument. In many of the abbeys of science she was deeply read, and acquired so much reputation, that it was proposed to give her a seat among the doctors of theology at Padua; this was opposed by the bishop; she was however honoured with a cap of doctor in philosophy. The ceremony used on the occasion was performed in 1678 in the cathedral of Padua, at which an immense concourse of people was assembled as witnesses of so extraordinary a sight. She was elected a member of all the principal literary societies in Italy, and no person of distinction visited the country without paying his respects to this excellent lady. She had a great desire to enter into some religious society; but by the entreaties of her father she remained under his roof, contenting herself with wearing the habit of the Benedictine nuns, and observing the rules of the order. She died in the year 1684, and her works were collected and published in 1689, but their merit is not equal to the high reputation which the author sustained during life. More.

CORNARU, in Geography, a town of Germany, in the circle of Wetphalia, and county of Diopholz; 6 miles N. of Diophoz.

CORNAVI, in Ancient Geography, a people of the isle of Albion, who were situated to the west of the Cornavii or Corn-Isen, in that country, according to Camden, which is now divided into Warwickshire, Worcestershire, Shropshire, and Cheshire. There were several British tribes of this name, in other parts of this island; and particularly in the most northern part of Britain, called Strathavven, which seems to retain some vestige of the name of its first possessors; and they all seem to have been called Cornavi, from the two British words Corn, a horn, and Aven, a river, descriptive of the form and situation of their respective countries. By the Cornavi, there was another British tribe or nation, seated in the countries above mentioned; and seeming to have possessed the part of the two counties of Warwick and Worcestershire. This nation is called by Tacitus (Ann.I. xii. c. 38.) the Jugatres, by a mis-sake as it is thought of his transcribers, for Wigantes, or Hiner, their real name.

The Wigantes, signifying in the ancient language of Britain, brave men, seem to have been an independent nation under their own prince Venutius, who married the famous Cartesionandus, queen of the Brigantes. But both the Wigantes and Cornavi, were in such firm alliance with the Icenii and Corn-Isen, that they were reduced at the same time, and by the same generals, under the dominion of the Romans. (Tacit. Ann.I. xii. c 29, 30.) That brave and indomitable people built many forts, laticums, and towers in the country of the Cornavi and Wigantes, to keep the inhabitants in subjection.

As the 1st cond journey of Antonius from beyond the wall of Severus to Richborough in Kent, passes through this country from north to south, it will conduct us to several of the Roman towns and laticums. The most northerly of these towns was Condate, supposed to be Northwich in Cheshire. We come next to Diva or Deva, now Chester, which was a city of great importance in the time of the Romans, a colony, and the citadel of the 20th legion. Purining the same route from thence, we meet with the following towns in their order; Boxtown, near Strickon; Melbournus, near Drayton; Rutamium, near Wem; Uriconium, near Wroxeter, the ancient capital of the Cornavi; Ux foria, near Sheriff Hales; Pennoerium, near the river Perk; Erecnum, near Wall near Litchfield; and Mandrefnedon, near Manchester, in Warwickshire. The precise boundaries of the several Roman provinces in Britain are so little known, that we cannot be certain whether the whole country of the Cornavi and Wigantes was within the limits of that which was called Britannia Prima, or some part of it belonged to Britannia Secunda.

CORNAX, MATTHIAS, in Biography, a native of Mel- nola, a small town in Italy, rudited medicine at Venier, where he afterwards continued to practice, and was appointed one of the teachers in the art. He is here noticed, on account of his having published a cafe of a woman who had carried an extra fetus in the abdomen, for the space of five years. An abscess at length forming, near the navel, and burrowing, our practitioner enlarged the aperture, and extracted through the wound, a half putrid fetus. The woman recovered, but becoming again pregnant, and it not being practicable to deliver her by the natural passage, she died.
It does not appear that the body was opened. The case was originally published at Venice in 1550, in 4to, "Historia quinquennis fere geftationis," &c. It was republished in 1564, with other similar cases, in the author's "Enchiridion Medici consultationis apud Egrotos, &c; Basiliz," 8vo. Haller Bib. Ch.

CORNAZZANI, Anthony, an eminent Italian poet, who flourished in the fifteenth century. He was born at Placentia, but resided chiefly in the early part of life at Milan, but after the death of Sforza he was obliged to take refuge at Venice, where he was hospitably received by Bartholomew Colleone, whose life he afterwards wrote. From Venice he went to France, and from thence to Ferrara, where he finally settled under the patronage of Duke Hercules the first, and his duchessa Lucretia Borgia. He is chiefly known by his sonnets and lyric poems, some of which are reckoned the most perfect of their kind in the language. He wrote the lives of the Virgin Mary and of Christ in verse; and among his prose works, we have, besides the life of Colleone, a treatise "De Mulieribus admirandis," and another entitled "De excellensim Vitorum principibus,"

CORNE, or CORNA, in Ancient Geography, a town of Cappadocia, towards the Euphrates, to the south of Melitene.

CORNE, in Geography, an island, ten miles long and one wide, in the gulf of Mexico, near the coast of Florida. N. lat. 30° 11'. W. long. 83° 32'.

CORNE, a town of France, in the department of the Mayne and Loire; 7 miles E. of Angers.

CORNE. See Horn-work.

Corne a amorcer, priming-horn. An ox-horn filled with fine powder for priming cannon.

END OF VOL. IX.
