been Alexander in a vision, by whose direction he erected a
royal tent, containing a throne of gold, with all the emblems
of majesty, where the captains were to offer incense, and
then deliver their orders in a common council. After this
there were disputes about the chief command, but when
Antigonus approached all agreed that Eumenes was the
only general, under whom they would fight. His situa-
tion was difficult and precarious, he was aware that many
of the other commanders were desirous of getting rid of
him, as the chief obstruction to their ambitious designs.
From those whom he most suspected he borrowed large
sums of money, that by such a pledge he might give them
an interest in his success. The war was protracted with
various successes to a second campaign, when a battle ensued,
in which Eumenes routed the enemies' infantry, but in the
meantime his cavalry took possession of the camp of
Eumenes. This circumstance occasioned so much discontent
in the army, that when Antigonus sent an offer to restore
the soldiery, their wives and property, on condition of their
delivering Eumenes into his hands, the Argryphides sur-
rounded him, seized his sword, tied his arms behind him,
and gave him up prisoner. Antigonus being asked how
he should be kept? As you would keep a lion or a wild
elephant, he replied. All the Asiac tribes submitted upon
this event, and it remained only to determine the fate of
the illustrious captive. This was so long kept in suspense,
that Eumenes expressed his surmise that Antigonus had
neither the courage to put him to death, nor the generosity
to make him his friend by setting him at liberty. A party
in the army, headed by Demetrius, favoured the latter
course, but the majority urged Antigonus to remove so
formidable a rival. This counsel prevailed, and orders were
given to deprive him of food. He had suffered the pains of
lunger two or three days, and was fast approaching his
death, when the army being suddenly obliged to decamp,
an executioner was sent to dispatch him. His remains
were treated with funeral honours, and his ashes were enclosed
in a silver urn, and sent to his family. This was in the year
315 B.C. Eumenes had a fine person, was highly ac-
nplished, and polished the manners and sentiments suited
to an elevated station; he was faithful to the cause of his
deceased master, and it was not till after his death that the
captains who divided the Macedonian empire among them
openly assumed the style of independent sovereigns.
Pintarch.

EUMENES II, king of Pergamus, succeeded his father
Attalus in the year B.C. 197. He cultivated the friend-
ship of the Romans, who were now beginning to extend
their influence into Asia, urging them to check the ambi-
tious projects of Antiochus the Great, of which he feared
he should be the victim. Eumenes joined his fleet to that
of the Romans, and by his personal bravery greatly con-
tributed to a naval victory, which was gained over the
king; nor was he less useful at the decisive battle of
Magnesia. On account of his important services he was
rewarded by an accession to his dominions, of all the countries
well of mount Nausus, which had belonged to Antiochus,
and also of all the provinces lying between that mountain
and the river Meander, except Lydia and Caria, which were
given to the people of Rhodes. Eumenes, now one of the
most potent princes in Lycia and Caria, was involved in a war
with Phrygians, king of Bithynia, in which he was defeated
both by land and sea. Peace was made, and another con-
test took place between Eumenes and Pharnaces; in this
the latter was obliged to fly for peace. Eumenes now
made an alliance with Antiochus, son of his old enemy
Antiochus the Great, and in conjunction with his brother
Attalus placed that prince on the throne of Syria, from
which he had been driven by an usurper. Perseus, king of
Macedon, fearing his military force, excised the jealousy of
his neighbours, and Eumenes took a journey to Rome, for the
purpose of acquainting the senate with all he had
discovered of his dangerous projects. On his return,
Eumenes, going to offer sacrifice at the temple of Delphi,
had nearly lost his life by assassins hired by Perseus to destroy
him. He received so much injury that he was carried
about lifeless on board his ship, and it was generally believed
that he was actually dead. Attalus, his brother, giving
credit to the news, assumed the royal insignias, and even
married the queen Statira. Eumenes, after his recovery,
gave his brother a friendly reception, advising him not to
marry his wife again till it was certain he was dead. From
this period he was engaged in contests with the Romans,
who began to regard him with suspicion, and it is thought
they encouraged Attalus to seize upon his brother's king-
dom for himself. Eumenes died in the year 159 B.C.
leaving an infant son to the protection of his brother and
successor Attalus. Eumenes was liberal, and even magni-
ficent towards his friends. He was a patron of letters,
and made considerable additions to the celebrated library

EUMENES, an orator, was an Athenian by descent, but
was born at Autun in Gaul, where he was for a considera-
time professor of rhetoric, and acquired great reputation.
He was secretary to the emperors Maximian and Con-
tanitus, and was much esteemed by Constantine the Great,
whom he harangued in favour of the inhabitants of Autun
in 311. He delivered an oration before the prefect of
Lyons, Gaul, in favour of the restoration of the public
schools in the province, towards which he nobly offered
to contribute his own salary, as secretary, probably, as well
as professor. He died about the middle of the fourth cen-
tury. Fragments of his orations are printed in the "Panc-
gyrii Veteres." Moveri.

EUMENIA, in Ancient Geography, a town of Asia, in
the greater Phrygina, seated on the Clauda.—Also, a
town of Asia Minor, in Caria.—Also, a town of Thrace,
on the confines of Lower Media.

EUMENIDEIA, Equusbus, an annual festival observed
in honour of the Furies. It was otherwise called Sylvia
Hespera, because the Athenians called the Furies Sylvia
Septem, i.e. seven goddesses.

EUMENIDES, in Antiquity. See Furies.

EUMETRES Bi, in Natural History, the same given
by the ancients to a gem which the Alcyonians held sacred
to their god, and which many other nations learned from
them to suppose very powerful against pestilence. Many
supposed this to be the one we now call obsida Bile: but
this is an error, since Pliny, in his account of the emetres,
says, that it was of a very fine green. It was probably
a gem of the emerald kind, that rose having ever been in
very high esteem in the Eastern part of the world, as it is
also to this day.

EUMINACUM, in Ancient Geography, a town of
462
Asia.
Mafa, marked in the Itinerary of Antonine; 24 miles from Viminacium.

EUMENES Fareges, or Omen Fareges, a canal of Egypt, joining lake Manzalah with the Mediterranean; supposed to be the mouth of that ancient canal, called the Tanit or Sisit branch of the Nile.

EUMOLPIDES, in Antiquity, priests of Ceres, who had the power among the Athenians of initiating into the mysteries of this goddess, or excluding from them.

EUMOLPUS, in Biography, a disciple of Orpheus, who, tracing the footsteps of his father Mucus, wrote concerning the mysteries of Ceres.

EUNAPIUS, a native of Sardis, in Lydia, flourished in the fourth century, and was a kinman of the celebrated bishop Chrysanthius, at whose request he wrote the lives of the philosophers of his time. This work has been characterized by Brucker as "a mass of extravagant tales, discovering a feeble understanding, and an imagination prone to superstition," besides being a sophist, he was an historian, and practiced physic. In his writings he seems to have entertained a great prejudice against Christianity, the martyrs to which he treats with a contempt that has given just offence to contemporary ecclesiastical writers. He wrote a history of the Cefars from Claudius II. to Arcadius and Honorius, of which only a fragment, "De Legationibus," is remaining. The "Vita Philosopherum" was published with a Latin translation by Junius in 1595. Moreci.

EUNILAK, in Geography, a place of Eal Greenland. N. lat. 61° 44'. W. long. 46°.

EUNOFIUS, a name given by some authors to the ætites, or eagle-lion.

EUNOMIANS, in Ecclesiastical History, a sect denominated from Eunomius, bishop of Cyzicus, who, in the fourth century, maintained most of the errors of Arius, and added others to them. He was a native of Dacora, a town of Cappadoch. and removing to Confinantinople, gained his subtilance first as a notary, and afterwards as a school- master. At Alexandria he became a disciple of Aetius, whose opinions he adopted and strenuously defended. Having been ordained a deacon by Eunomius, bishop of Antioch, he was deputed to the court of the emperor Constantius for the purpose of defending Eudoxius against the accusations of Bafil, bishop of Ancyra; but in his way thither he was seized by the partizans of Bafil, and banished to Myda, a city in Phrygia. In the year 360 he was ordained bishop of Cyzicus; but boldly avowing his opinions, he became obnoxious to the orthodox party, and underwent various and severe perfections. At the command of the emperor Constantius, he was at length condemned and deposed by Eudoxius. At Chalcodon, whither he retired, his enemies pursued him, and he was afterwards banished by the emperor Valens to Mauritania. At the close of the reign of this emperor, after he had been allowed to return to Confinantinople, he was charged with disturbing the peace of the church, and again banished to the island of Naxos. When Valens died, he returned to Chalcodon, but was soon sent into exile by the emperor Theodosius. Wearyed by incessant and grievous persecution, he obtained leave from the court to retire to the place of his industry, which he called an advanced age, about the year 394. He was the author of various works, most of which are now lost. Those that are extant are "Eunomius's Creed," presented to the emperor Theodosius in the year 383, and his "Apologeticus," or Defence of his Doctrine, in which, according to Dr. Cave, the fly arch-heretic reasoneth fraudulently. Fabricius has published this piece entire, and an English version of it may be seen in the fifth volume of Whitton's "Primitive Christianity revived."

EUNOMICUSPSYCHIANS, a sect of heretics of the fourth century, mentioned by Nicolepos, lib. xii. cap. 32, being the same with those called Eutychians by Sozomen, lib. viii. cap. 17. See Eutychians.

EUNUCH, Eunykh, a term applied in the general to all who have not the faculty of generating, either through imbecility or frigidity; but more particularly to such as have been castrated, or have lost some of the parts necessary for that purpose.

The word is formed of two Græc. q. d. leó̜tis curvam habet, guardian, or keeper of the bed.

In England, France, &c. eunuchs are never made but on occasion of some diseafe which renders such an operation necessary; but in Italy they make eunuchs for the sake of preferring the voice; and in the East they make eunuchs to be guards or attendants on their women.

Great numbers of children, from one to three years of age, are yearly castrated in Italy to supply the operas and theatres, not only of Italy but other parts of Europe, with fingers; though it is not one in three, that, after having lost their virility, have a good voice for a recompence. See Conservatories.

Tavernier alludes us, that in the kingdom of Boutan, in the East Indies, there are every year made twenty thousand eunuchs, and sold thence into other countries.

The heragies of the Eastern emperors are chiefly ferved and guarded by eunuchs; and yet we have very good testimonies, that the rich eunuchs in Peria and other countries keep heragios for their own use. This is a punishment of crimes in some countries. See Adultery.

By an arrest of the grand chamber of Paris in 1665, it is adjudged that an eunuch could not marry, not even with the consent of the woman, and all the parties on both sides.

Claudian has a very severe fatige against the eunuch Eutropius, who had been elected consul of Rome. He represents him as an old woman, dressed up in the honours of the consulate.

In the council of Nice those were condemned who, out of an indifferet zeal, and to guard themselves from sensual pleasures, should make themselves eunuchs. Such as thus mutilated their bodies were excluded from holy orders; witnesses Leontius, bishop of Antioch, who was deposed for having practised this cruelty on himself; and the bishop of Alexandria excommunicated two monks who had followed his example, on pretence of securing themselves from the impetuous motions of concupiscence.

Several of the emperors made very severe prohibitions against the making of eunuchs, or people's castrating themselves. See Castration.

EUNUCHS, Eunuchi, in Ecclesiastical History, is also the denomination of a sect of heretics in the third century, who had the folly or madness to castrate not only those of their own persuasion, but even all they could lay hands on.

They took their rise from the example of Origen, who, upon a misunderstanding of our Saviour's words in St. Mark's chap. 21st. ver. 12. made himself an eunuch, by cutting off the offending part, as some say; or as others (particularly St. Epiphanius), by the use of certain medicines. These heretics were also called Iakasants.

EVCATI, among the Romans, soldiers, who having served their time in the army, went afterwards volunteers at the request of some favourite general.

EVCATION, Evocation, among the Romans, a religious ceremony always observed by them at undertaking the
the siege of a town, wherein they solemnly called upon the gods and goddesses of the place to forfear it and come over to them. Without the performance of this ceremony, they either thought that the place could not be taken, or that it would be a sacrilege to take the gods prisoners.

The form of evocation used at taking the city of Carthage is related by Macrobius, Sat. Ill. 9.

They always took it for granted that their prayer was heard, and that the gods had deferred the place and came over to them, provided they were able to make themselves matters of it. The ancients had also two other forms of evocation; one was a magical operation, which they used in order to call up departed souls. This custom of raising the manes, or conjuring up fonts departed, was so ancient, that its origin is traced as high as the earliest periods of time; and it is generally esteemed by the ancient authors against those who consulted familiar spirits as proofs of the antiquity of this practice. Among the different forms of magic prohibited by Moses, that of calling up the dead is expressly specified. (See Witch of Endor.)

Prophane authors look upon Orpheus as the inventor of this art, in evidence of which it is alleged, that the hymns which are ascribed to him are mostly real pieces of conjuration, but it is probable that this practice was derived from the people of the East, and was carried into Greece with other religious ceremonies, by colonies which came and settled here. It is certain, however, that in the time of Homer, this sort of conjuration was practised, as it is mentioned in some passages of the Iliad. At that time it was not reckoned odious or criminal, since there were persons who made public profession of conjuring up ghosts, and there were temples where the ceremony of conjuration was to be performed. Paulianus (in Exod.) speaks of that which was in Thespia, where Orpheus came to call up the soul of his wife Eurydice. Ulysses's travels into the country of the Cimmerians, whither he went to consult the ghost of Tiresias, described by Homer in the Odyssey (I. xii.) seems to indicate a kind of conjuration. Historians, as well as poets, have mentioned this species of conjuration. Another sort of evocation was that which was used in calling up the gods. In order to understand this practice, it should be recollected, that it was a doctrine of the Pagan theology, that the gods resided in a peculiar manner over certain places, and that several of these places were under the protection of the same god; and as it was impossible for him to be in them all at the same time, it was necessary to use the ceremony of evocation, when his presence was thought needful. They had hymns proper to this operation, which they called evocatory, such as were most of those ascribed to Orpheus, and those of the poet Proclus. When they thought the patron god was arrived, they celebrated the festival named Eudodia. As soon as the danger, which made them invoke the gods was passed, they gave them liberty to go anywhere else; and they had other hymns for celebrating their departure, which hymns were called evolvent.

**Evo**

**Evo**

**Evocatio**

**Evocatoria Epistles,** among the Romans, letters sent by the emperors to command the attendance of any person; or letters granting licence to any one to wait on the emperor; every person not being allowed this privilege till they had defined and obtained the evocatorie epistles.

**Evodia,** in Botany, from *oidea* a foot-stool, Follit. Gen. 7. t. 7. See Fagara.

**Evoli,** in Geography, a town of Naples, in Principato Citra; 15 miles E.S.E. of Salerno.

**Evolvent,** in Geometry, a term which some writers use for the curve resulting from the evolution of a curve; in contradistinction to the evolute, which is the curve supposed to be open or evolved.

The evolute always both touches and cuts the evolvent at the same time; the reason is, that it has two of its infinitely small sides in common with the evolvent; or, rather exactly placed on two equal sides thereof; one of them within-side that of the evolvent, i.e., on the concave side thereof; and the other on the convex side of its corresponding side; so that the evolute touches the evolvent in two points; whence, instead of being a tangent, it is said to osculate the evolvent; and, hence, it is also called osculator, and *circulus osculator.*

There is one, and but one osculator, to each point of the evolvent; but to the same point there is an infinity of other circles which only touch, and do not osculate. The osculator, and the evolute, make no angle in the place where they touch and cut; nor can any curve lie be drawn between, as there may between a tangent and a curve.

**Evolute, Evoluta,** in the Higher Geometry, a curve first proposed by Mr. Huygens, and since much studied by the latter mathematicians. See CURVATURE.

The evolute is a curve, supposed to be opened, or opened; and which, in opening, describes other curves.

To conceive its origin and formation, suppose a flexible thread, wound exactly over the convexity of any curve, as *A B C G* (Plate VI. Analytis, fig. 1.) and suppose the thread fixed in *G,* and every where else at liberty, to *A.* Now, beginning to unwind the thread from the point, and continuing it to *D,* and, throughout, keeping it tight on the curve surface *A B C G,* when the thread is become quite straight, and is only a tangent, *F G,* to the curve in the point *G,* it is evident the extremity *A,* in its progress to *F,* has described another curve line *A D E F.*

Here, the first curve *A B C G* is called the evolute; each of its tangents *B D,* *C E,* &c. comprehended between it and the curve *A D E F,* called the involute, is called a *radius of the evolute,* or *radius of the circle,* radius osculator, or radius of curvature, of the curve *A D E F,* in the respective points *D,* *E,* &c. And the circles, whereof the osculators *B D,* *C E,* &c. are radii, are called *circuli osculatoris* of the curve *A D E F,* in *D,* *E,* &c. And, lastly, the new curve resulting from the evolution of the first curve begun in *A,* is called the *curve of evolution,* or *curve described by evolution.*

**Evolute, the radius of the circle,** then, is the part of the thread comprized between any point where it is a tangent to the evolute, and the correspondent point where it terminates in the new curve. Which appellation, radius, is the more proper, as one may actually consider this part of the thread in every step it takes, as if it described an arc of an infinitely small circle, making a part of the new curve, which thus consists of an infinite number of such arcs, all described from different centres, and with different radii.

Every curve, therefore, may be conceived as formed by the evolution of another. And we are to find that, whole evolution formed it; which amounts to the finding of the radius of the evolute in any point; for, as it is always a tangent to the generating curve, it is, properly, no more than one of its infinitely small parts, or sides, prolonged; and all its sides, whole positions are determined of course, are no other than the generating curve itself.

The same term is also called radius curvatus, or radius osculatoris, because a circle described thereby, from the centre *G,* is said to osculate, or kiss it, as both touching and cutting at the same time, i.e., touching both the inside and the out.

Hence, I. The evolute *B C F* (fig. 35.) is the place of all
all the centres of the circles that osculate the curve AM, described by evolution. 2. When the point B fall on \( x \), the radius of curvature, or radius of the evolve, MC, is equal to the arc BC; or to the aggregate of AB and the arc BC. 3. Since the element of the arc \( M.n \) in the curve described by evolution, is an arc of a circle described by the radius CM; the radius of the evolve CM is perpendicular to the curve AM, or to a tangent at the point M. 4. Since the radius of the evolve MC is always a tangent to the evolve CBF, curves by evolution may be described through innumerable points, if only tangents be produced, in the several points of the evolve, till they become equal to their correspondent arcs.

The finding of the radii of evolves is a thing of great importance in the higher speculations of geometry; and even, sometimes, is of use in practice as the inventor of the whole theory, Huygens, has shown, in applying it to the pendulum. (Horol. Oscil. part 3.) The doctrine of the oscula of evolves is owing to M. Leibnitz, who first showed the use of evolves in the measuring of curves.

We shall here subjoin a brief account of the method of finding the radius of the evolve in different kinds of curves and equations expressing the nature of evolves.

1. To form a general expression for \( BE \) the radius of the evolve, or of curvature at any point B in the evolve curve \( ABE \), whose axis is \( AX \), and evolve \( DE \), fig. 3.

With the radius \( EB \) describe the circular arc \( BK \), which will have the same curvature with the evolve curve \( AB \) at the point B. Draw the radius \( EK \) parallel to the axis \( AX \), and produce the ordinate \( BC \) to \( EK \), in which draw \( AN \) parallel: let the absciss \( AC \) be \( = x \), the ordinate \( CB \) \( = y \), radius \( EB \) or \( EK \) \( = r \), \( KN \) \( = a \), and \( AN \) \( = b \); then \( LE \) \( = r - a - x \).

If the absciss \( x \) be supposed to increase uniformly, and \( Bm \) to be a tangent at the point \( B \); and \( mn \) be drawn parallel to \( Bc \), and \( BN \) parallel to \( AX \); \( BN \) and \( BM \), which are the contemporary increments of the absciss, ordinate, and curve, will be as their fluxions respectively; or \( Bn \) will be as \( x, nm \) as \( y \), and \( Bm \) \( = B(a^2 + m^2) \) as \( x^2 + y^2 \).

Further, the triangles \( Bmn \) and \( BLE \) are similar; therefore \( Bn \cdot mn = Bn \cdot le \); \( B \cdot \varepsilon \cdot \hat{e} + j \cdot \hat{j} = y + b \); \( b - a - x \); consequently \( r - x = a - x \); \( x \) \( = y + b \); the fluxion of which equation (supposing \( x \) or \( y \) of the curve, and \( s \) or \( t \) approaching towards a parallelism with its axis, the fluxion of \( s \) as negative) is \( r \hat{s} = x \hat{s} = -\hat{y} \); and \( s^2 + \hat{s}^2 = \frac{\hat{y}^2}{\hat{y}} \).

Again, \( B : E \) : \( nB : Mn \); \( i, e \); \( x \) : \( y \); \( r : x \); \( \frac{\hat{x}}{\hat{x}} + \frac{\hat{y}}{\hat{y}} \); therefore \( y = \frac{\hat{x}}{\hat{x}} + \frac{\hat{y}}{\hat{y}} \), and substituting this expression for \( b + y \), the above equation will become \( x^2 + \hat{s}^2 = \frac{\hat{y}^2}{\hat{y}} \); consequently \( x^2 + \hat{s}^2 = \frac{\hat{y}^2}{\hat{y}} \), \( \frac{\hat{s}^2}{\hat{s}} = \frac{\hat{y}^2}{\hat{y}} \).

In deducing this expression, the increment of the ordinate \( y \), or the velocity or fluxion with which it flows, is supposed continually to decrease, therefore its second fluxion is negative; but when \( y \) increafes with an accelerated motion, its second fluxion will be affirmative; and above expression will be \( \frac{\hat{s}^2}{\hat{s}} = \frac{\hat{y}^2}{\hat{y}} \). By substituting \( 1 \) for \( x \), which is inv"
EVOLUTE.

nate \(CB = y\), line \(IG = z\), and arc \(FG = x\). Now by 35 E. 5. \(IG = D_{1}T_{1}E_{1}\), that is, \(z = 2 ay - y^{2}\); the fluxion of which equation is \(z = 2 a y - y^{2}\); and by the nature of the cycloid, arc \(DG = GB\); and therefore, arc \(FG = GI\), that is, \(x = a y - \frac{a y}{2}\); and the fluxion of this equation, making \(x = 1\), is \(1 = \frac{a y}{2 a y - y^{2}} + \frac{y y - a y}{2 a y - y^{2}}\), which, substituting for \(z\), makes the above equation \(1 = \frac{a y}{2 a y - y^{2}} + \frac{y y - a y}{2 a y - y^{2}}\); that is, \(1 = \frac{a y}{2 a y - y^{2}}\); therefore, \(y = \frac{a y - a y}{2 a y - y^{2}}\), and the fluxion of \(y\) being negative, \(y = \frac{a y - a y}{2 a y - y^{2}}\).

Now, by substituting \(2 a y - y^{2}\) for \(y\), and \(a y\) for \(y\), we have \(\frac{1 + 2 a y - y^{2}}{2 a y - y^{2}} = \frac{a y}{2 a y - y^{2}}\), or \(\frac{a y}{2 a y - y^{2}} = \frac{2 a y - y^{2}}{2 a y - y^{2}} = B E\), the radius of curvature.

Confronation. Make \(FH = CB\); and through the point \(H\) draw the right line \(BE\), making \(BH = HE = CD F G\); then will \(BE\) be the radius of curvature at the point \(B\); for a tangent to the point \(B\) is parallel to the chord \(CD\) and the radius of curvature is always perpendicular to the tangent; therefore, because by 31 E. 5. the \(CD G F\) is right, \(BE\) must be parallel to the chord \(CD\). Now, by 4 and 8 E. 6. \(DF = FG\), or \(F L\), or \(CB\); \(DF = D F \times C B\); \(D F = 2 a y + x\), and \(2 a y + x = B E\).

2. To form a general expression for the radius of curvature in spirals, or curves whose ordinates are referred to a fixed or central point.

Let \(y + 7\) be the curve, \(C\) the central point, or that from which all the ordinates rise; and \(BE\) the radius of the curvature at the point \(B\), that is, let the point \(E\) be supposed in the evolute curve; conceive \(C B\) and \(E B\) indefinitely near to \(C B\) and \(E B\); that is, let the points \(B\) and \(E\) be supposed indefinitely near to each other; and, let \(C F\) and \(C F\) be perpendicular to \(E B\) and \(E B\) respectively, then will the points \(F\) and \(r\) be indefinitely near to a coincidence; and therefore \(B r\) and \(C r\) may be taken as equal to \(B E\) and \(C F\). Now, if with the ordinate \(CB\) as a radius, the little circular arc \(B n\) be described and considered as a little right line perpendicular to \(CB\), and the increment \(B b\) be considered as coinciding with the tangent to the point \(B\), then the little right-angled triangle \(B n b\) will be similar to the right-angled triangle \(B F C\); and for \(\angle CBF = \angle E B b\), and therefore \(\angle E B n\) being common, the \(\angle C B F = \angle n B b\); and, consequently, the angles at \(F\) and \(n\) being right, \(\angle B C F = \angle B e r\); therefore by 4. E. 6. \(B b\): \(B n\): \(B C\) = \(B F\) or \(B r\); and \(B b\) = \(n B\): \(B C\) = \(C F\); that is, \(n B + y n = \frac{1}{2} C F\) or \(C r\); the increment of which is right \(f f\); that is, supposing \(x^{'\prime}\) to be the second, or \(y^{'\prime}\) to be the second, we have \(y^{'\prime} + y^{'\prime} x + x^{'\prime} y = \frac{1}{2} - y^{'\prime} y^{'\prime} y^{'\prime} = y^{'\prime}\).

\[\text{Now,}\] \[\frac{a y}{2 a y - y^{2}} = \frac{2 a y - y^{2}}{2 a y - y^{2}} = B E,\] the radius of curvature required.

Confronation. Make \(FH = CB\); and through the point \(H\) draw the right line \(BE\), making \(BH = HE = CD F G\); then will \(BE\) be the radius of curvature at the point \(B\); for a tangent to the point \(B\) is parallel to the chord \(CD\) and the radius of curvature is always perpendicular to the tangent; therefore, because by 31 E. 5. the \(CD G F\) is right, \(BE\) must be parallel to the chord \(CD\). Now, by 4 and 8 E. 6. \(DF = FG\), or \(F L\), or \(CB\); \(DF = D F \times C B\); \(D F = 2 a y + x\), and \(2 a y + x = B E\).

2. To form a general expression for the radius of curvature in spirals, or curves whose ordinates are referred to a fixed or central point.

Let \(y + 7\) be the curve, \(C\) the central point, or that from which all the ordinates rise; and \(BE\) the radius of the curvature at the point \(B\), that is, let the point \(E\) be supposed in the evolute curve; conceive \(C B\) and \(E B\) indefinitely near to \(C B\) and \(E B\); that is, let the points \(B\) and \(E\) be supposed indefinitely near to each other; and, let \(C F\) and \(C F\) be perpendicular to \(E B\) and \(E B\) respectively, then will the points \(F\) and \(r\) be indefinitely near to a coincidence; and therefore \(B r\) and \(C r\) may be taken as equal to \(B E\) and \(C F\). Now, if with the ordinate \(CB\) as a radius, the little circular arc \(B n\) be described and considered as a little right line perpendicular to \(CB\), and the increment \(B b\) be considered as coinciding with the tangent to the point \(B\), then the little right-angled triangle \(B n b\) will be similar to the right-angled triangle \(B F C\); and for \(\angle CBF = \angle E B b\), and therefore \(\angle E B n\) being common, the \(\angle C B F = \angle n B b\); and, consequently, the angles at \(F\) and \(n\) being right, \(\angle B C F = \angle B e r\); therefore by 4. E. 6. \(B b\): \(B n\): \(B C\) = \(B F\) or \(B r\); and \(B b\) = \(n B\): \(B C\) = \(C F\); that is, \(n B + y n = \frac{1}{2} C F\) or \(C r\); the increment of which is right \(f f\); that is, supposing \(x^{'\prime}\) to be the second, or \(y^{'\prime}\) to be the second, we have \(y^{'\prime} + y^{'\prime} x + x^{'\prime} y = \frac{1}{2} - y^{'\prime} y^{'\prime} y^{'\prime} = y^{'\prime}\).
and therefore \( R = \frac{y^2}{b} \); which, because \( y^2 = b^2 \), (and therefore \( y = \frac{b}{a} \)) will also be \( R = \frac{y^2}{b} \).

E. G. 1. Let the given curve \( A R \) (fig. 7) be the logarithmic spiral, whose nature is such, that the angle \( P R Q \) (or \( R P H \)) which the ordinate makes with the curve, is every where the same.

Then (denoting the sine of that angle by \( b \)) and the radius of the tables by \( a \) we have \( R = \frac{b y}{a} \), and

therefore \( R = \frac{y^2}{b} \); which being to \( PR \) 

(y) in the constant ratio of \( a \) to \( b \), or of \( P R \) to \( R H \), the triangles \( R O P \) and \( R P H \) must therefore be similar, and to the angle \( P O H \) which the ordinate \( P O \) makes with the evolute, being every where equal to \( P R Q \), will likewise be invariable. What hence appears that the evolute is also a logarithmic spiral, similar to the involute; and that a right line drawn from the centre, perpendicular to the ordinate of any logarithmic spiral, will pass through the centre of curvature.

E. G. 2. To find the radius of curvature at any point \( B \)

of the spiral of Archimedes, \( C B \), &c. fig. 8.

Put the circumference of the generating circle \( A F \), &c. = \( a \), and its radius \( C A = b \), ordinate \( C B = y \), arc \( A F = z \). Let \( C F \) be supposed indefinitely near to \( C F \), that is, let the \( \Delta F G F \) be supposed indefinitely small; and with the ordinate \( C B \) as a radius describe the little circular arc \( B n \), which put \( = x \); also put \( \Gamma f = y \).

Now, by the nature of the curve, \( a = b = z = y \), or \( a = b = y \), the line of the curve is \( \frac{a}{b} \); and by the similar sectors \( C D n \) and \( C F f \), \( y = z = b = \frac{x}{y} \), or, \( \frac{a}{b} = \frac{b}{y} \). Hence \( \frac{a}{b} = \frac{a}{y} \); that is, (making \( x = 1 ) \frac{a}{b} = \frac{b}{y} \); from which equation we have

\[
\frac{a}{b} = \frac{b}{y} \quad \therefore \quad b = \frac{a y}{b} \quad \text{and} \quad j = \frac{a - b y}{a y} = \frac{a}{a^2 y^2} \quad \text{by writing for } \frac{b}{y} \text{ its value},
\]

\[
- \frac{b}{a^2 y^2} = \frac{a}{a^2 y^2} \quad \text{and if we substitute for } j \text{ and } y \text{ their values, we shall have }
\]

\[
\frac{y \times 1 + b y}{1 + y = \frac{1}{b} y} = \frac{\frac{a}{a^2 y^2} + 2 a b y}{1 + y = \frac{1}{b} y} = \text{B E, the radius of curvature sought.}
\]

Constrution.—Through the centre \( C \) draw the indefinite right line \( H \) : perpendicular to the ordinate \( C B \); draw the tangent \( T B \); perpendicular to which draw \( B H \); produce \( B C \) to \( V \), making \( B R = T H \) and \( R V = C H \); with \( B V \) and \( B R \) as radii, describe the arcs \( V \) and \( R \); and from the intersecting point \( r \) draw \( r E \) parallel to \( H \); then will \( B E \) be the radius of curvature at the point \( B \); for, \( C T = \frac{y}{b} \), that is, by substituting \( \frac{a}{b} y \) for \( x \), \( C T = \frac{y}{b} \).

E F. To find the nature of the curve \( A E F \) (fig. 10) by whose evolution the cycloid \( A B D \) is described.

Put \( A C = x \), \( C B = y \), arc \( F G = z \), and \( O D \) or \( O F = \theta \) \( y \); then by Ex. 2. art. 1. above, \( j = \frac{2 a y - y^2}{2 y} \), \( j = \frac{a}{y} \); wherefore, \( B L = \)
E V O

The word *evolution* is formed from the preposition *e*, out, and *voluere*, to roll, or wind; q. d. an unwinding, or unfolding.

The equal evolution of the periphery of a circle, or other curve, is such a gradual approach of the circumference to rectitude, as that its parts do all concur, and equally evolve, or unwind; so that the same line becomes successively a leafl or of a reciprocally greater circle, till at last they change into a straight line. In the Philosophical Transactions, No. 263, a new quadratrix to the circle is found by this means, being the curve described by the equal evolution of its periphery.

**Evolution, in Algebra, is also used for the extraction of roots out of powers. In which sense it stands opposed to involution. See Extraction of roots.**

Evolution, as relating to Military operations, must be understood to be founded on the principles of Tactics (which see), and be considered indispensibly necessary to the safety, the progress, and the success of all bodies of men, whether large or small. The term is generally used as synonymous with manoeuvre, but in strictness they are by no means to be so accounted; for an evolution rather relates to an open, candid, and undisguised movement, made either for a change of position, or for the general purposes of attack and defence; while a manoeuvre applies artificially to deceptions movements, to points, and to that kind of trick which gives rise to the saying so common among us, "I have out-manoeuvred him." Thus the French, from whom we have directly borrowed the term, say, "un manœuvre," i. e. a cunning fellow; and among them a skilful feaman is designated "un manœuvre."

In every service, both in the military and naval departments, certain regulations exist which direct, that all candidates for promotion should be acquainted, not only with the several motions of the firelock, and the ordinary duties of individuals, but with a variety of movements to be made by entire battalions, or armies, and by either single ships, squadrons, divisions, or fleets respectively. It being our intention to amplify under the head of Tactics, military and naval, we shall in this place confine ourselves to those evolutions which, forming a part of the British discipline, ought to be thoroughly understood by every person whose pursuits tend towards the goal of martial celebrity; and should be thoroughly understood by every officer, of whatever rank.

The following nineteen changes will be sufficient for the purposes, under the remark, that we pre-suppose a battalion to be arranged at close order, and all in readiness for performing the required evolutions.

**Evolution 1.**

<table>
<thead>
<tr>
<th>Form close column of companies behind grenadiers.</th>
<th>Explanation — The column marches quick, 20 or 30 paces to the right, and, without halting, begins to deploy into line on the rear division. The commanding officer of the battalion gives the word, for each division to halt, front.</th>

</tr>
<tr>
<td>Face and march to the left.</td>
<td>Deploy on the front division.</td>
</tr>
</tbody>
</table>

**Vol. XIII.**
Evolution 3.
Form close column of companies on a central division. The close column is formed facing to the rear. It then countermarches each division, so as to return to the proper front. In the central deployment by companies, the company officers give the words respectively to halt, front.

Evolution 4.
On a central division. The battalion, thus, at an intermediate point, enters an alignment, on which it is to form.

Evolution 5.
Wheel back into open column of companies, the right in front. March forward 30 or 40 paces. Enter an oblique line (the three or four leading companies), by wheeling successively to the left, a half-wheel. Halt. The rear companies file into column. Wheel up into line.

Evolution 6.
The whole company is wheeled back till parallel with the original position. The left of the companies wheel into echelon. March to the rear. Form on the left company. After the countermarch by files, the column stands with its left in front. The column closes in quick time. The square is formed, and close column re-formed. The column opens out in quick time from its rear division, and halts. The countermarch by companies, from the rear to the front, is in ordinary time. When the line is formed, it is then considerably to the reviewing general's right, and with its rear to him.

Evolution 7.
Countermarch by files on the centre of the battalion. This brings back the battalion to its original front.

Evolution 8.
Form open column behind the left company, which is put in march when the third company has taken its place in column. The right sub-divisions double. The column halts, and pivots are corrected. Wheel up into line.

Evolution 9.
Wheel back into open column, the left in front. The third company is wheeled back, the 8th of a circle, and each of the others 3-16ths of the circle. Form line on the third company by the echelon-march.

Evolution 10.
The left company is wheeled up the 8th of a circle, and each of the others 1-16th. Form line by the echelon-march.

Evolution 11.
The battalion faces to the right. March in file 50 or 60 paces. Halts. Wheels up into line, except the light company, which files quickly to the right, and forms behind the colours.

Evolution 12.
The column of companies is formed by the rear men of each moving up quickly to the left of their leaders, and of each other: the officers move to pivot flanks, and pivots are instantly corrected. The column halts when the colours are opposite to the general.

The battalion retires (50 paces). Halts; fronts. Fire twice by companies from centre to flanks. Retire by alternate companies in two lines (250 paces, each retreat about 50 paces.) Form line. Retire in line (50 paces). Halt; front.
EVO

Evolution 13.

At the word "wheel back into line," the pivot flankers mark time, and the divisions wheel back in ordinary time. At the proper instant, when the battalion is formed, the commander gives the word "forward," for the whole to advance by the colours, and to correct any irregularity there may be in the battalion.

Hitherto the battalion may have been two deep, but if its companies can muster ten files each, the corps may now be formed three deep.

Evolution 14.

The square is formed by the echelon march of companies. After the march by the left face, the square is formed when opposite the general. The line is formed by the echelon wheel-up, and march of companies. When the order is given to form line, the light company marches quickly, and places itself two deep, and in two divisions, ten or twelve places behind the two centre companies.

Form the line.

Evolution 15.

When the line has palled the light company twenty paces, that company extends to cover the centre of the battalion, and follows at 50 or 60 paces distance; and when the column halts to form, the light company passes quickly through and beyond it. The companies file quickly to the rear.

The battalion forms line at the extremity of its ground; the light company 50 places in its rear.

Evolution 16.

Before the line advances the light company quickly forms, extended 50 places before the centre, and preserves that distance in advancing. When the column halts to form, the light company passes quickly to the rear, and assembles half of it behind each flank, then moves relatively with the flank-companies, till after the charge of bayonets. The alternate half-battalions fire, the two first ranks standing.

Advance in line (50 places.)

File from the right of companies to the front (50 places.)

Halt in open column, the left in front.

Wheeled up into line.

Advance in line (50 places.)

Advance by alternate half battalions, and fire four times.

EVO

Evolution 17.

After the volley, bayonets are ported; the battalion advances firm by the centre at the quick step, and at the word "halt," the front rank comes down to the charging position. The word "Prime and Load" is then given, and the light company, issuing from behind the flanks, pursues, return, and assemble, and join on the left of the battalion.

Retire in line (100 places.)

Retire by alternate half battalions.

Fire four times.

Retire in line (100 places, or more.)

Halt. Front.

Evolution 18.

In the volleys the front rank knells.

Halt.

Fire two volleys.

Port arms at the left, one, and half cock.

Open ranks.

Advance within 50 places of reviewing general.

Halt.

General salute.

We have selected this portion of the discipline ordered for the British army, because it comprises sufficient changes to give our readers a correct idea of what are termed evolutions. These are so contrived as to be performed on a very moderate extent of ground; each evolution serving to correct any obliquity, or lateral change of position, and confining the regiment within certain limits.

It may be proper to remark, that though the foregoing relate in this instance to a single regiment under review, the whole of the changes may be considered as representing those made by a large army; the several companies being the representatives of regiments, or of larger bodies. See Battalion.

F. Holte, a Jesuit, in 1677, printed a Treatise on Naval Evolutions, in folio. By naval evolutions he means the motions made by a fleet, squadron, or naval armament, in order to put themselves in a proper disposition for attacking the enemy, or defending themselves with the most advantage. See Tactics.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, acute, permanent segments. Cor. of one petal, regular, wheel-shaped, blunted, slightly five-cleft. Stam. Filaments free, capillary, spreading, almost as long as the corolla; anthers rather obtuse. Pprf. German superior, nearly globular; styles four, capillary, spreading, the length of the stamens; stigma simple

Willdenow has seven species, five of which are known to Linnaeus. Among the latter is *E. hispifolia*, Linn. Sp. Pl. 352. (Convulvus hispifolius; Am. Acad. v. 4, 326. Syll. Nat. ed. 10. v. 2, 924.; Brown. Jam. t. 10. f. 2.) whence he informs us he derived the above generic character, having the plant alive under his own inspection. It is a small inconspicuous annual, with slender, straight, spreading stems; narrow, lanceolate, hairy leaves; and little, blue, axillary flowers; native of low ground in Jamaica.

The other species have rounder leaves, but otherwise agree very much with the above. They grow in the East or West Indies, and are annuals of humble growth, and no conspicuous attractions, being inferior in beauty to the meagre species of *Convulvus*.

*E. tridentata*, Linn. Sp. Pl. 392, is now returned to *Convulvus*, see that genus, p. 19.

Gen. Ch. Cat. Perianth inferior, flat, in four or five deep, equal, roundish, concave segments. Cor. Petals four or five, ovate-oblong, flat, spreading, longer than the calyx. Filaments four or five, awl-shaped, erect, shorter than the petals, inserted, alternately with them, into a glabrous receptacle; anthers two-lobed. Fil. Gernan superior, pointed; style short, flat; stigma obtuse. *Peric.* Capitulum succulent, covered, depressed, with four or five angles, and as many cells and valves. Seeds solitary, ovate, each wrapped up in a papery arillus.

A genus of extra-tropical shrubs, the produce of Europe, North America and Japan. Willdenow has seven species. They are deficient in hairiness, and have opposite branches and leaves; the latter simple, deciduous, more or less elliptical, entire or toothed, with feebly any stipules. Flowers of a dull or greenish hue, in axillary forked panicles, not ornamental. Fruit much more conspicuous and often very beautiful, on account of the pink, waxy hue of the capitate, varying occasionally to white, and orange coverings of the seeds.

**E. Toliana.** Thunb. Jap. 99. (Toliana; Kamped. Am. Exot. 756, cum ic.), a native of Japan, has terminal flowers, and in many other respects seems not perfectly to accord with this genus.

*E. europaeus.* Sm. Fl. Brit. 262. Engl. Bot. t. 362; and F. verrucosus, Jacq. Aufr. t. 40; also E. latifolius, Jacq. Aufr. t. 269; are good examples of it. Linnaeus confounded them together as varieties, but Scopoli, and afterwards Jacquin, have well distinguished them. The last species in particular is very remarkable for its warty branches, slender habit, reddish flowers, and small pale capsules, out of which the black seeds, partially clothed with their scarlet arillus, hang by slender threads. The wood of all of them is tough, and used for skewers and spindles. It should be cut in the summer. The fruit serves in many places to decorate churches and rustic kitchens at Christmas.

It is reported to be dangerously emetic and purgative.

**EUONYMUS,** in Gardening, comprehends plants of the hardy flowering shrubby kind, of which the species cultivated are, the common spindle-tree (*E. europaeus*); the warted spindle-tree (*E. verrucosus*); the purple-flowered spindle-tree (*E. atropurpureus*); the ever-green spindle-tree (*E. americanus*); and the broad-leaved spindle-tree (*E. latifolius*).

The evergreen form of spindle tree has a variety with variegated leaves.

**Method of Culture.** All the four more common forms may be propagated either by seeds, layers, or cuttings of the young shoots; but the evergreen kind requires a different method.

In the first mode, the seeds should be sown in the châteaux or borders in the early autumn, covering them well in. In the following autumn the plants should be removed, and set out in nursery rows, being kept well cleared from weeds during the summer. After two or three years growth in this situation, they will be fit to plant out for good, in proper situations.

With respect to the young shoots, they may be layed down in the autumn, a flat being made at the joint placed the deep-cell in the ground. In the following autumn they will be well rooted, and may be taken off and planted out in the manner of the seedling plants.

The cuttings should be made eight or ten inches in length, and planted in a shady border in the autumn. When they have truck full root, they should be carefully removed, and managed as thsfe raised from the seed.

But the two last modes, and those of budding and grafting, are the only ones by which the green variety can be continued with certainty and success.

With regard to the last species, it is best increased by laying down the young branches after being tinged in the autumn, managing them afterwards in the same manner as the others.

These plants are sufficiently hardy to bear the open air, when planted in warm sheltered situations.

They are all very ornamental plants; the four common sorts producing a fine effect by their berry-like seeds, and the last sort but one by its evergreen leaves; the chief objection to the former kinds being their great aptitude to have their leaves completely eaten up by the caterpillars soon after they are fully expanded.

**EVORA, or Elvora,** anciently *Eburna*, in Geography, an ancient, walled and fortified, large but not populous, city of Portugal, the capital of the province of Alentejo, and an archbishop's see, situated on a gentle eminence in a fruitful plain, surrounded by hills, near the centre of the province; 75 miles E. Lisbon. The streets are narrow, crooked, and full of angles. It has no trade or manufactures; but contains five parish churches, twenty-three religious houses, and about twelve thousand inhabitants. The cathedral and other buildings are high and in the Gothic style. This city is said to have been founded by the Phœnicians, and walled round by Sertorius, who supplied the town with water by means of a beautiful aqueduct, (since entirely rebuilt by John III.,) and who, after having refixed there for a considerable time, was buried, as tradition reports, in this place. Julius Caesar constituted it a municipium, and named it Liberalitas Julia. It was taken by the Moors in the year 715, and taken by the Christians under Giraldo, whose heroic conduct is celebrated by Caesars in his Historiæ, in 1166, and then reduced under the dominion of Alphonso Henrique. In 1540 it was crested into
into an archiepiscopal see by pope Paul III.; and the first prelate founded an university, now fallen into decay. In this city are the remains of a temple of Diana, 7 pillars of which are standing, of the Corinthian order, connected by a plater-wall. This edifice, at full a pagan place of worship, was converted into a Moorish mosque, and is now the butchers' shambles. There are many other Roman vestiges, inscriptions, &c., particularly in the great square, which indicate the antiquity of this place. Its fortifications are 12 bastions, and two demi-bastions, and a castle in ruines. On the north side of Evora the hills rise, being round the town adorned with gardens, and on their summits with evergreen oaks. The road from hence to Montemour novo, which lies at the distance of five leagues, passes over granite hills, partly covered with corn fields, and partly with fine woody or evergreen oaks and pastures. N. lat. 38° 30'. W. long. 7° 42'.

EVARONTE, a town of Portugal, in the province of Alentejo, festoned on a rock, and containing about 800 inhabitants; 15 miles N.E. of Evora. N. lat. 38° 42'. W. long. 7° 21'.

EVORIA, a town of European Turkey in Livadia; 24 miles N. of Lepanto.

Gen. Ch. Col. Perianth inferior, in five deep, obovate, concave, equal, permanent segments. Cor. of one petal, bell-shaped; tube dilated, as long as the calyx, pellucid; limb in five broad, short, obtuse, spreading lobes. Stam. Filaments five, awl-shaped, shorter than the tube, infraverted into its lower part, alternate with the lobes of the limb; anthers incumbent, roundish, compressed. Ppal. Germen superior, oval, two lobed; style very short and thick; stigma capitata, four-lobed, on a level with the anthers. Peric. Capsule ovate, pointed, with a longitudinal furrow on each side, swelling irregularly from the projection of the seeds, of two valves, whose indented edges divide it into two cells; receptacles one in each cell, linear, triangular, parallel to the valves and close to the partitions. Seeds five or six in each cell, in two rows, oval, flattened on the inner side, all over rough with minute tubercles.

Eff. Ch. Calyx deeply five-creft. Corolla bell-shaped, with a five-creft border. Stigma four-lobed. Capsule superior, with two furrows and two cells, bursting at the top. Seeds seveal, oval, rough, affixed to a triangular receptacle.

1. E. albiflora. Andr. Repof. t. 520. Native of New South Wales, in the country near Port Jackson, from whence specimens and seeds were long ago sent by Dr. White. It is said to bear our winters in the open ground, flowering in April. Stem shrubby, with numerous, opposite, slender, square, leafy, slightly downy branches. Leaves opposite, on short stalks, lanceolate, acute, entire, smooth; thinning and deep green above; paler, opaque, and somewhat glaucous beneath. Stipulae small, bristle-shaped, in pairs at the base of each footstalk, somewhat hairy. Flowers in dense, axillary, bracteate panicles, much shorter than the leaves; snow-white, small, but copious, and very fragrant. Capsules about a quarter of an inch long, oblong, rippled, tipped with the short permanent style.

The characters above given will, we believe, distinguish this genus from Eucampt, to which it is most allied of any in the same natural order. See Excampt.

EVOVAE, a barbarous word, says Roufeau, formed of the six vowels, which begin the syllables of the words Eucampt, Eucalyptus, and which is only used in canto firma. It is from this that there is derived the name of the genus, which is found in the psalms and antiphonaries of the Roman Catholic church, and the notes by which the verses of the psalms and canticles must be terminated.

The evoe always begins by the dominant of the mode and ends upon the final.

EVO VUS, in Geography, a small island in the Southern Pacific ocean; 15 miles S. from Terra del Fuego. S. lat. 55° 33'. W. long. 67° 56'.

Gen. Ch. Cal. Perianth inferior, of five lanceolate, acute leaves. Cor. Petals from five to twelve, lanceolate, spreading, longer than the calyx. Stam. Filaments five; Ppal. Germen roundish, superior; style bristle-shaped, long; stigma filiform. Peric. Berry dry, globose, crowned with the permanent style, of one cell. Seeds numerous, roundish, small, affixed to a globose, fangous, central receptacle.

Eff. Ch. Calyx of five leaves. Petals from five to twelve. Berry superior, dry, of one cell, with many seeds. Receptacle globose.

E. annua is the only known species, gathered in New Holland by sir Joseph Banks and Dr. Solander. Gard. describes it as a procumbent plant, resembling Lythrum salicaria, but about one-fourth its size. Flowers of the colour of the Scarlet Pimpernel. He adds that "the seed-veil, which ever way prefed, would not open by regular valves, so that it is very nearly allied to Trifolium." Indeed his figure betrays the very close affinity, even the identity of these two genera, except that one is describ'd as polygamous, the other monogamous, and that the flammers of Euparea are not to be equal the petals in number, when the latter are more than five.

EUPATORIA, formerly Koslof, or Goffe, in Geography, a town and district of Raffia, in the province of Tunis, near the Black Sea. N. lat. 45° 40'. E. long. 33° 14'.

EUPATORIA, or Pompoeopolis, in Ancient Geography, Antioch, a town in the N.W. part of the Tauris Chersonesus.

EUPATORIA, Amid, a town of the kingdom of Pontus, situated in the gulf of Amida, and contiguous to a town of the same name. Mithridates Eupator is said to have built it, and to have given it his name.

Gen. Ch. Common Calyx oblong, imbricated; sepal linear-lanceolate, erect, unequal, mucronate. Cor. compound, uniform, dicocid. Lobes all uniform, perfect, little, monopetalous, funnel-shaped, with a regular, five cha, spreading border. Stam. Filaments five, capillary, very short, anthers united into a cylindrical tube. Ppal. Germen minute; style thread-shaped, very long, covered down as far as the top of the anthers, straight; stigma filiform, bluish, straight.
floruit. Port. none, except the permanent calyx. Seeds Shirley, oblong, angular; down long, rough, or feathery. Root, naked.

A large genus, chiefly, though not entirely, American. The roots are perennial. Stamens sometimes shrubby, Leaves ovate, mostly simple, and 'strongly serrated.' Flowers corymbose, terminal, numerous, white, blueish, or reddish. Whole plant, toughish, bitter, or aromatic. Willdewor has 84 species.

E. cannatianum, Engl. Det. t. 428, singular for having fingered leaves, which indeed are sometimes found undivided, is the only British species. It grows in watery places about the banks of rivers, or in mountainous boggy thickets, where it with us supplies the place of the Swiss Cardula alpina, which its pink flowers somewhat resemble.

Several of the American species are esteemed in that country, on account of their aromatic and tonic qualities, and known by the name of Fever root, or Fever root. Among these, we believe, are E. f. Hifidifolium, perisifolium, and aromatricum, but we wait further information on this subject.

E. Apa-pena, Venten. Jard. de la Malmant, t. 3, a native of the banks of the river of the Amazonas, is said to be "an excellent Fowler and amentharmic!" partaking therefore, no doubt, of the virtues of the above-mentioned species. Its leaves are lanceolate, nearly entire, and not accurately opposite. The flowers are purplish.

E. zeikianum, Linn. Sp. Pl. 1712, has decidedly alternate leaves, so as to have raised a doubt in the mind of Linnaeus whether it could belong to this genus; yet its fructification seems altogether like the generality of the species.

EUPEGIUM, in Ancient Geography, a town of Greece, in the Peloponnesus.

EUPEN, or Oerpen, in Geography, a town of France, in the department of the Ourthe, and chief place of a canton in the district of Malmedy; 4 miles E.N.E. of Liimburg. The place contains 6,749, and the canton 12,616 inhabitants, on a territorial extent of 1024 kilometres and seven communes. Here is a considerable manufacture of cloth.

EUPETALOS, in Natural History, the name of a gem described by the ancients as famous for its variety of colours. Pliny, lib. xxxvii. cap. xxo. tells us, that it thieved at once blue, fire-colour, red-lead colour, and yellow. It seems to have been the opal, and that Pliny's description of it in this place was taken from some author he did not perfectly understand, as is the case in many of his accounts from the Greeks.

EUPHASIE, in Geography, the ancient name of Hwaffie river in Tenecia, N. America; also the name of an Indian town on its S.W. bank, 28 miles from its mouth. See Hwaffee.

EUPHEMISMUS, Eufrcuryon, of u, well, and φαικ, I speak, in Rhetoric, a figure which expresses things in themselves disagreeable and shocking, by terms implying the contrary quality; that is, the Pontus, or Black sea, having the epithet of μιράκ, (i.e. inhuman) given it on account of the savage cruelty of the people inhabiting the neighbouring countries; this name, by euphemiom, was changed into that of Euxinus. Thus Ovid. Trist. lib. iii. eleg. 13.

"Dum me terrarum pars pene novissima Ponti Euxinum salio nomine teclus habet." In which sense it only makes a species of irony. But every euphemism is not irony; for we sometimes use improper and soft terms in the same sense with the proper and hard.

EUPHENEMUS, in Biography, proceeded to the high dignity of patriarch of Constantinople in the year 495. He was zealously attached to the doctrines of the Catholic church, of which he gave proof by striking out from the lists of persons in communion with the church, the name of Peter Mungus, patriarch of Alexandria, because that prelate had pronounced an anathema against the council of Chalcedon. This circumstance produced a violent schism between the two patriarchs, who convened their respective synods, in which they mutually procured excommunications of each other to be issued. In the year 491, on the death of Zeno, when Apanius was taking measures to secure the imperial throne, Euphemius warmly opposed him, on account of his known Arian principles, and when he found his opposition fruitless, he retired to crown the new emperor till he had delivered to him a written condemnation of orthodox faith, and engaged under his hand, and by the facility of an oath, to maintain the doctrines of the Catholic church, as established by the council of Chalcedon. In the year 493, Theodosius, having become master of Italy, sent ambassadors to Apanius to treat for peace, to which Euphemius was thought to be the chief obstacle. In a short time afterwards Apanius having confidentially informed the patriarch of his desire to terminate in an honourable manner the war in which he was engaged with the Haurians, Euphemius betrayed his secret to the patrician John, the father-in-law of Apanius, one of the chief of the Haurians. The emperor was made acquainted with the patriarch's conduct, and laid the case before an assembly of bishops, who were convened at Constantinople in the year 495, and by his influence with them, obtained a decree that Euphemius should be deposed, and cut off from the communion of the church. He afterwards obtained a sentence of banishment against Euphemius, who died at Arvina in the year 495. Moreni.

EUPHON, in Metaphys., a musical instrument lately contrived by Dr. Chladnii of Wittenberg, who, in consequence of a variety of experiments on the longitudinal vibrations of elastic bodies, contrived this instrument, so called from its pleasant sound, which consists of glass tubes dipped in a proper frame, and expressing their sounds by being rubbed longitudinally. The euphon has some resemblance to a small writing desk. When opened, the glass tubes, of the thickness of the barrel of a quill, and about 16 inches long, are seen in an horizontal position. They are wetted with water by a sponge, and stroked with the wet fingers in the direction of their length, so that the increase of the tone depends merely on the stronger or weaker pressure, and the flower or quicker movement of the fingers. The number of tubes is 12. In the back part there is a peculiarly sounding-board divided in the middle, through which the tubes pass. From this construction it appears, that the euphon should not be considered as an altered or improved harmonica, (See Armonica,) but as a totally new and different instrument. In regard to sweetness of sound, it approaches very near to the harmonica; but it possesses several advantages, peculiar to itself. It is simpler, with regard both to its construction and the movement necessary for producing the sound, as well as using no kind of stoppage, but merely the movement of the finger. It produces its sound more speedily; so that as soon as it is touched you may have the tone as full as the instrument is capable of rendering it; whereas in the harmonica, the tones, particularly the lower ones, must be made to increase gradually.
It has also greater dulnesses in quick passages, because the tones do not resound so long as in the harmonica, where the sound of one low tone is often heard when you only hear the following tone. The unison is purer than is generally the case in the harmonica, where it is difficult to have perfect gliss, which in every part give like tones with mathematical exactness. It is however as difficult to be tuned as the harmonica. It does not affect the nerves of the performer; for a person scarcely feels a weak agitation in the fingers; whereas, in the harmonica, particularly in concords of the lower notes, the agitation extends to the arms and even through the whole body of the performer. This instrument is less expensive than the harmonica; when one of the tubes breaks, or any other part is deranged, it can soon be repaired, and at very little expense; whereas, when one of the gliss of the harmonica breaks, it requires much time and is very difficult to procure another capable of giving the same tone as the former, and which will correspond sufficiently with the series of the reef. For an account of the experiments that led the author to the construction of this instrument, and of the various stages of his progress in the improvement of it, we refer to the Philosophical Magazine, vol. ii. p. 391, &c.

**EUPHONIC ACCENT.** See Accent.

**EUPHONY,** in Education and Composition, that sweet or pleasing quality in the succeive sounds of language, which results from happy combinations of the enunciative elements, such especially as, though effentially different in their characteristic powers, melt easily into each other so as to preserve an uninterrupted flow of utterance through the respective members of a sentence, without labour to the speaker, or offence to the hearer. The word is formed of εὐ, bene, well, and φωνη, vox, voice. Quantinum calls euphonic, vocalinis; Scaliger, jactis pronuntiatio. The most obvious rule with respect to euphonic composition is that a due mixture should be made of consonants and vowels; and the principle of this rule may be at once explained and illustrated by the following parody upon a famous but jocucomical couplet in Pope's Essay on Criticism.

"Your consonants with vowels well combine,
And twelve small words may flow in one smooth line."

But this is not all that is requisite for perfect euphony: every word does not blend with equal grace and facility with every consonant; nor is every succeion of mere vowels, or every succeion of consonants, equally offensive or cacophonous. Words or syllables, for example, terminating with thin vowels, may be followed by other words or syllables, commencing with broad or open vowels, or the reverse, with very happy effect; and some consonants may be brought together, in immediate succession, even as terminative and initial elements of following syllables or words, in such a way as to produce (while they increase the resonant qualities of such composition,) to diversify the time and expression, than to disturb the euphony of the sentence. All the liquids especially (those that properly ought to be, as well as they that commonly are so called) combine with almost equal facility with other liquids, and with vowels or with the consonants, whether semi-liquids, fribilant, or mutes. (See Liquid, Mute, &c.) Which of these, and under what circumstances, may be thus brought together, with the happiest effect of euphony and expression, it would require a much longer discourse than we have space for, to ascertain; and, after all, much must be left to the taste, the ear, and the experimental discrimination of the writer. But it is not upon the writer alone, that the effect of euphony depends. The reader or reciter must also do his part, for though it is very possible so to write, that no organ, and no management of those organs, can elicit in the delivery, any thing but the diffision of cacophony; there are some pedants who contrive to render even the smoothest compositions harsh and cacophonous, and then attribute to their native language, (of the various elements and of the whole composition they are utterly ignorant,) the disgusting diffision which does, in reality, belong to their own jargonized utterance. Euphony in the reader or speaker depends principally upon his skil and management in the articulation and application of the succeive elements, syllables, and words as explained under the term Enunciation; and upon his giving full tone, and sufficient quantity to the liquids and liquidizable consonants. Cacophony (the antagony of Euphony) on the contrary, results from the reader, from the laboured separation of terminative and initial, that might easily have been implicated; from giving unnecessary impulse and force to the mutes, from hurrying the liquids, and from partially tuneable elements, as if they were mere mutes, and from perpetual unnecessary interruptions in the stream of enunciative delivery.

Gen. Ch. Cel. Perianth inferior, of one leaf, inflated, somewhat coloured, with four, in some few cases five, marginal teeth, permanent. Cer. Petals, or Nectaries, four, sometimes five, turbinate, gibbous, thick, abrupt, unequal in situation, alternate with the teeth of the calyx, inserted into its margin by their claws, permanent, bearing plenty of honey. Stam. Filaments numerous, 12 or more, thread-shaped, jointed, longer than the corolla, inserted into the receptacle, coming to maturity at different periods, separated by bristly leaflets; anthers roundish, of two distinct lobes. Pet. Germen superior, roundish, three-sided, elevated on a stalk above the margin of the calyx, tubes three, cloven, biform obtuse. Perc. Capsule stalked, roundish, threelobed, of three cells, and three valves which separate clasically. Seed solitary, roundish.

Obf. The petals or nectaries are for the most part four, in some flowers five, which often happens on the same plant, such flowers being furnished with flaments only, without a pistil, and coming forth earlier than the rest. In many the petals are glandular, in others crecent-shaped, or toothed; in some few thin and membranous; they are commonly situated as it were on the outside of the calyx. The capsule is either smooth, or hairy, or warty.

Eff. Ch. Calyx of one leaf, inflated, inferior. Nectaries four or five, inserted into the calyx. Capsule stalked, three-lobed.

A vall, but very natural, genus, whose species amount in Willdew's work to 124. They are divided into several secciones. All abound with an acrid milk.

Thiofe of the first seccion have a very peculiar thick, shrubby, felithy, angular færa, armed with spines, and bearing few or no leaves. To this belongs E. officinarum, probably the original species. See its figure in Commelin's Hort. Arm. v. i. t. 11. Also E. antiquorum, l. t. 12, an East Indian plant, which forms very improperly named, as neither agreeing with the descriptions of the ancients, nor growing in the country whence they procured their specimem.

The second seccion has shrubby færa without thorns, neither forked nor umaliferous. As E. Caput Meduso, 2 Comm.
Comm. Hort. t. 17, common in Green-houses; and *E. petalwlsis*. Curt. Mag. t. 832.

The third has forked leaves, not umbelliferous, and the plants are mostly herbaceous and annual, as *E. peltata*, Jacq. t. 247, and *pitaliberis*, t. 428; also *E. Papu*, Engl. Bot. t. 2022, common on the sea shores of the south of Europe.

The fourth has the flowers in an umbel, three-branched in the first inflorescence, and the branches subsequently fork repeatedly, each subdivision of the inflorescence accompanied by a pair of heart-shaped, unequal sided, somewhat coloured bracteas, as our common weed *E. papu*, Curt. Lond. falc. t. 95p. Engl. Bot. t. 959.

The fifth has a four-branched umbel, as the great *E. Lathyrus* of the gardens, commonly called the Caper tree, remarkable for its long, dark, four-rowed leaves. There are but few species in this section.

The sixth, a numerous section, has a five-branched umbel, like the common *E. belgicofana*, Curt. Lond. falc. t. 95p. Engl. Bot. t. 883; and the rare and splendid *E. purpurea*, Sm. t. 32. Pict. t. 3, a shrubby Jamaicn plant, of which a most miserable specimen is drawn in Jacq. t. 6. Rar. t. 484.

The seventh and last section consists of four species as have numerous rays to the common umbel, like *E. Cyparififera*, Curt. Bot. 840, frequent in gardens, and *angulolobata*, t. 256, very common in woods.

**Euphorbia**, in Gardening, comprehends plants of the herbaceous, shrubby, succulent kinds, the principal cultivated species of which are: the triangular spurge (*E. antiquorum*); the Canary spurge (*E. canariensis*); the officinal spurge (*E. officin斧rum*); the Medusa's head spurge (*E. caput Medulae*); the myrtle-leaved spurge (*E. tithymaloides*); the seven-angled spurge (*E. heptagona*); the warty angled spurge (*E. mammillaria*); and the Cape spurge (*E. lathyrus*); the first species is a large plant, of which there is a variety with a naked three-cornered compressed stiff, sending out a great number of erect branches, which are likewise generally three-cornered, but sometimes four-cornered; armed with short crooked spines, having no leaves. The plants have not, we believe, yet produced flowers in this climate. This variety, like the species from which it is produced, is a native of the East Indies.

The fourth species has also a variety frequently denominated the "Little Medusa's head," which has a thick short stiff, seldom more than eight or ten inches in height, from which come out a great number of slender trailing branches, about a foot in length, intermixing, and having the same appearance with the other, but smaller and much shorter; the ends are beset with narrow leaves, between which the white flowers come out and appear. Its native situation is the same as that of the species from which it is derived. According to some there are likewise a double branching, a dwarf trailing, and other varieties.

The fifth fort has also laurel leaved and variegated leaved varieties.

**Method of Culture.**—These different sorts of plants may be raised by planting cuttings, which have been made at a joint, five or six inches in length, after having been rolled in sand, and laid upon a shelf for some days to have the wounds healed over, in the summer season about to middle, choosing small pots for the purpose filled with light, dry, sandy mould, with some rubbish at the bottoms, such as that formed of one fourth part of lime-rubbish which has been well screeched, the same quantity of sea sand, and one half of the whole of light fresh vegetable earth, which should be very well mixed and incorporated together, by being often turned over; then plunging the pots in the hot hot bed, giving due shade when the weather is hot and sunny, with a little water occasionally once or twice a week. As soon as the plants have thickened root, air should be admitted to them pretty freely in the situation in which they may be; or they may, in order to be hardened, be removed into the floor.

In the after management they should be allowed larger pots annually as they advance in growth, and be often refreshed with water during the summer months, but very sparingly in the winter season.

It may be remarked that most of these sorts of plants are capable of being kept in the hot-houses, on the shelves, and of some of them, as the fifth, sixth, and seventh sorts, in a dry airy Green-house, or glass house, during the winter months; great care being taken to protect them well from the fruits; being set out in the summer in the open air: but the fourth species requires some sort of support in order to prevent the branches, by their weight, forcing it upon the pots; as by this sort of treatment the plants will rise to the height of five or six feet, throwing out a great number of side branches. The eighth kind, however, requires little or no particular care after it has been once introduced, except merely that of keeping the young plants clean, as it will be continued by its flattering the seeds.

All these plants, with the exception of the last, afford great variety in collections of the hot and green-house kinds; and that also in the clumps and borders of the pleasure grounds, among others of the less hardy sorts.

**Euphorbe.** in Botany, the 56th natural-order in Jussieu's System, or the 11th of his 15th classes. The definition of this class is,—Corolla none, Petals none, Stamens in a separate flower from the pistils. Its characters are thus more fully explained. Flowers either monoecious, that is, males and females together on the same plant, or dioecious, on separate ones; very rarely hermaphrodite. Calyx in all but one leaf, or a scale supplying its place. Corolla none, except occasionally some scales, or internal divisions of the calyx, resembling petals. In the male flowers the filaments are inserted either into the upper or lower part of the calyx, or scale which supplies its place, definite, or rarely indefinite, in number; the filaments distinct, or rarely united into a central flake, or originating from the middle of the calyx. Germen in the females simple, or sometimes more than one, superior, or rarely inferior; style one, or several, rarely wanting; stigma either solitary or more than one. Fruit either superior or inferior, various in the structure and number of its cells.

The learned author, by his subsequent remarks and explanations, is evidently aware of the difficulties attending this class, which indeed is in no sense really a natural one, its orders having little or no affinity to each other, except the two last Amaranthus and Conifera.

The characters of the order of Euphorbeae are, Flowers monoecious or dioecious, or rarely hermaphrodite. Calyx of each tubular, or deeply divided, simple or double, the internal segments occasionally resembling petals. Petals none, except the segments just mentioned. Stamens, in the male flowers, definite or indefinite in number, their filaments inserted either into the receptacle, or the centre of the calyx, distinct or united, sometimes branched, sometimes jointed. In some these are variously united between the filaments. Germen, in the female flowers, solitary, superior, sessile or stalked; styles in some cases several, often three, with an equal number of cells to the capsule, each containing one or two seeds; in others the style is simple, with three or more stigmata, the fruit of several
veral cells, equaling the stigmas in number, with one or two seeds in each. In all the cells are furnished with two internally elastic valves; the seeds have a partial covering, and are attached at the upper part to the permanent central axis of the fruit. Corculum flat, enveloped in a feebly albumen. The plants are either herbaceous, or shrubby, or arboreoet; some of them milky. Leaves alternate or opposite, (in some few inalterate wanting,) either with or without stipulae. The first section confines of such genera as have several styles, mostly three. These are **Mercurialis, Euphorbia, Argyrogonia** of Browne’s **J. 1538.**

The seeds of these plants are mild and eatable in many instances, if freed from their integuments and corculum, the latter being very dangerously purgative, as in Euphorbia and even Ricinus, proving mild in the latter only from the copious oil of the cotyledons. **Euphorbia** is the name given to the genus order, and very imperially polygamous, not monocious; indeed Jussieu allows it to be hermaphroditic. See **Euphorbia.**

**EUPHORBIIUM,** is a moist acid gum resin, which exudes from the Euphorbia officinarum and other shrubs of the genus fama, and was formerly used in pharmacy, but is now nearly, if not, entirely rejected.

This gum is brought from Barbary and other parts of the Mediterranean in tears or drops of an irregular form, generally containing much impurity; of a pale yellow colour without, and white within. Euphorbian has no smell; when taken into the mouth it gives at first no taste, but after a little time a moist acid biting sensation is felt, which increases to an intolerable degree, and if not immediately rejected it proceeds to corrode the skin of the tongue and ruins. The fume is thrown when applied to the tongue in any other manner. In reducing it to powder the dust that flies off will excite the most violent sneezing, and often bleeding from the nostrils and throat, so that particular precautions must be taken. When laid for some time on the skin it blisters.

The spiritual tincture of euphorbiem is still more acid. This gum resin, on account of its extreme acrimony, can hardly be used with safety as an internal medicine, as it is liable to produce violent diarrhea and bloody foids, and much inflammation. The only purpose for which it has been employed in the latter dispensatories has been in mixture with cantharides to increase the vesicating and irritating property, but euphorbiem is now altogether diffused.

**EUPHORIA,** in Botany, so named by Comerion from αυραηαηες, fertile, a genus comprehending the two Chinese fruits Lit-chi and Longan, to which Jussieu lrepetai Forster’s Poeita may also belong. See **Scytalia.**

**EUPHYORI** signifies the name as Eranine.

Gen. Ch. Gal. perianth of one leaf, inferior, cylindrical, VOl. XIII.

four-cleft, equal, permanent. Cor. of one petal, ringlet; tube as long as the calyx; upper lip concave, notchcd; lower spreading, deeply three-lobed, the lobes equal, obtuse, notchcd. Stem. Filaments four, thread-shaped, situated close under the upper lip; anthers of two lobes, the lobes unequally spinosus at their lower extremities. Pet. German superior, ovate; style thread-shaped, agreeing in form and situation with the stam. stigma obtuse, undulate. Peric. Capsule ovate-oblong, comprcssed, of two cells and two valves; the partition contrary to the valves. Seeds numerous, minute, roundish, longitudinally striated.

E. officinalis, Linn. Sp. Pl. 841. Engl. Bot. t. 1416. Curt. Lond. falc. s. t. 42. common in heathy and mountainous pastures, which its gay blooms greatly enliven in autumn, is a genuine and original example of the genus. This is a small, upright, annual plant, with ovate sharply serrated leaves. The flowers are white, strongly streaked with purple, having a yellow spot on the lip. On the Alps they are often larger, light purple, and still more beautiful.

The dazzling brilliancy of these little blooms seems to have given rise to the vulgar opinion, that the plant was good for the eyes; whence its English name Eye-bright.

**EUPHRAFENSIS** in Ancient Geography. See Com- magene.

**EUPHRATES** of Alexandria, in Biography, a Stoic philosopher, who flourished in the second century was a friend of Dio and of Apollonius Tyaneus, who introduced him to Vespasian. Although a violent quarrel arose between the latter philosopher and Euphrates, in consequence of which Philostratus, the panegyrist of the former, inveighs with great severity against the latter, it appears from the testimony of Epictetus, Pliny the younger, and Eusebius, that Euphrates was universally esteemed for his talents and virtues, and that the cen自查 of Philostratus deferre only contempt. Pliny’s character of him is highly interesting. "If ever," says he (Ep. l. i. ep. 10), "polite learning flourished at Rome, it certainly does at present. Of this I could give you many instances; but I will content myself with naming only Euphrates the philosopher. When, in my youth, I served in the army in Syria, I had an opportunity of conversing familiarly with this excellent man, and took some pains to gain his affection, though that indeed was not difficult; for he is exceedingly open to access, and full of that gentleness of manner which he teaches. Euphrates is polished of shining talents, which cannot fail to interest even the unlearned. His style is copious and diversified, and so wonderfully sweet, as to captivate even the most reluctant auditor. Add to all this, his graceful form, comely aspect, long hair, and large white beard; circumstances which, though they may probably be thought trifling and accidental, contribute, however, to procure him much reverence. There is no disputing negligence in his dress; his countenance is grave, but not austere; his approach commands respect, without exciting awe."
With the finestest faculty, he unites the most perfect politeness of manner. He inveighs against vice, not against men; and, without chastising, regards the offender. You listen with fixed attention to his exhortations, and even when convinced, still hang with earphones upon his lips."

In conformity to the principles of the Stoic philosophy, Euphrates, when he found his strength worn out by disease and old age, voluntarily put a period to his life by drinking hemlock, having first, for some unknown reason, obtained permission from the emperor Adrian. Brucker's Hist. Phil. by Enfield, vol. ii.

Euphrates, the reputed founder of a religious sect in the second century, sometimes called "Ophians," or "Ophites," and sometimes "Serpentians," names derived from the peculiar tenet which he held, that the serpent, by which our first parent was deceived, was either Christ himself, or "Wisdom" concealed under the form of that animal, and that he was the occasion of all the knowledge which men had received. Hence he is said to have inculcated a particular veneration for the serpent, preferring a living one, offering to it a sublimated kind of divine honour, and bringing it out to partake of or to consecrate the euclariet. Origin and others contend that the followers of Euphrates were not Christians, but calumniators of Jesus Christ, and opposers of his doctrine; but Dr. Lardner, who has taken some pains in investigating the subject, considers them as believers in Christiinity, and maintaining that Jesus, who was born of a virgin, was a most excellent man, and that, having by his miracles and instructious manifested himself to be the true Messiah, was crucified, and afterwards raised from the dead, received into heaven, where he sits on the right hand of God. He conceives that what some have said of them, respecting the serpent being Christ, must be a mistake, founded on an opinion that the brazen serpent in the wilderness was a type or figure of Christ. The other accounts of worshipping the serpent, &c, this judicious and learned writer rejects without hesitation. Morel. Lardner.

Euphrates, in Ancient Geography, one of the most considerable and best known rivers of Asia, the source of which was in the mountains of Armenia north of Arbus, which after receiving several streams in this part of Armenia, at the towns of Elegia, Gymnias, and Bratus, pursues its course towards the south-west, separating Armenia Major, on the east, from Armenia Minor on the west. It then proceeded south-westward, washing the skirts of Syria, and dividing Arabia from Mesopotamia; and afterwards directing its course towards the north-east, it separated Chaldaea and Babylonia from Mesopotamia, till at length mixing its waters with those of the Tigris, with which it previously communicated by several canals, it emptied itself into the Persian gulf. The Euphrates, according to Ptolemy, above Babylon, near a town in Mesopotamia, called Syphara, divided itself into two branches, one running to Babylon, and the other to Seleucia, where it fell into the Tigris. Pley says the latter was partly artificial; for he places Seleucia at the confluence of the Tigris and Euphrates, adding that the Euphrates was carried to it by a canal. Pridaux, on the authority of Pley, ranks this artificial branch among the stupendous works of Nebuchadnezzar. Between these two branches a canal was cut from the Euphrates, above Babylon, to the Tigris at Apamea, 60 miles below Seleucia. This canal was denominated Naarmattha, and was dug by Nebuchadnezzar, as Abydenus informs us, to convey the waters of the Euphrates, when it overflowed, into the Tigris, before they reached Babylon. At the distance of 900 furlongs from Babylon to the south was another canal, called by Arrian Pallacopos, and by Appian Pallacotis, derived from the branch of the Euphrates that passed through Babylon, and continued to certain lakes or marshes in Chaldaea. On this canal, or river, as Arrian calls it, Alexander failed from the Euphrates to the above-mentioned lakes. But it is impossible, at this distance of time, and after the changes that have occurred, to trace out the numerous branches and canals which watered the ancient country of Babylon. This great river moved slowly through a great part of its course, and was ill adapted for navigation, as some parts of it were shallow and others rocky. They, however, of opinion that the Euphrates might, with little trouble, be made navigable, even by great ships, quite to the Tigris, only by clearing the channel of the homes with which it is choked in some places. The ancient mode of navigating this river was very extraordinary. The vessels were round, without distinction of head or stern, and no better than great wicker baskets, covered over with hides, guided by two oars or paddles. They were capable of carrying a very considerable weight; and when they had unloaded their cargo at Babylon, they were sold; but the hides were kept: and loading their axes with them, the navigators returned home by land, the rapidity of the stream not allowing them to return by water.

Euphrates, in Modern Geography, a river of Asia Minor, which rises from the mountains of Armenia, as some have said, in two streams, a few miles to the N. E. of Erzeroum, the streams uniting to the S. W. near that city; and chiefly pursuing a S. W. direction to Semifat, where it would fall into the Mediterranean, if not prevented by a high range of mountains. In this part of its course the Euphrates is joined by the Morad, a stream almost doubling in length that of Euphrates, so that the latter river might more justly be said to spring from mountain Ararat, about 160 British miles to the east of the impetuous source. At Semifat, the ancient Samofats, this noble river attains a southerly direction; then runs an extensive course to the S. E., and after receiving the Tigris, falls by two or three mouths into the gulf of Persia, about 50 miles S. E. of Baf- fora. N. lat. 29° 30'. E. long. 66° 57'. The comparative course of the Euphrates may be estimated at about 1400 British miles. This river is navigable for a considerable distance from the sea. This river in its course separates Aladulia from Armenia, Syria from Diarbekir, and Diarbekir from Arabia, and passing through the Arabian Iraq, there joins the Tigris.

Euphrates, a river of Africa, in the country of Whibah, on the Slave coast.

Euphrosyne, in Mythology, one of the three Graces. See Graces.

Euphrosynum, in Botany, a name used by Pliny and some others for the common borage. See BORAGE. Euphilis, in Ancient Geography, Paffiano, a lake of Italy, in Gallia Cisalpina, whence, according to Pliny, suffed the river Lambris.

Euphnea, of, or, well, and wise, I breathe, in Medicine, is a right and natural respiration.

Eupolus, in Homer, or an Athenian who flourished B.C. 440, was known as a comic writer, and one of that class who marked out by name the objects of their satire, which rendered him extremely popular with the many, as he was dreaded by the great. He is mentioned by Horace and Quintilian, who put him in the same class with Cratinus and Aristophanes. His comedies were of a political cast, in one of which Alcibiades was so feverishly attacked, that he is said to have hired assassins to throw him into the sea. The plot did not succeed, for Eupolis wrote several comedies after the period assigned to this fact, and Alcian relates

that:
that he died at Eginia. Fragments of his works have come down to us, and titles of twenty of his plays. Gen. Bion.

EUPORIA, in *Ancient Geography*, a town of Macedon, placed by Ptolemy in Bithynia.

Euporia, of οὐ and ποσαγε, in *Medicine*, is an easy preparation of medicines, or the calamine of their operation.

EUPSYCHIANS. See Euromatici and Eupyschiains.

EVRA, a town of Abyffinia; 12 miles S. E. of Sire.

EVRACMINA, a town of Sweden, in the government of Abo; 17 miles S. of Bjormeland.

EVRAN, a town of France, in the department of the North Coasts, and chief place of a canton in the district of Dinan, four miles S. of it. The place contains 3573; and the canton 9175 inhabitants, on a territorial extent of 11753 kilometres and seven communes.

EURANISLANDS, a cluster of small islands, on the coast side of the Gulf of Bothnia. Lat. 63° 54'. L. long. 22° 30'.

EURANUM, in *Ancient Geography*, a town of Asia Minor, in Caria.

EURE, in *Geography*, a river of France, which has its source in the forest of Logny, and terminates in the Seine, above Pont de l'Arche. Its course is northward, and extends 36 leagues.

Eure, formerly Oche, a department of the second or northern region of France, in 49° N. latitude, bounded on the north by the department of the Lower Seine, on the east by that of the Oise, on the south by the departments of the Eure and Loire and the Orne, and on the west by the department of the Calvados. It takes its name from the river Eure, which traverses it; and its capital is Evreux. It contains 357 square leagues, and 415,574 inhabitants in five districts, viz. Fontainebleau, Louviers, Les Andelys, Evreux, and Bernay, 55 cantons, and 843 communes. Its fertile soil yields grain, hemp, flax, and pastures; and it has considerable forests.

EURE and LOIRE, a department of the second or northern region of France, in 47° 15' N. lat. composed of a part of Beauce and of Perche, bounded on the N.W. by the department of the Eure, on the east by the departments of the Seine and Oise and the Loiret, on the south by the departments of the Cher and Loiret, and on the west by the departments of the Orne and Sarthe. It takes its name from the rivers Loire and Eure, which water it; and its capital is Chartres. It contains 350 square leagues, and 259,677 inhabitants. It is divided into four districts, viz. Nogent-le-Rotrou, Chartres, Chateaudun, and Dreux; 23 cantons, and 450 communes. This department, on account of its great fertility, is called the granary of Paris, and it abounds in fruits and rich pastures.

EVRE, or EYRE, a river of France, which discharges itself into the Cher by two streams, one near Vierzon, the other at Bourges.

EVRICY, a town of France, in the department of the Calvados, and chief place of a canton in the district of Caen; seven miles S.W. of Caen. The place contains 850, and the canton 13,110 inhabitants, on a territorial extent of 145 square kilometres, and 29 communes.

EVREGNIES, a town of France, in the department of Vendome; nine miles N.W. of Tours.

EUROS, in *Natural History*, the name of a fowl, described by Pline, and seeming plainly to be the same with the zizolthus, which he mentions in another place, and to be the same now called *topis judaicus*, and known at this time to be the petrified spine of a foot of cichlasus marinus, or sea urchin.

EVRING, MEDIOLANUM, Ebora, or Civitas Evringum, in *Geography*, a town of France, in the department of the Eure, of which it is the capital, and chief place of a district. Its north division contains 4260, and the canton 10,458 inhabitants, and the south division 4267, and its canton 10,833 inhabitants; the territorial extent comprehends 345 kilometres, and each division includes 30 communes. Before the revolution this was the seat of a bishop, suffragan of Rouen; containing nine parish churches, two abbeys, and ten convents. This is an ancient and considerable town, with large subsurbs, situated in a deep and fruitful vale on the river Seine, 23 miles N.W. from Paris. Its cathedral is a fine Gothic structure. The manufactures of Evreux consist of woollen and linen cloth, and its trade of rice, grain, wine, and cider; but they are not considerable. N. lat. 49° 1'. L. long. 1° 15'.

EURIPIDES, in *Biography*, the contemporary and rival of Sophocles, and one of the most ancient Greek tragedians, was born in the isle of Salamis, in the year B.C. 480, according to many writers, though the Arundelian marble places his birth five years earlier. His father's name was Menarchus, an Athenian, and that of his mother was Clito, a feller of herbs, according to the report of Aristophanes, the avowed enemy of Euripides; but by the testimony of later grammarians, founded on the authority of Philocterus, an ancient writer, she was of noble descent. Before the birth of his son, Menarchus is said to have consulted the oracle of Apollo concerning his future destiny, and to have received for answer, "that the child that should be born to him would reach the summit of glory, and gain the honour of the sacred garland," which was underlaid to signify the crown of victory at the Olympic games. When Greece was invaded by Xerxes, Menarchus and his wife retired for safety, among other Athenians, to the island of Salamis. In the autumn of the year 486 B.C. when this invasion took place, the fate of Greece was in great measure decided by the naval victory of Salamis over the Persians; and on the same day, it is said, Euripides was born. He who in memory of this battle, fought in the narrow channel, or Evripus, which divides Salamis from the continent, received his name. Euripides, at subsequent periods of his life, was accustomed to frequent the island of his nativity, where was drawn a cave, in which some of his tragedies are said to have been composed. Euripides, in conformity to the fuggitation of the oracle, and also to the custom of the country, qualified himself for honourable and successful contest at the public games, by an early initiation in the usual gymnastic exercises; but his views were directed to nobler pursuits. Accordingly, whilst he paid some attention to the art of painting, he studied rhetoric under Prodicus, celebrated for the allegory of the choice of Hercules, preferred by Xenophon, and received instructions in physics from Anaxagoras, and in morals from Socrates. In his 18th year he first applied himself to the composition of tragedies, the number of which, during the course of his life, amounted, as some say, to 75; but according to others, to 92. He does not appear, however, to have been very successful in his exhibitions on the theatre, for no more than five of his performances gained the prize at the Olympic games; but they were privately acted with avidity and highly applauded by his countrymen. To this purpose we may mention the following fact. After the unfortunate
EUR

unfortunate expedition of the Athenians against Syracuse, several captives were kindly treated by the Sicilians, and obtained relief from indigence and wretchedness, by going about from place to place, reciting and finging the verses of Euripides. Upon their return to their own country, the poet received their peroral acknowledgments. Socrates was the friend of Euripides, and is said to have given him advice and assistance in the composition of some of his dramas; and he occasionally attended the public exhibition of them. In the character of Palamedes, the poet was supposed to have delineated that of Socrates; and some verses are quoted denouncing the Greeks as having slain the best and wisest of their nation, which the audience applied to the fate of this philosopher, burfting into tears at the recollection of their crime. As Socrates had become an object of public persecution and calumny before the representation of the Palamedes, some application of the character to his circumstances might probably have been intended by the poet. But his death could only be alluded to by way of probable anticipation, as he survived Euripides some years. The remarkable effect ascribed to the passage of the Palamedes just mentioned might possibly have taken place at some representation of that play subsequent to the death of Socrates. Euripides was the confidant rival of Sophocles, and their mutual jealousy seems to have degenerated into declared enmity. Our poet was frequently the object of raillery to Arifotolophes. Euripides was twice married; but as he was disappointed in his expectation of domestic happiness, he is said to have indulged a kind of antipathy to women, for which this circumstance has been pleaded as an apology. Hence he obtained the name of Μηδερας, woman-hater, though his editor, Barnes, strenuously defends him from the charge implied in this appellation, observing, that if he has described some females with all the vices incident to human nature, yet he has delineated many others with all the virtues that can adorn their sex; and Sophocles is said to have observed, that the hatred which he expressed against women was confined to the stage. In advanced life he enjoyed so little felicity at Athens, that he accepted an invitation to the court of Archelaus, king of Macedonia, where he was honourably treated, though he did not altogether escape the effects of malicious jealousy. To the consequence of a quarrel from this cause some have ascribed his tragical death; for as he was walking in a wood, the king’s hounds were let loose upon him, and tore him in pieces. Others say that his death was owing to natural decay. He died at the age of about 75 years. The Athenians sent embassadors to Macedonia, to request the removal of his body to his native country; but Archelaus refusing to comply with their request, caused him to be interred with great magnificence, and erected in honour of him a noble monument in the vicinity of Pella, his chief city. The Athenians appointed a public mourning on occasion of his death, and erected in memory of him a cenotaph on the road leading from the city to the Pireus. The following epitaph is ascribed to Thucydides, the historian.

"Μηδερας Μηδερας, Ευριπις Ευριπις Πατρις Ευριπις "

"G E M a k e n i s, Ελλην Αθηνής Ευριπις "

"Ευριπις Ευριπις Ευριπις Ευριπις "

"Ευριπις Ευριπις Ευριπις Ευριπις "

"All Greece is the monument of Euripides; the Macedonian land pollutes his bones, for there he reached the boundary of his life. His country is Athens, the Greece of Greece; having afforded general delight by his muse, he enjoys the recompense of general praise."

It has been recorded to the reproach of Euripides, that many of the maxims which he attributes to his dramatic characters are favourable to vice; and though he cannot be wholly exculpated from this charge, he abounds with moral maxims, expressed in noble and elegant language, which deeply impress the mind of the reader. He has been also charged with moroseness of temper; but however this be, he introduces numerous passages of tender and delicate pathos. As a tragedian, when compared with Sophocles, it seems to be the general opinion, that with less pomp of diction, less force and elevation of character, and less knowledge of dramatic effect than his rival, he more excels in tenderness, suavity, and moral sentiment. Arifotole calls him the "most tragical" of all the poets, meaning either that he was the most skilful in the drama, or the most pathetic. Euripides, it should be recollected, was the favourite poet of Milton. Possessing a high notion of the preceptive office of the theatre, he was once defied by the auditors to retrench a passage in one of his plays, but he stepped forward and said, "I do not write in order to learn from you, but to teach you." Of his works nineteen complete plays, and the commencement of a twentieth, are still remaining. Of these, both figly and collectively, there are several editions. The belt of the whole works are those of Basil, 1551; of Plautin, 1571, of Commelin, 1597, of Paul Stephens, 1664, 1661, of Barnes, Camb. 1694, and of Mulgrave, Oxr. 1778. Bayle. Moreri. Barnes. Gen. Blog.

EURIPUS, Ευριπις, in Hydrography, properly signifies a certain limit of the sea which divides Ebena from Attica, Boiotia, and Locris, where the currents are so strong that the sea is said to ebb and flow seven times a day; in which place, as the story commonly goes, Arifotole drowned himself out of carbine, for not being able to account for so unusual a motion. This limit was so narrow over against Chalceis as scarcely to admit a galley. It is now called the gulf of Negropont.

Euripus has since become a general name for all straits, where the water is in great motion and agitation.

The ancient circuses had their Euripii, which were no other than pits or ditches, on each side of the course, into which it was very dangerous falling with their horses and chariots as they ran races. The term Euripus was more particularly applied by the Romans to three canals or ditches which encompassed the circus on three sides, and which were filled occasionally, to represent, narrumachie or sea-battles.

The fame people called their smaller fountains or canals in their gardens Euripus; and their largel, as cascades, &c. Niles.

EUROCLYDON, of Ευριπις, αετε-υιον, and Κλαυδος, αιωνος, is a species of wind, of which we have an account only in Atis, xvi. 14 and concerning the nature of which critics have been much divided. Boehert, Grotius, Bentley, and others, substitute another thing, supported by the Alexandrian MS. and the Vulgate, viz. Ευριπις, αετε-υιον, or Ευροκλυδον; but Mr. Bryant defends the common reading, and considers the Euroclydon, l. e. Ευριπις, αετε-υιον, as an eait-wind that causes a deep sea or vast inundation. He maintains, in opposition to Dr. Bentley's reasoning, that supposedly that the mariners in the ship, the voyage of which is recited in this passage, were Romans, that they were Greeks of Alexandria, and that the ship was an Alexandrine ship, employed in the traffic of carrying corn to Italy; and therefore, that the mariners had a name in their own language for the particular typhonic or stormy wind here mentioned. He also views from the passage itself, that the tempestuous wind called Euroclydon, beat (καλα, αετε-υιον) upon the island of Crete; and therefore, as this is a relative expression, referring to the
the situation of the person who speaks of it, who was at that time to the windward, or south of it, the wind blew upon shore, and must have come from the south or south-east; which, he adds, is fully warranted from the point where the ship was, and the direction it ran in afterwards, which was towards the north and north-west. Bryant's Observations, &c. 1767, p. 1 &c.

EURO-ASTER. See Winds.

EURO-NOW. See Winds.

EUROMA, in Ancient Geography, a town of Asia, in Phœnicia.

EUROMUS, a town of Asia, in Caria; situated E. of mount Giusus, N. of mount Latmus, and N.W. of the town of Mylana. It had a theatre and a magnificent temple.

ERVON, in Geography, a town of France, in the department of the Mayenne, and chief-place of a canton, in the district of Laval; 15 miles N.E. of Laval. This place contains 4044 and the canton 15,213 inhabitants, on a territorial extent of 205 kilometres and 11 communes. The fairs of this town are frequented.

EUROPA, in Mythology, daughter of Agenor, king of Phœnicia, by his wife Telephassa, who was so beautiful, that, according to the fable, Jupiter is said to have fallen in love with her, and to have ordered Mercury to convey her to the sea-shore, where that god, having transformed himself into a bull, took her upon his back, and transported her into Crete. Some have explained this fable by alleging that a captain of Canda, named Taurus, carried off that princess, after he had taken the city of Tyre from Agenor; but others, with greater probability, affirm, that some merchants of Crete, having arrived upon the coasts of Phœnicia, and seen the young Europa, were so much struck with her beauty, that they carried her off for their king Aferius; and as their ship bore upon the fore-castle a white bull, and that king of Crete had assumed the name of Jupiter, it was hence said that the god had transformed himself into a bull, in order to carry off the princess. Aferius is said to have married her, and to have had by her three sons; after which she is reported to have engaged the attachment and eftimation of the Cretans to such a degree, that they worshipped her after her death as a divinity. They even instituted a feast in honour of her, which was called Hellenot. They afterwards gave her the surname of Minerva, and celebrated her festival which was consecrated to that goddess among the Cretans. Several authors have been of opinion that Europe took its name from this princess; but the learned Bochart believes that this part of the world was so denominated from the whites of its inhabitants. M. Gebelin, however, deduces the name of Europa from Wrab, signifying Occidental, and expressing its situation with regard to Asia.

EUROPE, in Geography, rocks in the strait of Mozambique, S. lat. 21° 30' & E. long. 40° 16'.

EUROPE, one of the four grand divisions, or quarters, as they are somewhat improperly called, of the terrestrial globe. Although Europe be less considerable in extent than Asia, or America, or even Africa, it claims on a variety of accounts our more particular attention. In modern times it has been the seat of literature and science; in this part of the globe every kind of cultivation and improvement has made the most rapid progress, and it has been distinguished, not only by the general temperature of its climate, the fertility of its soil, and the abundance of its productions for the supply of necessitv and the gratification of luxury, but more especially for the wisdom, strength, and courage of its inhabitants, and for the excellence of its government, laws, and religion. The boundaries of Europe were very inaccurately ascertained by the ancient geographers, and the name itself seems to have originated in a small district near the Hellepont. More than a third part of Europe, towards the north and east, has only been known with precision in modern times. It lies chiefly in the temperate zone, north of Africa, and north-west of Asia, between 35° 25' and 71° 25' N. lat. and between 9° 40' W. and 61° 5' E. longitude. From the Fortunatus cape, denominated by our mariners the rock of Libon, in the west, to the Uralian mountains in the east, the length may be about 3,400 British miles; and the breadth from Cape Nord in Danish Lapland to Cape Matapan, the southern extremity of Greece, may be about 2,350. The contents in square miles have been variously estimated, but at a medium may be stated at about 24 millions. On the south, Europe is bounded by the Mediterranean sea, on the west by the Atlantic, which contains the most remote European islands, the Azores and Iceland, Greenland being regarded as a part of North America. On the north the boundary is the Arctic ocean, comprehending the remote islands of Spitzbergen, and Novaya Zemba, or the New Land. "Towards the east the limits, (says Mr. Pinkerton,) admit of some discussion: the Uralian mountains, a grand natural limit, not extending to the Arctic ocean, the river Cara, which flows into the sea of Karhoye, is admitted as a boundary. The Uralian limit extends to about 56° of N. latitude; to the south of which the grand confines of Europe and Asia have been fought in the petty distinctions of Russian governments. More natural limits might be obtained by tracing the river Oufa from its source, to its junction with the Belia. Thence along the Kama to the Volga, which would constitute a striking natural division, to the town of Sarepta; whence a short ideal line, the only one admitted in this delineation, will lead due west to the river Don, which would complete the unascertained boundary; that on the north and west of the Euxine being clear and precise."

The ancient inhabitants of Europe consisted of Celts in the west and south; Fins in the north-east; and Lapps or Laplanders, resembling the Samoeds of Asia in the farthest north, who enriched their rude language by adopting that of the more civilized Fins. The ancient inhabitants, who seem to have been thinly scattered, were driven towards the west and north by the Scythians or Goths from Asia, whose descendants occupy the greater part of Europe; by the Sarmatians or Slavonic tribes, also from Asia, the ancestors of the Russians, Poles, &c., and who were accompanied by the Herull, using what is now called the Letic speech, to be found in Prussia, Lithuania, Samogitia, Courland, and Livonia, somewhat akin to the Slavonic language, with various shades of distinction. The colony of Iberi, northern Mauretan, passed into Spain at a very early period; and the later accession of Hungarians and Turks from Asia have latterly been commemorated. The present population of Europe is commonly estimated at 150,000,000; and though some writers have asserted that this quarter of the globe was anciently more populous than it is now, the opinion does not seem to be well founded. It will not readily be adopted by those who only consider the number and magnitude of modern cities, towns, and villages; the abolition of feudal wars; the adoption of a mode of combat less destructive than that which formerly prevailed; the gradual extirpation of superstition, fanaticism, barbarity, and slavery; and the many extensive improvements made in agriculture, by eradicating forests, draining marshes, cultivating wastes, and opening canals of communication in the interior countries.
countries. It is generally allowed, that, notwithstanding the ravages of war, and emigrations to foreign parts, the population of most European states has been, for some time past, increasing. The prevalence of the Christian religion throughout Europe, except in some parts of Turkey, has been favourable to knowledge, industry, and civilization; and it has contributed to constitute the whole of Europe, as it were, into one republic, so that any useful discovery made in one state passes rapidly to the rest. The mutual intercourse between the different states of Europe is very much facilitated by its inland seas, as well as navigable rivers and canals. Of the inland seas the principal are the Mediterranean, the Baltic, and the White Sea, which see respectively. Its other seas are the German, often styled the North sea, the Irish sea, and various parts of the Atlantic. The gulfs and bays of Europe are very numerous, among which we may reckon the following, viz. the Bothian and Finland gulfs; the Murray frith, and Frith of Forth, on the east coast of Scotland; the bay of Biscay, a large inlet of the Atlantic, on the coast bounded by France, and on the south by Spain; the gulfs of the Mediterranean, viz. that of Lyons, S. of France; that of Genoa, between Corfica and the Genoese republic; the gulf of Venice, between Italy and Greece; the gulf of Lepanto, N. of Morea; the Archipelago between Greece and Asia Minor; the sea of Marmara between Europe and Asia; and the sea of Azoph on the north coast of the Euxine. The most confiderable straits are that of Waygaz at the N. E. extremity of Europe; the Sound of Elfinmore between the island of Zealand and Swinemunde; the Little Belt between Fyen and Jutland; the Catalgat, or entrance into the Baltic; the strait of Dover, or English channel, between England and France; the Bristol channel, between England and Wales; St. George's channel, between Great Britain and Ireland; Pentland frith, between Scotland and the Orkney Isles; the strait of Gibraltar, between Spain and Africa; the strait of Messina, between Italy and Sicily; the Dardanelles strait, or southern entrance into the sea of Marmara; the strait of Constantinople, that forms a communication between the sea of Marmara and the Euxine; and the strait of Caffa, between the Euxine and the sea of Azoph. The most remarkable capes are North Cape, the extreme point of Lapland; Cape Finsterre, on the N. W. coast of Spain; Cape St. Vincent, the S. W. extremity of Portugal; and Cape Matapan, the S. point of the Morea. Its principal lakes are those of Oaesa, Ladoga, and Peipus, in Russia; those of Geneva and Constance, S. W. and N. of Switzerland; Lago Maggiore, and others, in the northern parts of Italy. The largest rivers are the Volga, Don, and Dniess, in Russia; the Dnieper on the east border of Poland; the Danube, between Hungary and European Turkey; the Rhine and Elbe in Germany; the Rhone in France; the Po and Tiber in Italy; the Tagus in Spain; the Scheldt and Meuse in the Netherlands; the Thames and Severn in England; the Tay in Scotland, the Shannon in Ireland, &c. &c. The principal chains of mountains are the Carpathian or Krupach mountains, between Poland and Hungary; the Alps, between France, Switzerland, and Italy; the Apennines, in Italy; the Pyrenees between France and Spain; and the extensive ridge that separates Norway from Sweden. The most distinguished islands are Great Britain and Ireland, the Orkney Isles, the Hebrides, Zeeland, and Funen, in the Baltic; Iceland, in the North sea; and in the Mediterranean, Ivica, Majorca, Minorca, Sardinia, Corfica, Sicily, Malta, Candia, and the islands of the Archipelago.

The principal European states are the British empire, including England, Scotland, and Ireland; the states of Denmark, comprehending Denmark with the adjacent islands, Norway and Iceland; Sweden; Russia, formerly called Muscovy; Holland; France, including the Netherlands, Italian states, and other late acquisitions; Switzerland; Germany and Austria; Prussia; Bohemia and Hungary; Poland, now dismembered; Spain; Portugal; Sicily; Malta; and Turkey in Europe. See each under its appropriate title.

EUROPEAN Hours. See Hour.

EUROPEAN Ocean. See Ocean.

EUROPE, in Ancient Geography, a town of Asia, in Parthia, founded, as Strabo says, by Nicator, and called by the Parthians Arestica. — Alto, a town of Asia, in Syria, situated on the banks of the Emphates, E. of Hicopolis, and S. of Zeugma. — Alto, a town of Asia, in Caria. — Alto, a town of Macedonia. — Alto, a river of Greece, in Thessaly, which rises in mount Cataris, and flowed into the Penus.

EUROTAS, a river of Lacedaemon, which commenced on the frontiers of Arcadia, watered Sparta, and proceeding southward, discharged itself into the Laconic gulf. — Alto, a river of Greece, in Thessaly, near mount Olympus. — Alto, a river of Italy, near Tarentum, the fame with the river Gal-fus, according to Polybius.

EURUS, in Mythology, the genius of the south-east wind, according to the Grecian division of the compass into eight points; but according to the Roman division into four, Europeans is the intelligence that prevailed over the whole eastern quarter of the heavens. (See Wind.) "Eurus," says Spence, "according to the Roman poets, seems to have his character compiled from the Apotheosis and Eurus of the Greeks: by one description of him he should have a look that seems delighted, and in another he is spoken of as playful and wanton. He is sometimes described as impetuous, and sometimes as disordered with the storm he has been driving along the sea. Horace gives us a picture of the former, and Valerius Flaccus of the latter. I should be apt to imagine, from some expressions in the poets, that he was sometimes represented on horseback, or perhaps in a chariot, whirling through the air; but there are so few remains of the ancient artists relating to these airy beings, that we have nothing from them to confirm any such conjecture."

Gen. Ch. Cal. Perianth inferior, of five ovate, concave, obtuse, small leaves, with two lesser ones at its base. Cor. Petals five, roundish-ovate, concave, the size of the calyx. Nectary a glandular ring round the base of the germen. Stam. Filaments thirteen, extremely short; anthers erect, square, almost as long as the corolla. Pij. German superior, roundish, smooth; style wavy-shaped, shorter than the stamens; stigmas three, reflexed. Peris. Capsule globose, tipped with the permanent style, smooth, of five valves and five cells, scarcely so big as a pepper-corn. Seeds several, oblong or triangular, dotted, brown, destitute of pubescence. Obs. Thunberg observed the flowers to be most frequently dioecious.

Eff. Ch. Calyx double; the inner of five equal leaves; the outer of two smaller ones. Petals five. Capsule superior, of five cells and five valves. Seeds numerous.
EURYALE, in Mythology, one of the Gorgons, daughter of Phorcys, and sister of Medusa: she was subject neither to old age nor death.

EURYMPHUS, in Ancient Geography, a town of Macedonia, in Magnesia.

EURYANDRA, in Botany, from ρυς, broad, and ανδρα, a male, because the male organs, or stamens, are dilated at the summit. Horti. Gen. t. 41. Schreb. 567. Juili. 280. See Tetragon: to which genus Schreber, in his emendanda, 833, and Willdenow, Sp. Pl. t. 2. 1242, have at the recommendation of Solander referred it.

EURYDICE, in Mythology, the wife of Orpheus, who, flying from Aristaeus that endeavoured to ravish her, was slain by a serpent. Her husband went down to the shades, and by the force of his music persuaded Pluto and Proserpine to give him leave to carry back his wife; which they granted, provided he did not look on her till he came to the light; but he, breaking the condition, was forced to leave her behind him.

EURYMEDON, in Ancient Geography, Zacut, a river of Asia, in ancient Pamphylia, which had its source in mount Taurus, passed the town of Alpenus, and discharged itself into the sea of Pamphylia.

EURYMENÉ, a town of Greece, in Thessaly.

EURYNOYM, in Mythology, the mother of the three Graces.

EURYNOA, Eurynoea, in Antiquity, an anniverary solemnity in honour of Eurynoa, by some thought to be the same with Diana, by others one of Oceanus’s daughters.

EURYPHON, the Cnidian physician, in Biography, was a contemporary of Hippocrates, but probably older in years, since he is deemed the author of the Cnidian aphorisms, which are quoted by Hippocrates. These two physicians are said by Soranus to have met in consultation in the presence of king Perdices. Euryphon is mentioned by Plato the comedian, as having produced many fears on the skin of Cinclus, the son of Evagoras, by the employment of actual cauteries for the cure of empyema, or pulmonary consumption: a practice which Hippocrates pursued. See Le Clerc Hift. de la Med.

EURYTHLMIA, from eur and thymia, order, an old term in Surgery, signifying adrohines in handling instruments.

EURYTHYM, Eurythm, in Architectures, Painting, and Sculpture, a certain majesty, elegance, and compass, appearing in the composition of divers members or parts of a body, blding, or painting, and resulting from the fine proportions thereof.

The word is Greek, and signifies literally a composition or fine agreement, or, as we call it, a harmony of all the parts, being compounded of a, well, and phus, rythm, cadence, or agreement of numbers, sounds, or the like things.

Vitruvius ranks eurythmia among the essential parts of architecture; he describes it as consisting in the beauty of the construction or assemblage of the several parts of the work, which renders its aspect or whole appearance graceful; e.g. when the height corresponds to the breadth, and the breadth to the length, &c.

"From these three ideas or designs, viz. orthography, feconometry, and profile, it is that eurythmy, majestica, and venyia specie edifici, do result, which creates that agreeable harmony between the several dimensions, so as nothing seems disproportionate, too long for this, or too broad for that, but corresponds in a just and regular symmetry, and content of all the parts with the whole." Evelyn’s Account of Arch. &c.

EUSCOM, in Geography, a river of Canada, which runs into lake St. Clair. N. lat. 42° 45’. W. long. 82° 25’.

EUSDAL, or Eyisdale, a small island on the W. coast of Scotland, noted for its quarries of slate. N. lat. 56° 13’. W. long. 5° 48’.

EUSEBES, the name of a species of marble mentioned by Pliny: he has given us no description of it, but only tells us, that there was a seat made of it in the temple of Hercules at Tyre, from which the priests pretended that the gods used to arise.

EUSEBIUS, a denomination given to the sect of Arians, on account of the favour and countenance which Eusebius, bishop of Caesarea, shewed and procured for them at their first rite; or rather from the protection afforded to Arius, and the adoption of his opinions by Eusebius bishop of Nicomedia. See Arians.

EUSEBIS, pope, in Biography, a native of Greece, son of a physician, perhaps he himself at one period was a physician, succeeded Marcellus in the see of Rome. It is believed that he filled the pontificate but a very few months. He was a violent opponent to the readmission of lapsed Christians to communion, and his conduct on this head created great difcontents at Rome, to put an end to which the emperor Maxentius banished him to Sicily. Moreri. Bower.

EUSEBIUS, surnamed Pamphilus, was born at Caesarea in Palestine, of which he was afterwards bishop, about the year 270. Of his parents, and his inquirors in early life, we have no account; nor is any thing recorded concerning his family. His talents and learning may, however, be justly appreciated by his numerous and valuable works. Having been ordained presbyter, probably, by Agapins, bishop of Caesarea, he set up a school in that city, which produced many learned men, and whilst he was in this situation he formed an intimate acquaintance and friendship with Pamphilus, a learned presbyter of the same church, who is supposed to have afforded him much assistance in his studies. When Pamphilus was imprisoned in the year 309, Eusebius attended him to animate his fortitude and comfort him in his distress: and after the martyrdom of his friend in 309, he removed to Tyre, where he witnessed the firmness and patience with which many Christians endured the severity of persecution. From thence he went to Egypt, where the same feence was exhibited, and where he himself was imprisoned. As he did not suffer in common with others, some persons have intimated, that he procured his liberty by sacrificing, or by some other mean compliance, unbecoming his Christian principles and profession. But Dr. Lardner has alleged several circumstances which evince thisaccusation to be altogether unfounded. At the close of the Dio-
EUSEBIUS.

Eusebius returned to Palestine, and succeeded Agapitus, according to the more general opinion, as bishop of Caesarea in the year 335. It is certain, however, that he was bishop of Caesarea in the year 320 at the latest. After this period he was present at most of the synods held in that part of the world; and on all occasions distinguished himself by recommending peace and mutual forbearance. At the famous council of Nice in 325, he was placed by command of Constance on the right hand of the throne, and opened the meeting by a panegyric address. At this council he seems to have been devious of compromising the dispute between Arius, to whose sentiments he probably inclined, and the orthodox party; and with this view proposed a creed, which all the fathers allowed to be unexceptionable. Some of the most zealous partizans, however, suggested the propriety of introducing the word ἡμερομηνία, or consubstantial, as applicable to the Son; and the motion for this purpose was carried by a majority. Eusebius for some time demurred, alleging that the expression was unscriptural; but at length, being allowed to subscribe to the term in his own face of it, he submitted; and the word became afterwards the text of orthodox belief, but very ineffectual for allaying the dissensions of the Christian church.

In the year 330 Eusebius concurred with the council at Antioch in deposing Eulathius the bishop; but though the bishops and people concurred in electing him for this see, which was more honourable and profitable than that of Caesarea, he peremptorily refused the acceptance of it. Although they applied to Constance for the interposition of his authority, Eusebius wrote to the emperor, and obtained his permission to decline it, accompanied with encomiums on his moderation and disinterestedness, which he justly merited. At the council of Tyre in 335 he joined those bishops who condemned the proceedings of Athanasius, bishop of Alexandria; and he was deputed to attend the emperor, in order to justify the measures that had been adopted against that prelate. On occasion of this visit to Constantinople, he pronounced his panegyric on the emperor, and obtained angular marks of Constance's censure and favour. After his return to Caesarea, the emperor kept up an epistolary correspondence with him, speculations of which are preserved in Eusebius's life of that prince. This work was written soon after the death of the emperor; nor did the bishop long survive, for he died in the year 339 or 340. Of the learning and application of Eusebius, his works afford ample evidence. "From his works it appears," says Tillemont, "that he had read all sorts of Greek authors, whether philosophers, historians, or divines, of Egypt, Phœnicia, Asia, Europe, and Africa." Eusebius had opportunities for converse with the most learned men of his time, and he had access to the best libraries: to that from these different resources he was able to compose works of various kinds, in which he exercised a laudable caution with respect to his authorities and facts, and in which he also manifested a considerable degree of candour and impartiality. His works, however, as compositions, claim no very high commendation, as they are delitute of elegance and peripatry. Upon the whole we may observe, that he was a good man as well as a learned scholar; zealously attached to religion, without bigotry; an enemy to ecclesiastical tyranny and discord, and always desirous of accommodating differences, and reconciling contending parties. Nevertheless Dr. Lardner mentions with disapprobation his concurrence with the Arian party in the harsh treatment given to Eulathius, bishop of Antioch, Athanasius of Alexandria, and Marcellus of Ancyra. As to his sentiments with regard to the doctrine, warmly controvseted in his time, Dr. Jortin inclines to think, that he was neither an Arian nor an Athanasian, but that he endeavoured to steer a middle course, and yet inclining more to the Arians than to the Athanasians. Dr. Lardner, with his usual caution, observes, that this is a question which cannot be fully decided.

Of the works of Eusebius we can here enumerate only the principal, referring for an account of the rest to the writers cited at the close of this article. The first that deserves mention is the "Ecclesiastical History," in ten books, published in 326, and containing the history of the Christian church from the birth of Christ to his own times. The fourth edition is that of Valeius, published at Cambridge by Reading in three volumes folio. This contains Eusebius's "Life of Constance," in four books, written in 337 or 338, and other ecclesiastical historians, Socrates, Theodoret, &c. In this history we have several passages concerning the canon of scripture, in which the author treats of the order of the gospels, of the scriptures universally acknowledged, and of those that are not such of the epistles, &c. (See Canon.) Eusebius's "Chronicle" was a work of prodigious labour and learning, and is preserved only in a Latin version of Jerome. The "Ecclesiastical Preparation," in 15 books, and ten books of the "Ecclesiastical Demonstration," which originally comprised 20 books, are still extant; and contain the most learned defence of Christianity against both Jews and Pagans, transmitted to us from antiquity. A beautiful edition of these valuable works was published in Greek, by Robert Stephens, in 1544 and 1545, in 3 vols. fol., and reprinted at Paris, in 1628, in 2 vols. fol., with a Latin version of the former, and various readings from different MSS. and notes by Francis Vigerius, and Donatus's Latin version of the latter. Eusebius was also the author of a "Commentary upon the 150 Psalms," published by Montauclus in 1705, as far as the 119th psalm; "A Commentary upon the Prophecies of Hiffiah," published likewise by Montauclus; "An Exposition of the Song of Songs," published by Meursius in 1627; "A Treatise against Hierocles" who had made a composition of Apollonius Tymanus with Jesus Christ, fill extant in the original Greek; "Two books against Marcellus," who revived the hereby of Sabellius, and "Three books of Ecclesiastical Theology," written in 336; "An Apology for Origine," in 6 books, the joint work of Eusebius and Pamphilus, now existing in a Latin version; "Ten Evangelical Canons," or rules for harmonizing the gospels; the "Topics," in 2 books, being a kind of dictionary of places mentioned in the Scriptures; a "Description of the Church of the Sepulchre at Jerusalem, &c." composed in 335; "An Oration in praise of Constance," which is as much an argument for the truth of the Christian religion, as a panegyric upon the emperor, and much commended by Du Pin and Lardner; the "Life of Constance," in 4 books, already mentioned: "Fourteen small pieces in Latin," published by James Simond in 1643, 8vo, and many other treatises, that are no longer extant. Fabr. Bibl. Græc. v. vi. Cave's H. L. vol. i. Lardner's Works, vol. iv. Jortin's Rem. on E. H. vol. ii.

Eusebius, bishop of Salisburia in Philæuria, and afterwards of Nicomedia, in Bithynia, was advanced to the see of Constance in 358 and 330. He was a relation of the emperor Julian, who was educated by him, and probably also of Constance; and as he was a man not only distinguished by his abilities and learning, but favoured with free access to the court, his influence on behalf of the Arian party,
part, to which he was attached, was always of great importance to their cause. From the protection afforded to Arius and his followers by Eusebius they were frequently denominated "Euchthians." Although he remonstrated against the proceedings of the court of Nice in 325, at which he was present, he continued the creed, probably with the same explanation which was given by the bishop of Caesarea of the same name. That this was the case we may infer from the patronage which he afforded to the Arians, and which caused Constances to depose him from his fee and to send him into exile. He was afterwards, viz. in 328 or 329, recalled, and restored to his fee, as well as to the favour of the emperor. Afterwards, when the Arian party became triumphant at the court of Constantine, he encouraged the persecution of those who had been the persecutors of Arius. Having maintained his credit and influence with Constance till his death, he gained in an equal, if not greater, degree, the confidence of his son Constance; who promoted him, in 338, to the see of Constantinople. In this high dignity he was active in promoting the Arian interests, and in persecuting the Catholics. Soon after the council of Antioch, held in 341, probably in the same or the preceding year, he terminated his career. Eusebius was eminent for his abilities and learning; and his friends have extolled his piety and virtues; but no sufficient apology can be offered for his intolerance. His writings were numerous, but none of them remain, except a "Letter concerning Arius and his Community," prefixed by Theodoret. 

EUSEBIUS, bishop of Emesa, who flourished about the year 345, was defended of a very honourable family, and born at Edessa in Mesopotamia, at which place he enjoyed the benefit of a learned education, and of early instruction in the sacred scriptures. He afterwards removed to Palestine, where he studied under Patrophilus of Scythopolis, and Eusebius of Caesarea. He likewise went to Antioch, and from thence to Alexandria, in which city he studied philosophy, and then returned to Antioch. Some time after that, having obtained the offer of the see of Alexandria, from which Athanasius was deposed in 341, he was appointed bishop of Emesa; where his distinguished proficiency in literature and the sciences led the ignorant populace to charge him with the practice of magical arts. Under this accusation, he was obliged to retire to Lodoea, and to seek the protection of George, bishop of that city, who was afterwards his biographer. When the prejudices of the misguided people at Emesa subsided, he returned thither, and here he spent the greater part of the remainder of his life, which terminated at Antioch about the year 360. He is generally thought to have embraced the Arian tenets: though Cave thinks that he should be ranked among the Semi-Arians. However this be, his character was held in high estimation for virtue and piety, as well as for learning and eloquence. Although he was great and good, as Sozomen says, he experienced the envy of those who are offended at other men's virtues. The emperor Constantius, however, was much pleased with him, and his attendance was always required by the latter, who frequently consulted him. He wrote a great number of books, which were chiefly treatises against the Jews, against the Novatians, and against the Manichæans; 10 books upon the epistle to the Galatians; and many short homilies upon the gospels. His works are in general lost. His treatise against the Jews is said to be full extant in a Greek MS. in the library at Vienna. The homilies, that have been published under his name at Paris, in 1577, and at Antwerp in 1602, 8vo. Vol. XIII.

are now allowed to be the productions of other writers. Soc. Hist. Eccl. i. iii. Cave's H. L. vol. iv. Lardner's Works, vol. iv.

EUSEBIUS, bishop of Vercell, or Vercelli, in Italy, was born in Sardinia; and flourished about the year 354. In this year he was deputed by pope Liberius to plead the cause of Athanasius, after his expulsion from Alexandria, before the emperor Constantius; and in the council at Milan he was a zealous advocate for the deposed bishop, and for the Nicene creed. The Arian party, however, prevailed, and a decree was passed for condemning the conduct of Athanasius. Eusebius refuted, and for his unyielding stand he was banished to Scythopolis in Syria, afterwards to Cappodocia, and last of all into the Upper Thebais. The cause of orthodoxy, notwithstanding all his sufferings, found him an undaunted and persevering advocate. Upon the accession of Julian to the empire, he and other friends were allowed to return home; and during the remainder of his life he maintained his invincible attachment to the Catholic doctrine, and his zeal in promoting it. He died about the year 370, or soon after. Many of his works have been lost; but it is said that in the cathedral church at Vercelli there is a MS., containing a Latin version of the four Gospels, which is inscribed in the " Evangelarium Quadruplex Latina Versionis Antiquae, feu veteris Italicorum," published by Joseph Bianchini, at Rome, in 1749. Cave's H. L. vol. i. Lardner's Works, vol. iv. chap. 90.

EUSEBIUS, bishop of Doryleum in Phrygia in the fifth century, was at first an eminent advocate at Constantinople, but ensuing the ecclesiastical life, he obtained the above-mentioned see, and distinguished himself by his opposition to the Euchthians. Some few of his works remain, which are of a polemical nature, and not worth mentioning. Cave's Hist. Lit. vol. i.

EUSENE, in Ancient Geography, a town of Asia, in Paphlagonia. Ptolemy.

EUSHAR, in Geography, a town of Asiatic Turkey, in Natolia; 24 miles E. of Ibarthet.

EUSHEIM, a town of Germany, in the principality of Wurtzburg, 6 miles N.W. of Fulda.

EUSIMARA, in Ancient Geography, a town of Asia, in Miletina, a country of Cappadocia, located on the bank of the Euphrates. Ptolemy.

EUSKIRCHEN, in Geography, a town of France, in the department of the Rhoen; 20 miles S.E. of Juliers.

EUSTACE, or EUSTATIA, an inconsiderable American island, about 20 miles in circuit, forming with a long point of land the entrance to the harbour of St. Augustine, in East Florida. It was also called Metanans, or Slaughter, from a butchery made upon it by the Spaniards.

EUSTACHE, DAVI, in Biography, a French protestant minister, at Montpellier, afflicted at the national faction held at London in 1659, as deputy of the province of Lower Languedoc, and was nominated by the assembly to preside to the king the letter which they had addressed to him. He performed the task much to the satisfaction of those who had appointed him to the office. He was author of many theological pieces and sermons; the titles of some of the former are "Sabbatical Sermone against a Departure from God;" "The Triumph of Faith;" "An Answer to the Question asked of the Protestants, where was your Church before Luther?" "The Orator Tertullian convinced," which was a reply to the harangue suppressed to be made by the wife of the pretended reformed religion to the queen Maria Theresa, upon her entrance into the kingdom, in which they declared that being informed the had expressed great concern that part of the king her husband's subjects...
were heretics, they came toollen that concern by embracing her majesty's religion, and that this they did after having been satisfied, by the testimony of their most famous authors, that one may be saved in the Romish religion. Moreri. Bayle.

EUSTACHIAN Tube, in Anatomy, is the passage by which air is conveyed from the faucæ to the tympanum of the ear, so called from an Italian anatomist. See EAR.

EUSTACHIAN valves, is a part formed in the right auricle of the heart. See Heart.

EUSTACHIUS, Bartholomeu, in Biography, one of the most celebrated anatomists of the sixteenth century, was a native of a little village in Italy, called San Severino. He pursued his studies at Rome, where he first conceived a bias in favour of medicine, and especially of anatomy, which he cultivated with such success, that he was appointed to the professor's chair in that college. This is nearly the sum of our knowledge respecting the life of this celebrated man; he died at Rome in 1774. Eustachius was the author of several works, the greater part of which is lost. His treatise "De Controversiis Anatomicorum," which was one of the most considerable of his productions, is much regretted. Those of his writings, which remain, consist of his Opuscula, which appeared under the following titles, "Opuscula Anatomica, neme de Renum structura, officio, et administratione: de auditus organo: ossum exanime: de motu capitis: de vena que azygos dictum, et de alia, quæ ex flexu brachii communem profundam product: de dentibus." Venet. 1503, and again in 1674, with the notes of Pinus. An edition was also published at Leyden, 1707, under the superintendence of Boerhave.

Eustachius was the author of several discoveries in anatomy; he was the first who described the renal capsules, and the thoracic duct; and his name, still attached to the passage leading from the heart to the internal ear, (the Eustachian tube) announces the origin of our knowledge on that subject. A series of figures engraved on copper were mentioned in his Opuscula as nearly finished; but they were lost for more than 150 years, and were discovered, and published at Rome in 1714, by Lanceli, physician to pope Clement XI. in one volume folio. These plates were again published, but not well printed, at Geneva in 1717. The edition of Rome in 1728 is excellent; but the one published at the same city, 1740, by Petrioli, is less valuable. The same work was twice published at Leyden, under the direction of Albinus, viz. in 1744 and 1762.

EUSTATHIUS, in Ecclesiastical History, a name given to the Catholics of Antioch in the fourth century, on occasion of their refusal to acknowledge any other bishop but St. Eustathius, bishop of Sebastian in Armenia, deplored by the Arians.

The denomination was given them during the episcopate of Paulinus, whom the Arians substituted for St. Eustathius, about the year 350, when they began to hold their assemblies apart. About the year 350, Leontius of Phrygia, called the Eunuch, who was an Arian, and was put in the fee of Antioch, desired the Eustathians to perform their service in his church; which they accepted; and the church of Antioch served indifferently thus both for the Arians and Catholics.

This, we are told, gave occasion to two institutions, which have subsisted in the church ever since; the first was phalmody in two choirs; though Mr. Baillet thinks, that if they instituted an alternate phalmody between two choirs, it was between two Catholic choirs, and not by way of response to an Arian choir. The second was the doxology, Glory be to the Father, and the Son, and the Holy Ghost.

This conduct, which seemed to imply a kind of communion with the Arians, gave great offence to abundance of Catholics, who began to hold separate meetings, and thus formed the schism of Antioch. Upon this the rest, who continued to meet in the church, ceased to be called Eustathians; and that appellation became restrained to the dissenting party.

St. Flavianus, bishop of Antioch, in 381, and one of his successors, Alexander, in 432, brought to pass a coalition or re-union of the Eustathians and the body of the church of Antioch, described with much solemnity by Theodoret, Eccl. lib. iii. cap. 2.

Eustathians were also a sect of heretics in the fourth century, denominating from their founder Eustathius, a monk so sufficiently fond of his own profession, that he condemned all other conditions of life. Whether this Eustathius was the same with the bishop of Sebastian and chief of the Semiarians, it is not easy to determine.

He excluded married people from salvation; prohibited his followers from praying in their houses, and obliged them to quit all they had as incompatible with the hopes of heaven.

He drew them out of the other assemblies of Chirilians to hold secret ones with him, and made them wear a particular habit; he appointed them to fail on Sundays; and taught them that the ordinary failts of the church were needless, after they had attained to a certain degree of purity which he pretended to. He flowned great horror for chapels built in honour of martyrs, and the assemblies held therein.

Several women, seduced by his reasons, forsook their husbands, and abundance of slaves deserted their masters' houses.

He was condemned at the council of Gangra, in Phaphienus, held between the years 326 and 341. Socr. lib. ii. cap. 43 and Sozom, lib. iv. cap. 24. Hard. Concil. Coll. tom. i. p. 530.

EUSTATHIUS, in Biography, a saint in the Greek and Roman churches, and bishop of Antioch, was translated to that see from the bishopric of Beraea, in Syria, about the year 323. He was a fireneous opponent of the Arian doctrine, and is said to have been the first ecclesiastic of consecration who wrote against it. He was distinguished by his zeal at the council of Nice in 325, and by his exertions in carrying the decisions of that council into effect. This conduct so much exasperated the Arian bishops, that they got him accused of adhering to the doctrine of Sabellius, rather than to that of the council of Nice. His enemies also forbade an infamous woman to appear before the synod of the Eastern bishops, to charge Eustathius with being father of a child when held in her arms: other charges, equally disreputable, were made against him: of these he was declared guilty, and deposed from his pastoral office. He was afterwards banished to Thebarnopolis in Thrace, where he died. Of his numerous writings we have few remains, excepting the fragments collected by Fabricius. Jerome thought highly of his talents; Sozomen commends him for his piety and eloquence, and says that his works were in high estimation in his time. By Theodoret he is called the great Eustathius; but Socrates and others speak very highly of his talents, and Socrates says he is one of those obscure persons who had endeavoured to raise his own reputation.
reputation by opposing Origen. He is generally admitted to have been the author of "A Disquisition concerning the Ventriqulot or Pythoned," mentioned in Samuel, first book, chap. xxvii. written against Origen on that subject. This was published by Alladius in Greek, with a Latin version, in 1629, and may be found in the fifth volume of the "Bibliotheca Patrum," and in the eighth volume of the "Crucii Sacri." Fabr, Bib. Graec. vol. viii. Cave's H. L. vol. i. Lardner's Works, vol. iv.

EUSTATIA, or Eustatius, St., in Geography, one of the Leeward Caribbee islands; which is a huge pyramidal rock rising out of the sea, about 26 miles in compass; but for its size the Dutch, by their industry, rendered it one of the most remarkable in the Caribbee islands. The sides of the mountains are laid out in pretty settlements; but they have neither springs nor rivers. Sugar and tobacco have been the chief produce of this island, which the Dutch have cultivated even to the top of the pyramid, which terminates in a plain surrounded with woods, having a hollow in the middle that serves as a den for wild beasts. This island has afforded subsistence for four thousand white people, and fifteen thousand negroes, who roam hogs, kids, rabbits, and all kinds of poultry in such abundance, that they have been able to supply even their neighbours. It has but one landing place, which the original occupiers, finding difficult of access, fortified, so as to render it almost impregnable. Such for many years was the policy of the Dutch in the government of this island, that they have been jealous of admitting any strangers into their harbour, and kept them ignorant of its internal riches, whilst it has served as a storehouse for all European commodities. The property of it was first granted by the States-General to certain merchants of Flushing. It was first settled about the year 1600; but in the wars between the English and Dutch in 1665, the latter were dispossessed of it by an armament from Jamaica. The English were afterwards dispossessed by the combined forces of the Dutch and French; and the latter kept possession of it till it was restored to the Dutch by the treaty of Breda. Soon after the revolution, the French ejected the Dutch from this island, whence they were again driven by the English under Sir Timothy Thornhill, who, with a view to the protection of the Dutch, left a small English garrison in the fort. The peace of Rywick restored the Dutch to the entire possession of the island. In the year 1781 this island was obliged to surrender to the English under admiral Rodney, who confiscated the private property of the inhabitants under a plea that they had assisted France and the United States with naval and other stores. Before the close of the year it was taken by the French under the command of the marquis de Bouillé; but restored to the Dutch at the peace in 1783. It is distant 9 miles N. W. from St. Christopher. N. lat. 17° 30'. W. long. 63° 8'.

Eustatia, also the name of a town in the former mentioned island.

EUSTATIUS, in Biography, archbishop of Thessalonica, flourished in the 12th century, under the emperors Manuel, Alexius, and Andronicus Comnenus. He is celebrated for his great learning as a grammarian and critic, and is especially known as a commentator on Homer and Dionysius the geographer. His annotations on the former are copious, and abound in historical and philological descriptions; they were published at Rome in four volumes folio, between the years 1542 and 1550, and have been reprinted, particularly at Florence in 1730, with the notes and transliterations of Politi and Salumi. The commentaries on Dionysius were first printed in the Greek, by Robert Stephens in 1547, and have been several times reprinted. A Latin version of them was given by Politi in 1731, at Geneva, in two volumes quarto. Moreri.

Gen. Ch. Cal. Sheath oblong, divided to the base into four acute segments, withering. Cor. superior, of one petal, tubular, regular, in six deep, linear, obtuse, nearly equal segments, three of which are internal; without any appendage at the mouth. Neckary fix little cavities in the bale or tube of the corolla. Stem. Filaments fix, inserted into the bottom of the corolla, just above each nectariferous pore, linear, flat, somewhat longer than the corolla, and three-cleft just where they emerge from it, the middle segment long, erect, slender, bearing the anther, the lateral ones short, and horizontally divaricated, forming a crown in the mouth of the corolla; anthers incumbent, ovate. Pfl. German inferior, turbinate, triangular, gently thread-shaped, the length of the flamen; stigma swelling, undivided. Peric. as far as can be judged from the germs, a capsule of three cells. Seed...}

1. E. cocinea, Cavan, le. t. 238. Flowered in the royal garden at Madrid in May 1794, but its native country is unknown. Root perennial, bulbous. Leaves radical, seveal, linear, obtuse, somewhat falcated. Stalk solitary, above a foot high, stout, smooth, slightly compressed. Flowers four in a terminal umbel, drooping, leaf-like, resembling those of Cyrtanthus angustifolius, but very different in their structure. Sheath nearly as long as the partial flower-flanks and flowers together.

EUSTOCHIUM, or Eustochia, in Biography, a Roman lady in the 4th century, who is highly spoken of by St. Jerome, was a descendant from the families of the Scipios and Paulus Aemilius, and rendered herself celebrated for the piety which she had made in literature. She was well acquainted with the Hebrew and Greek, as well as the Latin tongues, and conversant with the most important theological subjects. In the Catholic world her memory is cherished on account of her early devotions to a religious course. She professed herself a disciple of St. Jerome, whom she followed from Rome to Cyprus, and thence to Antioch, Egypt, and numerous other places, and at length fixed her residence in a monastery at Bethlehem. Her mother Paula deft a young family to accompany her in these excursions. Moreri.

EUSTRATUS, a prebyster of the church of Constantinople, flourished about the year 578, and was author of "A Treatise concerning the Souls of the Dead," intended to prove that the souls of all men are active after their separation from the body, and that they act differently according to the difference of their merits. He was author also of "The Life of the Patriarch Eutychius," which appears to have been a funeral oration pronounced by Eustatius in the great church at Constantinople, a short time after the death of the subject of it.

Eustratius, archbishop of Nice in the twelfth century, is mentioned by Anna Comnena, and other Latin writers, as a person of profound learning and skill, as well in civil as ecclesiastical affairs. He was author of "A Treatise against Chryfolanus concerning the procession of the 4 K 2 Holy
EUtan, in Geography, a town of Germany, in the bishopric of Lubeck, situated by the side of a lake, the usual residence of the prince bishop, the bishopric, like that of Ohlburg, being secular; 20 miles N. of Lubeck. N. lat. 54° 10'. E. long. 16° 32'.

EUthocius, in Biography, a considerable mathematician, who lived at the time of the decline of the sciences in Greece, was a native of Acalon, in Palestine, and a disciple of Ildorus, one of the celebrated architects employed by the emperor Justinian. He probably flourished about the commencement of the sixth century, though we have no particulars respecting his life; but his works reflect much honour on his memory. He wrote elaborate and picturesque "Commentaries on the books of Archimedes concerning the Sphere and Cylinder," and also on the first four books of the Conics of Apollonius Pergaeus. These commentaries have not only elucidated many difficult passages in those profound writers, but have tended to throw light on the history of mathematics. There have been many editions of them, but the most magnificent was that in the edition of the works of Archimedes, printed at Oxford in folio, in the year 1792, which was prepared for the press by Torelli of Verona; and that in Dr. Halley's edition of the eight books of Apollonius, published at Oxford in 1710. Moreri. Montucla.

EUttropius, a Latin historian of the fourth century, is supposed to have been a native of Acquitain. He bore arms under Julian, in his expedition against the Persians, and is said to have risen to the senatorian rank. He wrote several works, of which the only one remaining is an abridgment of the Roman history, in ten books, from the foundation of the city to the reign of the emperor Valens. This is a neat compendium, and has long since been received as a school-book. Moreri.

EUttropius, the eunuch minister of the emperor Arcadius, who rose by base and infamous practices from the vilest condition to the highest pitch of opulence and power, was probably a native of Asia. In the year 395 he was made great-chamberlain to Arcadius, emperor of the East. After the fall of Rhanus, he succeeded that minister in the confidence of his master, and rule to unlimited authority: All perons of whatever rank humbled themselves before the favourite, who became the capricious dispenser of honours and emoluments of every kind, and in 399 he, an eunuch, even assumed the dignity of consul, a disgrace to Rome never before equalled. Honours, if such they may be denominated, of every kind were accumulated upon him: the towns were filled with his statues, and he was entitled the third founder of Constantinople. His predominant passion was the love of money, and of course the most shameless venity directed all appointments to the high offices of the state. As a security to his person, a law of treason was passed, which extended the penalties of that crime to every attempt against the ministers and servants, as well as against the person of the emperor. Such a shield was not sufficient to defend him from the influence of court intrigue. An in-
fult which he offered to the empress caused her to implore the protection of her husband, and at the same moment complaints were offered against him from other quarters, which induced the emperor to sign his condemnation, and the fallen and justly execrated favourite was obliged to seek refuge in the sanctuary of a church, from the pulpit of which Chrysofom pronounced an eloquent discourse, pointing him out to the people as an example of the inftability of human grandeur. He afterwards surrendered himself on promife that his life should be spared, and was condemned to perpetual exile in Cyprus. Thither he was conveyed, but being hastily brought back and tried on another charge, he was condemned and beheaded in the year 599. Gibbon.

EUTYCHIAN, in Ancient Geography, an island of the Aegean sea, before the Pagus gulf.

EUTYCHIAN, in Ecclesiastical History, ancient heretics, who denied the duplicity of natures in Christ; thus demonstrated from Eutyches, the chianitante, or abbot of a monastery at Constaninople, who began to propagate his opinion A. D. 448.

The averfion Eutyches bore to the herefie of Nestorius threw him into another extreme not less dangerous than that he so warmly opposed; though some passages in St. Cyril, which railed the unity of the perfon of Jesus Christ very high, contributed likewise to his delufion. At first he held that the Logos, Word, brought his body down with him from heaven; which was a near approach to the herefie of Apollinaris; and, though he afterwards testified the contrary, in a synod at Constaninople, where-in he was condemned, yet he could not be brought to acknowledge that the body of Jesus Christ was conflational with ours.

In effeft, he did not feem quite ready and conflent in his fentiments; for he appeared to allow of two natures, even before the union; which was apparently a confequence he drew from the principles of the Platonic philofohy, which fupposeth a pre-exifence of fouls: accordingly he believed that the foul of Jesus Christ had been united to the divinity, before the incarnation: but then he allowed no differentiation of natures in Jesus Christ from his incarnation.

See the difertation of H. Hardonin, "De Sacramento Altaris," wherein that Jeguit endeavors to unfold all the fentiments of the Eutychians.

This herefie was firft condemned in a synod held at Constaninople, by Flavian, in 448, approved by the council of Ephesus, called Conventus britonum, in 449, and re-examined and fulminated, in the general council of Chalcedon, in 451. The legates of pope Leo, who affifted at it, maintained, that it was not enough to define, that there were two natures in Jesus Christ, but infifted fervently, to remove all equivocations, they must add their terms, without being changed, or confounded, or divided.

The herefie of the Eutychians, which made a very great progress throughout the East, at length became divided into several branches. Nicephorus makes mention of no fewer than twelve; some called schismatics, or apperentes, as only attributed to Jesus Christ, a phantom, or appearance of flesh; and no real flesh; others Theodouius, from Thedouius, bishop of Alexandria; others Jacobites, from one James, Jacobus, of Syria; which branch established itself principally in Armenia, where it still subsists. Others were called Aerophytes, Q. D. without head; and Severians, from a monk called Severus, who feized on the see of Antioch in 513.

Thee four were sub-divided into five factions, viz. Ag-

EUTYCHIAN, in Biography, bishop of Rome, succeeded to that high office on the death of Felix, in the year 275, and presided over the church about eight or nine years, when he died. Catholics have considered him as a martyr to the cause of truth; but historians, in general, infer, from the unmoledled satire of Christian, at that period, in Rome, that he died a natural death. There are two decretal epistles of this pope extant, relative to subjicts of ecclesiastical discipline. Mereri. Bower.

EUTYCHIANUS, patriarch of Constaninople, was born in the year 512. He was brought up to the ecclesiastical profession, and obtained in early life the episcopal dignity in a town of Pontus, which he afterwards relinquished, and entered into a monastery in the city of Amasea. In 552 he was deputed by the bishop of that city to Constaninople, as his representative, in the approaching general council that was to be held there. Before the meeting of the council, he obtained the favour of Julianus, who raised him to the patriarchate of Constaninople, which became vacant in the year 555, by the death of Mennas. Almost immediately after he had assumed the new character, he induced all the council of Nicæa, and his followers were condemned. Some years after, viz. in the year 564, Julianus endeavoured to obtain the patriarch's sanction to a doctrine which he had adopted, viz. that the body of Jesus Christ was rendered incorruptible before his resurrection, by the union of the divine and human natures; but when Eutychus steadily refused to countenance the opinion, the emperor depoited him from the patriarchate and sent him into exile. In 578, he was reinstated in the see of Constaninople, by the emperor Tiberius II., and he died in the year 585, at the age of 73. There is extant, in the fifth volume of the "Collectio Conciliorum," an epistle of his to pope Vigilius.

He was author of other pieces; of these a fragment of one only remains, "Concerning the Souls of the Dead." Morei.

EUXINE SEA, called the Black Sea, as it is said, either from its black rocks, or dangerous navigation, an inland sea, situated partly in Europe, and partly in Asia; bounded on the north by the government of Caucasus and Ekatari-

E W A.

nadal, on the east by Mingrelia and Georgia, on the south by Natolia, and on the west by European Turkey. This sea is divided into the Euxine proper, the Pontus Euxinus, computed to be 1000 versts in length, and 500 in breadth, and the sea of Azof, (see Azof) the Palus Medides of the ancients, which, without including the bay of Tamanor, is slated to be 200 versts long, and 160 versts broad. Both these are now entirely within the confines of the Russian empire. The sea of Azof, called palus, or a marsh, by the ancients, because it was polluted by mud, is united to the Euxine by the straits of Caffa, or the ancient Cimmerian Dophorus. The most important of the bays formed by these seas are the Liman, at the mouth of the Dnieper, the bay near Perekop, and that close to Yenikale. The most confiderable island belonging to these seas in the vicinity of the Russian coasts, is Taman. The principal harbours are Caffa, now Theodofa, Schafopol, Kolos, Balaklava, and some others. At the western extremity of these seas, within the province of Tartaria, is a very large pool, called Sivash, or the Putrid sea, which is about 140 versts long, and 53 broad. The chief rivers that fall into the Euxine, are the Kuban, or Hypa-

nias of the ancients, the Don, or ancient Tanais, the Dnieper or Borytnenes of ancient geographers, and the Bogur, which rises in Poland, parting that kingdom, and a portion of European Turkey from Russia, and at Otchakof, falls into the Euxine. The Euxine sea was formerly denominated azof, or inhospitable, on account of the bar-

barity of the inhabitants of its coasts; but when they became civilized by their commerce with the Greeks, the name was changed into euxin, i.e. hospitable, or favourable to strangers.

E U Z E T, a town of France, in the department of the Gard; nine miles W. N. W. of Uzes.

EUZOIS, in Biography, was in early life a deacon of the church of Alexandria, from which office he was expelled by Alexander, bishop of that see, at the same time with Arius, on account of his espousing the principles of that celebrated character. They were both involved in the like condemnation at the council of Nica. About the year 355, he presented a confession of faith to the emperor Constantine, which met with the approbation of that sovereign, and which was the means of bringing him into consequence at the imperial court, when the orthodox party were thrown in the back ground. He was appointed to the see of Antioch, and called upon to bap-

tise the emperor Constantine. His influence was now very considerabe, and to this the friends of Athanasius attribute much of the persecution by which that bishop was harassed. Moreri.

EUZOIS, bishop of Caesarea, was educated in that city at the same time with Gregory Nazianzen. On the death of Acacius he obtained the bishopric of Caesarea, after maintaining a violent contest with the different rival candidates. He was in principle an Arian, or nearly so, and on that account was deposed from his see under the reign of the emperor Theodosius, about the year 380. He was author of numerous treatises now lost; possessed with much learning, and was very diligent in the discharge of his episcopal functions; but he is principally celebrated on account of his great exertions in promoting the interests of science and literature. He manifested much zeal in the restoration and improvement of the library at Caesarea, which had been originally collected by Origen and Pam-

philus, and was at this period fallen into decay. To this object he devoted his time and labour, taking care that faithful transcripts should be procured of such books as were in a perishing state, and increasing their numbers by new collections. Moreri.

E W A G, Encyclopaedia, in our Old Writers, the same with agoge, which is toll paid for water-passage. It is derived from the French eau, water.

E W A L D, John, in Biography, a Danish poet, was born at Copenhagen in the year 1743. His father was a clergyman, and when he found his own end approaching he sent his son for education to Strick, and died in a few hours after. Licht, the person to whose care young Ewald was entrusted, treated him in every respect as his own son, and gave him free access to his library. The books most agreeable to his taste were romances, which he read with the greatest avidity. The adventures of Tom Jones and Robinson Crusoe, particularly the latter, had made such an impression on his mind, and had excited his philanthropy and sympathy, that he elapsed from Copenhagen to Batavia, in order to proceed to Holland, that he might undertake a voyage to Batavia, in the hope of being shipwrecked and thrown on some desert island. Scarcely had he travelled four miles, before he was overtaken by his preceptor and friend, who carried him back by force. At another time having read and heard of many romantic tales respecting saints and martyrs, he was disarmed of becoming a martyr for the cause of Christianity. At length he resolved upon the profession of a soldier, which being opposed by his friends, he left home, in company with his brother, and joined the Prussian service, from this he defected to the Austrian army, in which he was first a drum-

mer, and then a serjeant. A commissary was offered him, provided he would embrace the Catholic religion, which he absolutely refused, and in a short time deserted again. On his return to Denmark he devoted himself to theology, and studied with so much diligence as to be fit for examination in the course of a year. He had paid his address to a lady, who, supposing him not to be in earnest, gave her hand to another. He retaliated this with a greater show of change in his disposition, and to give his ideas a melancholy cast. He now abandoned himself to pleasue, and injured his constitution. To give vent to the effusions of his mind, he wrote a piece, called "The Temple of Good Fortune," which proved the source of all his future fame. It obtained the approbation of the society of Belles-lettres; and procured him the friendship of M. Carless, a zealous votary of the muses, which he enjoyed, without interruption, during the remainder of his life. On the death of Frederic V. in 1766, he com-
piled an elegy, which was received with universal approba-
tion, and Ewald, intoxicated with the praises bestowed upon his work, began to consider himself one of the greatest poets that Denmark had ever produced. The society of Belles-

lettres proposed as the subject of a prize the ball odon on any of the attributes of the deity, and Ewald, determined to try his fortune, made choice of the divine goodness, and had alre-
dy formed his plan, when he learned that Benson, one of his most intimate friends, was employed on the same subject. Unwilling to enter the contest with a friend he abandoned his subject, and wrote his Adam and Eve, a sort of half drama, in one act, which possessed much merit, but without order or any regard to the laws of composition. He hoped that this might obtain the prize, but was disappointed, and began to study poetry, being now resolved to read; and not
EWE

not to write any more for two years. The works of Corneille and Klopstock fell into his hands, and gave his taste a new direction. His next work was "Rolfe Krag," a tragedy in the style of Ossian, and "The Songs of Skalden," which he wrote under the eye of Klopstock, who had a very great and sincere affection for him. During the time he was employed on this piece, he was attacked by a disease, under which he languished for ten years. It proceeded from the gout, and was often attended with excruciating pain, yet his spirits and cheerfulnes scarcely forsook him, and he wrote in the intervals of his cafe some small theatrical pieces, which in part related to present times and manners, and which abounded with humour and the keenest satire. Ewald had obtained from the king a pension of a hundred dollars, but this being insufficient for his maintenance, he was obliged, by writing temporary poems, to gain a part of his livelihood, till the profits arising from the representation of his theatrical pieces, and from the sale of his works, should place him beyond the fear of want. He died at Copenhagen in March 1781, in the thirty-eighth year of his age. In strength of imagination, spirit and originality, Ewald surpasses all the other Danish poets. His excellent qualities gained him the affection of those who knew him. He never prostituted his muse to improper purposes, and never, says his biographer, did an immoral or pernicious line flow from his pen. A complete edition of his works was published at Copenhagen between the year 1781-1791. Gen. Biog.

EWANICZOW, in Geography, a town of Poland, in the palatinate of Kaminice; 64 miles N.N.W. of Kaminicze. EWANO, a town of Poland, in Galicia; 56 miles S.E. of Halicz.

EWE, a small island on the W. coast of Scotland, at the entrance of Loch Ewe. N. lat. 57° 53'. W. long. 5° 37'.

Ewe, in Rural Economy, the female of the sheep kind of animals. It is of very great importance in the forming of this sort of rock to have good ewes. (See Sheep.) It is the practice in some of the more northern districts to have recourse to the milking of the ewes in order to make cheese from it. But it is said to have been lately found so injurious to the animals, and to be attended with so little profit, that it is, at present, much on the decline.

Ewe-Chese, is that sort of cheese which is prepared from the milk of the ewe. It is a very strong pungent kind of cheese, which is not well relished by many. Some, however, consider it as very rich and excellent, preferring it to the other sorts of cheese. In some places these cheeses are made of a considerable size, perhaps, nearly as large as those of the Cheshire dairies, one, two, or three hundred ewes being milked regularly for the purpose. See Cheese.

Ewell, in Geography, is a market town in the hundred of Cotchmore, and county of Surrey, situated at the foot of Banstead downs, distant S.E. by E. of London 13 miles. The weekly market is held on Thursdays, and it has two annual fairs, one the 12th of May, the other the 29th of October. The number of houses, according to the returns in 1801, is 154, and of inhabitants 1112. Here is the head of an extraordinary spring called natural jet d'eau, breaking out in several places. After watering Epsom-court meadows it flows in a fine stream called the Malden, and falls into the river Thames at Kingston.

Near this town flood the magnificent palace, from its grandeur and splendid decorations, denominated "None-Such," erected by king Henry the Eighth. Charles the Second having conferred it upon his favourite mistress, the famous duchess of Cleveland, she caused it to be taken down, and sold the materials.

EWENNY, a river which has its source in the mountains to the north of Peterfield mountain, and passing by Croychurch and Ewenny priory, joins the river Ogmore near Merthyr Merthyr, below which it falls into the Bristol Channel. A phenomenon on this stream has given rise to a geological error, which has generally been credited with ut proper investigation, that the river makes a " U " under a mountain, appearing again near N eben's bridge, after a subterranean passage of two miles. " Mr. Lethezian observes, 'that between Merthyr Mawr, near which also were deep sands, and Newmorn bridge, the river Ogmore, or rather a branch of it, runs a quarter of a mile under the hill, passing also under several natural bridges; after which, filling out with great violence, it joins the main stream. The maps again here mistake in giving this river the name of Ogmore before its junction with the Ewenny, after which only it assumes that name, being called before the Bridgegarden river, as it comes from Bridgegarden, where it runs under ground a little to the north of that place, and appears again from under Ogmore hill.' See Archaeologia, vol. iv. p. 27.

It occurs near the junction of the Ewenny with the river Ogmore. From the foot of a long ridge of down, where the hill makes a bold escarpement to the vale, issues a large body of water, exceeding the quantity previously flowing down the river, except after rains. In its passage from under the hill it is heard to boil and rage, and rushes out with foaming impetuosity, as though it had met with violent interruption in its course; and forms two springs, which immediately appear different in the velocity of their motions and quality of their contents; one being what is vulgarly called hard, and the other soft water. The stream to the southward is sought for culinary, and that to the northward for lavatory purposes. In trying it, Mr. Evans observes, "the water from the opposite sides of the stream had a different effect upon the tongue and palate, and by a brief analysis it was discovered, that the one contained a portion of calcareous matter in solution; and the other left but little residue, which was of an argilaceous nature." An attempt was then made to ascertain whether the river might not enter some other part of the hill, and by a subterranean passage here fork daylight again, as is reported of the Severn in Wiltshire, and the Mole in Surry. But after a fruitless search the smallest vestige of such a subterranean course could not be traced. The phenomenon therefore in question appears to proceed from two powerful springs, rising in the internal parts of the hill, the streams of which having flowed separately, here unite, but without intermingling their waters, till they join the Ewenny. Evans's Tour in South Wales.

Eweny Priory, in Antiquity, was a monastery of the Benedictine order, founded by John Maurice de Lunders, Lord of Ogmore, A.D. 1140; and given as a cell to Gloucester Abbey. Its revenues, as valued at the dissolution, were 78l. or 80l. It stands close to the road leading from Newton to Pyle in Glamorganshire, South Wales, in a marshy plain, near the banks of the river Ewenny. It was surrounded by strong embattled walls, having two gateways; and the one forming the principal entrance had two portcullises: these, with parts of masonry at the sides among its ruins, indicate it was intended as a place of security, as well as religious retirement. The buildings appear to have been very extensive, and some rooms, which formed the abbey's lodge yet remaining, are large and lofty; particularly the great hall or refectory. But the abbey church, still standing, is a noble edifice, the simple and uniform architecture of which must be gratifying to every admirer of the arts. It is a massive building of a cruciform shape, con-
EXA

EXACUM, in Botany, a name which Pliny says has been given to the Lesser Century, because it carries off all bad medicines by stool, apparently from its, out of, and away, to drive, or force outward. Linnaeus pt. v. 164. Sm. Fl. Brit. 182. Mart. Mill. Dict. v. 2. 142. Cottam t. 141. Chis and order, Tr.;

EXACTIS, in Natural History, a name given by Lin-kius, and some other authors, to a species of fish, of the more branched kind, whose rays are six in number, when they first part from the body, but very soon branch out into a great number more. See St. 5.

EXACTOR Regis, in Law, the king's exactor, or collector. Sometimes it is taken for the sherif. But generally, 'quinqueunque publicae pecuniae, tributa, vestigia & res fisco debitas exigunt, proprium nominatur exactor regis.'

EXACUM, in Bot. a name which Linnaeus has been given to the Lesser Century, because it carries off all bad medicines by stool, apparently from its, out of, and away, to drive, or force outward. Linnaeus pt. v. 164. Sm. Fl. Brit. 182. Mart. Mill. Dict. v. 2. 142. Cottam t. 141. Chis and order, Tr.;

Geo. Ch. Cal. Perianth inferior, in four deep, ovate, slightly spreading, permanent segments. Cor. of one petal, permanent, salver-shaped; tube inflated, the length of the calyx, limb in four deep, roundish, spreading lobes. Stam. Filaments four, thread-shaped, inserted into the tube, not so long as the limb; authors roundish. Pîf. Germen supérior, oval, filling the tube; style-thread shaped, rather oblique, the length of the stamens; stigma capitate. Peric. Capsule elliptical, as long as the calyx, compressed, with a longitudinal furrow at each side, of two cells, bursting at the top. Seeds numerous, small, roundish, affixed to a central receptacle which forms the partition of the capsule.

Eff. Ch. Calyx in four segments. Corolla salver-shaped, with an inflated tube. Capsule superior, with two furrows, two cells, and many seeds, bursting at the top. Stigma capitate.

Obc. The flowers in some species are five-cleft, with a correspondent number of stamens.

Since this genus was founded by Linnaeus on the examination of some dried East Indian specimens of his E. filiforme and pedunculatum, Sp. Pl. 163, several species have been added to it by different botanists, either entire new discoveries, or separated from the old genus of Gentiana. Vahl has also referred hither the Costusæ of Aublet, Guian. t. 27, 28, with unquestionable propriety, though Jullien and Schreber have kept it separate, the latter by the name of Vicfirm, alluding to its bitterness.

Our only British species is E. filiforme, Engl. Bot. t. 235, found in fopsy, or sandy bogs, in Dorsetshire, Devonshire, and Cornwall, flowering in July. This is a small, slender, inconspicuous annual, with a branched stem; opposite, sessile, lanceolate leaves; and small, terminal, solitary, yellow flowers, expanded only while the sun shines bright upon them. It was the Gentiana filiformis of Linnaeus and all following authors, till referred to Exacum in Engl. Bot. E. viscosa. Sm. Itc. Pict. t. 18. (Gentiana viscosa; Alt. Hort. Kew. v. 1. 321.) has pentandrous five-cleft flowers. This is a handsome green-house plant, brought from the Canary islands by Mr. Maffon. The stem is shrubby, three feet high, with oblong ribbed leaves, and large terminal panicles of yellow flowers. The annual species are scarcely to be cultivated, no suc-

EXAMINATION, in Astrology, is a dignity which a planet acquires in certain signs, or parts of the zodiac; which dignity is supposed to give it an extraordinary virtue, efficacy, and influence. The opposite sign, or part of the zodiac, is called the dejection of the planet.

Thus, the 15th degree of Cancer is the exaltation of Jupiter, according to Albumazar, because it was the ascendant of that planet at the time of the creation: that of the sun is in the 15th degree of Aries; and its dejection in Libra; that of the moon is in Taurus, &c. Itoley gives the reason of this in his first book De Quadrup.

EXAMEN, or Examination, an exact and careful search, or inquiry, in order to discover the truth or falsehood of a thing.

EXAMINATION, &c. See HEXEMLION, &c.

EXAMINATION, Self, is that point much insisted on by divines, and particularly the ancient fathers, by way of preparation to repentance. St. Ignatius reduces it to five points; viz. 1. A returning of thanks to God for his benefits. 2. A begging of grace and light, to know and distinguish our sins. 3. A running over all our actions, occupations, thoughts, and words, in order to learn what has been offensive to God. 4. A begging of pardon, and conceiving a sincere sorrow for having displeased him. And, 5. Making a firm resolution not to offend him any more; and taking the necessary precautions to preserve ourselves from it.

EXAMINATION of Bankrupts, in Law. See Bankrupt.

EXAMINATION of Prisoners. See Commitment.

EXAMINATION, of Inspection, Trial by, is when, for the greater expedition of a cause, in some point or issue being either the principal question, or arising collaterally out of it, but being evidently the object of a cause, the judges of the court, upon the testimony of their own senses, shall decide the point in dispute. Thus, in case of an suit to reverse a fine for non-age of the culprit, or to set aside a flat or recognition entered into by an infant; in this, and in similar cases, a writ shall issue to the sheriff (Rep. 31.), commanding him that he confine the suit party to appear, that it may be ascertained by the view of his body by the king's justices, whether he be of full age or not. If, however, the court, upon inspection, has any doubt of the age of the party, it may proceed to take proofs of the fact; and, particularly, may examine the infant himself upon an oath of voir dire, veritarum dicti, that is, to make true answer to such questions as the court shall demand of him; or the court may examine his mother, his guardian, or the like. (2 Roll. Abr. 573.) In like manner, a defendant pleads in abatement of the suit that the plaintiff is dead, and one appears and calls himself the plaintiff, which the defendant denies; in this case the judges shall deter-
EXAMINE, by inspection and examination, whether lie be the plaintiff or not. (9 Rep. 30.) Also, if a man be found by a jury an idiot, a naturiform, he may come in person into the chancery before the chancellor, or be brought there by his friends, to be inspected and examined, whether idiot or not; and if, upon such view and inquiry, it appears he is not so, the verdict of the jury, and all the proceedings thereon, are utterly void and instantly of no effect. (Ibid. 31.) The trial by inspection may be also used, upon an appeal of malum, when the offence joined is whether it be malum or no malum; this shall be decided by the court upon inspection, for which purpose they may call in the assistance of surgeons. (2 Roll. Abr. 578.) And by analogy to this, in an action of trespass for malum, the court (upon view of such malum as the plaintiff has laid in his declaration, or which is certified by the judges who tried the cause to be the same as was given in evidence to the jury) may increase the damages at their own discretion (1 Sid. 108.); as may also be the case upon view of an atrocious battery. (Hardr. 428.) But then the battery must likewise be alleged so certainly in the declaration, that it may appear to be the same with the battery inspected. Also, to ascertain any circumstances relative to a particular day past, it hath been tried by an inspection of the almanac by the court. Thus, upon a writ of error from an inferior court, that of Lynn, the error alleged was that the judgment given was on a Sunday, it appearing to be on the 26th February, 26 Eliz. and upon inspection of the almanac of that year, it was found that the 26th of February in that year actually fell upon a Sunday: this was held to be a sufficient trial, and that a trial by a jury was not necessary, although it was an error in fact, and so the judgment was reversed. (Cro. Eliz. 227.) But, in all these cases, the judges, if they conceive a doubt, may order it to be tried by a jury. Blackf. Com. vol. iii.

EXAMINATION of witnesses, in the trial by jury, derives peculiar advantage from its being conducted openly, viva voce, in the presence of all mankind. This mode of examination is much more conducive to the clearing up of truth, than the private and secret examination taken down in writing before an officer or his clerk, in the ecclesiastical courts, and all others that have borrowed their practice from the civil law, where a witness may frequently depose that in private, which he will be ashamed to testify in a public and solemn tribunal. Besides, the occasional questions of the judge, the jury, and the counsel, propounded to the witnesses on a sudden, will lift out the truth much better than a formal set of interrogatories previously penned and settled; and the confronting of adverse witnesses is another opportunity of obtaining a clear discovery, which can never be had upon any other method of trial. Nor is the presence of the judge, during the examination, a matter of small importance; for besides the respect and awe with which his presence will naturally inspire the witnesses, he is able by use and experience to keep the evidence from wandering from the point in issue. In short, by this method of examination, and this only, the persons who are to decide upon the evidence have an opportunity of observing the quality, age, education, understanding, behaviour, and inclination of the witnesses; in which points all persons must appear alike, when their depositions are reduced to writing, and read to the judge, in the absence of those who made them; and yet as much may be frequently collected from the manner in which the evidence is delivered as from the matter of it. See Evidence.

Examination of witnesses in Chancery is done with a view to the proof of facts that are disputed, and their decisions are taken in writing, according to the manner of the civil law. For this purpose interrogatories are formed or questions in writing; which, and which only, are to be propounded to, and asked of, the witnesses in the cause. For the examination of witnesses in or near London, there is an examiner's office appointed; but for such as live in the country, a commissioner is granted to four commissioners, two named on each side, or any three or two of them, to take the depositions there. And if the witnesses reside beyond seas, a commission may be had to examine them there upon their own oaths, and (if foreigners) upon the oaths of faithful interpreters. And it hath been established that the deposition of an heathen who believes in the Supreme Being, taken by commission in the most solemn manner according to the custom of his own country, may be read in evidence. The commissioners are sworn to take the examinations truly and without partiality, and not to divulge them till published in the court of chancery; and their clerks are also sworn to secrecy. The witnesses are compellable by process of subpoena, as in the courts of common law, to appear and submit to examination. And when their depositions are taken, they are transmitted to the court with the same care that the answer of a defendant is sent. See Commission to examine witnesses, and Interrogatories.

EXAMINERS, in Chancery, are two officers, whose business is to examine, on oath, the witnesses produced on both sides, upon such interrogatories as the parties to the suit do exhibit for the purpose.

EXAMPLE, in Rhetoric, denotes an imperfect kind of induction or argumentation; whereby it is proved, that a thing which has happened on some other occasion, will happen again, on the present one, from the similitude of the cases. That is usually called an example, which is brought either to prove or illustrate some general assertion, as if one should say, that "human bodies may be brought to sustain the greatest labours by use and exercise:" and in order to prove this should relate what is said of Milo of Croton, that "by the constant practice of carrying a call several furlongs every day, he should carry it as far after it was grown to its full size." (Erasm. Phil. p. 193.) But the word example is used in oratory for any kind of similitude; or, as Vellius defines it (Orat. Partic. I. iii. c. 7 § 16), "When one thing is inferred from another, by reason of the likeness which appears between them." Hence it is called an "imperfect induction," which infers something from several others of a like nature. With regard to examples, we may observe, that those have the greatest force in reasoning, which are taken from facts. See Induction.

EXANIA, from ev, out of, and anus, the complaint now more commonly named by practitioners in surgery prolapsus ani. See Prolapsus.

EXANNUAL Roll. In the old way of exhibiting sherif's accounts, the illegible lines and desperate debts were transcribed into a roll, under this name, which was yearly read, to see what might be gotten by it.

EXANTHEMA, in Medicine, synonymous with efflorescence, from εὖ, and σῇ, a flower, a term applied by the older writers nearly in the same sense in which we now employ the word eruption, and comprehending every species of spot, discolouration, or elevation of the skin. The systematic nomenclatists at present understand by this word all eruptions on the skin, which are accompanied with fever; such as the small-pox, measles, scarlet fever, &c. Dr. William ues the term in a more limited sense, DER. to express that appearance only which is in English denominated a rash; which is a blushing or redness of the skin, varying as to extent, continuity, and brightness of colour, and occasioned by...
EXARCH, from the Antiquity, an appellation given by the emperors of the East, to certain officers sent into Italy, in quality of vicars, or rather prefects, to defend that part of Italy which was yet under their obedience; particularly the city of Ravenna, against the Lombards, who had made themselves masters of the greatest part of the realm.

The residence of the exarch was at Ravenna; which city, with that of Rome, were all that was left to the emperors. The first exarch was Longinus, who was sent in the year 568 by the emperor Justin I. the successor of Justinian, to govern Italy in the room of Narses. Longinus, being invested with absolute authority and power, suppressed the magistrates, who had been previously appointed to govern the provinces of Italy; and he himself took the title of exarch, which by the Greeks was given to those who presided over a diocese, and consequently over the numerous provinces of which the diocese was composed. This title was adopted by the successors of Longinus, who resided as he had done, at Ravenna, were on that account called the exarchs of Ravenna. They governed all Italy, naming and removing the magistrates, called duces, at their pleasure; and to them the people had recourse in all matters of consequence.

Longinus was sent by Justin to rule all Italy; but a great part of that country, in the first year of his government, was feized on by the Lombards, who had been called in by Narses. This magistrate maintained the power and authority of the emperors of the East in Italy, for the space of 183 years, that is, from the year 568, when Longinus was sent into Italy, to the year 751, when Eutychius, the last exarch, was expelled, and Ravenna taken by Aulfolphus, or Aulfolphus, king of the Lombards. See Lombards.

According to Gibbon (Decline and Fall of the Roman Empire, vol. vii.) Narses was the first and most powerful of the exarchs, and administered above fifteen years the kingdom of Italy. A duke was stationed for the defence and military command of each of the principal cities of Italy; and the eye of Narses pervaded the ample prospect from Calabria to the Alps. During a period of 205 years, says the historian, Italy was unequally divided between the kingdom of the Lombards and the exarchate of Ravenna; and 12 successive exarchs were invested, in the decline of the empire, with the full remains of civil, of military, and even of ecclesiastical power. Their immediate jurisdiction, which was afterwards confecrated as the patrimony of St. Peter, extended over the modern Roman, the marites or valleys of Ferra and Comacchio, five maritime cities from Rimini to Ancona, and a second, inland Pentapolis, between the Adriatic coast and the hills of the Apennines. Three subordinate provinces, of Rome, of Venice, and of Naples, which were separated by hostile hands from the palace of Ravenna, acknowledged, both in peace and war, the supremacy of the exarch. The remainder of Italy was possessed by the Lombards. When Aulfolphus, as we have already mentioned, had made himself master of the exarchate, he thought that he had a just title to all the places depending on that domain, and consequently to the Roman dukedom and to Rome itself. He, therefore, required by a menace, and forced the inhabitants of that city to acknowledge him for their sovereign; and at the same time began his march towards Rome. The pope, Stephen I., was alarmed, and attempted to divert Aulfolphus from his declared purpose of plundering Rome and massacring the inhabitants, by a solemn embassy; but the king, rejecting the pretexts accompanying this embassy, insulted upon being acknowledged by the pope and the Romans for their sovereign. The pope in this diftre threaten to the emperor; but Constantine was not in a condition to affilt him. He then determined to recur to the protection of France, which had been transferred, seven years before, from the Merovingian to the Carolingian line; and the celebrated Pepin, son to Charles Martel, was then king. Indeed Pepin had previously promised to pope Zachary, that he would protect his see against all its enemies, especially against the Lombards. Pope Stephen visited France in person: and having stated the deplorable condition to which he was reduced by the Lombards, and implored his assistance and protection, Pepin promised to assist him against the Lombards with the whole strength of his kingdom, and to drive them out of the exarchate and Pentapolis, which were to be restored, as Pepin understood, to the emperor, from whom the Lombards had taken them; but the pope, finding the king well disposed, took advantage of this favourable opportunity for aggrandizing himself; and, therefore, intimated to Pepin, that he could not better acquit himself of his obligations to the apostolic see, consult the welfare of his soul, or reward him for the dangers he had undergone, and the pains he had taken for the safety of Italy, and the church, than by granting both the exarchate and Pentapolis to St. Peter, that is, to himself. The pope, at the same time, pretended that Constantine had forfeited all right to those countries, by forsaking the protection of Italy, and perfecuting the church. Pepin not only put him in possession of the exarchate and Pentapolis, if he should succeed in expelling the Lombards, but confirmed his promise with an oath, in which his sons Charles and Carloman concurred. In consequence of this engagement Pepin marched with his army against the Lombards, and having routed them, Aulfolphus fled precipitately to Pavia. Pepin pursued him, and having beligered his capital, granted him peace on condition of his restoring the places which he had feized in the Roman dukedom, together with the exarchate and Pentapolis, to the pope. Hostages were also delivered in order to secure the fulfillment of this condition. Aulfolphus, regardless of his oath and hostages, invaded the Roman dukedom, feized several cities, and beligered Rome itself. In this extremity, Stephen had again recourse to his protector, who, highly incensed at the treachery of Aulfolphus, marched again into Italy, and closely invested Pavia, into which the Lombard king had retired. Aulfolphus once more sued for peace, which was granted him upon his promising to perform immediately the treaty made the year before, and, besides, to surrender to the pope the city of Commanchio, which was then a place of great importance.

Pepin then renewed his donation; and having caus'd a new instrument to be drawn up, he caus'd it to be delivered, signed by himself, by his two sons, Charles and Carloman, and by the chief barons and prelates of France, into the pope's hands. He then left Italy, and returned with his army to France. The exarche comprised, according to Sagonius (ad ann. 755) the following cities, viz. Ravenna, Bologna, Imola, Faenza, Forlimpopoli, Forli, Cenina, Bobbio, Ferrara, Commanchio, Adria, Servia, and Secchia, which were all delivered to the pope, except Faenza and Ferrara. Pentapolis, or Morea d'Ancona, comprehended Rimini,
Pefaro, Conca, Fano, Sinigaglia, Ancona, Osimo, Umana, Jefi, Fossombrone, Montefeltro, Urbino, the Balcanian territory, Caglì, Lucolci, and Eugubio, with their territories and districts. As appears by the donation of Lewis the Pious, by which Pepin's donation was confirmed. The pope committed the government to the exarchate to the archbishop of Ravenna, who thereupon took the title of exarch, not as archbishop, but as an officer of the pope, now a temporal prince. Thus was the sceptre added to the keys, the sovereignty to the priesthood, and the popes were enriched with the spoils of the Lombard kings, and the Roman emperors. As those countries belonged, without doubt, to Constantinople their emperor, some authors have thought that this donation was made in his name, and that this gave rise to the title of the donation of Constantinople. Hence it appears that the popes by degrees became sovereigns of Rome. The exarchate of Ravenna, says Petrus de Marca, being yielded to the pope, the government of Rome, of course, devolved upon him; for the Roman dukedom had been always subject to the exarch. The pope, therefore, when he became master of the exarchate, claimed the administration, and continued to govern Rome, not as sovereign, but only with the authority that had been vested in the exarch, till the year 876, when the authority of the emperors, successors of Charlemagne, declining in Italy, Charles the Bald yielded all his eis aim to, and sovereignty over Rome, to the apostolic see. Hence Constantinople Porphyrogenitus, describing the state of Europe in his time, that is, about the year 914, writes, that Rome was subject to the pope, as its sovereign. It was upon the declension of the western empire, when it was confined to Germany alone, that the pope, as well as the several princes of Italy, assumed the sovereignty, which they afterwards enjoyed. The donation of Pepin was confirmed by Charlemagne at the request of pope Adrian; for having ordered Iterius, his secretary, to draw up a new instrument, he signed it himself, and gave it to bishops, abbots, and other great men, who had attended him to Rome, and, with his own hand, laid it on the altar of St. Peter.

F. Paprock, in his Propylæum ad Afa Sanét. Mai., has a dissertation on the power and office of the exarch of Italy, in the election and ordination of the pope.

The emperor Frederic created Heraclius, archbishop of Lions, a descendant of the illustrious house of Montbéliard, exarch of the whole kingdom of Burgundy; a dignity, till that time, unknown anywhere else, but in Italy, particularly in the city of Ravenna. Membrif. Hill. de Lyon.

Homer, Philo, and other ancient authors, give likewise the name exarch to the choragi, or master of the singers, in the ancient choruses, or him who sung for the fire; the word αἰχερος, or αἰχέρας, signifying equally to beg, and to command.

Exarch of a diverse was, anciently the name with primate. This dignity was inferior to the patriarchal, yet greater than the metropolitan.

Exarch also denotes an officer still inhabiting in the Greek church; being a kind of deputy or legate a latere of the patriarch, whose office it is to visit the provinces allotted him, in order to inform himself of the lives and manners of the clergy; take cognizance of ecclesiastical causes; the manner of celebrating divine service; the administration of the sacraments, particularly confession; the observance of the canons; monastic discipline; affairs of marriages, divorces, &c. but, above all, to take an account of the several revenues which the patriarch receives from several churches; and particularly as to what regards the collecting of the same.

The exarch, after having greatly enriched himself in his post, frequently riles to the patriarchate itself.

Exarch is also used, in the Eastern Church Antiquity, for a general, or superior over several monasteries; the name that we otherwise call archimandrite: being exempted, by the patriarch of Constantinople, from thejurisdiction of the bishops; as are now the generals of the Roman monastic orders.

In 493, Sebas was established exarch, or chief, of all the archbishops within the territory of Jerusalem. Du Bois.

EXARMA, from εἰκόνας, to be elevated, in Surgery, a high, prominent, swelling.

EXARTHREMA, from ἔξω, out of, and αἱρεῖν, a joint, an old term, having the name signification as the word dislocation. See Luxation.

EXARTHROS, from ἔξω, out of, and αἱρεῖς, a joint, a term denoting a person whose joints are so large and mis-shapen, that they look as if they were luxated.

EXARTICULATION, a dislocation of some of the jointed bones; or a breach of articulation. See Luxation.

EXAUCTORATIO, among the Romans, differed from misto, or a discharge. In the latter, the soldiers were quite disenchanted from the service; and this was done after they had served twenty years; but in the former case, they only lost their pay, being still kept under their colours or vexilla, though not under the eagle, aquila, which was the standard of the legion. Whence, instead of legionario, they were called subjecti, and were still retained till they either served out their time, or had lands assigned them. The exarcturio commonly took place after they had served fourteen years.

EXAUDET, in Biography, a performer on the violin in the opera band at Paris from 1749 to 1760; remarkable for nothing as a composer, but for the minuet which bears his name in France, and which in England is better known by the title of "Marshall Saxe's Minuet," the belt "Minuetto per ballo," or for dancing, perhaps, that ever was composed.

EXCALCEATION, ex, of, and calceus, shoe, dislocation, or the act of putting off the shoes.

Among the Hebrews there was a particular law, whereby a widow, whom her husband's brother refused to marry, had a right to demand him into a court of justice; and, upon his refusal, might exculcate him, i.e. pull off one of his shoes, and spit in his face; which were both actions of great ignominy among that people.

The horse of the person who had undergone them was thenceforward called the horse of the exculcated.

EXALCED, EXCALCIT, different orders of friars, hermits, and nuns, who amongst their other auleries wore barefooted, or wore nothing on their feet but sandals, were distinguished by the name of excalcet, as the Franciscans, Carmelites, Poor Clares, &c. whilst other branches of the same institute, but less rigid, were called calectic, from their members wearing shoes. A particular branch of the Waldeisen, Vandois, or poor men of Lyons, in the 12th century, had great thongs on the wearing of sabots or wooden clogs instead of shoes, and therefore obtained the name of Sabatini and Infabatini.

EXCAMBIATOR. See EXCAMBIO, and Exchange.

EXCAVATION, formed of ex, and cavus, hollow, or cave, a pit, &c. the act of hollowing or digging a cavity, particularly in the ground.

The excavation of the foundations of a building, by the Italians
Excavation of Valleys, in Geology, is a subject which has exercised the thoughts of many ingenious men, the greater part of whom have supposed that these stupendous and important operations were effected by violent currents of water, which at some period made their way down them; but a more careful examination has shewn, that in scarcely any instances are the excavated materials to be found, or any part of them, as must inevitably have happened at the bends and junctions of valleys, particularly those which lie far inland, have the mere washing of water been the cause of valleys: but Mr. Farey, and Dr. William Richardson, have of late, and separately as it should seem, come to the conclusion (Philosophical Magazine, vol. xxxii. p. 204 and 262.) that these excavations were effected by canals acting as 'from above the surface of the earth,' which completely carried off the matter which once filled up the valleys, and originally joined those corresponding parts of flata, whose edges are now in a great number of instances to be traced in their opposite sides: these opinions of the former gentlemen have been already slightly noticed, and referred to, in our articles Coal, Colluvia, and others.

**EXCELLENCY, a quality, or title of honour given to ambassadors, and other persons, who are not qualified for that of highness, as not being princes; and yet are to be elevated above the other inferior dignities.

In England, and France, the title is now peculiar to ambassadors: but it is very common in Germany and Italy. Those to whom it was first appropriated were the princes of the blood of the several royal houses; but they quitted it for that of highness, upon several great lords assuming excellency.

The ambassadors have only borne it since the year 1593, when Henry IV. of France lent the duke de Nevers ambassador to the pope, when he was first complimented with excellency. After that, the same appellation was given to all the other ambassadors residing at that court; from whence the practice spread through the other courts.

The ambassadors of Venice have only had it since the year 1636, when the emperor and king of Spain consented to allow it them.

The ambassadors of the crowned heads dispute the giving of that title to the ambassadors from the princes of Italy; where the practice is not established.

The court of Rome never allowed the quality of excellency to any ambassador who was a churchman, as judging it a secular title. The common rules and measures of excellency were a little variable, with respect to the court of Rome. The ambassadors of France, at Rome, anciently gave the title of excellency to all the relations of the pope when reigning; to the Cardinals; to the duke of Bracciano, and the eldest sons of those lords; as also the dukes of Savelli, Cesarini, &c. But they have been since more refined in this respect; though they still honoured all the Roman princes with excellency.

The court of Rome, in their turn, and the Roman princes, bestowed the same title on the chancellor, minilters, and secretaries of state, and presidents of the foreign courts of France; the presidents of the councils in Spain; the chancellor of Poland; and those of the first dignities of other states, if they were not ecclesiastics.

The word excellency was, anciently, a title of kings and emperors; accordingly Ananias the library-keeper calls Charlemagne his excellency. The same title is still given to the senate of Venice: where, after halting the doge under the title of ferrum, the senators are addressed under that of your excellencies. The Liber Diurnus Pontif. Rom. gives the title excellency to the arch and patricks.

The Italian and French have improved on simple excellency; and made excellentialissimo, and eccellentissimo, which have been bestowed on certain popes, kings, &c.

**EXCELSIS. See Gloria in excelsis.

**EXCENTRIC, in Geometry, is applied where two circles, or spheres, though contained, in some measure, within each other, yet have not the same centre; and, consequently, are not parallel; in opposition to concentric, where they are parallel, having one and the same common centre. The sun's orbit is excentric, with regard to the globe of our earth: Mars is very excentric, with regard to the fun; that is, his motion is about a very different centre.

**EXCENTRIC THEORY, in Ancient Astronomy, one of the theories adopted by the ancient astronomers to explain and calculate the different irregularities which they had observed to take place in the motions of the heavenly bodies.

It is not exactly ascertained at what period practical astronomy had attained sufficient perfection to indicate the rectitude of such a theory. Probably both the Indian and Egyptian astronomers were early acquainted with the more obvious inequality in the sun's orbit; but Hipparhus is the first astronomical writer who seems to have aimed at determining it with any degree of precision.

The theory embraced by Hipparhus is said to have been first taught in Greece by the disciples of Pythagoras. Though their knowledge on the subject is supposed to have been derived from the oriental nations, yet it is highly probable they contributed to strengthen the prejudices in favour of a circular and uniform motion, which afterwards proved the fource of so much difficulty and error in all the systems of ancient astronomy. It was from this prejudice, early assumed as a principle, that nature could not, consistently with the observed simplicity of her designs, adopt any other form for the celestial orbits than that of perfect circles, nor any other motion than what was perfectly uniform. The problem, therefore, that occupied the astronomers and philosophers of those days, was to explain the various irregularities which they observed in the planetary motions, without infringing on the above principle.

There were two theories chosen for this purpose, nearly equivalent in their principle, the concentric and the excentric.

In the concentric theory the earth was supposed to be placed in the centre of a circle, on the circumference of which the centre of another circle revolved, and on the circumference of this second circle, called an epicycle, the planet was supposed to move. The first circle was called the deferent, and by assigning a suitable ratio to the deferent circle, and to its corresponding epicycle, none of the more obvious irregularities were pretty accurately represented. Fig. 110. Plate XIII. Astronomy, is the representation of the concentric theory. Let C be the centre both of the earth and of the circle FBD, and let H G K be a smaller circle, or epicycle, whose centre B moves uniformly in the circumference FBD, from well to east, or in consequentia, while the fun moves also uniformly and with the same velocity in the circumference of the epicycle, in antecedentia in the upper part, but in consequentia in the lower part. If the point G of the epicycle, called its apex, as being most distant from the earth, be supposed at the beginning of the ammonitic revolution to be placed in the point A of CE produced; and if when it comes to C, the arc GH be taken similar to FB, the point H will be
be the place of the fun when the centre of the epicycle has moved from P to B. If then in C E, to which B H is parallel, we take C E = B H, and on E as a centre, with the distance E A = C F, describe the circle A H P; the fun would be from E to move in this circle equally; for the angle A E H is equal to the angle F C B; but when C, the centre of the earth, it will appear to move in it inequably; for the angle A C H, in the first circle of anomaly, that is, in the passage of the fun from A to P, is always less than A E H or F C B; and its true place H will be less advanced in longitude than its mean place B. When again the centre of the epicycle or the mean place of the fun, having defribed a semicircle, shall have come to D, the fun, having defribed a semicircle of the epicycle, will be found in P, the perigee of the orbit A H P, and its mean and true places B and H will be seen from C to coincide as they did in the apogee A. But in the fun's passage from P to A, that is, in the second semicircle of anomaly, its true place H, as seen from C, will be always more advanced in longitude than his mean place B: for in this semicircle the angle P C H is always greater than P E H or D C B. The angle E H C or B C H, which is the difference between the mean and true places of the fun, is called the equation of the orbit, and it is evident that this equation will be greatest in N or M, where the centre B of the epicycle is 90° distant from either of the apogees.

It was thus that the ancients originally proceeded in their representation of the solar inequalities, and the representation seemed to be sufficiently justified by observation: at least, till the days of T. Brahe: no observations had been made with sufficient accuracy to subject it to suspicion. Their success also, while no lunar inequality except the small anomallical one was discovered, was equal in the application of the fame concentric theory to the motions of the moon: and having, in two cafes, thus successfully, by means of one subordinate sphere or epicycle, reconciled apparent inequality of motion with real uniformity, it was natural to suppose that other inequalities, though more various and complicated, might be explained in a similar manner, and required only the addition of other epicycles. The same method of procedure, therefore, was continued, and every new inequality which observation discovered, was accounted for by a new sphere or epicycle producing it, till the whole number employed in the system amounted to 34. Arzibolde, on narrower examination, found these to be insufficient, and added to them 22: but all these were deemed insufficient; and the number was at last increased to 72. But though it was not till long after the days of Arzibolde, that the theory was carried to such a degree of extravagance, the multiplication of epicycles rendered it, even in his time, almost as intricate and complex as the appearances which it was intended to explain. Some examples of this kind will occur on the revival of it by Copernicus and T. Brahe: and when Hipparchus and Ptolemy introduced eccentric orbits, and by means of them somewhat diminished the multiplicity of the spheres employed by their predecessors, they were thought to do a signal service to astronomy.

The manner in which Hipparchus explained the solar inequalities, in his eccentric theory, was to this purpose. Let O (fig. 111.) be the centre of the earth and of the fiery sphere. Let B C D E be the eccentric, or great circle in the primum mobile in which the fun seems to perform its annual revolutions; and, in the same plane, but on a different centre Z, let the circle A L P be described. This is the circle, or orbit, in which the fun is supposed actually to move, and to describe round its centre equal arcs or angles in equal times: or rather, he is supposed to be carried round by the equal motion of the circle itself; which, because its centre is not occupied by the earth, is called an eccentric circle. It is evident, in this representation, that if the earth were placed in Z, a spectator so it would perceive the fun, if he is supposed to move uniformly in this eccentric, to move also uniformly in the ecliptic. But the earth is placed in O, at the distance O Z from the centre of the eccentric; and therefore, when his motions are referred to the ecliptic by a spectator in O, they must appear unequal. When, for example, he departs from A to the apogee of the eccentric, and comes to K, he would be seen from Z in the point R of the ecliptic; but from O, the centre of the earth, he is seen in C, a point farther advanced in longitude. On the contrary, when he departs from P, the perigee of the eccentric, and comes to N, his place in the ecliptic, as seen from Z, is the point V; but seen from O it is the point P, more advanced in longitude than V. Any line, as Z K, drawn from the centre of the eccentric to the fun, or any parallel to it drawn from O, is called the line of mean motion, and determines the mean anomaly A Z K; and any line, as O K, drawn from the fun to the centre of the earth, is called the line of true motion, and determines the true anomaly A O K; and the angle A O K Z is the difference between the calculated difference, or equation, of the orbit. In the apogee and perigee this equation vanishes, in the same manner as in the concentric theory; because there the lines of mean and true motion coincide; and at the points L, L, where a perpendicular to the line of apsides, drawn through O, meets the eccentric, it comes to its greatest amount. Thus, by the sagacious supposition that the fun's orbit was eccentric to the earth, Hipparchus supplied the place of the epicycle added to the concentric: nor is it difficult to perceive that the representations, given by both theories of the solar inequalities, were in their effects precisely the same.

In both these theories, it is evident that the inequalities of the fun were considered as purely optical: and what was principally required was to find the point O, in the line A P of the apsides, in which the earth must be situated, in order to give to the solar motions the jult inequality which observation required; and to determine the longitude A of the solar apogee, that is, the point B of the ecliptic to which it is referred from O. Without finding the jult eccentric, O Z, or the difference between the calculated difference, or equation, of the sun's mean and true places, would not correspond with the observed differences: and without discovering the position of the apogee, the calculated equations, however accurate, would not be applied in their proper places. In these investigations the procedure of Hipparchus was as follows. Let B (fig. 112.) be the place of the fun at the vernal equinox, B D an arc of the eccentric equal to his mean motion for 94½ days, that is, from the vernal equinox to the summer solstice, D F an arc equal to his mean motion for 92¼ days, or from that solstice to the autumnal equinox: let the chord B F be drawn, and from D another chord D E G perpendicular to B F. The point E of the intersection of these chords is evidently the point where the earth must be situated: for it is the only point from which B, D, F, G, can appear at the distance of 90° from one another, and as they appear actually in the heavens.

It was required, therefore, to determine the eccentricity E C, or the distance of the point E from C, the centre of the solar orbit. Since the arc B D F of the mean motion, and which the ancients supposed to be the only real motion of the fun, from B the vernal to F the autumnal
The mode of determining this equant was as follows.

Let A be the centre of the earth, (fig. 113) suppose the centre of the world D, the centre of the orbit of a planet, or of the eccentric circle, F K M L E, called the deferent, (see EPICYCLE.) Upon the point F is described the epicycle G Q, and above D a point E is supposed equal to the eccentricity A D; and from the point E another circle is described, R K O L R, of the same magnitude as the deferent. This second circle is called the equant, because the centre of the epicycle, which moves upon the deferent, has nevertheless an equal motion round the centre of the equant, for the epicycle describes its deferent with an unequal motion, which should disappear when referred to the centre of the equant, so that the angle, such as F E I, formed by the line of apsides A F, and by the line drawn to the centre of the epicycle, arrived at I, may be always equal in equal times; for this reason Ptolemy calls the point E the point of equality. The angle F A I is the true anomaly of the eccentric, the angle F E I the mean anomaly, and which is always formed at the centre of the equant.

Kepler had endeavoured to explain physically the cause of the equant, that is, why there should be a point E different from the point D, about which the motion was regular and uniform, (Mydler. Cosmogr. c. 22.) He was perfused the cause was general, and that the equant must take place in the orbit of the earth, as well as in the other planets. Neither Tycho nor Copernicus had employed an equant, but Kepler was persuaded that the points E and D in an eccentric were not the same, particularly when Tycho informed him that the annual orbit, or eccentric of the sun, appeared to him not to be always the same.

Kepler suspected that this variation arose from the point of equality not being the centre of the circle; and in the course of his investigation of this question, he was led to the discovery of the bisection of the eccentricity in the case of the earth, whereas the ancients only admitted it in the case of the inferior planets. See EXCENTRICITY, bisection of.

EXCENTRICITY of the Orbit of a Planet, in Astronomy, is the distance between the centre and the focus of the ellipse in which it revolves. The discovery of the eccentricity in the orbits of the sun and moon is attributed to Hipparchus, who wrote a treatise on this subject 150 years before our era.

The eccentricity of the orbit is computed from the greatest equation of the centre, by the following proportion, As 5; 17 44 " 9, (the arc = rad.) is to half the greatest equation, so is rad. = 1 to the eccentricity. See EQUATION, an ELLIPTIC Motion.

But when the greatest equation has been found, and accurately determined by observation, the eccentricity may be practically deduced by using the rule of false position, or by supposing the eccentricity known, and finding by trial the greatest equation corresponding to it.

The excentricities of the planetary orbits are usually calculated on a scale which supposes the mean distance of the earth from the sun divided into one hundred thousand parts, and the eccentricity is expressed in proportional parts of that scale.

The following formula for calculating the eccentricity is given by Lambert in the Ephemer. de Berlin.
Let \( E \) be the greatest equation of the centre, \( e \) the eccentricity, make \( E = e \).

The eccentricity will then be expressed by the following series:

\[
e = \frac{1}{2} a - \frac{11}{768} a^3 - \frac{87}{93040} a^5 - \frac{40583}{2642411520} a^7, \ldots
\]

The quantity \( a \) is always a small fraction, particularly for the Sun; if we suppose with La Place, \( E = 2.1429 \) decimal for 1750. Then,

\[
e = \frac{2.1429}{63.0620} = 0.033519
\]

\[
\frac{1}{2} a = 0.016814.
\]

The second term, \( \frac{11}{768} a^3 \), is less than 0.000001, and may therefore be entirely neglected.

**Eccentricity, bipedon of.** The biphon of the eccentricity is a curious principle assumed by Ptolemy, and the ancient astronomers, to explain the irregularities of the planetary motions. It is thus described by Dr. Small.

The inequalities of the planets were so various and intricate, that the explications of them were for a long time extremely imperfect, and so partial, that no Grecian astronomer before Ptolemy supposed it practicable to give a complete theory of all. In the more ancient times the explications of them appeared to have been made by orbits concentric to the earth, and charged with epicycles; but, as Ptolemy had found no method of representing the second inequalities, except by means of epicycles, so, to avoid the perplexity occasioned by the multiplication of them, he gave the preference to an eccentric orbit for the representation of the first; and, by the superior simplicity of the representation, the authority of the eccentric theory was for many centuries established. With respect to those first inequalities, at least of the superior planets, it appears to have been originally supposing, that they might be sufficiently accounted for by the more simple polar hypotheses. For, if the planet, in consequence of its centripetal inequalities, be represented as moving in the circumference \( a e \) of an epicycle, the centre \( A L P Q \), of this epicycle will represent the places which it would occupy, if it were developed of all second inequality; and it was thought a sufficient explication of the first inequality, to suppose that this centre moved equally round \( Z \), the centre of the orbit, and consequently equally round \( O \), the centre of the earth. But when, according to Kepler's conjectures on this subject, they endeavoured to account for the inequality of the latitudes in opposition, and of the displacements of the planets, especially their greatest digressions, from the point opposite to the Sun, by variations of their distances from \( O \), it appeared that the point \( Z \), round which the planet moved equably, could not be the same with the centre of the orbit; for, both the latitudes, and also the angles \( a O e \), \( a O f \), which the epicycle subtended at the centre of the earth, were found to be greater at the apogee, and less at the perigee than the limits of the eccentric A L P Q permitted; and that, consequently, the centre of the orbit occupied a place nearer than Z to the centre of the earth. It was therefore a matter of much greater difficulty to form an hypothesis for the motions of the planets, than for those of the Sun: for, if their first inequalities required one determined eccentricity, or distance between the centre of uniform motion and the centre of the earth, the variations of their latitudes, and of their second inequalities, showed that this was not the eccentricity of the orbit in which the epicycle moved, and that this orbit evidently required another. In what proportion the distance \( Z O \) between the center of uniform motion and the center of the earth ought to be divided by the centre of the orbit, appears to have been for a long time a matter of much uncertainty. But Ptolemy tells us that, on applying himself to investigate the measure of the approach of the centre of the epicycle, within the circle A L P Q at the apogee, and its consequent withdrawing from it beyond the perigee, he found, by multiplied observations, that the centre of the orbit lay precisly in the middle, between \( Z \) the centre of uniform motion, and \( O \) the centre of the earth. This is the famous principle, known by the name of the biphon of the eccentricity: and, as Ptolemy gives no account of the means by which it was discovered, nor of the observations from which it was inferred, his assuming it has justly excited the wonder of all astronomers. The greater part believed him to have assumed it merely from conjecture, and not to have derived it, as Kepler more generously supposing, from any observations; and there seems to be some reason for thinking that it came to him by tradition, from the more ancient astronomy of the East.

**EXCEPTIO, in the Roman Law.** See Pleading.

**EXCEPTION, something referred, or set aside, and not included in a rule.**

It is become proverbial, that there is no rule without an exception; intimation, that it is impossible to comprehend all the particular cases under one and the same maxim. But it is dangerous following the exception preferably to the rule.

**EXCEPTION, in Law, is a stop or stay to an action.**

The term is used indifferently, both in the civil and com-
EXCHANGE, in Commerce, and Political Economy, is the act of paying or receiving money in one country for its equivalent in the money of another country, by means of bills of exchange.

This science, therefore, comprehends both the reduction of monies, and the negotiation of bills: it determines the relative value of the currencies of all nations, and shows how foreign debts are discharged, loans and subsidies paid, and other remittances made from one place to another, without the risk or expense of transporting specie.

This important subject may be considered under the following heads, namely:

2. Par of exchange.
3. Counter of exchange.
5. Arbitration of exchange.

Bills of exchange. — A bill of exchange is a written order for the payment of a certain sum of money at an appointed time. It is a mercantile contract in which the parties concerned, viz. 1. The drawee, who receives the value. 2. His debtor in a distant place, upon whom the bill is drawn, who is called the drawer, and who is to accept and pay it. 3. The person who gives value for the bill, and who is called the buyer and remitter; and, 4. The person to whom it is ordered to be paid, who is called the payee, and who may, by indorsement, pass it to any other holder.

Most mercantile payments are made in bills of exchange, which, until due, generally pass from hand to hand, like any other circulating medium. The laws of all trading nations afford the most ready and effectual means of enforcing the payment of bills, and hence that credit which they universally obtain, and which greatly facilitates the operations of commerce. — For the laws, customs, and regulations of bills of exchange, see BILL of EXCHANGE, and MERCANTILE LAW. See also AGIO, USANCE, and DAYS of Grace.

Bills are distinguished into inland and foreign, according as they are made payable in the country where they are drawn, or in a foreign country. Their functions, however, are similar in both cases, and therefore in explaining the theory of exchange, we shall begin with the operations of inland bills as the most simple and familiar.

Suppose A. of London is creditor to B. of Edinburgh. C. of London debtor to D. of Edinburgh. These two debts may be discharged by the operation of one bill: thus, A. draws on B. and sells his bill to C. who remits it to D. and the latter receives the amount from B. when due. Here, by a transfer of claims, the London debtor pays the London creditor, and the Edinburgh debtor the Edinburgh creditor.

By the foregoing example it appears that reciprocal and equal debts due between two places, may be discharged without any cash remittance, and it may be supposed that such an operation is of equal convenience to the parties concerned, in both places; but when debts are unequal, the advantage must be likewise different, as the obligation of remittance is no longer mutual; for the debtor place must pay its balance either by sending cash or bills; and as the latter mode is generally preferred for several reasons, an increased demand for such bills must be the consequence; and this enhances their price, as it would that of any other valuable article.

This is the plain principle of exchange which is constantly exemplified in the premium paid for inland bills on London; for this city, being the grand emporium of commerce that furnishes most other places of the kingdom with foreign merchandise, and being also the refidence of numerous
numorous landlords whose rents must be remitted to them from the country, it has generally a large balance of debt in its favour, a great part of which must be lent in bills; this creates a demand, and consequently a premium which is mostly commuted for time; thus, if A. of London be creditor to B. of Edinburgh 200l. and C. of London debtor to D. of Edinburgh only 100l. the balance of 100l. against Edinburgh cannot be cancelled by a transfer of claims, but must, we will suppose, be remitted by a bill, which can be only obtained at a certain number of days after date. The most general term for bills from Edinburgh on London is 40 days, and the interest for this time is about half per cent. The number of days here is called the exchange, which has been known to vary considerably according to the balance of debt, or the plenty or scarcity of bills. A similar premium or date is allowed for bills from all other places of Great Britain on the capital, but bills at sight on any of those places may generally be had in London without any premium whatever.

Although the principle of foreign exchange is the same as that of inland, yet the former is more complicated in its operations than the latter, owing to the denominations of money not being the same. This causes a difference in the mode of paying the premium for bills, in which, however, the date is taken into consideration as well as the comparative rates at which the monies are valued.

In foreign exchange one place always gives another a fixed sum or piece of money for a variable price, which fluctuates according to the balance of debt, as before stated; the former is called the certain price, and the latter the uncertain price. Thus London is paid to give to Paris the certain for the uncertain; that is, the pound sterling for a variable number of francs; and to give to Spain the uncertain for the certain; that is, a variable number of pence sterling for the dollar of exchange.

Whatever the uncertain price is, at any time, is called the course of exchange. Now suppose Paris gives London 25 francs for the pound sterling, and that this sum is found to contain the same quantity of pure silver as 20 shillings, then the exchange is said to be at par; but if France should give a higher price, it is said to be in favour of London, and vice versa. This is the common mode of judging whether the exchange be favourable or unfavourable to a place, though it is not always the correct method, nor that which merchants generally act upon. But before we enter into any further explanation of the course of exchange, or the causes of its fluctuation, it will be necessary to explain more fully what is to be understood by the par of exchange, a subject on which there is some difference of opinion, even among writers of the first authority.

Par of Exchange.

The par of exchange may be considered under two general heads; namely, the intrinsic par, and the commercial par, each of which admits of subordinate divisions and distinctions.

The intrinsic par of exchange is the value of the money of one country compared with that of another, with respect both to weight and fineness. Thus, two sums of different countries are intrinsically at par when they contain an equal quantity of the same kind of pure metal, separated from its alloy, which is always deemed of no value. See Coins.

There should be two intrinsic pars, the one between gold coins, and the other between silver coins; and hence the intrinsic par of exchange can be only determined with accuracy between places which pay their bills in the same kind of metal, as between England and Portugal, that pay in gold coins, or between France and Spain, that pay in silver coin, for the relative value between these metals is scarcely the same in any two countries.

It may be even observed, that the value of the same metal differs considerably in different countries, and therefore this intrinsic par of exchange cannot be always considered as a true equality in the value of monies; thus in the case of France and Spain, where the latter country supplies the former with the materials of its coinage, silver must be most valuable in France, and the difference should be equivalent to the charges attending the removal, such as the duty paid (in time of peace) to the Spanish government, for the exportation of dollars, the expenses of carriage, insurance, commission, interest, &c. all of which amount to nearly 7 per cent.

A similar computation might be made between gold in England and in Portugal, as the latter country supplies the former with the materials of its coinage.

But where one country pays its bills in gold, and another in silver, no intrinsic par of exchange whatever can be permanently established. An equivalent can only accrue for bills; as merchandise the gold of one place, and the silver of the other, according to the market price of the day; but this is the commercial par, which shall be more fully explained below.

In ascertaining the intrinsic par between coins of the same metal, a question occurs, whether the computation should be made according to the mint regulations of the respective countries where the monies are struck, or according to actual assays. The former is the most general method, though the latter is certainly the most correct; for while some governments make coins according to their full standard, as in England, others take advantage of the allowance for remedy, and sometimes make it a source of considerable emolument.

There are some countries with which no par of exchange, either intrinsic or commercial, can be permanently fixed. These are such as pay their bills in paper, which must have a fluctuating and precarious value. Even the bank money of Amsterdam and Hamburg comes in a certain degree within this description, as it bears a fluctuating value; and always takes the market for currency. The commercial par is the comparative value of the monies of different countries, according to the weight, fineness, and market price of the metals. This is the par which merchants generally consider of importance in their exchange speculations, and we cannot define it better than in the following passage, taken from the Minutes of the Committee of the House of Commons, appointed in 1804, to inquire into the state of exchange between Ireland and England. Several of the most intelligent merchants of both countries were examined on the occasion, and their evidence produced much new and practical information.

In the examination of Benjamin Winthrop, esq. governor of the bank of England, an interesting enquiry and investigation took place respecting the par of exchange, from which the following appropriate question and answer are extracted.

Question.—"When a sum of Hamburg currency, which will buy a pound of bullion of given purity in the market of the English bank, can purchase a bill for a sum of English currency, which will buy a pound of bullion of the same standard in the English market, is not then the exchange at par between those two countries?"

Answer.
EXCHANGE.

Answer,—"I confess it does appear to be a complete par of exchange." This par of exchange is variously denominated by different writers on political economy; thus it is called the current, the momentary, the political, and the eventual par; and though each of these terms seems to convey a correct idea of the subject, yet we have adopted the word commercial as equally appropriate and more generally understood.

Some notice might be here taken of what is called a monetary par, in which an allowance is made for feignorage and mint expenses, and also of a common or estimate par, which generally differs from the true one; thus the pound sterling of England is estimated at 11 guilders current of Holland; but such definitions are of little utility in the illustration of exchange.

The following opinion on the par of exchange seems to deserve quotation. It is translated from the preface of a most elaborate work, entitled "Dictionnaire des Arbitrages," by Francois Corbaux, published at Paris in 1802.

"Without dwelling any longer," says this author, "on the arbitrary notions which have been formed of the par of exchange, and without feigning to adopt new ones, which might be rendered very curious, we shall conclude by observing, that although the intrinsic or pretended real par is made the foundation and principal element in the determination of the price of exchange, yet not being the same in the gold as in the silver coin, the par of these two metals should be kept totally distinct; and that besides, as neither of them finds any direct application in the common course of exchange affairs, it is through ignorance that so much importance has been attached to them, and that they have been considered as the most correct expression of the relative value of the monies of two countries. In short to seek for a true and rational par is to suppose what cannot exist, that is, the fixing of different principles and elements which are subject to continual variation, and, after all, if this could be accomplished, it would prevent no object of real utility."

However well-founded the opinion of Monseur Corbaux may be, we think it must be at least satisfactory to merchants to understand the intrinsic par of exchange, and therefore we shall give new tables of it at the conclusion of the present article, computed both in gold and silver, with rules and examples for performing all such calculations; and shall now proceed to the explanation of the course of exchange, which is a subject of great importance, whether we consider it in a commercial or political point of view.

Course of Exchange.

The course of exchange is the current price or proportion between the monies of two places; which is always fluctuating according to circumstances.

When merchants have occasion to draw or remit foreign bills, they meet upon the Royal Exchange, where this kind of business in London must be transacted. The market is constantly attended by exchange-brokers, to whom the wants of the parties who wish to buy or sell bills are privately communicated. These brokers, whose confidential situation demands strict impartiality, bring parties together; and settle the course of exchange for the day, as soon as they learn how the market stands with respect to the number of drawers and remitters. The commission for this business throughout Europe, is one per mille (or thousand) which is equally paid by the buyers and sellers of bills.

When the course of exchange rises above par against any country, it is then concluded that the balance of trade is against that place. Now, if England should import from France goods to the value of 100,000l. and export only to the value of 80,000l., it may coil England 120,000l. to pay the whole debt, if it should be publicly known that to great a balance exists, and therefore secrecy is of peculiar importance in this kind of business.

The fluctuations of exchange are mostly greater or less according to the known amount of the balance, and the expense and difficulty of conveying specie. By the expense of such conveyance is meant the carriage and insurance, and by the difficulty the hazard of evading those prohibitory regulations which, in most countries, impede the exportation of coin; and so powerful is the operation of these caufes, that the exchange is sometimes very high, or unequal, even between neighbouring countries, affording room for very profitable speculations for those merchants who circulate bills in the way of arbitration of exchange.

An unfavourable state of the exchange with a country furnishes a motive for exporting commodities to it. The merchant under these circumstances can afford to sell his goods as much cheaper as the premium which he receives for his bill amounts to. Hence the course of exchange tends to correct itself, and, in peace, it seldom continues, for any length of time, more unfavourable than the amount of the expenses which might be incurred by transporting bullion to pay the balance which is to be remitted; for bullion may be considered the universal currency of merchants, though it is not always of ready or immediate application.

Although an unfavourable balance of trade has been generally considered an invariable cause of an unfavourable course of exchange, yet recent experience has shown that this is not always the case. Thus, in the investigation already alluded to, which took place in the House of Commons relating to the exchange between England and Ireland, it was demonstrated that the balance of trade was in favour of Ireland, while the course of exchange was highly unfavourable; it was, however, thrown in subsequent publications on the subject by Messrs. Parnell and Fother, that though the balance of trade was in favour of Ireland, the balance of debt was unfavourable, or, in other words, the balance of remittance, on account of the number of Irish absentees resident in England; but perhaps the political rate of the country was the chief cause.

In time of war the fluctuations of the course of exchange are sometimes very great, particularly where large remittances are to be made in the way of foreign loans or subsidies. The exchange is likewise lowered by any devaluation of the coin of a country, or by the depreciation of any other circulating medium. Each new of currency has the effect of turning the rate of exchange against place where it prevails, and the exchange raises the price of all commodities beyond their value in those places where no such redundancy exists. It may, however, be observed, that the nature of exchange operates to effect the general distribution of the surplus specie, and to maintain the level of money throughout the commercial world. In short, in all cases, the exchange tends to an equilibrium.

Although the depreciation of the circulating medium of a country raises the course of exchange against it, the circulation is not always a disadvantage. Thus, before the reformation of our silver coinage, in the reign of William the Third, the exchange between England and Holland, computed by the standard of their respective mints, was 25 per cent. against England, but the current coin of England was more than 25 per cent. below its nominal or standard value; and therefore the exchange was virtually in favour of
of England, according to the statement of Dr. Adam Smith.

It may be further observed, that the wealth of a country will sometimes raise the course of exchange against it, on account of its importations of luxuries from abroad. Rich countries are likewise liable to have the course of exchange turned against them by the fulcuses which they may have to remit to less opulent ones, as before noticed.

Thus in 1793, the trade between Holland and England was completely open; and yet the course of exchange was 10 or 12 per cent. against Amsterdam, owing probably to the balance of trade being so much in favour of London. But, in 1794, when England undertook to subsidize Prussia, large remittances of bills were made through Amsterdam, which caused an immediate fall in the course of exchange between that place and London, even below par: and therefore at subsequent periods of the war, it has been thought prudent by the English government to export specie on such occasions, rather than to turn the course of exchange against London by the operation of remitting large subsidies in bills. During the present war between France and Austria (1809) the latter power has been subsidized by the English government, which has been chiefly done in bills, and this has tended to raise the exchange against England, in the places where those bills were negociated. But the caufe which has operated more powerfully to produce this effect is the great importation of goods to England, from Germany, France, and Holland, without any adequate importation of English merchandise. Hence the exchange with London has been for some time greatly in favour of those places, while between London and most of the other parts of Europe it has continued nearly at par.

From what has been said respecting the causes, both commercial and political, which produce the fluctuations of exchange, and which frequently counteract each other, the following simple conclusion may be drawn; that whatever produces a demand for bills on any place tends to enhance their value, and therefore the course of exchange rises and falls according to the proportion which exists between the plenty and scarcity of bills, that is, between the demand and the supply.

Monies of Exchange.

The following tables contain the monies of exchange of the principal trading places of Europe, in all their varieties and combinations. Explanations are also given of the quotations or lifts of the courses of exchange, which are transmitted from one country to another for the government and advice of merchants. These quotations seldom give more than the figures of the uncertain prices, omitting the denominations of money and the certain prices, all of which are here explained.

Note.—In all the uncertain prices the words more or less are to be understood.

Amsterdam.

Monies of Exchange.

Exchanges are computed in florins, stivers, and pennies; or in pounds, shillings, and pence Flemish.

16 Penningen = 1 Stiver
20 Stivers = 1 Florin or guilder
12 Grotes or 6 frivers = 1 Stiver
20 Shillings Flemish, or 6 florins = 1 Pound Flemish.

There are two sorts of money in Holland; namely,

Banco and currency: banco generally bears a premium against currency of 4 or 5 per cent. which is called agio.

Examples for calculating the exchanges of London with the above places are here given; whence the method of computing the exchanges of other places one with another may be easily comprehended, as all operations of this kind may be performed by the Rule of Three Direct.

**London and Amsterdam.**

English money is reduced to Dutch by saying; as 1 florin is to the rate of exchange, so is the given sum to the sum sought.

Reduce 7821. 12. 6d. sterling to Dutch money, exchange at 34 shillings, and 8 pence Flemish per pound sterling.

As

\[
\begin{align*}
1 & \text{ : } 34 & 8 \text{ Flem. : : } 7821 & 12 & 6 & : & 8139 & 66
\end{align*}
\]

\[
\begin{align*}
12 & = & 20 & \text{ (L.
4 & 16 = & 1565 & 2
8 = & 12 & \text{ (S.)
332 & 8 & = & 15026 & 30
3756 & 60 & = & 563490 & 16
24062509 & 8240 & = & (2604576 & \text{ (Pennings}
48 & = & 20 & (L.
145 & & & & & & \text{ (S.)
4 N & \text{ (Dutch
8139 & 780 & \text{ Flour. Stiv.}
\end{align*}
\]

Vol. XII.
Dutch money is reduced to English by reversing the foregoing operation; thus,

\[
\begin{array}{c|c|c}
\text{s. d.} & \text{£.} & \text{Flor. Stiv.} \\
\hline
\text{As} & 34 & 8 \text{ Flem.} \\
\end{array}
\]

\[
\frac{1}{6} \times 8139 = 782.126
\]

**London and Hamburgh.**

English money is reduced to that of Hamburgh by an operation similar to the foregoing.
Reduce 108l. 17s. 6d. sterling to Hamburgh money; exchange at 33 shillings 4 groats Flemish per pound sterling.

\[
\begin{array}{c|c|c|c|c}
\text{s. d.} & \text{£.} & \text{w.} & \text{r.} & \text{p.} \\
\hline
\text{As} & 35 & 4 & 10 & 6 \\
\end{array}
\]

\[
\frac{1}{6} \times 116.17.6 = 1416.126
\]

Hamburgh money is reduced to English by reversing the foregoing operation; thus,

\[
\begin{array}{c|c}
\text{s. d.} & \text{£.} \\
\hline
\text{As} & 35 & 4 \text{ Flem.} \\
\end{array}
\]

\[
\frac{1}{6} \times 1416.1 = 239.261
\]

**London and Paris.**

English money is reduced to French by saying; as 1£. is to the rate of exchange, so is the given sum to the sum fought.
Reduce 728l. 15£.sterling to French money, exchange at 23 livres 10 sous per pound sterling.

\[
\begin{array}{c|c}
\text{s. d.} & \text{£.} \\
\hline
\text{As} & 23 & 10 \\
\end{array}
\]

\[
\frac{1}{6} \times 728.15 = 17125.126
\]

But if the answer be required in vellon, the reals must be multiplied by 80 and divided by 81; thus,

\[
\text{As, 81 : 80 = 17125.126} \quad \text{16914.19} \quad \text{17125.126}
\]

The exchange of Paris on London is, however, generally expressed in francs, and then the reduction may be performed by a single analogy; thus,
EXCHANGE.

But if the answer be required in lire, the sum thus found should be multiplied by 23, and divided by 4; thus,

<table>

6 12

4 N 2

Or
Irish money is reduced to English by reverting the foregoing analogy; thus,

\[
\text{As } 11\frac{1}{2} : 100 :: 879 : 6 \text{ Ir : } 787 \text{ 15 Eng.}
\]

When the exchange between the two countries is at par, English money is turned to Irish by adding \(\frac{1}{2}\), and Irish to English by subtracting \(\frac{1}{2}\).

Thus reduce 787 l. 15s. English money at par.

\[
\begin{align*}
&787 \text{ l. 15s.} \\
12 & \text{Irish} \\
&55 \text{ 12 11}
\end{align*}
\]

Arbitration of Exchange.

Arbitration of exchange is a comparison between the courses of exchange of several places in order to ascertain the most advantageous method of drawing or remitting bills. It is distinguished into simple and compound arbitration; the former comprehends the exchanges of three places only, and the latter of more than three places.

Simple Arbitration

Is a comparison between the exchanges of two places with respect to a third; that is to say, it is a method of finding such a rate of exchange between two places, as shall be in proportion with the rates quoted between each of them and a third place. The exchange thus determined, is called the arbitrated price, and also proportional exchange; and the proportional par.

16. For example, the course between London and Paris be 24 francs for 1l. sterling, and between Paris and Amsterdam 54d. Flemish for 3 francs, (that is, 36s. Flemish for 24 francs,) the arbitrated price between London and Amsterdam, through Paris, is evidently 36s. Flemish for 1l. sterling; for as 24 fr. :: 54d. Flem. :: 24 fr. :: 36s. Flem.

Now when the actual direct price (as seen by a quotation or otherwise advised,) is found to differ from the arbitrated price, advantage may be made by drawing or remitting indirectly, that is, by drawing on one place through another, as on Amsterdam through Paris; which may be performed in three different ways:

18. London may draw on Paris, and order his correspondent there to draw on Amsterdam.

2d. London may draw on Paris, and order his correspondent in Amsterdam to remit the same sum to Paris.

3d. London may order his correspondent at Paris to draw on Amsterdam, and to remit the value to London.

The operation of remitting indirectly, or of remitting to one place through another, may be likewise performed in three different ways:

18. London may remit to Paris, and order his correspondent there to remit the sum to Amsterdam.

2d. London may remit to Paris, and order his correspondent in Amsterdam to draw on Paris.

3d. London may take bills on Paris, and remit them to Amsterdam, there to be negotiated.

To exemplify this by familiar illustrations, suppose the arbitrated price between London and Amsterdam to be as before stated, 36s. Flemish for 1l. sterling; and suppose the direct course, as given in Lord's bill, to be 37s. Flemish, then London, by drawing directly on Amsterdam, must give 37s. Flemish for 1l. sterling; whereas, by drawing through Paris, he will give only 36s. Flemish for 1l. sterling; it is therefore the interest of London to draw indirectly on Amsterdam through Paris.

On the contrary, if London remits directly to Amsterdam, he will receive 37s. Flemish for 1l. sterling; whereas, by remitting through Paris, he will receive only 36s. Flemish: it is the interest of London therefore to remit directly to Amsterdam.

Example 2.—Suppose the exchange of London on Lisbon to be at 66d. per milre, and that of Lisbon on Madrid 500 rees per dollar, the arbitrated price between London and Madrid is 34d. per dollar; for as 1000 rees :: 66d. :: 500 rees :: 34d. But if the direct exchange of London on Madrid be 35d. sterling per dollar, then London, by remitting directly to Madrid, must pay 35d. for every dollar; whereas by remitting through Lisbon he will pay only 34d.: it is therefore the interest of London to remit indirectly to Madrid through Lisbon.

On the contrary, if London draws directly on Madrid, he will receive 35d. sterling per dollar; whereas, by drawing indirectly through Lisbon, he would receive only 34d.: it is therefore the interest of London to draw directly on Madrid.

From these examples, the two following rules are manifest.

Rule 1. — Where London gives the certain price, draw through that place which gives the lowest arbitrated price, and remit through that which produces the highest.

Rule 2. — Where London gives the uncertain price, draw through that place which produces the highest arbitrated price, and remit through that which gives the lowest.

What is said here of London will equally apply to any other place from whence the operation is made.

Suppose the exchange of London on Amsterdam to be 34d.; on Genoa, 47; on Leghorn, 52; and the exchange of Amsterdam on Genoa, 86; on Leghorn, 93; what is the most advantageous method for London to remit to, or draw on Amsterdam?

18. Because 47d. ft. give 1 pezza in Genoa, and this pezza in Amsterdam gives 86d. Flemish, say, as 47d. ft. :: 86d. Flemish :: 240d. ft. :: 430d. Flemish, or 56s. 7d. Flemish, which is the arbitrated price through Genoa.

2d. Because 52d. ft. give 1 pezza in Leghorn, and this pezza in Amsterdam gives 93d. Flemish, say, as 52d. ft. :: 93d. Flemish :: 240d. ft. :: 429d. Flemish, or 57s. 9d. Flemish, which is the arbitrated price through Leghorn.

Hence, according to the first rule, the interest of London is to draw directly on Amsterdam, instead of drawing through Genoa or Leghorn; and to remit through Genoa, instead of remitting directly to Amsterdam, or indirectly through Leghorn.

And according to the second rule, the interest of Amsterdam would be to remit directly to London, and to draw on London through Genoa.
ExchangE.

Compounded Arbitration

Is a comparison between the exchanges of more than three places in order to find how much a remittance passing through them all amount to at the last place, or to find the arbitrated price between the first place and the last, and thus to determine on the most advantageous mode of negotiating bills.

Compound arbitration is therefore a repetition of simple arbitration, and may be solved by a continuation of several flautings in the Rule of Three; but all such operations are bell performed by conjoint proportion; commonly called the "Chain rule," which shall be here explained and demonstrated, after giving an example of compound arbitration by the Rule of Three.

Suppose the exchange between London and Amsterdam to be 3 ½ shillings Flemish for 1 l. sterling; between Amsterdam and Lisbon, 4 ½ pence Flemish for 1 old cruade; and between Lisbon and Paris, 4 ½ rees for 3 francs, what is the arbitrated exchange between London and Paris?
1st. As 35 l. Flem. = 1 l. Sterling.
2nd. As 1 old cruade, or 400 rees = 24 ½ d. Flem, or 3 ½ l. Flem = 24 ½ d. Flem.

The Chain Rule explained and demonstrated.

Distinguish the several courses of exchange into antecedents and consequents, and place them in two columns, the antecedents to the left and the consequents to the right, by way of equation.

The first antecedent must be of the same denomination as the quantity of which the value is required. The first consequent must be of the same denomination as the second antecedent, and the second consequent as the third antecedent; and so on throughout.

The last consequent must be of that denomination in which the answer is required.

The terms being thus arranged, the antecedents must be multiplied continually for a divisor, and the consequents for a dividend, and the quotients will be the answer.

The calculation may be abridged by expunging such antecedents and consequents as are alike, and reducing such their lowest terms as admit of a common divisor.

Example from the foregoing Question.

1 l. Sterling = 35 Shillings Flemish.
3 ½ Shillings Flemish = 400 Rees.
400 Rees = 3 Francs.

How many francs will 1 l. sterling give?
3 x 400 x 3 ½ = 42000
1 x 1800 x 3 ½ = 1680

In this example, 480 and 400 have the common divisors 8 and 16, and they may therefore be reduced to 5 and 5; 5 again the antecedent 6 may be reduced to 2, by striking out the first consequent 3; the fraction is the correct reduced to

Now to find what number of the last denomination (E) is equal to a given number of the first denomination (A), let z = the times the first, that is, let z E = y A.

Multiply all these equations together, the antecedents by the antecedents, and the consequents by the consequents, which will give

and this equation reduced is

Now if the number of the last denomination be required, E = ; but if the number of the first denomination be required, y = .

Example 2.—If London remit 1000 l. sterling to Cadiz by way of Holland at 35 l. Flemish per pound sterling; thence to France at 58 d. Flemish per eeu of 3 francs; and thence to Cadiz at 2 ½ francs per doubleoon of 4 dollars, what is the price between London and Cadiz resulting from the operation? and how many dollars will the 1000l. amount to in Spain?

1 Pound Sterling = 35 Shillings Flemish
1 Shilling Flemish = 12 Pence Flemish
5 ½ Pence Flemish = 3 Francs
1 ½ Francs = 1 Doubleoon
1 Doubleoon = 4 Dollars

How many dollars are equal to 1000 l. sterling?

58 x 12 x 3 x 4 x 1000 = 544000
58 x 15 ½ = 899
28 mar. which gives the exchange at 42 ¼ d. nearly.

The indirect course of exchange between London and Cadiz may be also found by an inverse operation, called the Doctrine of Contraries; thus,

4 Dollars = 1 Doubleoon
1 Doubleoon = 1 ½ Francs
3 Francs = 58 Pence Flemish
12 Pence Flemish = 1 Shilling Flemish
35 Shillings Flemish = 2 ½ Pence Flemish

How many pence Flemish equal 1 dollar?

Now if the direct course of exchange was above the indirect, the circular remittance would be most advantageous; but if under, the direct operation would be preferable.

In computing the profits or losses of exchange operations, allowance should be made for the expenses, commission, and interest of money, all of which may be comprised in the statement by the Chain Rule, that is, by deducting from those terms of the consequents to which they may relate; thus, in the following example, the per centage is subtracted from 100 in the last place of the consequents.

Example 3.—London takes bills on Madrid at 33 ½ per dollar of exchange, remits them to Amsterdam, with order to negociate at 30 l. grotes per ducat of exchange, and make the returns in bills on Paris at 5 ½ grotes per eeu of 3 francs: what does London gain or lose per cent? by this operation, supposing the bills on Paris are negociated at 25 livres 18 sous per pound sterling; and that all the charges, including interest for the time that London is out of its money, amount to ¼ per cent?

125 3 ½ Pence Flemish = 272 Maravedis

5 ½ Maravedis = 90 ½ Grotes
EXCHANGE.

\[
\begin{align*}
51 \frac{1}{4} \text{ Grotes} & = 3 \text{ Francs} \\
3 \frac{9}{16} \text{ Francs} & = 81 \text{ Livres} \\
1 \text{ Livre} & = 1 \frac{1}{3} \text{ Sous} \\
259 \frac{5}{16} \text{ Sous} & = 4 \frac{1}{8} \text{ Pence sterling} \\
1 \frac{25}{2} \text{ Pence sterling} & = 98 \% \text{ On account of charges.}
\end{align*}
\]

How much does 100\% sterling give?

\[
27 \frac{1}{2} \times 90 \frac{1}{2} \times 81 \times 92 \frac{1}{2} = 105,853, \text{ answer.}
\]

The profit is therefore \(17 \frac{1}{3} \text{ d. per 100\% sterling.}\)

Operations in compound arbitration may be greatly facilitated by the help of logarithms; thus, "from the sum of the logarithms of the consequents, subtract the sum of the logarithms of the antecedents; the difference will be the logarithm of the answer."

In this case, however, the reduction of the numbers as above is superfluous, as it is as easy to find the logarithm of a large as of a small number; but when equal terms are on both sides they should be struck out; and if a common divisor can be found which will reduce any term to unity, it will likewise shorten the operation.

In questions of this kind much time and labour may be sometimes saved by making use of fixed numbers; thus, when several terms are unchangeable in both the antecedents and consequents they can be reduced to one; and the confluent logarithm of this number may be used with those that vary; such as the logarithms of the rate of exchange, the amount of the charges, &c.

Besides the foregoing rules for facilitating the arbitration of exchange, various other methods have been proposed for shortening and illustrating the subject; even triangles and other diagrams have been constructed for this purpose; (see Poldthwait's Commercial Dictionary, vol. i. p. 94.) but geometrical projections do not seem well adapted to elucidate this rule.

A graphic operation, however, of a very useful and ingenious description, has been lately executed in London, in which scales of the monies of exchange of the principal places in Lloyd's bill are so graduated and arranged, that the arbitrated price between any two of them, with respect to a third place, may be immediately found by the application of a right line. The invention is by William Waldron, M.D. S. and F.R.S.

We shall conclude this article by giving rules for calculating the intrinsic par of exchange, and also tables of the same in gold and silver according both to mint regulations, and to adulterations.

The intrinsic par of exchange may be calculated by the rules laid down for computing the value of coins. (See Coin.) But the operation may be performed with greater precision by the Chain rule, as in the following examples.

Example 1.—What is the intrinsic par between London and Lisbon, in gold, when taken from the Johanes of 6400 rees, which, according to the mint regulations of Portugal, contains 224\% grains of English standard gold?

6400 Rees = 224\% Grains of standard gold

480 Grains standard = 93\% Pence sterling.

How many pence sterling will 1000 rees give?

Striking out the common divisor 1000, \(\frac{224\% \times 93\%}{04 \times 48} = 67\frac{35}{36} \text{ d. sterling for the milree.}\)

Example 2.—What is the intrinsic par between London and Madrid, in silver, the weight of the dollar being 17 dwt. 8 gr. Troy, and its menues & dwt. worse than English standard, according to average assays lately made at his majesty's mint at the Tower of London.

85 Dollars of exchange = 612\% hard dollars

1 Hard Dollar = 416 Grains Troy

222 Grains in dollars = 214 Grains standard

480 Grains standard = 62 Pence sterling.

How many pence sterling does 1 dollar of exchange give?

Striking out the common divider \(\frac{416 \times 414 \times 62}{53 \times 125 \times 4 \times 259 \times 100} = 35\% \text{ sterling for the dollar of exchange.}\)

Example 3.—What is the intrinsic par between London and Amsterdam, in silver, when taken from the rixdollor current, which weights 18 dwt. Troy, and is (according to assays) 16 dwt. worse than English standard, taking the agio of banco on currency at \(\frac{7}{22} \text{ per cent.}\)

62 Pence sterling = 22 Dwt. standard silver

202 Dwt. standard = 222 Dwt. in rixdollors

18 Dwt. or 1 rixdollar = 52 Shillings currency

1 Silver = 2 Grutes

12 Grutes = 1 Shilling Flemish

104 Shillings Flemish = 100 Shillings Flemish currency

How many shillings Flemish banco do 100 pence sterling give?

\[
\begin{align*}
\text{Brought down and reduced:} \\
31 \frac{3}{4} \text{ d.} & = 20 \frac{5}{8} \\
103 \frac{5}{8} & = 37 \frac{1}{2} \\
8 \frac{5}{8} & = 50 \\
13 \frac{1}{2} & = 25 \\
& = 20
\end{align*}
\]

\[
5 \times 37 \times 52 \times 35 \times 22 = 375 \times 2d. \text{ Flemish for the pound sterling.}
\]

Table of the intrinsic par of exchange between London and the principal places in Lloyd's list, gold against gold, and silver against silver, calculated according to the mint regulations of each place respectively.

</table>

From the two foregoing tables it appears, that the par in gold generally varies from that in silver, and in some places very considerably.

It also appears that the assays do not differ essentially from the mint regulations; but where any difference is found to exist, it is mostly in deficiency.

The intrinsic par of exchange between any other places, besides the above, may be determined by the foregoing rules, and from the money tables in the present article, with those given in the article Coin.

It should be observed, that in the calculation of the par for Amsterdam, the ducat is reckoned at 5 florins 5 silver currency, but this price is subject to alteration, and therefore no permanent par in gold can be established with Holland, even if the agio were fixed. It should be also remarked, that in computing the par with Hamburgh the ducat is reckoned at 6 marks Hamburgh banco, and the Cologne mark of fine silver at 27½ marks banco, which are the common, but not constant prices, and therefore no permanent par can be established with Hamburgh, any more than with Amsterdam.

Authors on exchange are very numerous, though few can be mentioned that have produced full and accurate systems: the principal are, Krue of Hamburgh; Ricard of Amster- dam; Gerhardt of Berlin; Marien of Spain; Senebier of Geneva; Girauden, Reulle, Reihemauer, and Corbaux of France; and Duboil of London. Among the productions of these writers Krue’s Hamburgh Contorrit has been the most universally approved; an English translation of this system of exchanges, monies, weights and measures, with considerable additions and alterations, is now nearly printed, and will be shortly published, under the title of the “Universal Cambit;” from which the present article has been chiefly extracted.

Exchange also denotes a public place, in most considerable cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, meet, on certain days, and certain times thereof, to confer, and treat together of matters relating to exchanges, remittances, payments, advances, assurances, freightments, and other mercantile negociations both by land and sea.

In Flanders, Holland, and several cities of France, these places are called boufes; at Paris and Lyons, places de change; and in the Hanse towns, colleges of merchants. These assemblies are held with so much exactness, and merchants and negociants are so indispensably required to attend at them, that a person’s absence alone makes him be suspected of a failure or bankruptcy.

The most considerable exchanges in Europe are those of Amsterdam, and that of London, called the Royal Exchange. For an account of the latter, see Royal Exchange.

The former is a large building, 230 feet long and 130 broad, round which runs a peristyle or portico, 20 feet wide. The columns of the peristyle, amounting to 46, are numbered, for the convenience of finding persons.

That of Antwerp was little inferior to either of them, till a variety of circumstances concurred to effect its ruin, and to transfer its trade to Amsterdam: the era of this important event in commercial history is about the year 1585.

Even in the time of the ancient Romans there were places for the merchants to meet, in most of the considerable cities of the empire. That laid by Rome to have been built at Rome in the year of the city 259, 393 years before our Saviour, under the confluence of Appius Claudius and Publius Servilus, was called collegium mercatorum, whereof it is pretended: there are still some remains, called by the modern Romans legatio, the lodge; and now, usually the “Place of St. George.”

This notion of a Roman exchange is supposed to be founded on the authority of Livy, whose words are as follow, viz. “Certamen confurbation indicatur, uter dedicaret Mercurii sedem. Senatus a fe rem ad populum rejecti utri
corum dedicatio jussu populi data effet, cum praefesse annone, mercatorium collegium inultuare jussit.” Liv. lib. ii. But it must be here remarked, that collegium never signified a building for a society in the purer ages of the Latin tongue; so that “collegium mercatorum inultuare” must not be rendered to build an exchange for the merchants, but to incorporate the merchants into a company. As Mercury was the god of traffic, this sede Mercurii seems to have been chiefly designed for the devotions of this company or corporation.

Exchange, in Law, is a mutual grant of equal interests in lands or tenements, the one in consideration of the other, and in our common law it more particularly denotes the compensation which the warrantor must make the warrantee, value for value, if the land warranted be recovered from the warrantee. Bracton, lib. ii.

The word “exchange,” is so individually requisite and appropriated by law to the case now stated, that it cannot be supplied by any other word, or expressed by any circumlocution. (Co. Litt. 50. 51.) The citates exchanged must be equal in quantity (Litt. § 63. 65.), not of value, for that is immaterial, but of interest as fee-simple for fee-simple, a lease for 20 years for a lease of 20 years, and the like. And the exchange may be of things that lie either in grant or in livery. (Co. Litt. 51.) But no livery of feisin, even in exchanges of freehold, is necessary to perfect the conveyance.
EXC

cession (Litt. 63.)

EXCHANGERS.

the king's, is the place appointed by the

exchange, bill of. See Bill of Exchange.

What we call re-exchange, is the due, or premium of a
second exchange, when a bill is protelied. See Re-ex-
change.

Exchange brokers. See Exchange Brokers.

Exchange of Prisoners. This measure, which is

dictated both by humanity, and, in general, by mutual in-
terest, is frequently adopted by two hostile nations, for the
purpose of exchangng themselves from the great charge incurred
by the retention of prisoners of war in prisons, deports, &c.

Sometimes an exchange becomes a consideration while draw-
ing up the articles of a capitulation; especially where the be-

nies consider it a matter of policy to get possession of a
fortress, without being too strict in the conditions of sur-
render.

Thus we frequently observe, that a garrison is allowed to
retire, under the express stipulation, that "no part thereof shall serve again until regularly exchanged." In
such case, an immediate liberation of an equal number of
those confined in the enemy's prisons ought instantly to take
effect, and the persons thus discharged should be forwarded
to their country; but if, as sometimes occurs at the very
 commencement of a war, when one party has been exten-
vively successful, the other may not have the means of equal-
ization in regard to the liberation of prisoners, it may occur,
that months, or even years, may elapse, before such restric-
tion may be removed.

This, indeed, is not the only point on which the matter
may rest: it may sometimes happen, that a prince may feel
it to be his interest not to carry an exchange into effect; and
this he may justify under the ordinary circumstances at-
tendant upon capitulation. Say, that an army surrenders
simply under this condition; "that it shall not serve until
duly exchanged." Here we see no objection on the part of
its superiors to make any exchange: therefore, when policy
dictates such forbearance, we cannot affix any imputation on
the prince, power, &c., if no exchange takes place.

If, indeed, the garrison are allowed to return to their
country, or to retire unmolested, on condition that "they
shall be exchanged," then, we naturally expect, that no
time will be lost in liberating an equal number; advertling to
the several classes of thofe allowed to retire, and pairing
them off in a correct manner.

We have heard of evasions contrived for the express pur-

pose of detaining some individual, who, by his prowefs, or
abilities, may have become highly obnoxious to the enemy.
This, however, can only take place where there is no person
of corresponding rank, against whom he can be passed off;
then the exchange necessarily becomes in a degree arbitrary;
though it is a matter of courtesy, to form some equivalent,
in such manner as may suit the wishes of his own govern-
ment.

With a view to facilitate the exchanges occasionally
ordered, as well as to obviate the million of frivolous com-
plaints which would else be made, it is customary for powers
at war either to receive agents, or to appoint supervisors,
whose duty is confined solely to such matters as relate to the
due subsistence of the prisoners, and to conducting whatever
may relate to exchanges. Through this medium a govern-
ment may always avail itself of the means of releasing
any particular persons, confined as prisoners of war in the
enemy's country; but, to effect this, at least to be able to
command it, there must be in its power some equivalent:
for it would be unreasonably to expect that a general officer
should be given up, when only a colonel could be offered
in exchange; but a general may be liberated by any govern-
ment, for the purpose of liberating any officer of inferior
rank then in the power of the enemy: and so through-
out.

EXCHANGERS are those who return money beyond
sea, by bills of exchange, &c. called anciently also excom-
titors, and since remitters.

EXCHEQUER, or simply Chequer, originally denotes
a chefs-board; or a frame divided into sixty-four squares,
of two colours, whereas to play at draughts, chefs, &c.
See Chess, &c.

The word is formed from the French eschequier, which
signifies the same. Hence, trees are said to be planted
chequer-wise, in quincuncem, when disposed so as to form
divide squares representing a chequer.

EXCHEQUER is more particularly used for a chamber, or
apartment, in Westminster-hall, consisting of two parts;
the court of exchequer and the lower exchequer. See
Court of Exchequer, and Court of Exchequer-chamber.

EXCHEQUER-bills are a species of paper-stuff established
by Mr. Montague, in 1696, as a more convenient kind of
security than the tallies and orders for repayment then in use,
and also to supply the want of circulating cash, during the
re-coining at that period. They were then taken at the
exchequer for all payments of the revenue, and, when re-
issued, they were allowed 7d. 12s. per cent. interest. They
have since been issued yearly for anticipating the produce
of particular taxes; and they have almost constantly formed
the principal article of that part of the public debt called the
unfunded debt. Of late years the total amount of out-
standing exchequer bills (exclusive of those charged on spe-
cific branches of the revenue) has usually been about 12
millions. The state of England, ever since the year 1706,
has been the contractors for their circulation, at a certain
premium. The commissioners of the treasury are em-
powered, by various statutes, to borrow money, within a
specific sum, limited by those statutes, by issuing exche-
quer bills on the credit of certain duties; which bills, by
12 Ann, cap. 11. and 12 Geo. I. cap. 11. bear an interest
of 2d. a day per cent. payable to the bearers. But the in-
terest payable on them has differed according to the current
rate of interest at the time when they have been issued.
Thos. now in circulation bear interest at the rate of 3½ d.
a day per cent. They are often made for 100l. each, but of
late years they have been chiefly for 100l. each, and some-
times for larger sums. These bills are numbered arithmeti-
cally,
EXCISE

E X C

EXCISE, an inland duty, or imposition, charged on commodities of general consumption, and paid sometimes upon the consumption of the commodity, or frequently upon the retail sale, which is the tail flage before the consumption. This mode of taxation was adopted among the Romans; for Augustus, after the civil wars, introduced an excise which, though very moderate, was general. It feldom exceeded 1 per cent. but it comprehended whatever was sold in the markets or by public auction, from the most considerable purchases of lands and houses, to those minute objects which can only derive a value from their infinite multitude and daily consumption. Such a tax, however, as it affects the body of the people, has ever been the occasion of clamour and discontent. Augustus was obliged to declare by a public edict, that the support of the army depended in a great measure on the produce of the excise; and Tiberius diminished the excise to one-half, though the relief was of very short duration. It has been adopted, in more modern times, as the most economical mode of taxing the subject; the charges of laying, collecting, and managing the excise duties being considerably less in proportion than in other branches of the revenue. Besides, it renders the commodity cheaper to the consumer than charging it with customs to the same amount would do, because this tax is generally paid in a much later stage of it. Nevertheless, the rigour and arbitrary proceedings of excise-laws seem hardly compatible with the temper of a free nation. For the frauds that might be committed in this branch of the revenue, unless a strict watch is kept, makes it necessary, wherever it is established, to give the officers a power of entering and searching the houses of such as deal in excisable commodities, at any hour of the day, and, in many cases, of the night likewise. And the proceedings in cases of transgression are so summary and sudden, that a man may be convicted in two days' time in the penalty of many thousand pounds by two commissioners or justices of the peace; to the total exclusion of the trial by jury, and disireg of the common law. Obscure as the excise duty has always been, it was first tuggled by the earl of Bedford, lord treasurer to king Charles I., but never actually introduced in that prince's reign. Its original establishment took place in the year 1643, when it was introduced, on the model of the Dutch prototype, by the long parliament after its rupture with the crown; and its progress has been gradual. It was at first laid upon those perons and commodities, where it was supposed the hardship would be least perceptible, viz. the makers and vendors of beer, ale, cider, and perry; and though it originated with the long parliament, the royalists at Oxford soon followed the example of their brethren at Wellminfter, by imposing a similar duty; both parties, however, protesting that it should be continued no longer than to the end of the war, and then be utterly abolished. But the parliament at Wellminifter soon after imposed it on leath, wine, tobacco, sugar, and such a multitude of other commodities, that it might be fairly denominated general. This was done in pursuance of the plan laid down by Mr. Pymne, who had been intended for chancellor of the exchequer under the earl of Bedford, and who seems to have been the father of the excise. In his letter to sir John Hotham (30 May, 1643) he intimates, "that they had proceeded in the excise to many particulars, and intended to go on farther; but that it would be necessary to use the people to it by little and little." Having accustomed the people to it for some years, the succeeding champions of liberty boldly and openly declared (Ord. 14th August, 1649, ch. 50) "the impost of excise to be the most easy, and indifferent levy that could be laid upon the people;" and accordingly it was continued during the whole usurpation. Upon the restoration of king Charles II., as it had been long established, and its produce was well known, some part of it was given to the crown, in 12 Car. II., by way of purchase for the feodial tenures and other oppressives parts of the hereditary revenue. (See Revenue.) Notwithstanding its general unpopularity, it has been imposed on abundance of other commodities in the reigns of king William III. and of every succeeding prince, towards defeting the enormous expences occasioned by our wars on the continent. In the year 1732, the gross produce of the excise-duty amounted to 2,964,617l. About this time fir Robert Walpole, being of opinion, that taxes on consumable commodities, to which every citizen contributes in proportion to his consumption, and which, being included in the price of the commodity, are insensibly paid, constituted the most eligible mode of raising the revenue necessary for the public service, formed a project for the gradual abolition, not only of the taxes on land, houses, and windows, but also of the customs, by the substitution of productive excise duties. Fully apprized of the abuses and frauds to which the collection of the customs was subject, and which he had no hope of remedying, he thought that the scheme of convert-
ing the greater part of the customs into duties of excise, would be equally advantageous to government and to the fair trader; and that the excise laws might be so anaelec-
ated, that, notwithstanding the odium generally attached to
them as arbitrary and oppressive, no just ground of com-
plaint should remain. With a view to the execution of this
plan, he obtained a revival of the sunk-duites, which had been
repealed some years before; but upon proposing, in the fol-
lowing year, to transfer the duties on wine and tobacco to the
excise, "faction," says Dr. Smith (Wealth of Nations, vol.
iii. p. 358,) "combined with the interest of intriguing
merchants, raised so violent, though unjust a clamour against
that bill, that the minister thought proper to drop it.
The defeat of this scheme was celebrated by general re-
joicing, as a deliverance from the greatest political danger.
The several commodities now subject to excise duties are,
ale, beer, cider, rum, mulleoin, and mead; things
sold by auction; bricks and tiles; candles; coaches and coach-
makers; coffee, tea, chocolate, and cocoa-nuts; glasses; hops;
leather; linen cloths, licks, cottons, and callicoes; malt;
paper; plate; soap; spirituous liquors; starch, hair-powder,
and flone-blue; sweetmeats; tobacco and snuff; wine-
gar and verjue; wine; and wire. See each of these articles.
In the year 1787 the various rates of duty which had
been imposed at different times were consolidated; and
other regulations were also adopted, by which the produce
of the revenue was augmented, and the expense of collect-
ing it materially reduced.
By 24 Geo. ii. c. 40, all fines, penalties, and forfeitures,
imposed by this or any other act relating to the duties of
excise, shall be for, levied, recovered, or mitigated by
such ways and means as any fine, penalty, or forfeiture is
or may be recovered or mitigated by any law or laws of excise,
or in the courts at Wealnhir, and shall be half to the king
and half to him that shall inform or sue—that is to say, if
within the limits of the chief office in London, the offence
shall be determined by the commissioners (or any three of
them, 1 Geo. ii. fl. 2. c. 16,) or, in case of appeals, by
the commissioners of appeals; in all other places they shall
be heard and determined by any two or more justices of the
peace, residing near the place where the offence was com-
mitted, or forfeiture incurred; and in case of neglect or re-
ufal of such justices, for the space of fourteen days next
after complaint made, and notice thereof given to the
offender; then the sub-commissioners may hear and deter-
mine the same; and if the party find himself aggrieved by
the judgment given by the said sub-commissioners, he may
appeal to the next quarter-feesions, whose judgment therein
shall be final. The paid commissioners for appeals, and
chief commissioners for excise, and all justices of the peace
and sub-commissioners aforesaid, are required, upon any
complaint or information exhibited of any such forfeiture
made or offence committed, to summon the party accused,
and upon his appearance or contempt to proceed to the ex-
amination of the fact, and on due proof thereof either by the
voluntary confession of the party, or by the oath of one cre-
dible witness, to give judgment or sentence, and if the
warrants under their hands, for levying the fame on the
goods and chattels of the offender, and to cause the same
be made thereof, if not redeemed in (not less than four, nor
more than eight days, 27 Geo. ii. c. 20.) and for want of
sufficient diiffsres, to imprison the party offending till sat-
sfaction be made. The justices, commissioners, or sub-
commissioners, respectively, where they shall see cause
may mitigate, compound, or kelfen, the forfeiture, penalty, or
fine; fo as the fame be not made less than double the value
of the duty of excise which ought to have been paid, besides
the reasonable costs and charges of such officers, or others
as were employed therein, to be to them allowed by the
said justices. (12 C. ii. c. 24.) No appeal in any case of
excise shall be admitted, till the appellant hath deposited
the single duty with the commissioners or sub-commissioners,
and given security to the commissioners of appeal, or jus-
tices of the peace, where the cause is to be finally adjudged,
for such forfeiture as was adjudged against him. (15 C. ii.
c. 13.) By the same statute all differences and appeals
about the excise shall be heard in the proper county, and
not elsewhere, and appeals within London and its limits,
shall be within two months after judgment, and notice given
or left at the dwelling house of the party, in all other
places in four months and not otherwise.
By 43 Geo. iii. c. 69, after fifth of July 1803, all duties,
allowances, bounties and drawbacks of excise, and other du-
ties under the management of the commissioners, granted
by any act of parliament then in force, shall cease; except in
cases relating to the recovery of arrears, or of any fine, &c.
previously incurred. Provided that the act shall not extend
to alter the duties upon malt, rum, cider, and perry, grant-
ed by 43 Geo. iii. c. 3, or upon malt, tobacco, and snuff,
continued by 43 Geo. iii. c. 4; (except as to the duties
on tobacco licences, and on tobacco of Spain and Portu-
gal): nor shall the act extend to the counterrewing duties
on importation from Ireland, or the drawbacks payable on
exportation thither, according to the "Act of the Union;"
(except those in respect of beer, ale, and wines, bricks
and tyles, cyder and perry, hops, mead or melebin, spirits,
vellum and parchment, gilt and silver wire, and gold and
silver thread, lace or fringe.) And in lieu thereof shall be
railed and collected upon the several goods, wares, merchan-
dize, and commodities, described in schedules annexed to
the said act, and for the said by auction, and upon licen-
ces mentioned in one of these schedules, the several sums
and duties respectively set forth in the said schedules; and
that there be allowed in respect of goods, &c. for which any

duty of excise is imposed, the several drawbacks of excise

as set forth in another schedule, and also all allowances di-
rected to be made by any act in force on the said 1st of July
1803, except as herein altered. And by 43 Geo. iii.
c. 81 certain in addition duties inserted in an annexed sche-
dule are directed to be paid, and the drawbacks in another
schedule shall be allowed: to commence from July 5, 1803,
where no date is inserted in the act, and the amount of the
additional duties may be added to the price of articles con-
tracted for prior to the act. And the said new duties shall
be raised, levied, collected, consumed, paid, recovered,
adjudged, mitigated, and allowed, (except where altered
by these acts or either of them) in the like manner, and by
such means, ways, and methods as the former duties. And
all conditions, regulations, rules, restrictions, and forfei-
tures; and every pain, penalty, fine, or forfeiture of any
nature or kind whatsoever, for any offence against any act
of parliament then in force; and the several clauses, powers,
and directions therein contained, (unless altered hereby,) shall extend to and be applied in the execution of these acts,
in a full and ample manner, as if the same were repeated and
re-enacted in the body of these acts, 43 Geo. iii. c. 69. § 4.
&c. 81. § 3. And in all cases where duties are imposed or
drawbacks allowed by these acts on any specific quantity of

 glycerides, &c. The

goods, the fame shall apply after the same rate to any less
quantity. Id.
The excise duties of England are under the management
of nine commissioners, who sit in the general "Excise
office," having salaries of 1200l. a-year each, and they are
obliged, by oath, to take no fee or reward, but from the
king only. These commissioners sit, and try appeals to
five others, called "Commissioners of Appeal." The

commissioners

6
comissioners of excise in Scotland are five in number, and have salaries of 600l. per annum each.

The number of officers employed in this branch of the revenue is very great. Beide the comissioners above-mentioned, and their subordinate officers, as regilders, messengers, &c. there is an auditor of the excise, and an auditor of hides, with their clerks, &c. A comptroller of oats, and another of accounts, with their clerks; a register; secretary; receiver-general, with his clerks; clerk of securities; five general surveyors; five general surveyors of distillery; and brandy; examiners of the distillery, of the brewery, and of soap and candles; surveyors of glass, of coaches, and plate licences; inspector of spirituous liquors, licences, and coaches; inspectors general of coffee, tea, &c. and of brewery through England and Wales. Beide which, there are in England and Wales, exclusive of the bills of mortality, within which is the principal head office of excise, to which all other offices in the kingdom are subordinate and accountable, about fifty collectors, who go their respective rounds once in six weeks; the province of a collector comprehends several districts, within each of which there is a supervisor, under the inspection of the collector; and each district is parcelled out into out-rides and footwalks, within each of which there is an inferior officer, constituted under the hands and seals of the comissioners, or sub-commissioners, in their respective divisions, as necessity requires, and called gauger, or excise-man, under the inspection of the supervisor, who every six weeks draws out a diary of every day's business, with remarks, and transmits it to the chief officer. Every person, previous to his appointment to the office of gauger, must procure a certificate of his age, which must be between 21 and 30; he must understand the four first rules of arithmetic, know what business he hath followed, and that he is not encumbered with debts, be of the communion of the church of England, and, if married, not have more than two children; he must nominate two able persons to be his sureties; and the certificate, containing these particulars, and written by himself, must be signed by the supervisor of the district where he lives, and accompanied with an affidavit, that he has used no bribes for obtaining this office. He is then ordered for instruction, under the care of an experienced officer, and to wait, under the denomination of an "expectant," till a vacancy happens.

Upon admission of officers of every kind relating to the excise, the oaths of allegiance and supremacy, and an oath of faithfulnes in the execution of the particular office, must be taken, and the declaration against transubstantiation must be subscribed. The officers of excise are appointed, and may be dismissed, replaced, or altered by the commisioners under their hands and seals; their salaries are allowed and established by the treasury; and by W. and Mary, c. 24. § 15. if it be proved by two witnesses that any officer has demanded or taken any money, or other reward whatever, except of the king, such offender shall forfeit his office. Officers of excise, taking a bribe, are liable to a forfeiture of 10l. 15 Car. II. cap. 11; liable to excise duties offering them a bribe, &c. shall forfeit 50l. 11 Geo. cap. 30. Officers medling in elections are subject to a penalty of 10l. and an incapacity of holding any office under the king, 5 W. cap. 20. And an officer, either of the excise or customs, dealing in excisable goods, shall forfeit 50l. and be incapable of any office in the revenue, 12 Geo. cap. 28. The concealment of excisable goods is subject to a forfeiture of those goods, and treble value, 11 Geo. cap. 30. Any person obstructing an officer in the execution of his duty, shall forfeit 10l. 6 Geo. cap. 21. Actions of assault upon any officer may be tried in any county, 9 Geo. II. c. 35. And if any person shall disturb or oppose any excise officer in the execution of the powers and authorities by this act granted, or any or either of them, except where other penalties are by the act provided, he shall forfeit 200l. 42 Geo. III. c. 38. And the same penalty is inflicted by 43 Geo. III. c. 81, in relation to that act.

Officers of excise are empowered to search at all times of the day, enter warehouses, &c. And if officers suspect that exciscable goods are concealed in any place within the limits of the chief office of excise in London, upon oath by such officers before the comissioners, or any two or more of them; or if such place be in any other part of Great Britain, on oath before one or more justices of the county, &c. or suspected place, setting forth the ground of suspicion, the said comissioners, or the said justices or justices may, by special warrant, authorize such officers by day or night (but if in the night, in presence of a constable or other peace officer) to enter into such place and to seize all such goods; and if any person shall obstruct any such officers so authorized, or any one acting in the execution of such warrant, he shall forfeit 100l. 42 Geo. III. c. 82. The officers, in their permits for removing excisable goods, shall express as well the time for which they shall be in force for removing such goods, as the time within which they shall be received into stock by the person to whom they are sent; and if not removed within the time limited (unavoidable accidents excepted); or, in default of such removing, if the permit shall not be returned to the officer who granted the same, the person procuring the permit shall forfeit treble value of the goods; and if not received into stock, within the time limited, by the person to whom they were permitted to be sent, they shall be deemed goods removed without a permit 21 Geo. III. c. 55. No writ shall be sued out against any officer of excise, or his affidavit, for any thing done in the execution of his office, until one calendar month's notice shall have been delivered to him, or left at his usual place of abode, clearly and explicitly containing the cause of action, the name and place of abode of the person who is to bring such action, and the name and place of abode of his attorney or agent; and the officer may at any time within such month tender amends, and plead such tender in bar of the action; and if, upon such joined, the jury shall find the tender to have been sufficient, they shall give a verdict for the defendant; but if the jury find that no amends, or such as were not sufficient, were tendered, they shall give a verdict for the plaintiff, and such damages as they shall think proper with costs of suit. 23 Geo. III. c. 70. If any action shall be brought against an officer, &c. it shall be brought within three months after the cause of action shall arise, and not afterwards, and shall be laid in the proper county; and if the plaintiff shall be nonsuit, or diletente, or if upon a verdict or demurrer judgment shall be given against him, the defendant shall recover treble costs.

The additional duties, which the progress of the public expenditure has rendered it necessary to impose, have greatly increased the produce of the excise, and rendered it the most important branch of the public revenue. The duties which it comprehends are divided into the permanent conilituted duties, the temporary war taxes, and the annual duties; the latter consist of the old annual malt duty, and of an additional malt duty, which, with some duties on tobacco and snuff, and some custom duties, have, since the project for selling the land-tax, been granted annually in lieu thereof.

An
## EXCISE.

An Account of the Groves' Actual Receipt in Money, Charges of Management, and Taxes paid to Officers, Expt Temporary War Taxes, and Malts and Tobacco, Annual in England, for the Year ending Exchequer, on each Article;—together with the Balance in the Hands of

</tbody>
</table>

The total revenue of inland excise and licences, together with other fees received by revenue excise collectors in Ireland, for one year, ending the 5th of January, 1809, amounted to 1,659,838/. 8 s. 92 1/2 d. and the total payments for management, militia, bounties, &c. out of the grofs and net revenue of excise, during the same period, amounted to 531,910/ 9s. 5 1/2 d. If we add to the above sum 1,659,838/ 5 s. 9 1/2 d. the amount of the inland duties, viz. 429,824/- 11s. 2 1/2 d. the grofs produce will amount to 2,089,662/. 19s. 9 1/2 d. and the amount of the net produce was 1,772,615/. 16s. 2 1/2 d.  

EXCISION, in Surgery, is a word often used to signify the operation of cutting away any tumour, or any foreign substance, off, or out of, a part of the body.

EXCITABILITY, in Dr. John Brown's hypothesis, or the Brunonian hypothesis, as it has been called, is nearly synonymous with the vital principle of medical writers in general, and signifies that quality or property of living beings, on which the phenomena of life depend.

Life itself is, in the opinion of Brown, a forced state, arising altogether from the action of certain agents, which he denominates exciting powers, upon the excitability; for death enuiues equally, whether the exciting powers are withdrawn, or the excitability is lost. The exciting powers consist of heat, air, food, drink, and other substances taken into the stomach, the blood, and the fluids secreted from it; as well as of certain functions of the sytem itself, such as muscular exertion, sensation, thought, and passion or emotion. The effect of the exciting powers acting upon the excitability, is denominated excitement.

This word "excitability" is to be considered as a general term, expressive of the facts ascertained by observation, but of the essential nature of which we must remain ignorant; as in the case of gravitation, &c. "We know not what excitability is," says Dr. Brown, "or in what manner it is affected by the exciting powers. But whatever it be, whether a quality or a substance, a certain portion is affixed to every being upon the commencement of its living state." He observes, however, that such expressions as a determinate portion of excitability in each living being, the exahution, or the accumulation of excitability, are necessarily borrowed from the qualities of material substances, in consequence of the poverty of language; and are not to be received in a strict and literal sense.

Every power, then, that acts on the living frame, according to this doctrine, is excitant, and produces excitement by exciting excitability; whence it follows, that the whole phenomena of life, every state and degree of health and disease, are also owing to stimuli, and no other cause.

By too great stimulation weakness is induced, because the excitability becomes defective; this is said to constitute a state of indirect debility; when the exciting powers or stimuli are withheld or diminished, weakness is likewise induced, the excitability being accumulated, or in excess; and this is denominated a state of direct debility. (See Debility.) For "this mutual relation obtains between excitability and excitement; that the more weakly the powers have acted, or the less the stimulus has been, the more abundant the excitability becomes;—the more powerful the stimulus, the excitability becomes the more exhausted." It is only then, when a mean degree of stimulus operates upon excitability at a medium, that perfect health is produced: in illustration of which a scale was drawn by Brown. (See Elements of Medicine, ch. iii. § 39, note) divided into 80 degrees of excitability opposed inversely to 80 degrees of exciting power, at each end of which is death; there being, in the one case, 80 degrees of excitability, and no exciting power; and in the other, 80 degrees of stimulus and no excitability; whereas perfect health holds the middle flattion, where there are 40 degrees of stimulus and of excitability respectively. Good health, however, may be considered to exist within a range of 30 or 40 degrees (15 or 20 on each side of the mean) in consequence of the constant variation of stimulus, to which man is exposed, in his food, drink, passions of the mind, &c.; but every departure from the mean of perfect health constitutes a predisposition to diseases of direct or indirect debility. As life is entirely regulated by excitement, and the exciting powers have a stimulating effect only, Dr. Brown affirms that "the notion of health and disease being different states is disproved," the operation of the powers producing or removing each state being perfectly identical: and efficacious remedies being such as oppose deficient stimulus to excessive excitement, and excessive stimulus to deficient excitement. In a word, there are but two forms of diseases; and both are always preceded by pre-diffusion: those which arise from excessive excitement are called febrile (from fene, length) and those which originate from a deficient excitement, afebrile. The direct tendency of this hypothesis, therefore, was to reduce the art of medicine to the simple regulation of stimulus, or of the exciting powers; it required
us only to increase the quantity of stimulation on the one hand, or to withdraw, or rather diminish, the stimulus on the other, as the excitement happened to be too great or too little, above or below the medium of the scale of health.

As this concise statement of a medical hypothesis, which has excited great attention and much controversy, may, perhaps, be obseure to those who are unacquainted with the study of the phenomena of animal life, we shall cite an illustration of Brown's tube, drawn up by one of his pupils from a familiar operation, by which a conception of his fundamental principles may be facilitated.

"Suppose a fire to be made in a grate filled with a kind of fuel not very combustible, and which could only be kept burning by means of a machine, containing several tubes, placed before it, and constantly pouring streams of air into it. Suppose also a pipe to be fixed in the back of the chimney, through which a constant supply of fresh fuel was gradually let down into the grate, to repair the waste occasioned by the flame, kept up by the air-machine.

The grate will represent the human frame; the fuel in it the matter of life (the excitability of Brown, and the fermental power of Darwin); the tubes behind, supplying fresh fuel, will denote the power of all living systems constantly to regenerate or reproduce excitability; while the air-machine, of several tubes, denotes the various stimuli, or exciting powers, applied to the excitability of the body; and the flame, drawn forth in consequence of that application, represents life, the product of the exciting powers acting upon excitability.

As Dr. Brown has defined life to be "a forced state," it is fitly represented by a flame, forcibly drawn forth, from fuel little dispersed to combustion, by the constant application of streams of air poisoned into it from the different tubes of a machine. If some of these tubes are supposed to convey pure, or oxygenous air, they will denote the highest class of exciting powers, such as opium, musk, camphor, spirits, wine, &c. (the diffusible stimuli of Brown) which bring forth for a time a greater quantity of life than usual, as the blowing in of pure air into a fire will temporarily draw forth an uncommon quantity of flame. If others of the tubes be supposed to convey common or atmospheric air, they will represent the ordinary exciting powers, or stimuli, applied to the human frame, such as heat, light, air, food, drink, &c.; while such as convey impure air may be used to denote what have formerly been termed sedative powers, such as poisons, contagious miasmas, foul air, &c. (Sedatives are deemed by Brown diffusibles of a minor force.)

The reader will now be at no loss to understand the seeming paradox of the Brunonian system, that food, drink, and all the exciting powers applied to the body, though they support life, yet they confine it: for we must see, that the application of these powers, though it brings forth life, yet at the same time, it weakens the excitability, or matter of life; just as air blown into the fire brings forth more flame, but weakens the fuel, or matter of fire. This is conformable to the common saying, "the more a spark is blown, the brighter it burns, and the sooner it is spent." A Roman poet has given us an elegant illustration of the Brunonian system, when he says,

"Balnea, vina, Venas, confumunt corpora nostra; Sed vitam facient balnea, vina Venas." 

"Wine, warmth, and love our vigour drain; Yet wine, warmth, love our life fullain."

It will be equally easy to illustrate the two kinds of debility, termed direct and indirect, which, according to Brown, are the causes of all diseases; if the quantity of stimulus, or exciting power, is proportioned to the quantity of excitability; that is, if no more excitement is drawn forth, than is equal to the quantity of excitability produced, the human frame will be in a state of health: just as the fire will be in a vigorous state, when no more air is blown in, than is sufficient to support the fresh supply of fuel, constantly poured down by the tube behind. If a sufficient quantity of stimulus is not applied, or air not blown in, the excitability in the man, and the fuel in the fire, will accumulate, producing indirct debility; for the man will become weak, and the fire low.

This, carried to a certain degree, will occasion death to the fire, and extinction to the life. If again, an over proportion of stimulus be applied, or too much air blown in, the excitability will soon be wafted, and the matter of fuel almost spent: hence will arise indirect debility, producing the same weakens in man, and lawnesses in the fire as before, and equally terminating, when carried to a certain degree, in death and extinction.*

The simplicity of this doctrine, contrasted with the complicated hypotheses of preceding physicians, and its happy illustration of some of the phenomena of life, (which we have noticed under the word Debility,) speedily obtained for it a number of professors, in the schools of medicine, wherever it was introduced. A generalization of speculations was, indeed, well calculated to arrest the attention, and gratify the ardor of young minds; and accordingly it was received with enthusiasm by the most fashionable and speculative students, and was debated and defended with a vehemence and intolerance of opposition, almost unknown in scientific discussions; and this not only at Edinburgh, where the doctrine originated, but successively in the different universities of the continent to which it was carried.

To learn that there were but two forms of disease, and therefore but two indications of cure, and two sorts of remedies, was particularly gratifying to those who preferred indolent hypotheses to the labour of observation. It superseded at once the practice and maxims of the Hippocratic school of experience and unremitting investigation, and reduced the art of medicine within the compass of a nut-shell.

But, true as this doctrine of excitement may be, in its application to many of the phenomena of life, it is by no means adequate to the explanation of the whole, and especially of the causes and remedies of numerous diseases; it is, moreover, inconsistent with itself in some points, and its advocates are not agreed in the interpretation of these difficulties.

There is one inconstancy so gross and obvious, in the Brunonian doctrine, that it is inconceivable how the author could have been infensible of it, or have persevered in maintaining it. In the illustration above quoted, a tube or chimney is provided, by which the fuel, or excitability, is supposed to be constantly replenished: but no such provision is mentioned by Brown. He affirms that "a certain portion of excitability is assigned to every being at the commencement of its existence, that the action of stimuli necessarily exhausts it, and that life consists in the incessant action of stimuli upon this excitability;" i.e. in the incessant exhaustion of it. With this statement the notion of accumulated excitability (which is said to constitute direct debility) is altogether incompatible: non-consumption, or rather diminished consumption, might preserve the excitability, but furedly could never increase it: though somewhat might be saved, nothing could be gained, by the abridgment of stimuli; and on the re-application of the discontinued stimuli, the excitability should never be found increased or accumulated, but should be stationary at the point of interruption; or, more correctly speaking, it must always be found
found somewhat wasted, since, while life remains, it must be acted upon in some degree; while, on the other hand, every violent inflammation should, upon the same principle, rapidly wane, and bring the irreversible exhaustion of the powers of life. The proposition, then, that a determinate portion of excitation is assigned to every individual, being equally inconsistent with the subsequent theories of the fytlem, and with matter of fact, has been either given up, or explained away, by the pseudo-Brunonians of the present day. They admit that the excitation may be partially restored or renewed by rest and food. But to make the hypothesis consistent with common sense, it requires that the proofs of generating excitation be constantly going; for even during the most profound sleep, stimuli, or, in other words, exhausting powers, are incessantly applied, the cessation of all excitation being synonymous with death.

Another inconstancy in the hypothesis, scarcely less palpable, is, the statement, that indirect debility, which consists in the exhaustion of the excitability from excessive stimulation, is to be cured, i.e. the excitability is to be restored, by a continuance of strong stimuli, or variously, by having "a little flirt of the fytlem," which procured the over-excitement. But, by so saying, it is obvious from the hypothesis, that they must exhaust excitability, if they act at all; they must, therefore, wear out what remains of the excitability more and more, and ultimately exhaust the power. No attempts to explain away this incongruity of language can be considered successful; the alleged loss of power in the stimuli, in consequence of repetition, will only account for the less rapidity of the complete exhaustion; but exhaustion of excitability cannot be separated from the notion of stimulation.

In its application to the practice of medicine, as well as to the explanation of the action of many causes of disease, the Brunonian system is marked by a gross neglect or defiance of observance and experience. The connections and dependencies of the different functions, the local derangements which take place in the different organs, and the curative indications deduced from these, are altogether overlooked; and the variety of phenomena which result from the specific operation of various agents on the animal economy, is equally neglected. The affinity that all powers, whether the animal body, whether productive or curative of disease, are stimulating, is an abuse of language not often equalled by the framers of theories. There is not only not identity in their action; there is scarcely any thing in common. "With regard to contagions," to use the words of an intelligent critic, "when we consider the regular and progressive series of actions, induced by these on the fytlem; when we have observed that each contagion gives rise to a train of peculiar and characteristic phenomena, defining the disease, whence the contagion originated, and terminating often in the formation and separation of a quantity of morbid matter, alone capable of propagating the same disease in others, we cannot acknowledge that identity in the action of the exciting powers, which the Brunonians contend for. In diseases induced by contagions, in the small-pox, for example, or in lues venerea, we perceive something more than simple excitement and unaltered stimulation. Individuals of every description, whether predisposed to phthisia or phthisis, whether labouring under direct or indirect debility, may be infected; and when the disease has taken place, it runs its course under every possible modification of the excitability, &c." (See Edinburgh Med. and Surg. Journal, vol. i. p. 369.) And again, with respect to the agents of the Materia Medica, besides their action upon the excitability, or the degree of excitement and exhaustion which they produce, there are various other peculiarities in their mode of operation. "They differ in the succession of phenomena to which they give period; the intoxication produced by wine, opium, and some other narcotics, cannot be imitated by aromatics, by the preparations of antimony or of mercury; nor the effects of these by narcotics: they differ in their power of specifically affecting particular organs and functions, as the stomach, intestines, kidneys, skin, salivary glands, abscess or vesicular fistula, by narcotics, purgatives, diuretics, sudorifics, mercury, digitalis, &c. They differ in their power of opposing and inducing particular organic changes and morbid affections of the fistula; as phthisis and bilary diseases are cured by mercury, scurvy by vegetable acids, and uric diseases by alkalies: they differ in the durability of effect or change produced; as is obvious by comparing the momentary and fleeting effects of the diffusible stimuli, with the permanent excitement and vigour produced by tonics, as by cinchona and preparations of iron, by wholesome food and pure air." Lec. cit.

In short, it is obvious that the word stimulating, as applied to all those various causes by which the body is prolonged, is no longer retained any definite meaning; but produces a jargon which may be interpreted by each individual according to his own notions. In this respect, the theory pollutes an universal stincts, like Bayes' prologue, and will do for any practice that may be found most expedient. Thus mercury will be considered as the proper stimulant for phthisis, cinchona and arsenic for intermitents, citric acid for scurvy, and so on; for fortunately mankind have still good sense enough to accommodate their hypotheses to the results of experience: hence we do not apprehend, that many of the most implicit believers in this jargon would endanger their patients by applying the same remedies to typhus, gout, and dropsy, because they flound in the name numerical portion of the scale; or by treating phthisis, apoplexy, and the plague alike, because they are classed together in the same way!

Notwithstanding its many inconstancies and defects, however, the Brunonian doctrine has had some beneficial influence on medical science, by inducing a particular attention to the degree of excitation, which accompanies many diseases, although it cannot be considered as the cause or essence of them. The regulation of the excitation often constitutes the most useful means of conducting these diseases through their course to a safe termination, by moderating symptoms, and keeping action within due bounds on the one hand, or supporting the languid forces of the system on the other. This is especially true with regard to contagious febrile diseases.

The doctrines of Brown are contained in the "Elementa Medicina," which were first published in Latin, and afterwards translated by himself. After his death a revised edition of this translation was published by Dr. Beddoes, in 2 vols. 8vo. 1795; and another by the author's son, Dr. William Cullen Brown, in 3 vols. 8vo. in 1804. See Brown.

EXCITATION, (from the Latin excito, I excite,) denotes the act of awakening, of rousing, or of producing some power or action; thus we hear of the excitation of motion, excitation of heat, excitation of passions, &c. In natural philosophy, the word is principally employed in the subjects of electricity and of heat; and of these two kinds of excitation the particulars are as follows.

When a piece of amber, or of glass, or of sulphur, or in short, of any other solid, called electric, or non-conductor, is observed in common, it does not appear to have any particular power; but if it be rubbed with a dry hand, or with something else, then after a few strokes it will be found that...
that it has acquired the electric virtue, so that now it will attract small bodies that are presented to it, and it will also exhibit other electrical phenomena (for which see the article Electricity.) In this case the electric power in the amber, or glass, or sulphur, is said to have been excited by the friction of the hand or other body, which therefore is called the rubber; for, previous to the friction, the amber, or sulphur, &c. showed no signs of electricity, that power being, as it were, dormant in it.

Rubbing is the most general, and upon the whole, the most effectual method of exciting electrics, but there are several other modes of excitation, and indeed hardly any action, or any motion, takes place among natural bodies, which is not attended with the excitation of electricity. In general, however, the electricity is not produced in quantity sufficient to affect our senses, without the aid of proper instruments, and of course it passes unnoticed. The principal causes of the excitation of electrics are rubbing or friction, heating and cooling, melting or coagulating, evaporation and condensation, expansion and contraction, the mere juxtaposition or contact of certain bodies, solution and effervescence, and lastly some unknown action of the body in certain aquatic animals. But these methods are not indiscriminately applicable to all substances. They are confined within certain limits of application as well as of effect; and of these particulars we shall now give a regular account.

Rubbing, or friction.—In the science of electricity the various bodies of the earth are distinguished into electric and conductors (see Electricity and Conductors;) and whenever two bodies are rubbed against each other, unless they be both very good conductors, some electricity is always produced; that is, one of the bodies acquires the positive or vitreous, and the other acquires the negative or resinous electricity; for by this means one kind of electricity cannot be produced without the other. The circumstance which, in the superficial manner of performing the experiment, makes it appear as if one kind only of electricity were produced, is that the better conductor of the two bodies concerned, being not inflated, looses its electricity as soon as it receives it; but when both bodies are inflated, each of them will become electrified by the friction, one of them acquiring the positive, and the other the negative electricity. Even two inflated perfect conductors, by the least contact or friction against each other, acquire a slight degree of electricity; but of this hereafter. The friction which is required for this excitation of electricity is not that which can scrape off or injure the surface, but a gentle pressure progressively applied with a pretty quick motion. The former kind of friction generates heat, but little or no electricity.

The very same body, by changing the rubber, may be caused to acquire either the positive or the negative kind of electricity; and the change is often produced by a remarkably slight alteration of circumstances, such as altering the direction of the friction, increasing or diminishing the temperature by a few degrees, and so forth. The following table exhibits the principal cases of this kind of change, viz. it shews what kind of rubber is required for exciting a given body positively, and what kind for exciting it negatively. Thus it appears that sealing-wax acquires the positive electricity when rubbed with a metallic body, and that it acquires the negative electricity when rubbed with furs, leather, woollen cloth, &c. Thus also it shews that baked wood is excited positively by silk, and negatively by flannel.

When two electric substances, equal in every respect, are rubbed against each other, that substance which suffers the greater degree of friction acquires the negative, and the other acquires the positive electricity. Thus, if a piece of silk, A, be drawn across another piece of silk, B, in every respect equal to A, so that the surface of the whole piece,

When two electric substances, equal in every respect, are rubbed against each other, that substance which suffers the greater degree of friction acquires the negative, and the other acquires the positive electricity. Thus, if a piece of silk, A, be drawn across another piece of silk, B, in every respect equal to A, so that the surface of the whole piece, 

Mr. Henly inflated several bodies, and in that slate rubbed them one by one, against his woollen garments, or against silk, by which means they became electrified; but he observed very great inequalities in the effects which were
were produced by substances much allied to each other, or of the same class. Thus, a guinea, a fix-pence, and a piece of tin, became negative; a piece of copper, a steel button, and a silver button, positive, at least when the cloth was warm; animal substances, excepting hairs, generally acquired the positive electricity; vegetables became almost always negative; but the smooth skins of bears became positive; common pebbles, marble, coal, and jet, acquired the negative electricity; gems and crystals, the positive; glazed wares and writing paper, the positive influence; pitch, a tallow candle, oiled silk, Indian ink, and blue vitrual, (viz. sulphate of copper,) acquired the negative electricity. Other phenomena have extended the list considerably farther, but it is useless to specify the particulars.

The principal requisite in the subject of electricity, is to determine the proper construction of the rubber, and the method of employing it, so as to excite the greatest possible power in a given current.

The bell rubber for a tube of smooth glafs, Mr. Cavalla says, (Treatise on Electr.) is the rough side of black oiled silk, especially when a little amalgam has been rubbed upon it; but the bell rubber for a rough glafs tube, a fliek of baked wood, sealing-wax, or sulphur, is soft new flannel. The rubbers of common electrical machines, wherein a glafs globe, or cylinder, or circular plate is revolved, has been varied and improved progressively. The more common construction consists of nothing more than a silk cushion fluffed with hair, over which is placed a piece of leather, and upon this leather some amalgam, (see A. Maclean, for electrical purposes) is forced so as to adhere pretty fast to it. Some time ago this was customary, (and the practice even at present is not entirely laid aside,) to make the rubber of red bafil skin fluffed with hair; but the above-mentioned silk one, which was contrived by Dr. Noot, is much preferable. If this silk cushion, on account of adapting it to the surface of the glafs, is to be fixed upon a metallic plate, then care should be taken to render the plate free from sharp points, edges or corners, and it should be concealed or covered over with the silk. In short, to construct the rubber properly, it must be made so, that the side of it which the surface of the glafs enters in whirling, may be as perfect a conductor as can be made, in order to furnish an ample and ready supply of electricity, and the opposite part should be as much a non-conductor as possible, in order that none of the electricity that has been accumulated upon the glafs may go back to the rubber. A piece of silk is generally fixed to the extremity of the leather which flains against the surface of the glafs. The rubber of Mr. Nairne's electrical machine (see Electrical Machine,) consists of silk only put over the leather cushion, the piece of silk projecting a considerable way beyond the cushion, and very little amalgam is used with it: in truth no amalgam at all is put upon the rubber of this machine; but whilst the clean rubber is on, and the cylinder is turning, a piece of leather, with some amalgam spread upon it, is applied for a few seconds to the under part of the cylinder, by which means a sufficient number of particles of amalgam will fly along the surface of the glafs, from the leather to the rubber.

The rubber should be supported by a spring, by which means it may easily adapt itself to the inequalities of the surface of the glafs, which, with cylinders, often are very considerable. It should likewise be insulated in whatever manner it may be most convenient; for whenever insulation is not wanted, a chain or wire may be occasionally hung upon it, by which means it will communicate with the ground or with any other body at pleasure: when there is no possibility of insulating the rubber, several of the most interesting experiments in electricity cannot be performed with the machine.

Mr. Nicholfon made a great variety of experiments, respecting this mode of excitation, which are described at large in the Philosophical Transactions for the year 1789, and from those experiments he deduces the following importance.

"Those experiments," he says, "showed that the office of the silk is not merely to prevent the return of electricity from the cylinder to the cushion, but that it is the chief agent in the excitation, while the cushion serves only to supply the electricity, and perhaps increase the pressure at the entering part. There likewise seems to be little reason to doubt but that the disposition of the electricity to escape from the surface of the cylinder, is not prevented by the interposition of the silk, but by a compensation after the manner of a charge, the silk being then as strongly negative as the cylinder is positive; and, lastly, that the line of light between the silk and the cushion in weak excitations, does not consist of returning electricity, but of electricity which passes to the cylinder, in consequence of its not having been sufficiently supplied, during its contact with the rubbing surface.

"When the excitation was very strong in a cylinder newly mounted, flashes of light were seen to fly across its inside, from the receiving surface to the rubbing surface, with the cylinder, as indicated by the bright figure. These made the cylinder ring as if struck with a bundle of small twigs; they seem to have arisen from part of the electricity of the cylinder taking the form of a charge. This appearance was observed in a nine-inch, and a twelve-inch cylinder, and the property went off in a few weeks. Whence it appears to have been chiefly occasioned by the rarity of the internal air produced by handling, and probably restored by gradual leaking of the cement."

In order to determine what takes place in the inside of the cylinder, Mr. Nicholfon undertook a series of experiments with a plate machine, (see Electrical Machines,) and from their result it appears, "that no advantage is gained by rubbing both surfaces, but that a well-managed friction on one surface will accumulate as much electricity as the present methods of exciting seem capable of collecting; but that when the excitation is weak, on account of the electric matter not passing with sufficient facility to the rubbed surface, the friction enables the opposite surface to attract or receive it, and if it be supplied, both surfaces will pass off in the positive state, and either surface will give out more electricity than is really induced upon it, because the electricity of the opposite surface forms a charge. It may be necessary to observe, that I am speaking of the facts or effects produced by friction; but how the rubbering surfaces act upon each other to produce them, whether by attraction or otherwise, I do not here enquire."

From further experiments with the cylinder, Mr. Nicholfon deduced the following conclusions: 1. the line, he says, of light on a cylinder departing from a simple cushion, consists of returning electricity. 2. The projecting part of the cushion compensates the electricity upon the cylinder, and by diminishing its intensity prevents its striking back in such large quantities as it would otherwise do. 3. That if there were no such compensation, very little of the excited electricity would be carried off; and, 4. That the compu-
EXCITATION.

temperament is diminished, or the intensity increased, in an
higher ratio than that of the distance of the compensating
substance; because if it were not, the electricity
which has been carried off from an indefinitely small dis-
tance, would never fly back from a greater distance, and
from the edge of light.

"I hope the considerable intensity I shall speak of will be
an apology for describing the manner in which I pro-
duce it. I wish the theory of this very obscure process were
better known; but no conjecture of mine is worth men-
tioning. The method is as follows:

"Clean the cylinder and wipe the filk.

"Grease the cylinder by turning it against a greased
leather till it is uniformly obscured. I use the tallow of a

candle.

"Turn the cylinder till the filk flap has wiped off so
much of the grease as to render it semi-transparent.

"Put some amalgam on a piece of leather, and spread it
well, so that it may be uniformly bright. Apply this against
the turning cylinder. The friction will immediately in-
crease, and the leather nalt not be removed until it ceases
to become greasy.

"Remove the leather, and the action of the machine will
be very strong.

"My rubber confines of the filk flap passed to a leather,
and the cushion is pressed against the filk by a slender spi-
ral spring in the middle of its back. The cushion is loosely
retained in a groove, and rels against the spring only in such
a manner, that by a fort of libration upon it as a fulcrum,
it adapts itself to all the irregularities of the cylinder, and
never fails to touch in its whole length. There is no ad-
justment to vary the pressure, because the pressure cannot
be too small when the excitation is properly made. Indeed,
the actual withdrawing of the cushion to the distance of
one-tenth of an inch from the filk, will not materially
affect a good excitation.

"The amalgam is that of Dr. Higgins, composed of zinc
and mercury. If a little mercury be added to melted
zinc, it renders it easily penetrable, and more mercury may
be added to the powder to make a very soft amalgam. It
is apt to crystallize by repose, which seems in some measure
to be prevented by triturating it with a small proportion of
glycerine, and it is always of advantage to triturate it be-
fore using it.

The following curious fact may, perhaps, be referred to
the action of friction. — If a flock of sealing-wax be broken
into two pieces, the fractured parts, that is, those extremi-
ties of the pieces which were contiguous to each other,
will be found electrified, one of them positively, and the
other negatively.

HEATING AND COOLING.—The property of exhibiting electro-
ical phenomena by means of heating and cooling, was first
observed in a hard semi-transparent foil, known under the
name of tourmaline (called afterbrick by the Dutch,
from its property of attracting ashes, &c. when held near the
fire. Linnæus, in his Flora Ceylonica, calls it lapid elec-
tricus.) This foil, which generally is of a deep red or purple
colour, and seldom exceeds the size of a small walnut, is com-
mon in several parts of the East Indies, and especially in
the island of Ceylon. Tourmalines are also found in a great
many other parts of the world, and often in pretty large
masses, but they are mostly opaque, and then they hardly
ever show any peculiar electric properties. (See its min-
erological characters under the article TOURMALINE.) The
tourmaline's properties with respect to electricity are as fol-
lows.

1. The tourmaline, while kept in the same degree of heat,
shows no signs of electricity; but it will become electrical
by increasing or diminishing its heat, and stronger in the
latter than in the former circumstance. An exceedingly
small variation of temperature is often sufficient to render
it feebly electrical.

2. The electricity of the tourmaline does not appear all
over its surface, but only on two opposite sides, which may
be called its poles, and they are always in one right line
with the centre of the foil, and in the direction of its flrats;
in which direction the foil is absolutely opaque, though
on the other semi-transparent.

3. Whilst the tourmaline is heating, one of its sides (distingu-
ished by A) is electrified plus, or positively, and the other
side B, minus; but when it is cooling A is minus, and B is
plus.

4. If it be heated and suffer'd to cool without either of
its sides being touched, then A will appear positive, and B
negative, all the time of its heating or cooling.

5. If this foil be excited by friction, like any other elec-
tric, then each of its sides, or both at once, may be made
positive.

6. If the tourmaline be heated or cooled upon some other
inflated body, that body will be found electrified as well
as the foil; and will be found polsified of the electricity
contrary to that which is acquired by that side of the foil
which was laid upon it.

7. The electricity of each side, or of both, may be rever-
sed by heating or cooling the tourmaline in contact with various
substances; thus if it be cooled, or heated, in contact with
the palm of the hand, that side of it, which would have been
positive if cooleed in the open air, is now negative; and that
which would have been negative is now positive.

8. If a tourmaline be cut into several parts, each piece
will have its positive and negative poles, corresponding to
the positive and negative sides of the foil from which it
was cut.

9. Thee properties of the tourmaline are also observable
in vacuo, but not so strongly as in the open air.

10. If this foil be covered all over with some electric
substance, as sealing-wax, oil, &c. it will in general shew
the same appearances with this coating as without it.

11. Mr. W. Canton observed a very vivid light upon
the tourmaline while heating in the dark; and this is
sufficient to point out which end of the foil is become
positive, and which negative. Also, when the foil is
strongly excited, it emits very strong flashes from the positive
to the negative end, in the dark. That foil which is
commonly called the "Brazilian emerald" from its colour,
but which in fact is a tourmaline, also emits the above-men-
tioned electrical light.

12. Lastly, it is to be remarked that the power of the
 tourmaline is sometimes injured by the action of a strong fire,
at other times it is improved, and frequently it is not at all
affected by it. The laws, however, of such uncertain effects,
have not yet been investigated.

Most of the above-mentioned properties, which were first
observed in the tourmaline, have been found to belong to
some other bodies; i.e. there are some other substances
which have the electric virtue excited in them by heating
and cooling. It is to be observed that such bodies are
generally, if not always, in a crystallized state; also it has
been remarked that the parts which exhibit the different
flares of electricity differ from each other with respect to
their form, although they are similarly situated; while in
those crystals that are not electric, the similarly situated
parts correspond also in form. If a crystal, for instance,
consists of a prism terminated at each extremity by a pyra-
mid, and these pyramids differ as to the kind of electricity they are capable of acquiring, it will be found that they also differ in their form; one consisting of a greater number of surfaces than the other; and the part which has the greater number of faces acquires the positive electricity, the other the negative. Kidd's Outlines of Miner. vol. i.

The Abbé Hailly says, that the electricity which is produced by heat has been observed in six species of minerals, viz. the tourmalin, the borated magnesia or boracite, the topaz, whether from Brazil, from Saxony, or from Siberia, the metabore of Hailly, or zeolite, the perhnite, and the oxidized zinc, or electrical calamine. See the nature of these minerals under the articles of their peculiar names. We are informed, however, that lately a gentleman, highly versed in electrical experiments, examined a vast number of specimens of the above-mentioned six minerals, and among them, (independent of the tourmalin,) he found two only that became electrical by heating and cooling; namely, the boracite and the oxidized zinc; with respect to a specimen of the latter, which had a pyramid at one end, and was truncated at the other end, he particularly observed that whilst cooling, the pyramid became negative, and the truncated side positive; but whilst heating, the pyramid became positive, though slightly so, and the truncated side did not manifest any sensible degree of electricity.

Melting or coagulating.—Melting or pouring a melted electric substance into another, excites electricity in various instances, and with peculiar phenomena.

If sulphur be melted in an earthen vessel, and be left to cool upon conductors; then if taken out of the vessel, when cold, it will be found strongly electrical; but not at all so, if it be left to cool upon electrics.

If sulphur be melted in glass vessels, and afterwards left to cool, they will both acquire a strong electricity, the sulphur negative, and the glass positive, whether they be left to cool upon electrics or upon conductors; however, they always acquire a stronger power in the former case than in the latter; and a stronger still, if the glass vessel is coated with metal. It is to be remarked, that this electric power of the glass continues till it begins to cool; its power increases in proportion as it contracts, and is the strongest when in the state of greatest contraction; but then the electricity of the glass vessel is at the same time the weakest.

If melted sulphur be poured into a vessel of baked wood, it acquires the negative electricity, and the wood the positive; but if it be poured into sulphur, or rough glass, it does not acquire any sensible degree of electricity.

Melted sulphur poured into a metal cup, and there left to cool, shews no signs of electricity whilst remaining in the cup; but if separated, they will then appear strongly electrified, the sulphur positively, and the cup negatively. If the sulphur is replaced in the cup, every sign of electricity will vanish, but, if whilst they are separate the electricity of either of them is taken off, then, on being replaced, they will both appear possessed of that kind of electricity which had not been taken off.

Melted wax, poured into glass or wood, acquires the negative electricity, and leaves the glass or wood positive. But if melted wax be poured into sulphur acquires the positive electricity, and leaves the sulphur negative. The wax-chandlers, in making their candles, often find it extremely difficult to prevent the attraction and adhesion of dust and other light bodies, in consequence of the electrified state of the wax.

Chocolate fresh from the mill, as it cools in the pans in which it is received, becomes strongly electrical. When turned out of the pans, it retains for some time this property, but soon loses it by handling. Mr. Heath, who made these observations upon chocolate, found that by melting it again in an iron ladle, and pouring it into the tin pans as at first, would for once or twice renew its power; but when the mass became very dry and powdery in the ladle, the electricity could no longer be revived by simple melting. However, he found that if in that state a little olive oil was added and mixed well with the chocolate in the ladle, then on pouring it into the tin pan as at first, the electric power will be found to be completely recovered.

Evaporation and condensation.—It was Mr. Volta who first discovered that the evaporation of water, and of most other bodies either solid or fluid that can be converted into smoke or vapour produced electricity, and not long after it was discovered that the condensation of vapour also produced electricity, but of the contrary kind. Thus when water is evaporated from an infusated vessel, that vessel remains electrified negatively, and if the vapour be received and condensed upon an infusated surface, that surface will acquire the positive electricity. These discoveries, besides their affording an easy explanation of the origin of the electricity in the clouds, fogs, &c. seem to point out a general law of nature; namely, that the capacity of water or other fluids for holding the electric fluid, is increased by the expansion of those bodies into the form of vapour; and is diminished by the contrary operation, viz. by the contraction of the vapour into the form of water. Therefore, in the first case, by imbuing an additional quantity of electric fluid the vapour would leave the bodies from which it departed in a negative state; and in the second case, viz. in the conversion of vapour into water by giving out a quantity of electric fluid, would leave the bodies that touched it in a positive state. And this is analogous to what takes place with respect to caloric and vapour.

The easiest way of shewing the production of negative electricity by evaporation is, to place a metallic cup upon a delicate electrometer, and to put a red-hot coal in it; then on pouring a few drops of water upon the coal, a sudden evaporation takes place, and the instrument signifies with negative electricity. In order to shew the positive electricity which is produced by the condensation of vapour, let a pretty long wire (viz. about a foot long) proceed from the top of the electrometer, and fix some pieces of paper to the farther end of the wire, then if the steam of water which issues out of the spout of a boiling kettle be directed towards the paper, the steam will be condens'd upon it, and the electrometer will open with positive electricity.

The production of electricity by evaporation is not, however, always proportional to the quantity of evaporation; for instance, when water is evaporated from certain substances it produces a considerable quantity of negative electricity, but when evaporated from certain other substances, it produces little of it or none at all. Thus the faking of quicklime produces a copious evaporation, but no electricity; and such is likewise the case with a few other substances.

All the experiments that were made, during some years subsequent to the original discovery, shewed, that if vapour had produced any electricity at all, this was of the negative kind; but at last two remarkable exceptions from this general rule were discovered, viz. one by a learned professor of the academy of Mantua, and the other by Mr. Cavallo, and these exceptions seem to point out a more intimate connection between the electric fluid and other bodies.

The first of the above-mentioned gentlemen found that when water is evaporated by being poured over a red-hot piece of very rusty iron, it would leave the iron and vessel upon which
EXCITATION.

which it flew electrified positively; and the fame would be
the它可以 be the case if the red-hot piece of rusty iron was thrown into
the water: supposing that the latter is contained in an insu-
fated vessel. If the iron be clean and free from rust, the
electricity will be negative; if very rusty, the electricity
will be positive, and if partially rusty, it will acquire little
or no electricity; for in this last case the negative electricity
which arises from the evaporation of water from over the
clean part of the iron, is balanced by the positive electric-
city, which is produced by the evaporation from over the
rusty part. In consequence of this, a rusty piece of iron
will not serve for more than one or two experiments, for,
by rendering it red-hot, part of the rust is shaken off, and
at last it will act like a piece of clean iron. Gardelli Differt.
de Électricité Ignis Natura. § 84, 85, 86.

The other exception (which was discovered by Mr. Ca-
vallo, and is published in the 4th edit. of his Treat. on Él.)
is known by means of red-hot glas. “The various degrees,”
Mr. C. says, “of electric powers that are produced by the eva-
poration of water from different substances induced me to
diversify the experiments as much as I could, in order to
discover, if possible, the reason why these different
effects took place when the evaporation seemed to be equally
quick and copious. Amongst other substances I tried glass,
and found that it generally produced little or no electricity.
The water was sometimes poured upon the hot glass, but
in general the hot glass was dropped into the insulated water
which was contained in a tin cup. However, the difference
of effect was found not to be occasioned by these two dif-
ferent modes of proceeding. Having repeated this experi-
ment a great many times, I at last found that the effect
depended upon the different nature of the glasses. If white
and clean flint glasses be made red-hot, and in that state be
dropped into the vessel of water, a quick evaporation will
follow, and the vessel be electrified positively. If the flint
glasses be not very clear, there will not be any electricity
generated by the evaporation. And, lastly, if the experiment
be tried with glasses more impure, as that of which wine bot-
tles are made, then the negative electricity will be pro-
duced.

“In performing this experiment, it is necessary to take care
that no pieces of coal adhere to the glasses, which will fre-
quently happen when a piece of glass is heated in a common
fire; for in that case negative electricity will be produced
by the evaporation, though the best flint glasses be used.”

Expansion and contraction.—The mere expansion of parts
produces electricity in various instances; such as the dispersion
of powders by projection or blowing; and the electrometer
is affected by the same. It is owing to this electrified state
of the powders, that several curious phenomena are exhibited
by them, which could not otherwise be explained. Thus
the configurations which are produced by projecting pow-
ders upon an electrophorus, or upon any electrified surface,
are owing, in great measure, to this cause; thus also the
dust upon the roads when properly attended to is often found
to expand itself more than it apparently should, and to assume
peculiar movements, in consequence of its actual electrified
state, which may be easily discovered by means of a very
delicate electrometer. For further particulars respecting
this kind of excitation, see the article Electrical Experi-
ments, and the description of Mr. Bennett’s gold-leaf elec-
rometer, under the article Electrometer. Mr. Cavallo, in
his Treatise on Electricity, gives the following directions for
exciting powders. “Inflate,” he says, “a metal plate upon
an electric stand, and connect it with a cork-ball elec-
rometer; then the powder which is required to be tried, being
held in a spoon, or other thing, at about six inches above
the plate, is to be let fall gradually upon it. In this man-
ner the electricity acquired by the powder, being communi-
cated to the metal plate, and to the electrometer, is ren-
dered manifest by the divergence of the threads; and its
quality may be ascertained in the usual manner.”

“It must be observed, that if the powder is of a con-
ducting nature, like the amalgam of metals, or sand, &c.
it must be held in some electric substance, as a glass phial,
plate of sealing-wax, or the like. Sometimes the spoon
that holds the powder may be insulated; in which case,
after the experiment, the spoon will be found possessed
of the electricity contrary to that of the powder.”

It is, however, proper to remark with respect to this
kind of excitation, that the production of the electricity
is in some measure due to the friction; for in the act of
pouring any substance in powder from a plate, a vessel, &c.
a degree of friction between the latter and the former must
necessarily take place.

Contact, or juxtaposition.—That the mere contact of two
perfect conductors would generate, or excite electricity, is
a discovery of a very late date. Mr. Cavallo seems to have
been the first who proved that by dropping a piece of
metal upon another, a slight degree of electricity was
thereby produced. (See the 4th edition of his Treatise on
Electricity, published in 1795; third vol. Experiments on
Metallic Substances.) Mr. Bennett also, independent of Mr.
Cavallo’s experiments, seems to have a claim to this
discovery. The electricity thus produced was so very
light, that it could only be discovered by the nicest meth-
ods; but it was the forerunner of a most astonishing dif-
covey. In short Mr. Volta, by repeating the contact of
metallic substances, and at the same time exposing them
to the action of a saline substance, produced a most pow-
erful electrical instrument, which has opened a new field
of ample and promising aspect, and has furnished the
chemical philosopher with the most active engine of de-
composition.

This, and the other modes of excitation that have been
mentioned subfrequent to it, viz. by means of solution, or
effervescence, and by the action of the animal body,
cannot be well explained, nor thoroughly understood, with-
out a full, historical, and circumstantial account of that
new and admirable branch of electricity, which is now com-
monly called Galvanism; but which in justice ought rather to be
called Voltaism; and as it would be useless to fill this Cyclopedia
with repetitions, we must refer our readers to the articles of the two last mentioned
denominations, wherein those other modes of excitation are parti-
cularly described.

Excitation of Heat—The temperature of bodies is rais-
ed either by the approach of a body hotter than themselves,
or by the extrication of heat from the bodies themselves,
occasioned by some particular action or disposition. The
former of these methods of elevating the temperature is
a mere communication of heat; for that principle contin-
ually tends to diffuse itself amongst surrounding bodies,
until they all acquire the same degree of temperature. The
latter is called the excitation of heat, since an elevation of
temperature takes place amongst bodies which were not
hotter than the surrounding bodies a short time before.
Thus, when a person stands before a common fire, heat is
said to be communicated to him, but with respect to the
fire itself, the heat is said to be excited, or produced by
that particular decomposition of fuel which is called com-
bustion. Thus also heat is excited by friction, by the
mixture of water with sulphuric acid, and by a great many
other
other means; but it is communicated by the rays of the fun.

The means by which various degrees of sensible heat are produced and communicated, are not more than eight; viz. 1. Animal heat, or that power in animals which keeps them warm, and enables them to communicate heat to other bodies. 2. Compression. 3. Friction, or percution of hard bodies. 4. Electricity. 5. Mixture. 6. Fermentation, or putrefction. 7. The fun's rays; and, 8. The inflammation of fuel. However, by excluding the consideration of the fun's rays for reasons already assigned; by comprehending animal heat, fermentation, and inflammation under the general denomination of decomposition; and by referring the action of electricity to friction; the various modes of exciting heat, which demand our consideration in the present article, may be reduced to four; namely, comprefion, friction, mixture, and decomposition, and even this number may be diminished by two, since, as it will appear in the sequel, both friction and mixture may be comprehended under the head of comprieffion; for in these two cases the excitation of heat seems to be occasioned by the comprefion or concentration of the integrant parts. We shall, however, for the sake of perfeftncc, treat diftinctly of the above-mentioned four modes.

The flattening or stretching of metallic substances, whether it be effected by means of the hammer, or screw presses, or flattening mills, or wire drawing, or any other such like means, is constantly attended with an excitation of heat, and a comprefion of the metallic substance. The former of these effects is perceived by the feel, or, more accurately, by the thermometer; the latter by an increafe of specific gravity in the substance that has been operated upon. Not only the metals, but all other substances that are susceptible of comprefion, fuch as wood, cotton, the aerial fluids, &c. are likewise heated by the fame means. On the other hand, water, hard flones, and all fuch bodies as cannot be condensed into a smaller space, at leat not in any confiderable degree, will not be heated by the above-mentioned means.

The heat, which is thus excited, differs in degree according to the nature of the subftance, the violence of the preffure, and the quicknefs of the operation; thus a metallic subftance, powerfully and quickly compreffed, becomes hotter than a piece of wood similarly treated, and hotter than if it were preffed gently or flowly; for with a gentle preffure little heat is excited, and when the preffure is applied flowly, the heat is diffipated nearly as fast as it is excited.

A dexterous blacksmith, by giving a dozen or twenty smart strokes with a hammer, to the extremity of a fledge iron rod upon an anvil, will render that extremity of the rod vividly red-hot, even in the day light; and this is the way by which several blacksmiths light the fire of their forges when they go to work in the morning. With regard to this operation, Dr. Black, in his Lectures, remarks, that the fame extremity of the iron rod cannot be rendered red-hot a fcond time by hammering, unlefs it be first annealed, or softened in the fire. "On account," he says, "of this and other fafts, I began to fufpect that malleability and ductility of metals depend on a certain quantity of latent heat exifiting in them, which being extricated by hammering, the metals remain rigid, and require to be placed in the fire or annealed, in order to recover that latent heat."

A mixture of oxygen and hydrogen gales, if comprefTed, takes fire, and explodes with great violence. The mechanical condensation of vapour, and of all the aerial fluids, is attended with a confiderable elevation of temperature. The condensation of common air excites a confiderable degree of heat, and, when quickly performed, it gives a variety of combustibles, such as cotton, charcoal previously warmed, tinder, &c; and upon this principle a curious instrument has of late been contrived, by which a candle or fire may be lighted. It is nothing more than a small fire-ring, or little condeffer, about six inches long, and not much above a quarter of an inch in diameter, (meaning the diameter of its cylindrical cavity.) It has a pitton, the rod of which comes out at one end, and a flop-cock at the other end; this flop-cock is not perforated quite through, but only little more than half way, so that its cavity may either be exposed to the external air, or it may be turned towards the cylindrical cavity of the fire-ring. The operation is performed in the following manner: the pitton is first drawn out as far as the extremity of the fire-ring, a little br. of amadure, (more commonly known by the name of German tinder,) is placed into the cavity of the flop-cock, which is afterwards turned towards the cylindrical cavity of the fire-ring; this done, the pitton is pushed in quickly and forcibly, with one smart stroke, by which means the sudden condensation of the air excites a degree of heat sufficient to set fire to the tinder; and in fact if the flop-cock be turned outwardly immediately, after having pushed the pitton in, the tinder will be found burning, and a match may be lighted by it.

From a general consideration of the effects of comprefion, it appears that the caloric, or that principle to which the effects of heat are attributed, is contained within the pores of other bodies, somewhat like water in the cavities of a sponge, and that by comprefsing the body, part of that caloric is difengaged, and becomes sensible heat. Thus when a mixture of oxygen and hydrogen gales is quickly and forcibly condensated, that operation forces the gales to abandon a quantity of caloric, which becomes sensible heat, and as it cannot be diffipated immediately, rifies their temperature to a degree insufficient for their inflammntion. This explanation is corroborated by the converse of the above operation, viz. by expansion; for when gales are expanded, they absorb an additional quantity of heat, which does not raise their temperature.

Friction is well known to excite heat, the degree of which differs in proportion to the nature of the bodies concerned, and the force which is employed. This effect of friction is so commonly experienced, and so generally used, as to require but little illustration. Rubbing the hands against each other, or against any part of the body in order to excite heat, is a general practice. Filing, turning, grinding, striking a piece of steel against a flint, the motion of the axles of wheels in their holes, &c. are common and well-known instances of friction, which excite heat. In these cases the consideration of two remarkable circumstances forcibly lead us to conclude, that the heat is excited by the comprefion of the parts of the bodies concerned. One of the circumstances alluded to is, that comprefion is the necessary conquence of friction; the other is, that such substances as are not compreffeable, or the compreffeability of which is next to nothing, cannot be heated by means of friction.

Thus Dr. Irvine says, in his Lectures, "The most violent agitation of simple fluids, such as water or mercury, will not sensibly affect the thermometer. Heat is produced by agitation on those fluids which are compound, and whose state of existence is changed by the agitation; such as milk, and the solution of certain salts in water."
Dr. Joseph Read found that by agitating water in a tin vessel, or in a glass one for a few minutes, the temperature of that fluid was raised about eight degrees, as it appeared from a thermometer left in it all that time. We are, however, strongly inclined to suspect that this apparent result was owing to some fallacy in the mode of conducting the experiment.

It seems, therefore, most probable, that friction produces a compreッション, and that the caloric is expelled from the bodies concerned, so as to become sensible heat, in consequence of that compression.

The hypothesis most in accordance with this theory is that of Professor Rumford, who instituted some capital experiments, which are described at large in the Philosophical Transactions, and in which he succeeded in setting a quantity of water actually a boiling by the friction of metal against metal. In short, the metal submitted to friction was enwrapped by water, and air was carefully excluded from the surfaces in motion; yet the water became hot, and was kept boiling a considerable time. In this experiment the only obvious source of caloric, from without, is the count images, since the borer employed to produce the friction; if it be true, that the water could not at the same instant be in the act of giving out and receiving heat. Mr. Wm. Henry (Trans. of the Manchester Society, vol. v. p. 2.) reasoning upon this experiment of count Rumford, says, "I cannot admit that the argument is demonstrative in proving the evolved caloric not to be derived from external substrates; for no abdurance is implied in supposing that a body may be receiving caloric in one state, and giving it out in another." Thus these gentlemen seem to exclude the action of the compression between the metallic bodies, which is occasioned by the friction, and upon which the whole effect seems most probably to depend.

With respect to this excitation of heat by means of friction, two useful practical considerations naturally occur; viz. to determine what kinds of friction are capable of producing the greatest degree of heat, and in what manner the heat which arises from the friction of the parts of machinery in general, may be prevented.

The production of heat, and of actual fire, by the friction of wood against wood, seems to be the first that occurs to the human being, since the materials necessary for it are to be met with everywhere, and do not require any previous preparation, excepting a trifling adaptation of shape. In fact all rude nations that have notion of fire, light their fires by this means. For this purpose, a piece of wood is laid flat nearly in an horizontal situation, and another slender piece of wood is rubbed with one extremity backward and forward over the surface of the former, until it excites heat enough to set fire to the dust that has been abraded from the wood by the friction. Otherwise a blunt pointed piece of wood is held perpendicularly over an horizontal piece, with its point in a little cavity on the surface of the latter, and is worked therein, like a drill, by rolling it between the hands of the operator, after the manner of a chocolate mill. Though this operation may at first sight appear to be easy and simple, and though it be readily performed by the individuals of rude nations; yet certain it is that the practice of it is not easily acquired; and in fact there are very few perfons in Europe who are able to succeed in it. Professor Bartholdy says, that the best kinds of wood for this purpose are, box wood rubbed against mulberry, or laurel against poplar, or against ivy. But the use of this mode of exciting heat amongst all civilized nations is superceded by the incomparably easier, and much more effectual method, of striking a piece of steel against the edge of a siliceous stone. In this operation small particles of the steel are violently compressed and scraped off in an ignited state, so as to fire tinder, gun-powder, &c. The very common and general use of this method, for domestic convenience, for gun-balls, &c. renders any further descriptions of it perfectly useless.

We have ventured to refer the excitation of heat by electricity, to friction, in consideration that electricity does not excite any heat, unless it is actually passing through bodies, which in some measure obstruct its free passage. But we must refer the reader for the further consideration of this matter to the articles which relate to electricity.

It is a matter of great importance in mechanics to prevent, or, at least, to diminish the heat which is excited by the friction of the parts of machinery in general; and for this purpose the common practice is to interpose something of a lubricating quality between the contiguous parts of machines, viz. something which may hinder the too intimate contact of the parts, and whose particles are easily separated from each other. On various considerations olive oil has been found superior to any thing else in metallic machinery, and especially in watches and clock-work, when steel works in metal or in hard stone. Where wood and metals work against each other, hog's lard, or mutton-fuet or such other fat or grease, is most useful; and when wood works against wood, then the powder of black lead is found to be the most useful.

The heat which is excited by the mixture of certain bodies, comes next under consideration; the influences of this kind are very numerous, and different degrees of heat may be excited by this means, as from actual inflamation. The following are selected. If spirit of wine be mixed with water, the mixture will instantly become hot enough to be perceived not only by means of the thermometer, but likewise by the mere application of the human hand. This heat will be gradually dissipated, so that in a few minutes' time that mixture will be found to have acquired the temperature of the surrounding bodies. On mixing a quantity of the strongest sulphuric acid with an equal quantity of water, a degree of heat is excited which exceeds that of boiling water. If a mixture of nitre and fulhoric acids be poured upon an inflammable essential oil, such as oil of cloves, oil of turpentine, &c.; the latter is thereby so heated as to burst out in flames. Water mixed with quicklime excites a considerable degree of heat. There is a kind of earth found in Derbyshire, which is called black-wood. If a quantity of this earth, as about half a pound or more of it, be sprinkled over with linseed oil, and be then left undisturbed, and exposed to the air, about an hour after it will be found in a state of incandescence, burning far more hot than small coal.

In all the cases of the excitation of heat by the mixture of fluids, two remarkable circumstances deserve particular consideration. One is, that the heat will be excited only when the fluids have a chemical action upon each other, such as between acids and water, spirituous liquors and water, &c.; whereas, if oil be mixed with water, or water with quicksilver, no heat will be excited, because no real mixture will take place amongst these bodies. The other circumstance is, that whenever heat is excited by the mixture of fluids, an incorporation, or a concentration of the substances is observed; for it is always attended with a diminution of bulk. Thus a pint of alcohol and a pint of water, mixed together, will measure less than two pints. These circumstances seem to indicate, that the affinity, or the mutual attraction of the particles of the bodies concerned, occasion...
ions a kind of compre¬hension, in con¬se¬quen¬ce of which a certain part of the caloric is forced out, and becomes fes¬tile heat.

The fourth cause of the excitation of heat is decompo¬si¬tion; and under this head we must comprehend the origin of animal heat, fermentation, putrefac¬tion, combus¬tion, and all other pro¬cesses in which the heat is mani¬fes¬tly excited in con¬se¬quen¬ce of the decom¬position of compound bodies. But as these pro¬cesses will be found treated at large under the articles of their peculiar denomi¬na¬tions; we shall here only add a few remarks on the heat which is produced by decompositions in general. In short it feems that the caloric, like several other principles, enters more or lefs into the for¬mation of compound bodies, and that in the decom¬position of these bodies, where certain principles are set at liberty, and other new combinations ensue, the caloric also undergoes its changes; viz. it is expelled from certain bodies, and is either set en¬tirely at liberty so as to become fensitive heat, or is par¬tiall¬y re¬in¬foc,l in which latter cafe but little heat is manife¬sted. This liberation of caloric is sometimes effected slowly, as in the proc¬es of animal life, in fer¬men¬ta¬tions, &c. or it proceeds so quickly and abundantly, as to occa¬sion au¬toma¬t¬ic al¬layma¬tion. By the concurrence of various favourable cir¬cum¬¬stances it happens, not unfrequently, that decom¬po¬si¬tions and spontaneous in¬fiamma¬tions take place among bod¬ies, which, in gen¬eral, are not capable of produc¬ing such phenomena. Thus, vegetable sub¬fi¬l¬u¬l¬a¬tu¬nes that have under¬gone putrefac¬tion, when laid in facks of cloth in contact with the ambient air, as coffee, the meal of grain, French beans, &c. have fometimes been known to take fire. The like effect is also produced by the generation of sulphurated and phosphorated hydrogen gas. The caufe of sub¬fe¬rene¬rous live¬s and volc¬a¬noes in great mea¬re has been atri¬bu¬ted to the decom¬po¬si¬tion of pyrites, or metallic sulphur¬ites, buried in the interi¬or of the earth. These ma¬fes of pyrites are decom¬posed by the contact and concurrence of wa¬ter and air; and the decom¬po¬si¬tion is always accompanied by a great extrac¬tion of caloric, and a difengagement of a very in¬flammable gas, called sulphur¬ated hydrogen gas. This gas is in¬flamed at an elevated temperature, and communicates the in¬fiamma¬tion to other combustible that may be at hand.

With re¬spect to the heat which is produced in fer¬men¬ta¬tions, several que¬stions of economi¬cal ufe may be afked, such as the determination of the cheap¬fepest and most economical mode of employing fuel, the method of preventing the diffipa¬tion of heat, &c. but these particulars will be found under the articles Fire, Fuel, and Heat.

EXCITEMENT, in Dr. Brown's Syllion of Medicine, nearly fynonymous with life. See Excita¬bility.

EXCLAMA¬TION, of Ecpho¬nesis, in Rhetoric, a fi¬gure, wherein, by rai¬fing the voice, and ufing an interjection either express¬ly or under¬foold, we telli¬fy an uncommon ar¬du¬our, em¬o¬tion, and pa¬ffion of mind; and ex¬press the magni¬tude of the thing, or the impor¬tance of the oc¬ca¬sion.

Such is, "O heavens! O earth!" &c. Such also is that of Cicero again¬st Catiline: "O times! O times! this the feme knows, the conful fees—and yet he lives! Lives, said I? nay, and comes into the feme!"

In English the interjections O! or oh, alas! or good God! are generally ad¬jo¬ined in an exca¬la¬ma¬tion. In Latin they ufe O! heu! eheu! ah! vah! pro fuper! pro fun¬dum atque homine fidentem! Sometimes, however, the interjection is under¬foold, as, Woe is me! Miferum me! boccine facculam!

Cicero ufe this figure to ex¬press a variety of pa¬ffions. It often denotes ren¬ten¬ment or indemnac¬tion. Thus, after his return from ban¬i¬fhment, he ex¬claims, (Pro Sext. c. 12.) "O mournful day to the Senate and all good men; ex¬ca¬la¬mi¬tous to the flate, affi¬cu¬tive to me and my family; but glorious in the view of po¬fere¬try!" At other times it is ufed to ex¬press diftain or contempt. Thus, speaking of Pompey's howe, which was bought by Mark Antony, he says, (Philipp. II. c. 12.) "O con¬flam¬mate impi¬dence! Dfre you go within that howe! Dare you enter the ven¬e¬rable threshold, and shew your audacious countenance to the tutelar deities which reside there?" It is no lefs adapted to ex¬press grief. Thus, Cicero fays of Milo, (Pro Milone, sub fin.) "O that happy country, which fhall receive this man! ungrateful this, if it banifh him! miserable, if it lose him!" It also ferves to ex¬press admiration, as when Cicero, in compliment to Cefar, fays, (Pro Ligur. c. 2.) "O admirable ecle¬mency! worthy of the greatefe praise, the highest em¬coniums, and moft la¬ting monuments!" It has its ufe alfo in ridicule and irony. Thus Cicero, in his oration for Ballhus, deriding his accu¬fier, ex¬claims, "O excellent in¬ter¬preter of the law! master of antiquity! corre¬ctor and ame¬nder of our con¬stitu¬tion!" The fa¬cred writers fometimes ufe it by way of in¬treaty or with, Pf. lv. 6., and at other times in exula¬tions and triumph, fo St. Paul ex¬claims, (1 Cor. xv. 25.) "O death, where is thy tri¬umph! O grave, where is thy vic¬tory!" It is fometimes joined, as in one of the preceding in¬fances, with the figure Inter¬rogation. It generally follows the repre¬ta¬tion of the thing which excita¬ions it; though it is fometimes ufed to intro¬duce it, and thus it ferves to prepare the mind by ex¬cit¬ing its at¬ten¬tion.

EXCLUSION, the act whereby a per¬son or thing is ex¬cluded, i. e. shut out or fet aside. A crown imports an ex¬clusion from the papacy; he appointed a ftranger his heir, in exclusion of his own relations.

Great efforts were made towards the clofe of the reign of king Charles II. to procure a bil plex of ex¬clusion, for fetting aside the duke of York, the king's brother, on ac¬count of his being a papif. See Crown.

Exclusions, in Mathematics. The method of exclu¬sions, is a way of coming at the folution of prob¬lems (in numerical cafes) by previously ex¬cluding, or ex¬cluding out of con¬ideration, fuch numbers as are of no ufe in sol¬ving the que¬tion; whereby, of con¬quence, the proc¬eds may be regularly and judiciously abbrevi¬ated. Exclusive, is fometimes ufed ad¬jevly, for the force or power of exclu¬sion; as, a patent carries with it an exclusive privilege.

Somes¬times it is alfo ufed adver¬sally; as, he fent him all the Gazettes, from No. 197, to No. 500 exclu¬sive; i. e. all between thofe two numbers, which them¬selves were ex¬¬¬¬cepted.

Exclusive Propositions, are thofe wherein the predic¬¬a¬te fo agrees with the subjeqt, as to agree with no other. See Proposition. E. gr. Virtue alone makes nobili¬ty: no¬thing elfe renders a man truly noble.

EXCE¬CARI, in Botany, from exccare, to deprive of fight, because, according to Rumphius, the failors who firit landed on the iflands of the Emil Indies, where this tree grows, were greatly incommoded, and sometimes even en¬tirely blinded, by the acid juice which fiptered forth, as they felled the wood for burning. Linn. Gen. 515. Schreb. 677. Jufl. 390. Gartn. t. 108. Claif and order, Diccia Tri¬andra. Nat. Ord. Triceoec. Linn. Euphorbier, Jufi.

Exc.

angular; styles three; stigmata simple. Peric. Capsule three-lobed, smooth, of three valves, each marked with a furrow, and three cells. Seeds solitary, smooth.

E. Aegyptiaca. Linn. Sp. Pl. 1451. (Arbor excelsa; Rumph. Amb. v. 2. 237, t. 79, 80.) Native of rocky, dry, and sandy places about the coast in Amboina and other East Indian islands, flowering in January and February, as well as occasionally at other seasons. It forms a crooked inelongant tree. The leaves are alternate, elliptical, bluntish, smooth, more or less leaved or bluntly creste. Catkins cylindrical, lateral. Capsule the size of a pea. The seeds milk with which the tree abounds, causes the inhabitants of the countries where it grows to hold it in abhorrence; but Rumphius says it is chiefly dangerous to the eyes. The bark, as well as the milk, are used in medicine, being powerfully purgative. There seems to be no propriety in applying the Greek name 

Greek name 

to this tree.

How far the Cammetti, Rheede Hort. Malab. v. 5. 89. t. 45., is a distinct species from the above, we have not materials to decide. Its leaves are more pointed and less distinctly waved. Koening gathered it by the sea side on the coast of Coromandel, in low ground, overflowed during the rainy season, which does not agree with what Rumphius relates of the following.

Loureiro describes what is probably another species, by the name of E. cochinchinensis, in p. 612. of his Flora Cochinchin. This, he says, has beautiful shining leaves, red underneath, for the sake of which it is cultivated as an ornamental shrub. Its qualities are aromatic and glutinous, nor did he ever hear of its being hurtful to the eyes.

EXCOMMUNICATION, an anathema, or ecclesiastical censure, and punishment: whereby a heretic is cut off from the society of the faithful, or an obstinate sinner from the communion of the church, and the participation of the sacraments.

This censure of excommunication was originally instituted for preserving the purity of the church; but ambitious ecclesiastics converted it by degrees into an engine for promoting their own power, and inflicted it on the most frivolous occasions.

The power of excommunication properly belongs to the bishop; but he may delegate it to any grave priest, with the chancellor.

Every excommunication should be preceded by three public admonitions, two days at least distant from each other; but this is to be understood of excommunications imposed by the ecclesiastical judge; for those imposed by the law are incurred to all intents and purposes the moment the action is committed.

These latter are called excommunications by the canon, or late sententiae; and are so very numerous, that it would be difficult even for the best canonists to give an exact list of them; there are fifty in the Clementines; twenty in the bull Cæna Domini; &c. Wilkins's Mag. Brit. Con. vol. iv. p. 664. Rebuffes, on the Concordat, reckons up sixty penalties accruing upon excommunication.

Excommunication is founded on a natural right which all societies have, of excluding out of their body such as violate the laws thereof.

Excommunication is either major or minor, i.e. greater or lesser; the first, which is that understood when we say, simply, excommunication separets, or cuts off, the delinquent, not only from the sacraments, but from all communion and fellowship with other Christians. The second, or lesser, only excludes from the participation of the sacraments.

The greater excommunication, called alio ab homine, is when a prelate, or his deputy, excommunicates any man personally, and interdicts him all society with the faithful, all use of sacraments, &c.

In the ancient church, the sentences of the greater excommunication were solemnly promulgated four times in the year, with candles lighted, bells tolling, the crofs, and other solemnities.

The lesser excommunication is incurred pleno jure, by having any communication with a person excommunicated in the greater excommunication. And this too imports a privation of communion, but not an interdict from entering the church, or having commerce with the faithful.

Anciently, the excommunicated were obliged to procure abjuration from their bishop, and make satisfaction to the church in forty days' time; otherwise they were compelled to it by the secular judge, by a seizure of their effects, imprisonment of their persons, &c. (See Excommunication Capitado.) In France they were allowed a whole year.

By an edict of St. Louis, in the year 1228, vaillants, tenants, &c. were deposed, or freed from the oath of fidelity, homage, &c. they had taken to their lords, or inferiors, when excommunicated, till they had made their submission.

In Spain, to this day, a person who is not absolved from his excommunication in a year's time is deemed a heretic. There was a time, when the people were fully convinced, that the bodies of excommunicated persons, unless they were first absolved, would not rot, but remain entire for several ages, a horrible spectacle to posterity! as is attested by Matthew Paris, and other writers. And the Greeks are full of the opinion, and affirm, they have many proofs thereof, as is shewn by Du-Cange, from the testimony of a vast number of authors.

By the laws, an excommunicated person was not to be buried, but the body flung into a pit, or covered with a heap of stones; which were called imboldac corpus. And by the rubric, in the Book of Common Prayer, the burial office shall not be read for any that die excommunicated. See Funeral, &c.

In the ancient church, there were diverse degrees of excommunication. In effect, excommunication did not always import an interdict of the sacraments; but frequently, a separation, or kind of excommunication, between the several churches, or a fulmination of spiritual communion between the bishops. But afterwards the occasions of excommunications growing more frequent, they began to use it with less omen and reservedness.

In the ninth century the ecclesiastics were continually making use of this spiritual weapon, to repel any violence or afores offered them; and time and familiarity rendering offenders more and more obdurate, they proceeded, by degrees, to rigours unknown to antiquity; as the excommunicating of whole families, or provinces; prohibiting the exercise of all religion therein; and even accompanying the excommunications with horrible ceremonies, and direful imprecations.

In the tenth and eleventh centuries, the severity against the excommunicated was carried to its highest pitch; nobody might come near them, not even their own wives, children, or servants; they forfeited all their natural legal rights and privileges, and were excluded from all kinds of offices. Thus was an excommunicated king reduced to the condition of a private man. By thus stretching the power of the church to extravagance, they rendered it contemptible.
The power of excommunication was lodged in the whole church in general; that is, the bishops and priests had the administration thereof by and with the consent of the people, which was practised even in St. Cyprian's time. But afterwards they ceased to consult the people about the matter; the bishop and clergy arrogated the whole power to themselves. Reconcile, however, might still he had to the synod of the province, to judge of the validity of an excommunication.

Excommunication was also practised among the Jews, who used to expel from their synagogue such as had committed any grievous crime. See the Gospel according to St. John, ix. 22. xii. 42. xvi. 14. And Joseph. Antiq. Jud. lib. ix. cap. 22. and lib. xvi. cap. 2.

The Effraim, when excommunicated, durst not so much as receive food at any person's hand, for fear of violating their oath, but contented themselves to live on herbs; insomuch that they frequently perished and died for want. See Joseph. de Bell. lib. ii. cap. 12.

Godwyn, in his Mofes and Aaron, distinguishes three degrees, or kinds, of excommunication among the Jews.

The first he finds introduced in St. John ix. 22. The second in St. Paul Epift. i Cor. v. 5. And the third, in the 1st Ep. to Corinth. xvi. 22. See Niddui.

The rule of the Benedicitions gives the same excommunication to the being excluded from the oratory, and the common table of the house in our ins of court called discomposing. This was the punishment of such monks as came too late.

Excommunication, or a being secluded, or cut off from a participation in the mysteries of religion, was also in use under paganism.

Such as were thus excommunicated were forbidden to sit or attend at the sacrifices, or to enter within the temples; and were afterwards delivered over to the demons and furies of hell, with certain imprecations; which was called among the Romans, diris devovere. See Execration.

The Druids, among the ancient Britons and Gauls, likewise made use of excommunication against rebels; and inadverfed the communion of their mysteries to such as refused to acquiesce in their decisions. See Druids.

That this is the true origin of the extensive and horrid influence of the European and papal excommunication, will appear evident by the following passage of Cesar, De Bello Gallico, lib. vi. cap. 13. "Si qui aut privatus aut publicus Druidam decreto non fetit, sacriheis interdictum. Hic pena apud eos eft graviiffima. Quibus ista eft interdictum, in numero impiorum et sceleratorum habentur, ab ipsis ommem deprecat, aditum eorum fermoque defagitur, ne quid ex contagione incommodi accipiant; neque ipse potestibus sua redditur, neque homines alias communicaverint." EXCOMMUNICATIO CAPIENDO, so called from its effects, or Significatio, thus denominated from the bishops' certificate, a writ directed to the sheriff, for the apprehension of one who stands obstinately excommunicated the space of forty days.

Such a one not seeking absolution, hath, or may have, his contempt certified into the chancery; whence this writ issues for taking him up and imprisoning him in the county gaol, without bail or mainprice, until he is reconciled to the church, and such reconciliation is certified by the bishop. EXCOMMUNICATO DILIBRANDO, is a writ directed to the under sheriff, for the delivery of an excommunicated person out of prison; upon certificate of the ordinary of his conformity to the ecclesiastical jurisdiction. F. N. B. 62. EXCOMMUNICATO RECIPIENDO, is a writ whereby persons excommunicated,
EXC,

excommunicated, being for their obstinacy committed to prison, and unlawfully delivered from thence before they have given security to obey the authority of the church, are commanded to be fought for and laid up again.

EXCORIATION, in Surgery. A part is said to be excoriated, when it is deprived of its cuticle, by reason of inflammation, the action of irritating matter, or of stimulating substances, &c. applied to the skin.

Very superficial ulcerations are, also, frequently denominated excoriations.

In consequence of inattention to cleanliness, and not occasionally washing away the festuous secretion, which is naturally produced on the prepuce, the matter acquires an irritating acid quality, brings on inflammation all round the corona glandis, followed by extensive excoriations and suppuration. This sort of cafe is seriously annoying to the patient, on account of the violent itching, and troublesome foemen, which always attend the complaint. The disorder has sometimes been named the falsa gonorrhoea, and the patient is often rendered very uncaiy in his mind by an apprehension of the affection being venereal. Indeed, ignorant and careless practitioners have occasionally mistaken mere excoriations for chances, and, quite improperly, have prescribed a course of mercury.

The proper treatment consists in washing away all the acid secretion under the prepuce with some soap-fud; injecting under the same part, four or five times a day, the faturine lotion; and keeping linen, wet with this application, round the extremity of the penis. The excoriations, if very bad, are to be dressed with the faturine ointment. The prepuce, if much swollen, and in a state of phymoey, should have two or three leeches put upon it; but the principal means of cure is attention to keeping the parts clean, and tenderly washed with plenty of soap once or twice a day. As in all other cases of inflammation the bowels ought to be kept open.

Eccoration of the nipples is a most distressing complaint. It is more common in the fift, than the subsequent nursings, and when independent of any disease in the child’s mouth, is owing to the irritation occasioned by the fuction. In many instances, a cure may be effected by bathing the parts with a little port wine, or brandy. A more effectual remedy is said to be the tincture of opium.

EXCORICATION, the act of stripping off the cortex or bark from any thing; called also decortication.

EXCREMENT, in Chemistry. See Feces.

EXCREMENT, in Physiologv, is the residue of our food, after the nutritious particles have been extracted from it, and it has undergone certain changes by its residence in the large intestine. See Digestion.

EXCREMENT is also attributed, by way of analogy, to plants. Thus gums, diverse juices, balms &c. issuing spontaneously from their respective trees, are sometimes called excrements.

EXCRESCE, in the language of Surgery, implies a preternatural protruberance, or any morbid growth, which projects out of the substance or surface of a part. When the disease is involved in the surrounding flesh, though it may be attended with a considerable swelling, it does not rank as an excrescence, which word essentially signifies that the tumour, or whatever the disease is, grows out of the part. Pimpls, polypi, and warts of all kinds, are very often, and with strict propriety, denominated excrescences.

Excrescences, of the nature of warts, are particularly apt to grow about the anus. Some of them are generally regarded by surgical authors as venereal complaints, because they sometimes get well under a course of mercury. This, however, is a very fallacious criterion of a disease being syphilitic; for mercury is a cure for numerous affections besides venereal ones. Some surgeons have doubted whether there is any such thing as a really venereal excrescence; and as far as our observations extend, all those warty growths, which arise about the anus and perineum, and are commonly regarded to be of a syphilitic nature, may be cured upon the same principles as any other ordinary tumours, not of a specific kind.

Excrescences in general, not being original parts of the body, are known to be weak in the vital power, and to be incapable of bearing the action of such stimulating applications as would not destroy a part, which may be said to enter into the natural composition of the body. Hence it is, that sprinkling on warty excrescences a powder containing of savin and arugo aris, in equal proportions, generally effects a cure. The swellings are partly diminished by absorption, and partly by sloughing. We have never seen about the anus any excrescences which could withstand this application.

But the plan which we particularly recommend to be adopted, when such excrescences are large and numerous, as they frequently are, is to remove them at once with a knife, or a pair of forceps. When they grow from a narrow neck, their destruction might be accomplished by tying them with a ligature. The latter method, indeed, is often practiced by surgeons who are fearful of hemorrhage, or whose patients have a remarkable dread of a cutting instrument, even in cases in which the object could be fulfilled much more easily, and with less pain, by means of excision; that is to say, in examples in which the base of the swellings is rather broad. Indeed, where the excrescences are connected with the skin by a wide root, the mode of removing them with a ligature becomes exceedingly troublesome and painful; for the practitioner is first under the necessity of introducing, through the centre of their base, a needle armed with a double ligature. The needle being cut off, one ligature is then to be firmly tied over one side of the root of the tumour, and the other over the opposite one. In this manner the supply of blood to the excrescence is suppressed, and the part sloughs away. Sometimes when the base of the disease is very broad, and the ligature has not been applied with due tightness, it becomes necessary to apply another one, the doing of which is attended with much, if not more, pain than the first operation.

Upon the whole, when the excrescences are small, we prefer stimulating them with the powder of savin and arugo aris; when they are large, we recommend extirpating them with a cutting instrument.

EXCRETION, from excrete, I throw off, or separate, is the separation of any impeded noxious matter from the blood in any of the organs of the animal body. The process itself is not essentially different from that of fecution. But the latter term is applied to those substances which, when formed, are applied to useful purposes in the animal economy. Thus the mucous membranes impart to them a necessary moisture, and defend them from the action of the foreign matter which comes in contact with them; the serous exhalation of serous membranes preserves them constantly smooth and polished, and therefore in a fit state for their impeded surfaces to move without any obstacle, &c. The excretions are matters impeded to be noxious to the body, and to be separated on that account, as the urine, bile, perpiration, &c. The matters voided from the large intestine, constituting the refuse of our food, are often called the alvine excrescences.
EXCRETOIRE, is applied to certain little ducts or vessels in the fabric of the glands. Excretory ducts are the tubes through which the humours separated in the several glands are emitted or discharged out of the gland, into some convenient receptacle or emaculatory.

A capillary artery, to which a capillary vein is joined, with an excretory duct, convoluted or wound together, make up the body of the glands, the organs of secretion. The excretory ducts spring from the extremities of the arteries and veins, and carry off a liquor separated from the blood. Drake.

The lymphatic glands have either lymphœducts for their excretory ducts, or lymphœtubes, as in the mesentery. Idem.

EXCURSION, in Astronomy. See ELONGATION.

EXCURSION, circles of. See CIRCLES.

EXCUSABLE Homicide. See Homicide.

EXCURSUS, in Church History, a term used to denote slaves, who, flying to any church for sanctuary, were excused and pardoned by their masters; but these were obliged to take an oath to that purpose, before they could have them again; and if they broke the oath, they were punished and fined as persons guilty of perjury.

EXDORF, in Geography, a town of Germany, in the county of Hesseberg; 7 miles S.E. of Meinungen.

EXE, a river in England, has its origin among the wild eminences of Exmoor, in the western corner of Somersetshire, and after uniting with the Barle, enters the confines of Devonshire, near Exe bridge; thence flowing near Bampton, it sinks into a rich wooded vale, and passing Tiverton, has its current increased by the streams of the Loman. Soon after, the Creedy, from Crediton, in the north-west, and the Culm, or Col mixer, from Cullompton, in the north-east, intermingle their waters with the Exe, and the vale expanding, opens into a beautiful plain, encircled by towering eminences, clothed with wood. Passing Exeter, the river proceeds through a fine range of meadows to Topsham, where meeting the tide, and suddenly widening to an extent of more than a mile, it becomes navigable for vessels of several hundred tons burthen. Hence spreading into a grand estuary, it rolls onward; but its direct course being impeded by a vast sand-bank, called the Warren, it winds to the eastward, and flows into the British channel near Exmouth, its whole course being about 60 miles. See CANAL.

EXEA DE LOS CAVALLEROS, an inconvenient town of Spain in the province of Aragon, seated between two rivulets, in the northern part of the province. Its surname commemorates the bravery of some French and Gascon cavaliers, when Alphonso I. king of Aragon, took it from the Moors. N. lat. 42° 6'. W. long. 15° 6'.

EXEAT, in Church Discipline, a Latin term used for a permission which a bishop grants a priest to go out of his diocese; or an abbot to a religious, to go out of his monastery.

The word is also used in several great schools for leave given a scholar or student to go out. His master has given him an exeat.

EXECRATION, EXECUTIO, among the Ancients, a kind of punishment, consisting of direful curses and marks of infamy. Livy relates an instance of it, which was used against Philip king of Macedon, by the Athenians. A general assembly of the people being called, they made a decree, that all the statues and images of that king, and of all his ancestors, both of the male and female sex, should be demolished, and their very names railed; that all the festivals, aediles, prœfices, and whatever else had been instituted in honour of him, should be profaned; that the very place where there had been any monument or inscription to his honour, should be detestable, and that nothing should be set up, or dedicated in it, which could be done in clean places; and, lastly, that the public prayers, as often as they were said for the Athenian people, allies, armies, and fleets, should as many times detest and execrate Philip, his children, kingdom, land, and sea forces, and the whole race and name of the Macedonians.

Cornelius Nepos, in his life of Alecibiades, calls it devotion.

At the taking or demolishing of a city, it was frequent to pronounce direful curses and execrations upon any person who should endeavour to rebuild it; which some imagine was the reason that Troy could never be raised out of its ashes, though several pers was attempted it, being devoted to eternal and irreparable ruin by Agamemnon. This seems to have been a very ancient custom, and derived from the Eastern nations; for we find Joshua, at the destruction of Jericho, to have fixed an impredication upon the person who should rebuild it, which was thought to be accomplished in Hiel the Bethchite many ages after. Potter, Arch. tom. ii. p. 97.

EXEEREBRONCHOS, in Surgery, from ξείος, to abound, and βρόχος, a throst, a term which probably signifies a swelling of the thyroid gland, which affection is now almost always named bronchocele.

EXECUTANT, Fr. in Music, a participle used sblstensively. A musician or performer who executes his part in a band, in the same sense as concertant implies a performer in a concert. See CONCERTANT, EXECUTER, and EXECUTION.

EXECUTED Contrat, Effate, Fine, and Remainder. See the subjunctives.

EXECUTER, Fr. he execute, play, sing, or perform a composition, or piece of music, in all its parts, whether vocal or instrumental, and to let every note and passage be held agreeable to the notation in the score.

As music is an object for the ear, it can only be judged by its effects in the execution. Many pieces of counterpoint look correct and learned on paper, which no real judge can hear without difficulties; and others that look thin, simple, and common, which in the execution afford the highest pleasure, by unexpected effects. Vulgar composers, attentive to symmetry and the filling up all the parts, often appear to be great contrapuntists, while they are judged merely by the eyes; and such composers often have the address to employ so many different instruments, and such a number of parts in their music, that it is with great difficulty a sufficient band can be collected to do justice in the execution. Roufeau.

EXECUTION, the act of executing, i. e. of accomplishing, fulfilling, or achieving any thing to be done.

We say, the execution of a testament; of a law; of a treaty; of a building, or the like.

EXECUTION, in Common Law, signifies the last performance of an act; as of a writ, a judgment, or the like.

Execution of a judgment, denotes the putting of the law in force, or it is the obtaining the possession of anything recovered by judgment of law.

This is performed in various ways, according to the nature of the action upon which it is founded, and of the judgment which is had or recovered. If the plaintiff recovers in an action real or mixed, whereby the seif or possession of land is awarded to him, the writ of execution shall be an hanc facias fe ipsum, or writ of seifon, of a freehold; or an hanc facias possessionem, or writ of possession,
EXECUTION.

of a chattel interdict. (Finch, L. 470.) These are writs directed to the sheriff of the county, commanding him to give actual possession to the plaintiff, of the said goods recovered; in the execution of which the sheriff may take with him the poiffor comitatus, or power of the county, and may justify breaking open doors, if the possession be not quietly delivered. But if it is peaceably yielded up, the delivery of a wagn, a turf, or the ring of the door, in the name of felon, is sufficient execution of the writ. Upon a presentation to a benefice recovered in a quare impedit, or allise of dominum profectum, the execution is by a writ de clero admittere; directed not to the sheriff, but to the bishop or archbishop; and requiring him to admit and hold unto the clerk of the plaintiff. In other actions, where the judgment is, that something special be done or rendered by the defendant, then, in order to compel him so to do, and to see the judgment executed, a special writ of execution lies to the sheriff, according to the nature of the case. As, upon an allise of nausance, or quaedi permittat profecerit, where one part of the judgment is quod nocentum amovitor, a writ goes to the sheriff to abate it, at the charge of the party, which likewise issues even in case of an indictment. (Comb. 10.) Upon a relevin, the writ of execution is the writ de returno baleato; and if the defendant be absolved, the defendant shall have a capias in custorum; but if the plaintiff's tendering the damages, and committing to a fine, the process in custorum shall be stayed. (2 Leon. 174.) In detinue, after judgment, the plaintiff shall have a dmirata, to compel the defendant to deliver the goods, by repeated difficulties of his chattels, (1 Roll. Abr. 737. Rail. Entr. 215;) or also a feire facias against any third person in whole lands they may happen to be, to shew cause why they should not be delivered; and if the defendant shall continue obstinate, then (if the judgment hath been by default or on demur) the sheriff shall summon an inquest to ascertain the value of the goods, and the plaintiff's damages; which (being either so affirmed, or by the verdict in case of an issue, Bro. Abr. tit. Damages, 29.) shall be levied on the person or goods of the defendant.

Executions in actions, where money only is recovered, as a debt or damages, (and not any specific chattel,) are of five sorts: either against the body of the defendant; or against his goods and chattels; or against his goods and the profiss of his lands; or against his goods and the poiffion of his lands; or against all three, his body, lands, and goods. The first of these species of execution is by writ of Cupias ad facias interdictum, which fee. This writ is an execution of the highest nature, inasmuch as it deprives a man of his liberty, till he makes the satisfaction awarded. When a defendant is once in custody upon this process, he is to be kept in arre fuva cufdadia; and if he be afterwards seen at large, it is an escape, which fee; and the plaintiff may have an action thereupon against the sheriff for his whole debt. If a copias ad facias interdictum be fixed out, and a non fesxternum is returned thereon, the plaintiff may sue out a proceds against the bail. The second species of execution is against the goods and chattels of the defendant, and is called a writ of Peli facias, which fee. A third species of execution is by writ of Leveri facias, which fee. This affects a man's goods and the profiss of his lands. This writ is now little used, the remedy by elegit being more effectual. This writ of elegit is the fourth species of execution. Moreover, upon some prosecutions given by statute, as in the case of recognizances or debts acknowledged on statutes merchant, or statutes staple; (purpant to the statutes 13 Ed. 1. de Mercatoribus, and 27 Ed. 111. c. 9.) upon forfeiture of those the body, land, and goods may all be taken at once in execution, to compel the payment of the debt. This proceeds is the fifth species of execution, and is usually called an extent, or extendi facias, which fee. - It is to be observed, that all these writs of execution must be fixed out within a year and a day after the judgment in entered, otherwise the court concludes prima facies, that the judgment is satisfied and extinct; yet, however, it will grant a writ of feire facias, in pursuance of statutes Wills. 2. 13 Edw. 1. c. 45. for the defendant to shew cause why the judgment should not be revived, and execution had against him; to which the defendant may plead such matter as he has to allege, in order to shew why proceeds of execution should not be fixed; or the plaintiff may still bring an action of debt, founded on this dormant judgment, which was the only method of revival allowed by the common law. (Co. Litt. 290.) Blackf. Comm. B. III.

Sir Edward Coke, in his Reports, makes two sorts of executions; one final, another with a quoysque, as only tending to an end.

EXECUTION final, is that which maketh money of the defendant's goods, or extendeth his lands, and delivers them to the plaintiff; which he accepts in satisfaction; and this is the end of the suit, and all that the king's writ commands to be done.

EXECUTION with a quoysque, is that which only tends to an end; as in the case of a capias ad facias interdictum, &c.

This is not final; but the body of the party is to be taken, to the intent and purpose to satisfy the plaintiff; and his imprisonment is not absolute, but till he doth satisfy; so that the body is but a pledge for the debt. 6 Rep. 87.

EXECUTION, Tenant by. See Tenant.

EXECUTION of criminals, must be according to judgment; and the king cannot alter a judgment from hanging to beheading, because no execution can be warranted, unless it be pursuant to the judgment. (3 Inf. 52. 211. H. P. C. 252.) But there are ancient precedents wherein men condemned to be hanged for felony, have been beheaded by force of a special warrant from the king. (Bract. 164. Staund. 13.) And the king may pardon part of the execution in judgment for treason, viz. all but beheading. It has been said by Sir Edward Coke, and Sir Matthew Hale, that the king cannot change the punishment of the law, by altering the hanging or burning into beheading. But others have thought (Toll. 270. F. N. B. 244.), and as judge Blackstone says, more jully, that this prerogative being founded in mercy, and immemorially exercised by the crown, is part of the common law. The court may command execution to be done without any writ; (Finch, L. 475.) though sometimes execution is commanded by writ. (2 Hawk. P. C. 453.) Judgment belongs to the judge; but the execution may be done by the sheriff, or his deputy; and an execution cannot be lawfully made by any but the proper officer, whose warrant for so doing was anciently by precedent on the judge under his hand and seal; as it is still practised in the court of the lord high wardour, upon the execution of a peer; (2 Hal. P. C. 429.) though in the court of peers in parliament, it is done by writ from the king; and if the sheriff, or other officer alters the execution, or any other executes the offender, or if he is killed without the authority of law, it is felony. (2 Hawk. ib.) The usage now is for the judge to sign the calendar, or lift of all the prisoners' names, with their separate judgments in the margin, which is left with the sheriff. As for a capital felony, it is written opposite to the prisoner's name, "Let him be hanged by the neck;" formerly,
and, formerly, in the days of Latin and abbreviation, "inf. per
coll," for jussusdator per collum. And this is the only warn-
ment which the sheriff has for so material an act, as taking
away the life of another. (5 Mod. 22.) Upon this judge
Blackstone observes, that it may certainly affect matter of
speculation, that in civil causes there should be such a variety
of writs of execution to recover a trilling debt, issued in
the king's name, and under the seal of the court, without
which the sheriff cannot legally sit one leap; and yet that
the execution of a man, the most important and terrible
tale of any, should depend upon a marginal note. The
sheriff, upon receipt of his warrant, is to do execution
within a convenient time, which in the country is no left
at ages, a manner form and becoming exacted in itself, both as to the warrant of execution, and the
time of executing thereof; for the recorder, after report-
ing to the king in person the cases of the federal prifoners,
and receiving his royal pleasure, that the law must take its
course, infuses his warrant to the sheriffs, directing them to
do execution on the day, and at the place assigned; and
in the court of king's bench, if the prisoner be tried at the
bar, or brought there by habeas corpus, a rule is made for
his execution, either specifying the time and place. (State
Trials, p. 332. Fott. 43.) or leaving it to the discretion
of the sheriff. And, throughout the kingdom, by statute
27 Geo. II. c. 37. it is enacted, that in case of murder, the
judge shall in his sentence direct execution to be per-
formed on the next day but one after sentence passed. But
otherwise, the time and place of execution are by law no
part of the judgment, as was held by the twelve judges.
(Mitch. 10 Geo. III.) Becaria has well observed, (On
Crimes, &c. ch. 19.) that it is of great importance, that
the punishment should follow the crime as early as pos-
sible, that the punishment of a great fatum or advantage, which
tempts a man to commit the crime, should instantly awake
the attendant idea of punishment. Delay of execution
serves only to separate those ideas, and then the execution
itself affects the minds of the spectators rather as a terrible
fight, than as the necessary consequence of transgression.

"In a case a man condemned to die, come to life after he is
hanged, as the judgment is not executed till he is dead,
he ought to be hung up again. (2 Hal. P. C. 412. 2 Hawk.
P. C. 463.) For the former hanging was no execution of
the sentence; and if a false tenderness were to be indulged
in such cases, a multitude of collusions might ensue. The
body of a traitor, or felon, is forfeited to the king by the
execution. Execution may be avoided by a reprieve or a
pardon, which he respectively.

Execution of decrees, in Scots Law, is effected by
diligence, either against the peron, or against the estate of
the debtor. The first flep of personal execution is by
letters of horning, which pass by warrant of the court,
with the decrees of magistrates of boroughs, sheriffs,
admirals, and commissaries. If the debtor does not obey
the will of the letters of horning, within the days of the
charge, the charger, after denouncing him rebel, and re-
gistering the horning, may apply for letters of caption,
which contain a command, not only to meffengers, but to
magistrates, to apprehend and imprison the debtor. All
meffengers and magistrates who refuse their assistance in
executing the caption, are liable fulsdiarii for the debt;
and such subsidiary action is supported by the execution of
the meffenger employed by the creditor, expressing that
they were charged to concur, and would not. Letters of
caption contain an express warrant to the meffenger, in case
he cannot get access, to break open all doors, and other
lock-built places. The law seizes peers, married women,
and pupils, against personal execution of caption upon civil
debts. Such commoners also as are elected to serve in par-
liament, are seured against personal execution by the privi-
lege of parliament. No caption can be executed against a
debtor within the precincts of the king's palace of Holy-
road-house; but this privilege of sanctuary afforded no
security to criminals, as that did which was by the canon
law conferred on churches and religious houses. When
the personal presence of a debtor, under caption, is necessary
in any of our supreme courts, the judges are empowered to
grant him a protection, for such time as may be sufficient
for his coming and going, not exceeding a month. Pro-
tection from diligence is also granted by the court of fis-
ion, under the late bankrupt statute, when it is applied for,
with concurrence of the trustee, or a certain number of the
creditors, as the case may require.

Execution, military, is the pillage or plundering of a
country by the enemy's army.

Execution also denotes every kind of punishment in-
icted on an army by sentence of a court-martial. This is
of various kinds; as tying up to three halberds, and
receiving a number of lashes with a whip composed of nine
cord-lashes, and each lash of nine knots, from the drum;
or running the gantlope through the parade at guard-
mounting, drawn up in two lines for that purpose. On
this occasion the provost marches through with twigs or
switches, and every soldier takes as many as there are crim-
inals to be punished; the criminal then marches through
the two lines, and each soldier gives him a hard stroke, the
major riding up and down, to see that the men lay on pro-
perly. When a solder is to be punished with death, a
detachment of about two hundred men from the regiment
to which he belongs forms the parade, and a file of gre-
adiers shelters the prisoner to death. Different nations
have different modes of punishment. The cat with nine
tails is digned to punish foot-folders; but dragoons and
cavalry-men are generally picketed.

Execution, in Musical Performance, the action of
conveying to the ear, by the assistance of the eye, what has
been written in the score. As much music is composed of
many parts so interwoven and linked together, that both
the time and intonation are very difficult to seize; and of
which the spirit depends more on taste than notation of such
pieces, nothing is so common as a perfect execution.

The reading of the parts exactly is no great merit, the per-
former must enter into all the ideas of the composer, and
feel, and make the hearer feel, the fire or pathos of the
expression; but above all he must be possessed of a nice and
acute ear, always attentive to the effect of the whole.
In French music the leader must be particularly careful to
pres and relax the time according to the taste of the me-
loidy, the power of voice, and the gesticulation of the finger;
the other parts must consequently be extremely attentive in
following him. "The totality of the opera at Paris, where
music had no other measure than the gestures of the finger,
must, in my opinion, require an admirable musician indeed
to keep all the performers together." N. B. This was
written by Rouffieu near 40 years ago, and at that time
d little disputed; but the editors of the late edit. of the Enc-
cy. men of taste and judgment, will, perhaps, say with Mo-
herie, "medicin malgre moi," this may have been so for-
mery; mais nous avons change tout ca."

"If the French," says St. Evremont, "compose in a
bolder style than formerly by their intercourse with the
Italians, the Italians in their turn have gained by their
commerce with the French, by learning of them a more
agreeable
EXECUTION.

agreeable touching, and perfect execution." Letter to the duke of Buckingham.

The reader (says the author of the Lettre fur la Muf, Fran.) will, I believe, excuse me if I wave making any remarks on this passage, I shall only observe, that the French think all the world interested about their mufic; but on the contrary, in three fourths of Italy, Italian musicians are totally ignorant that there exists a mufic in France different from their own.

A facility of reading and performing a single part is likewise called, if difficult, execution; particularly when rapid passages are played correctly, and without hesitation, at sight.

Execution of this kind depends in an especial manner on two things; the first in having a powerful hand and quick eye; and the second in having read much mufic, and being able to phrase it at a glance; for when we only look at single notes, we shall hesitate in pronouncing them: a great facility of execution is only acquired by uniting them into meaning, and putting the thing itself in the place of the sign.

In this manner the memory of the reader of a book is no less affiAid than by his eyes; and what he would read with great difficulty in a foreign language, though written or printed with the same characters as his own.

EXECUTION, in Painting, is a technical term signifying the style and manner in which a painter performs his work: in other words, the mechanical part of the art, as far as relates to the handling of the pencil in laying on the colours of a picture.

It is evident from this definition, that without possessing it in some degree, all knowledge of the other branches of the art is totally nugatory; to what purpose would the theory be made perfect, if no practical means of applying it were understood? but besides that degree of execution absolutely requisite to produce any thing in the shape of a picture, it will descrive to be made an object of particular study, as its various modes are productive of much utility in the progress of a picture. A great deal of the character of many objects in painting depends on the manner in which they are wrought, that is, on the peculiarity of the strokes of the pencil: such, for instance, are all kinds of beasts; feathers of birds; trees; various kinds of drapery; armour, &c. in producing the effects of which, execution will alone go very far, in fright of bad form and bad colour. There is a charm in it which few perhaps but painters know, and which, unhappily, too many painters feel and value too highly, and desert for it qualities of a much more valuable kind: and are content too often to let their works pass imperfect, even with the knowledge of their imperfections, rather than disturb the beauty of charasters of touch which they may happen to possess.

It is indeed a task of no easy nature fully to obtain this quality; as it requires the utmost precision of judgment so to execute a work of art, that spirit and vigour should be maintained, accompanied with softness and truth. Without which union the display of it is a vice of art instead of an excellence, and damns instead of exalting the work.

Knowledge of the general character of the object about to be represented is the only foundation of a beautiful, decided, and just execution: possessed of that, the artist holds in his hands the master-key of the expression of its qualities, and renders its effect without difficulty. Wanting it he produces his work with heaviness, with blundering, and confusion.

It has been remarked that the countenances of men scarcely differ more than do the characters of their handwriting, and not far, if at all, short of the variety of either of these, is that of the manner in which painters have executed their works. Each may in this also has his peculiarity; no two are so exactly alike in the execution of their pictures that an able connoisseur would not distinguish between them, and prefixly attribute each to its respective author.

This discrimination of hands constitutes almost the tout-ensemble of the knowledge of the host of would-be connoisseurs; and unhappy, too many of them have obtained an influence over the opinions of men well able to teach them in better things appertaining to the arts, if common sense were allowed to rule; and this merely by having served over the works of painters to endeavour to ascertain the distinguishing characteristics of each man's workmanship; a species of knowledge agreeable and useful, to a certain degree, but of easy acquirement, and to which those who have a genuine feeling for the really good and valuable qualities pictures may possess, seldom give sufficient attention to obtain an extended information in it. The works of good artists will force themselves upon our notice, and after sufficiently admiring the general effects of beauty, of sublimity, or character they exhibit; we naturally seek to know by what means or in what manner their various parts are executed, and for the purposes of connoisseurship a satisfactory acquaintance soon takes place on that head.

The works of those whose power in art is not sufficient to attract by those better qualities are purely not worthy of that close inspection which is required to become acquainted with their peculiarities of execution. But the trick of the connoisseur dealer is, by some fancied resemblance or some slight reality of resemblance, to pass off an inferior work under the function of a great name; while, as we have observed, if common sense were allowed to rule, the name would add no value to the picture, and would be lost to no mistake under the gold, and the bubble be soon loft.

This indispensable portion of the art of painting requires early tuition in order to possess a ready power over the hand, so that it shall move freely at the command of the will to effect its desires. The fame in fact is the case with regard to the acquirement of free execution in any other art, such as music, writing, &c. For though our muscles appear to act merely on our willing that their office should be performed, and without any particular direction of the power of the mind over the particular muscles which produce the motion, yet, in fact, that immediate influence is applied, although from habit and its extreme rapidity, we are insensible of the communication. This is plain when we require the use of muscles, in a direction we are not constantly in the habit of using them in. For instance, a man not accustomed to ride, or shrill mounting a horse, finds it necessary to exert all his mental influence to cause those muscles to act which are requisite to maintain his seat on the back of the animal, and the communication of that influence is evidently felt; but when habit has rendered him in his seat on horse-back, though those same muscles continue to act when he is mounted, he is unconscious of constraining them to do so, the effects of his will are then so insensibly excited, that the connection between the exertion of its influence, and its effect is completely unsensible.

It is therefore requisite for men desirous of making considerable progress in the practical part of an art, early in life to apply themselves earnestly to its attainment. The best mode of obtaining it in painting is, by copying the works of those most skilful in their display of it, taking care at the same time to lay in a good store of knowledge of the materials requisite for the art, particularly (if historical painting be the course intended to be pursued) of the human figure, the foldings of drapery, &c. &c., and after some
time spent in making copies of fine works, to paint from nature herself, keeping in view the manner in which the great painters, whose works they have imitated, saw her productions; observing how they disposed of those touches allowed to remain visible, and decided both of light and of dark; also how they characterized by their execution of the different parts; for, in a well-executed work no touches are allowed to remain that are not necessary in some measure to determine the character of the object; the rest are all blended or softened together, and serve as a base to receive those finishing touches (as they are called) which are the decided features of the style of the master, (see Style, in Painting,) the spring of energy and vigour in the work, and without which it would appear tame; and jilipid.

A picture, wherein the colours and forms are blended all over, is sure to appear either solid like a stone, or have the texture of dust, of something soft and spiritless. On the contrary, where to softening takes place, and every touch remains visible, confusion inevitably reigns, with the character of tin&l, and a flattering want of solidity.

While the student is endeavouring to acquire facility of handling his pencil, or of execution, he must take care not to be led away by its fascination, but to remember that it is only the means of presenting to the world, in an agreeable shape, other more dignified, and more valuable qualities in art, which deeper than the surface; and without which this is worse than an empty nothing. 'Tis the bane of many an ingenious youth who, happening to possess it early, and outshining his companions in years, fattishes himself that he has made a large advance in his art, when in fact he has obtained only a means of doing something, which more important part, his vanity leads him to forget to make the studies requisite to enable him to perform, or, to acquaint himself thoroughly with the nature of bodies, and the happiest and best modes of combining them in forms and colours; and as he advances in life he is mortified to find himself far surpassed by those he had regarded with contempt, but whose more steady and better directed minds have pursued attentively more valuable objects of study, and the more useful principles of their art, and now soar to a height which leaves his weaker talent far beneath.

It must, however, be remarked, that a good execution is a highly valuable quality in a picture, which being wrought with judgment, with spirit, and ease, acquires thereby an additional relish to the enjoyments its better properties diffuse, and raises the artist in our estimation.

Of all those who have exhibited this talent with success, Giacomo Rubulii, called Il Tintoretto, stands foremost for vigour, as has been noticed under the word Energy, in Painting. He has no competitor in the freedom, the boldness, and the spirit of style in which his best works are executed.

Of this his picture of St. Mark defending from heaven to rescue a Christian slave condemned to torture among the Turks, originally painted for the Scudo di San Marco at Venice, but now among the spoils adorning the Louvre at Paris, is a most decided and astonishing proof. This picture is an immense work containing twenty figures or more, those in front larger than life, yet it is wrought all over with the rapidity and ease generally characteristic of small pictures, or a sketch within the compass of the hand to perform at once; and at the same time it has all the effect of rotundity of finish the most labouring works possess. In the midst of the fine pictures which surround it, it stands quite alone in its vigour of effect and splendour of value; even a work of Rubens, who is extremely skilful in this as well as in all other branches of the art; even his, appeared comparatively clumsy in its execution, though one of his finest productions, the opening of the Temple of James, or, as it is usually called, the Peace and War. Titian, from his senes and truth in the St. Peter martyr, belt withstands the power of Tintoretto. The comparison of these two works may be said to be somewhat similar to that of a man of wit with a man of sense; the former shines for a moment by the brilliancy and gaiety of his genius, but when the latter is attentively heard, and his observations considered, his greater value becomes apparent.

Titian perhaps on the whole is the best model to follow for execution: he does not, like Tintoretto, leave his heads without a character in the heat of workmanship, though they are not always of the best; they are not wrought too minutely; the lights and darks are freely placed, his pencil is full and rich, and each part is made out to its full relieve, and his finishing touches are laid on with the nicest discrimination of truth in direction of light and hue of colour; nothing can exceed the delicacy and still his apertures are wrought with as to character; and though not so strong as Tintoretto's, they have sufficient force, and are far more jubly disposed and characterized. After Titian in imitating him are, Velasquez and Vandyke for excellence in their execution. Of the former, a Spanish painter, there are but few works in this country, but what there are, are fully justify the remark. The latter in his very finest works equals his great predecessor in this respect, many of whose pictures he carefully copied. His touch is exceedingly delicate, and his understanding of his subject enabled him to place it with the greatest jufnifs and propriety. There is rarely seen in his works a confusion in effect or relieve, and his power in his earlier productions seems to have encroached with his canvas; the large picture at Wilton of the Pembroke family is wrought in a style so broad and matterly, that it appears to have been as easily managed as any of his smaller pictures; and he knew how to give with the greatest ease the just character of every object he attempted to represent. Gout and consequent weakness effects a change in his execution so great, that his hand is hardly cognizable in some of his latter works by those who have only seen his former ones. He was in Italy almost all his life; but with a somewhat of Tintoretto; from this bravura style, as it may be termed, he fell afterwards to more tame and spiritless; softened, and rounded up, with few of those vigorous touches, and with less brilliancy of effect. Infinities of both these, and also intermediate degrees, are at the earl of Egremont's at Petworth. Of the first are whole length portraits of Sir Robert and lady Shirley, which he painted when he was very young at Venice; of the others, are portraits of several branches of the Pony family, who once possessed that noble mansion. Vandyck certainly surpassed his master Rubens in beauty of execution, but was more than equally surpassed by him in vigour and variety of imagination; yet the execution of Rubens was extremely powerful, but apt to become slovenly, and he is not, generally speaking, a good model to be followed on that head.

For those who are intent upon yielding the fott, the delicate, and gentle impressions produced by highly labouring works without minutefips. Correggio is the exemplar of the whole class of that ftyle of painters. In one particular he, and our own Sir John, in some of their works, stand unrivalled in execution. Other painters have given a beautiful surface, which, at a proper distance, deceives the eye, and presents the full appearance of flesh; these two have, we may almost say, made flesh itself; the closest inspection merely confirms the delusion, and the observer fancy he could indent his finger in the surface, and expect it to spring again like nature; such
execute the will; he may refuse the charge, before he has administered as executor, or performed such acts, as paying debts due by the testator, or receiving debts due to him, or giving acceptances for the same; but if he meddles with the goods of the testator, as executor, his subsequent refusal is void, and he shall be charged as executor. A person to whom a legacy is left may be compelled either to stand the executorship, or to resign his legacy. The refusal of executorship must be entered and recorded in court. If several executors are named in a will, and some of them refuse, and others prove the will, they who refuse may afterwards administer and act; and they must be joined in all suits, where the co-executors are plaintiffs; but not where they are defendants; because the plaintiff in the action is not bound by law to take notice of any besides those who have proved the will. Such joint-executors, though they are accounted in law but as one person, shall not be charged by the acts of their companions, any further than for effects actually come to their hands. (Moore, 620. Cro. Eliz. 218. 2 Leon. 209.) But if two or more executors join in a receipt (in writing) and one of them only actually receives the money, each is liable for the whole, as to creditors at law, but not as to legatees or next of kin. (1 Saik. 318.) If joint-executors, by agreement among themselves, agree that each shall intermeddle with a certain part of the testator's estate, yet each shall be chargeable for the whole (to creditors) by agreeing to the other's receipts. Hard. 314.

The interest, vested in the executor by the will of the deceased, may he continued and kept alive by the will of the same executor, so that the executor of A.'s executor is to all intents and purposes the executor and representative of A. himself. (Stat. 25 Edw. III. f. 5. c. 5. 1 Leon. 275.) But the executor of A.'s administrator, or the administrator of A.'s executor, is not the representative of A. For the power of an executor is founded upon the special confidence and actual appointment of the deceased; and such executor is therefore allowed to transmute that power to another, in whom he has equal confidence; but the administrator of A. is merely the officer of the ordinary, preferred to him by act of parliament, in whom the deceased has reposed no trust at all; and therefore, on the death of that officer, it returns back to the ordinary to appoint another.

As to the office or duty of an executor, it is to be observed that he may do many things before he proves the will, which an administrator cannot do; because the former derives his power from the will, and not from the probate or appointment of the ordinary, as the latter does. (Comyns, 151. Wentw. ch. 3.) He may maintain actions of trespass, replevin, or detinue; release an action, assent to a legacy, be sued, alien, or otherwise intermeddle with the goods of the testator; by administering, the executor is entitled to receive all debts due to the testator, and all payments made to him are good, though he should die, and never prove the will; but he cannot maintain a suit or action of debt, or the like, before he has proved the will. The ordinary, &c. may cite the executor, either to prove the will, or refuse the office; and he may sequestrate the goods of the deceased, till the executor has proved it; and, if he does not appear on the process, the ordinary may excommunicate him. On the other hand, the ordinary is compellable by mandamus to proceed to probate, when the will is not controverted. The executor must bury the deceased in a manner suitable to the estate he leaves behind him; necessary funeral expenses are allowed, previous to all other debts and charges; but if he be extravagant, he is chargeable with devolution, or waste of the substance of the deceased, which shall be only prejudicial to himself,
and not to the creditors or legatees of the deceased. (Salk. 196 Godolph. p. 2. c. 26. § 2.) He is then to make an inventory of all the goods and chattels, whether in possession or action of the deceased, which he is to deliver in to the ordinary upon oath, if lawfully required. He is then to collect all the goods and chattels so inventoried; for which purpose the law confers on him ample powers, as the representative of the deceased; (Co. Litt. 209.) and having the same property in his goods as the principal had when living, and the same remedies to recover them; and if there be two or more executors, a sale or release by one of them shall be good against all the rest. (Dyer. 29.) The executor must in the next place pay the debts of the deceased, in the order of their priority. See Debt, and DRXTER Executor. Among debts of equal degree, the executor (and also the administrator) is allowed to pay himself first, by retaining in his hands so much as his debt amounts to. (10 Mod. 406.) If a creditor constitutes his debtor his executor, this is a release or discharge of the debt, whether the executor acts or not. (Plove. 184. Salk. 290.) provided there be affets sufficient to pay the debtor's debts.

If no suit has commenced against him, the executor may pay any one creditor in equal degree his whole debt, though he has nothing left for the rest; for, without a suit commenced, the executor has no legal notice of the debt. After the debts, the executor is to pay the legacies, which he is to pay as far as his affets will extend; but he may not give himself the preference herein, as in the case of debts. In case of a deficiency of affets, all the general legacies must abate proportionably, in order to pay the debts; but a specific legacy, as of a piece of plate, horse, &c. is not to abate at all, unless there be not sufficient without it. (2 Vern. 111.) If the legatees have been paid their legacies, and debts come in more than enough to exhaust the residue, they are afterwards bound to refund a rateable part. (1 Ib. 209.) See LEGACY, and DONATION Causa Mortis.

When all the debts and legacies are discharged, the surplus or residuum must be paid to the residuary legatee, if any be appointed by the will; if there be none, he is to be put into the same underlod to belong to the executor; (Perkins, 525.) but it seems to be now the general opinion, that, if there be an express legacy given to an executor, and no devise of the surplus, such surplus shall not go to the executor; but be disposed of to the next of kin, according to the statute of distributions; the executor standing on the same footing as an administrator. (Prec. Chanc. 323. 1 P. Wms. 7. 544. 2 P. Wms. 338. 3 P. Wms. 43. 194. Stra. 559.) See INTESTATE.

Where no express legacy is given to the executor, the surplus shall go to the executor, and not otherwise disposed of by will. When there are several executors, and some of them are dead, the legatary must sue the surviving executors, and not the executors or administrators of those that are dead. And if all the executors are dead, he must sue the executors or administrators of those that died last, and of the rest.

By the French law, an executor should be selfed of all the moveables of the deceased during one year; at the end whereof he is to account for them. To the validity of a testament, it is not necessary there be an executor nominated therein.

EXECUTOR de fœn terti, or of his own wrong, is he who takes on him the office of an executor by instruition, not being constituted thereto by the testator or deceased, nor authorized by the ordinary to administer. If an executor in his own wrong takes upon himself the office of an executor, without lawful authority, he is chargable to the rightful executor, and to all the creditors of the testator, and likewise to the legatees, so far as the goods amounted to, which he wrongfully posseffed; and such an executor is made by any act of acquisition, transferring, or posseffing himself of any of the estate or goods of the deceased; but not by acts of necessity, piety, or charity. (2 Nellon Abr. 793.) Such an executor cannot bring an action in right of the deceased; but actions may be brought against him; neither can he retain for his own debt or legacy. In case of his death, his executors or administrators are liable to the suit of the lawful executor, creditors, and legatees, by (Co. Litt. 209.)

EXECUTOR, Deleece. See DEEM.

EXECUTORY, that which has, or carries with it a sufficient authority for being executed.

EXECUTORY contrail. See CONTRACT.

EXECUTORY devises of lands, is such a disposition of them by will that thereby no estate vests at the death of the devisor, but only on some future contingency. It differs from a remainder (which fee) in three very material points: 1. That it needs not any particular estate to support it. 2. That by it a fee-simple, or other fees estate, may be limited after a fee-simple. 3. That by this means a remainder may be limited of a chattel interef, after a particular estate for life created in the same. The first case happens, when a man devises a future estate to arise upon a contingency; and, till that contingency happens, does not dispoife of the fee simple, but leaves it to devide to his heir at law. As if one devises land to a feme-fole and her heirs upon her day of marriage; here is in effect a contingent remainder without any particular estate to support it; a freehold commencing in futuro. This limitation, though it would be void in a deed, yet is good in a will, by way of executory devise. (1 Sid. 153) For, since by a devise a freehold may pass without corporal tradition or livery of seisin, it may therefore commence in futuro; because the principal reason why it cannot commence in futuro in other cases is the necessity of actual seisin, which always operates in present. And since it may thus commence in futuro, there is no need of a particular estate to support it; the only use of which is to make the remainder, by its unity with the particular estate, a present interest. And hence it follows, that such an executory devise, not being a present interest, cannot be barred by a recovery, suffered before it commences. (Cro. Jac. 593.) The second case happens when a devilor devises his whole estate in fee, but limits a remainder thereon to commence on a future contingency. As if a man devises land to A. and his heirs; but if he die before the age of 21, then to B. and his heirs; this remainder, though void in a deed, is good by way of executory devise. (2 Mod. 289.) But in both these species of executory devises, the contingencies ought to be such as may happen within a reasonable time; as within one or more life or lives in being, or within a moderate term of years; for courts of justice will not indulge even wills, so as to create a perpetuity, which the law abhors. (12 Mod. 287. 1 Vern. 117.) Thirdly, by executory devise a term of years may be given to one man for his life, and afterwards limited over in remainder to another, which could not be done by deed; for by law the first grant of it, to a man for life, was a total disposition of the whole term; a life estate being esteemed of a higher and larger nature than any term of years. (8 Rep. 95.) On this subject, see Blackl. Comm. vol. ii. p. 176, 8vo.

EXECUTORY estate. See Estate.

EXECUTORY fine. See Fine.

EXEDENS
EXEDENS Herpes. See Herpes.

EXEDRAE, Νίκος, among the Ancients, were places wherein the philosophers, sophists, rhetors, &c. used to hold their conferences and disputations.

M. Pernult is of opinion, the exedrae were a fort of little academies, where the men of learning met together. See Academy.

Budens rather thinks, that what the ancients called exedrae, might answer to what we call chapters in the cloisters of monks, or collegiate churches.

EXEGESIS, Εξήγεσις, a term sometimes used by the learned, to signify explication.

Several interpreters of the Bible are of opinion, that in the passages of Scripture, where we meet with Abba Pater, two words, the first Syriac, and the second Greek or Latin, but both signifying the same thing; the second is only an exegesis, or explanation of the first.

Exegesis is also used for an entire discourse by way of explanation of a thing.

Exegesis numeris, or linealis, signifies the numeral, or linear solution, or extraction of roots, out of affected equations, first invented by Vieta. Ozanam calls it la rhetorical. See Extraction of roots.

EXEGETES, formed of Εξηγημα, Ἀξιοποιεῖν, among the Athenians, persons learned in the laws, whom the judges used to consult in capital causes.

EXEGETICA, as Ελεγχος, the art of finding, either in numbers or lines, the roots of the equation of a problem, according to the problem is either numerical or geometrical. See Root and Equation.

EXELCOSIS, from εξελικτικος, an ulcer, in Surgery, an incipient ulceration, or an excoration, which is just beginning to tuppurate.

Exemplar, a model or original to be imitated or copied.

Exemplar also denotes the idea or image conceived or formed in the mind of the artist, whereby he conducts his work. Thus is the idea of Cæsar, which a painter has in his mind when he goes to make a picture of Cæsar. The exemplar is ordinarily numbered among the causes. See Cause.

EXEMPLIFICATION of Letters Patent, denotes an exemplar, or copy of letters patent, made from the original thereof, and sealed with the great seal of England.

Such exemplifications are as effectual to be `[omitted]` or pleased, as the letters patent themselves.

EXEMPLIFICATION, in Law, is a writ granted for exemplification of an original record. Reg. Orig. 290.

EXEMPTION, a privilege, or dispensation, whereby a person is excepted out of some general rule.

Exemption is particularly applied to churches, chapels, and monasteries, which have a privilege given them by the popes, or princes, whereby they are exempted from the jurisdiction of the bishop or ordinary.

The council of Constance revoked all exemptions, to restore to the general-law, weakened and diminished by a relaxation of several ages, its ancient force and vigour, and make it everywhere obtain in all its latitude.

The council of Trent prohibited, and declared them null for the future; confirming only such as were well founded on legal concessions from the holy see.

Exemption, in Law, denotes a privilege to be free from service or appearance; thus, knights, clergymen, &c. are exempted from appearing at the county courts by statute, and peers from serving on inquests. (6 Rep. 23.) Permons seventy years of age, apothecaries, &c. are also exempted by law from serving on juries, and justices of peace, attorneys, &c. from parli. offices. 2 Inst. 247.

EXERCISE, a repetition of any operation, for the strengthening or retaining of a habit.

Exercise, or bodily motion, constitutes, in the language of the older physicians, one of the four non-naturals, and has been justly considered, from the earliest times, as an important measure in the preservation of health, as well as in the cure of several diseases.

The value of corporal exercises in the elevation of the ancient physicians, from Hippocrates downwards, is manifest from their writings, in which the various ends of exercise, as well as the degrees and times in which they are useful, are particularly discussed. Euculides himself was led by Galen to have recommended riding on horseback, and other exercises, as the means of benefiting invalids. But Herodicus, a Thracian, seems to have been the first who paid serious attention to exercise, as a remedy for diseases. He was master of one of the academies, called Gymnasia, in which the military and athletic exercises were taught; and having remarked that his pupils usually enjoyed good health, he turned his attention to the regulation of the gymnastic exercises, and with a view to attain or preserve good health; thus adding the medical gymnastic art, to the two others just mentioned. (See Gymnastic, and Herodicus.) This matter of the gymnasm, however, went to work empirically, and is accused by Hippocrates of doing considerable mischief, in attempting to cure febrile diseases by his exercises. (De Morb. Epidem. lib. vi.) Hippocrates and his commentator, Galen, have left many observations relative to the different exercises, and their particular effects in the alleviation of particular diseases. Friction, especially by means of the fregill, or flesh brush, is much in use; on which subject Galen has composed his second book, "De Sanitate Taelenda." The various modes of wrestling, the exercises of the corpuse, or hanging ball, &c. are commented on by Hippocrates in lib. ii. De Dieta; and Galen wrote a little treatise de parea pila. (the little ball,) which he recommends as an exercise that influences both the body and the mind at the same time. In his discourse to Thaumulus he discusses the question, whether the preservation of health properly belongs to medicine, or to the gymnastic art: he inveighs against the athletic and other violent practices of the gymnasm, but approves of the more moderate exercises, which he considers as subservient to the purposes, and consequently a part of the art of the physician. Antyllus, and other Greek writers, have treated of the various exercises in the same light, as is evinced by the collections of Oribasius. (See Collect. Med. lib. vi.) The Romans even exceeded the Greeks in their attention to the medical gymnastics. Aseleipia, in the time of Pompей, as Pliny informs us, considered the different modes of exercise, as friction, walking, and gymnastics, as the chief auxiliaries of the physician, especially when combined with the proper regulation of diet; and by the employment of these exercises, the infirmities of baths, the invention of hanging beds, lettis pendulis, and other means of making phyticus agreeable, is laid to have acquired the general applause of all mankind: "ut universum prope humanum genus circumseget in, &c." (Plin. Nat. Hist. lib. xxvi. cap. 3.) Many eminent examples of the benefits of exercise among the Romans are on record. Suetonius states that Germanicus was cured of a fort of atrophy of the lower extremities, (curum gracilium) by riding. And Cicero himself, when reduced to a state of infirmity, which rendered it necessary for him to desist from pleading, recovered his health by travelling, and by exemplary diligence in the use...
of friction. (Plutarch.) Friction was an exercise, indeed, reduced to a regular systen among the ordinary habits of the Romans, and was preferred to a great extent by their physicians. See friction.

That exercise, especially in the open air, is highly beneficial to the constitution, is a truth which universal experience has established. It is scarcely necessary, therefore, to appeal to the arguments of physiology to corroborate the proposition. It may be sufficient to state, that the immediate result of bodily exercise is an acceleration of the circulation of the blood; a quicker and stronger contraction of the heart, by which the blood is pushed more effectually to every part of the system, and especially through the small and extreme branches of the vessels. Hence a glow is produced on the surface, and the complexion assumes a redder hue, from the diffusion of the capillary vessels with blood; and the exhalent arteries begin to pour out the thinner portions of the fluids in perspiration. In the same manner, the extreme arteries of all the other parts of the body are dilated, and excited to greater action; whence all the organs of secretion, which are principally made up of convolutions of the extreme arteries, are necessarily stimulated to an active performance of their several functions. The vessels of the stomach pour out the gastric liquors more abundantly, and the work of digestion is more perfectly and actively completed; the appetite for a new supply of aliment quickly returns, and the stomach is prepared for repeating the digestive proc©ss, by the increased supply of the digestive liquor. The liver and the pancreas, in like manner, elaborate their respective fluids, the bile and pancreatic juice, more copiously, and thus contribute an increased aid to the operations of the alimentary canal. The lungs, in the mean time, being called upon for an augmented supply of the vivifying principle derived from the oxygen of the atmosphere, by the increased circulation of the blood through them, respiration is increased in proportion to the quantity of venous blood which they receive. Thus, notwithstanding the greater rapidity with which the blood is carried to the secreting organs, it is rendered adequate to the secretion of the healthy fluids peculiar to each, by the increased operation of the lungs; as well as to the support of the greater muscular action, in which the exercise confits.

It must be obvious, then, that this general activity of the whole systen, this free circulation through the most minute ramifications of the vessels, and through the glands and organs which they compose, and this prompt separation of the excrements and other parts of the blood, by the secretions, cannot but contribute to the general health of the body. It is not less obvious that it contributes to the evolution and growth of the different parts of the body; whether we consider the great influx of the blood, from which all growth is derived; or observe the fact, that those muscles and limbs, which are most actively exercised, invariably acquire superior bulk, as well as superior strength. The muscles of the arms in blacksmiths, and those of the loins in porters, and all others employed in raising or carrying great weights, invariably acquire a disproportionate size; and on the contrary, those muscles which are little employed are apt to shrink, and to be comparatively enfeebled, as in the legs of tailors. The effect of exercise in giving strength and rigidity of fibre to the muscular or fleshy part of animals is well known, and daily exemplified in the difference of texture in the wings and legs of birds which we use for food. In the common fowls, which seldom use the wing, and constantly employ the legs in walking, the hardness of the flesh of the latter, and tenderness of that of the former, are notorious. From this influence of exercise in contributing to the growth and strength of the animal body, we may obviously trace the final cause of that inlusive disposition to activity and motion, which the young of all animals posse{s.

Regular exercise, not too violent in degree, nor continued too long, so as to induce excessive fatigue, is therefore to be considered as the most important preventive of diseases. It is not safe to lay down rules by which it should be regulated; since the constitution, age, strength and habits must modify its effects in different individuals. A sudden transition from a state of rest to violent exertion is injurious to the invalid, especially after a full meal, or if continued until a profuse perspiration, or great latitude takes place; for this over-exertion necessarily leads to a languor and imperfect performance of all the vital actions, every organ partaking of the general fatigue. The various kinds of exercise may be considered under two classes, the active and the passive; the former being the result of our own muscular activity, such as walking, dancing, running, swimming, fencing, the military exercise, and different athletic games; the latter the result of communicated motion, as riding in a carriage, failing, swimming, friction, &c. riding on horseback, or driving a carriage, partakes in some measure of both the active and passive exercises.

Walking, which seems to be the most natural exercise, is capable of producing all the effects above detailed, if adapted in degree and duration to the various circumstances. Hence the most obnoxious cases of hypochondriacal disorders, of indigestion, and other stomach complaints, have been frequently removed by perseverance in walking, especially in the open air of the country. But when the exercise of walking is adopted with a view to banish the complaints just mentioned, which a feudant life is apt to induce, it is most effectually when regularly and occasionally pursued. That degree of walking, which, when reftored to the comparatively, or with considerable intermittence, produces great fatigue and languor, and therefore is rather prejudicial than advantageous, would, if daily continued, soon cease to fatigue, and would then contribute greatly to restore the healthy state of the functions. It must be recollected that the animal vigour is consumed, or, to use the language of Brown, the excitability is exhausted, by the mental functions as well as by muscular exertion; therefore, to carry with us, in our walks in search of health, the brooding anxieties and cares of our professions,—to attempt to combine study with such exercise by reading, or by serious reasoning in convocation, is to thwart the good effects of the plan. We may observe that, fo incompatible is deep thought with muscular exertion, that most people fltop in the midst of their activity, when their arguments require great reflection. Serenity of mind, and a relaxation from the feverous occupacions of life, are therefore necessary, when walking is reftored to as a remedy.

Of the more violent species of active exercise, which can only be reftored to as a preventative from disease, by those who are in a state of good health, it is unnecessary to speak.

The modes of exercise which are particularly useful in the cure of diseases, or in the restoration of the health of convalsecents, are the different species of gymnastics, especially riding in carriages, or on horseback, and asling.

The motion of a ship produces the most gentle exercis©e, and is therefore adapted even to the relief of very infirm conditions of the body, and it has been employed from early times in the cure of consumption. The Romans, in the time of Pliny, used to send their consumptive patients to Egypt; not, as that author takes care to inform us, on account
EXERCISE.

account of any peculiarity of that country, but in con-
sequence of the length of the voyage. Aurelius Gallio, who
had been confus, was cured of a consumption by such a
voyage. (Nat. Hist. lib. xxxi. cap. 6.) Celsus seems to
have considered failing, when referred to early, as the prin-
cipal remedy for consumption: "opus est, it vires patinu-
tur, longa navigatione," he says; and where the strength is
not equal to it, he recommends short voyages, or the use of
a litter, or other means of gentleness. (De Medicina,
lib. iii. cap. 2.) The advantages of a sea voyage, especially
to a warmer climate, are well known to modern physicians;
and instances of the success of such a voyage to Madeira,
Lisbon, &c. when undertaken in the incipient stage of con-
sumption, as Celsus recommends it, are very numerous.
This, however, like all other remedies for consumption, is
too often referred to when the disease has already advanced
too far to admit of any effectual relief. See Consump-
tion.

The exercise of gellation by means of a carriage, and the
more active exercise of riding on horseback, being more
easily obtained, are of more importance in our consideration
of the subject. Horseback exercise was not much adopted
by the ancients, with a view to the cure of diseases, partly
because that valuable animal was less used by the Greeks
and Romans, and partly because their mode of riding, with-
out stirrups, was incompatible with the weaknesses of invalids.
(See Fuller, Medicina Gymnastica, p. 231.) Hence we
may understand the observation of Autyllius, that "riding
is of little use to those who are sickly, because a slow pace
is productive only of latency, especially in the loins," he
admits, however, that "a quick pace of the horse, although
it occasions a troublesome shaking of the whole body, is
nevertheless somewhat beneficial, and strengthens the fyltem,
especially the flamach and the organs of sense, more than
all other exercises." (Oriskios, loc. cit. lib. vi. cap. 24 de
Equitatione.) The great advantages of riding in the pre-
vention and cure of many diseases are inflected upon in the
strongest terms by Sydenham, who, indeed, appears, in sev-
eral parts of his writings, to have considered it as a remedy
of inestimable value, provided it be performed in con-
duclancy, in the manner which we have inculcated in respect
to walking. Speaking of the mode of cure in chronic dif-
cates, that sagacious physician observes, "nothing, among
all the remedies which have hitherto come to my know-
ledge, so effectually supports the spirits and strength, as the
long and constant riding on horseback." (Diff. Epistolaria.)
Again in his Treatise on the Gout, and particularly respecting
the prevention of the paroxysms by exercise, he says, "rid-
ing on horseback is far preferable to all other exercises for
this purpose; in truth I have frequently considered, that
if any person were acquainted with a medicine, which
he chose to keep secret, of equal efficacy in this, and in
the greater number of chronic diseases, with a constant
and perverting exercise on horseback, he would speedily
accumulate the most ample wealth." And to express his
full conviction of the value of this exercise in consumptive
complaints, he uses these strong terms: "in short, however
fatal consumption is deemed to be, and actually is, since
it destroys two thirds of those who die of chronic diseases,
yet I solemnly affirm, that neither is misery a more effectual
remedy for the lues venerea, nor Peruvin bark for agues,
than is the exercise just commended for consumption,
provided that the patient be always careful to sleep in
dry beds, and that his journey be sufficiently long." The
truth of this great encomium is indeed questioned by modern
practitioners in general, however weighty the authority of
Sydenham may be. But there are many cases on record,
which seem to justify this observation. Witness the case of
the late Dr. Clarke, of Liverpool, as related by himself, in the
Zoological Memoirs of Darwin. (Vol. ii. c. 1. p. 56.) In this
case, the patient had an hereditary predisposition to con-
sumption, and was restored by travelling from a state of de-
bility, in which the erect posture could hardly be borne
without fainting, to good health; having begun with the
exercise of a carriage, and afterwards ridden on horse-
back, as his strength augmented. Sydenham has related
several examples of the value of this exercise, and others
may be found detailed by Fuller, &c. We cannot therefore
doubt, that in many instances, in which it has seemed to be
delusive of the efficacy ascribed to it by Sydenham, the
failure must be attributed to the imperfect or too late use
of the remedy. "I must here repeat," says Fuller, quaint-
ly, "that when I speak of riding, I understand the habit
of riding, the want of which distinction has made it inef-
factual to many a man. He that in this dilemmer (con-
sumption) above all others rides for his health, must be
like a Tartar, in a manner always on horseback; and then
from a weak condition he may come to the strength of a
Tartar." (Med. Gymnast. p. 106.) We have di-
lated upon this topic, from a conviction that many chronic
diseases which are included under the epithets of bilious
and nervous, as well as many morbid conditions of the vis-
cera, for which drugs, and even the waters of Britoil,
Bath, and Cheltenham, are ineffectually swallowed, might
be removed by a steady and unremitting exercise, in a carriage,
or still more certainly on horseback.

It is unnecessary to enter into a particular enumera-
tion and discussion of every possible form of exercise, the
principle being the same with respect to all. A late
intelligent writer has laid down some useful practical
precepts on these topics, mixed with a good deal of
trifling observation, and absurd hypothesis. (See Willich's
Lectures on Diet and Regimen, chap. 7.) The following
remarlds on the injuries occasioned by want of exercise are
from that popular writer.

"We are now to consider the consequences arising from
want of exercise. This, indeed, is still more debilitating
than too violent motion. The fold parts of the human frame
are relaxed by it; the circulation of the fluids is retarded;
they gradually flagitate in the smaller capillary vesseis;
the secretions are diminished; and abundance of moisture or fat
is generated, which renders the body, as well as the mind,
more indolent and lethargic, relaxation of the muscles,
obstructions of the intestines, hemorrhoids, apoplexy, fits,
various species of dropy, and at length a premature death,
are the chief consequences. Men of letters are the most
unhealthy of all human beings, because their bodies have
screared any other exercise but the imperceptible
motion of the arms. Want of appetite, flatulence, anxiety,
at one time obstructions, at another diarrhoea, and the most
diversified nervous symptoms are their attendants. Sleep
is beyond their reach a thousand tormenting inconveniences,
lycopodrias, and at length a complete state of melancholy,
is too frequently their lot. Temperance alone will not
remedy all these evils; for, since we cannot remain vigorous
and healthy for two days together, with the famine mias
of blood, a new access of the newel and inoffible parts of
our fluids must daily support the nervous system, in order
to preserve its regular functions. It this be not continually
reftored, weaknefs and relaxation of body and mind are the
inevitable consequences; with this difference only, that in a
state of debility from too much bodily exercise, the thick
and coarse particles of the fluids are carried into circulation
with the others, and the next nacel or the first sleep after it,
foon
E X E

EXETER, in Geography, a city in Devonshire, England, is of great antiquity, and, as Ridolph emphatically style it "may be called the emporium and principal ornament of the west." Its Roman name, as it appears in Ptolemy, is Iceni, and it is conjectured that the second legion of Augufa was stationed here for some time: this was commanded by Uufafann, who was the conqueror of Britannia Prima, in which province this place was included. In the Itinerary of Antoninus, Exeter is called Ica-Damnoniorum, and is the most westerly station he has noticed; though, from the Inscriptions of Ptolemy and Richard; from the remains of Roman roads over, and around Haldon; and from the vestiges of ancient ways through Drew-Teignton to Oakhampton, and perhaps of a road hence over Dartmoor, by Hollow-street in the parish of Chagford; it is apparent that various principal roads ran westward from this city; and, therefore, it is probable that the Romans had other stations west of this. How long Exeter retained the name of Ica-Dammentorium is uncertain; though it seems probable that it fell into disuse very soon after the Romans quitted the island, about which time it appears to have been re-occupied by the Britons who had preferred their independence by retiring to the wilds of Cornwall. They did not, however, continue in the possession of it many years; for Cerdic, the founder of the kingdom of Wessex, having greatly extended his territories, either by conquest or intrigue, included the most considerable portion of Devonshire within his dominions; and at length Exeter became tributary to the power of the Saxons. Under their government its name was changed to Exon-Cerur, Ex-Cerur, &c., and thence, through various similar appellations, softened to Exeter.

This city has been several times besieged; but the greatest calamities it experienced were inflicted by the Danes, who, in the reign of Alfred, in violation of a solemn treaty, surprized and routed the king's horsemen, and mounting their fleet, rode to Exeter, and remained there for the winter. Alfred collected all his forces and invested the city by land, while his fleet blocked up the harbour; the Danes capitulated, and agreed to evacuate all the territories of the West Saxons. Between the period of the death of Alfred and the reign of Athelstan, the Cornish Britons had recovered possession of Exeter; but Athelstan having defeated and driven them to the west of the Tamar, they were never afterwards able to oppose the Saxon arms. To secure his conquests he surrounded Exeter with a wall of hewn stones defended by towers; and under his auspices, says Malmesbury, "it became such a place of trade, that it abounded with opulence." He adds that many other remarkable works of Athelstan were to be seen in the city and its neighbourhood. - In the year 1003 Exeter was the first sacrifice to the fury of Swein king of Denmark, when he came to revenge the inhuman massacre of his countrymen: being delivered up by the treachery of its governor, after a siege of two months, many of the inhabitants were put to the sword, and most of the buildings destroyed by fire. Before it was well recovered from this calamity, it was again besieged and taken by William the Conqueror. In the reign of Stephen, this city was alternately garrisoned by the forces of the king and the emperors. It again became the scene of hostility during the contest between Henry VI. and Edward IV. In the reign of Henry VII. it was closely, though ineffectually, besieged by three thousand men under Perkin Warbeck. The last siege Exeter experienced was in Edward VI.'s reign, when religious innovations occasioned an alarming insurrection in the west of England: the inhabitants, though reduced nearly to famine,
so bravely defended the city for thirty-five days, that the
infringers abandoned their design.

The ground inclosed within the walls of the city is
nearly in the form of a parallelogram, of four furlongs in
length, and three in breadth; this space is intersected by
the four principal streets which meet near the centre, and
diverging at right angles, connect the city with the suburbs.
The whole extent occupied by buildings is about one mile
and three quarters in length, and one mile in breadth. In
the year 1759 the surrounding walls were entire; but many
parts have been since destroyed. Stukeley speaks of them
as being, in his time, in pretty good repair, and having many
turrets and towers, various parts of which are still remain-
ing. Leland, speaking of this city, observes, that it is
"a good mile and more in compass, and is right strongly
wanfull and maintained. Thus be diverse fair towers in the
town wall bytwixt the fouth and the west gate. Ther
be four gates in the town, by the names of eft, west,
noth, and south. The eft and the west gates be now
the faireft, and of one facion of building; the fouth gate
hath beene the strongest." In the year 1769 the
north gate was taken down, to make a more convenient
entrance into the city; and in 1784 the eft gate was re-
moved for the fame purpofe. The fouth gate, the interior
arch of which Dr. Stukeley remarks to be of Roman work-
manship, is intended to experience the fame fate.

The situation of Exeter is commanding and pleafant; it
flants on the acclivity of an eminence on the easterm banks
of the river Exe, which flows in a femi-circular direction
round the fouth-west fide of the city. "What adds to its
wholefomenefs and cleanliness," fays Stukeley, "is, that
the ground is higher on a ridge along the middle of
its length declining on both fides. Further, on the fouth-west
and north-west fides it is precipitous; fo that with the river,
the walls, the declivity of ground, and ditch without
fide, fwas a place of very great strength, and well
chofe for a frontier." In the highest part of the city, on
the north fide, flant the remains of Rougemont castle, which
was formerly the feat of the Weft Saxons kings, and after-
wards of the dukes of Exeter. This building has little to
recommend it but its antiquity and pleafant situation. The
ruins of the exterior walls are nearly all that remain; these
include a confiderable fp ace, of a pentagonal form, and
were defended by four towers; two on the eft, and two on the
eft fide. The ramparts of the castle command a most deli-
ighted view over the adjacent country. When the castle
was erected is unknown; though Graffon's tale, that it was
built by Julius Cæsar, is unquestionably false. William the
Conqueror either rebuilt, or much repaired, the whole edifi-
c, and belowed it on Baldwin de Brione, husband of
Abreda his niece, whose defendants, by the female line,
 enjoyed it, together with the office of fheriff of Devon,
which seems to have been annexed to it, till the fourteenth
year of Henry III.'s reign, when that prince, refunding
into his own hands fundry castles and forts in this realm,
difpropriated Robert de Courtenay, in whose family it had
been for three defcendants. In the civil war of the seventeenth
century the castle was completely ruined, when the city
withdraw a blockade of two months againit Fairfax, one of
whose forts, Mr. Gough fays, flill remains in a field to the
north. Within the area inclosed by the walls, a small
capel was erected by lady Elizabeth de Fortibus, countess
of Devon, who endowed it with lands, called the prebends of
Hays and Catton, for the payment of certain weekly
services therein to be performed. A fenfions-houfe, of
Portland-stone, has been recently built within the area
on the north-west fide.

Within the walls of the city are fifteen parish churches,
and in the suburbs four; but most of them being small, they
prefent nothing worthy of particular description.

The cathedral is a large interefting edifice, and, according
to Hooker and fome other writers, was five hundred years in
building; it consists of a nave with two ailes, a choir with
aisles, a north and fouth tranfept, which are terminated by
lofty towers. On the south fide was a large cloifter, which
is mortally deftroyed. To the eaf of this is the bishop's
palace, which, with its gardens, are inclosed within a lofty
wall. For a particular history and defcription with feveral
architectural points, fee a large folio work publifhed by
the Society of Antiquaries.

The epifcopal fee of Devon was feated at Crediton
previously to its eftablifhment at Exeter; but Leftric, who
was bishop of that fee, and lord chancellor of England,
prevailed on Edward the Confessor to remove it to the latter
town in the year 1059. That monarch, in perfom, with
Eadyna, his queen, attended the installation, and placed the
bishop in his new fee; which at the fame time he endowed
with the lands and emoluments appertaining to that of
Crediton. The fee being thus eftablifhed, it appears
probable that a fuitable cathedral was foon afterwards
erected: but whether it was conftucted by the enlargement
and alteration of fome exifling edifice, or whether a fmaller
and entire building was now raifed, is uncertain. "It feems
not unlikely," obferves sir Henry Englefield, "that the fift
cathedral was not more than about fifty feet in length, and
occupied the fite of the preffent chapel of St. Mary." That
the chapel, in its preffent flate, was not the Saxon church,
is satisfaétorily proved by an examination of its architecture.
No particular alteration appears to have been made in the
cathedral before the time of William Waldeilaft, the third
bifhop, who was a Norman, and had been chaplain to the
Conqueror, and his two fons, William and Henry; the
latter of whom induced him to this fee in 1107. This
prelate was a liberal benefactor to his cathedral; and it ap-
pears that he conffderably enlarged it, and laid the foun-
dation of the preffent choir: to him the towers yet remaining
are probably to be ascribed; they are perfectly similar in
fyle to the buildings of Gundolphus his cotemporary, and
bear much more refemblance to the magnificence of the
Norman architects, than to the fimplicity of the English
Saxons.

Exeter has been from time immemorial, and fill is, infefted
with great privileges. At the period of the Norman sur-
vey it enjoyed the fame exemption from taxes as London,
York, and Winchester. Since that time it has obtained
many charters, and grants of immunities, from severaL
monarchs. In the reign of Henry I. the fee-farm rents were
granted to Matilda his queen; and in king John's time, Ia-
bel, his confoft, held Exeter in dower, with a fair thencnto
belonging. In the third year of John's reign, the burgeffes
paid a fine of 110 marks for a confirmation of their charters;
and about this period the city, which had been previouly
governed by port-rever and bailiffs, was incorporated, and
had a mayor for its chief officer. We find in the Natu-
ria Parliafmentaria, that "in the reign of Edward I.
The burgeffes and citizens pleaded that their city was an
ancient demefne, and that they held it in fee-farm of the
crown, paying 39 l. 15s. 3d. To support this claim, they
referred to Henry III.'s charter, made to his brother Ri-
chard, king of the Romans; whereby they further chal-
 lenged return of writs, a gallows, pillory, &c. and a faire
of four days, besides three weekly markets; which liberties
they certified they enjoyed since the time of the con-
quell; upon which they were allowed." Henry VIII.
confounded Exeter a county of itself; thus rendering it independent of Devon, and investing it with corresponding privileges.

The corporation now consists of a mayor, twenty-four aldermen, a recorder, chamberlain, town-clerk, sheriffs, four weeders, and several inferior officers. The corporate bodies within the city are thirteen, each of which is governed by officers annually chosen from among themselves. Exeter was one of the first cities that returned members to parliament: the right of election is vested in the magistrates and freemen, who are supposed to amount to about one thousand persons. The trade of Exeter is extensive; yet would probably have been much more so, but for a contention between the inhabitants and Hugh Courtenay, earl of Devon, which deprived the city of the use of its river for navigable purposes during several centuries. The dispute is reported by Isaac to have arisen about some pots of fish; which, being exposed for sale in the market place, were seen nearly at the same time by the cators of the earl, and of the bishop of Exeter, both of whom wanted the whole. The mayor, to whom the difference was referred, adjudged one part to the earl, another to the bishop, and the third he directed to be kept for the use of the market. This decision, and a subsequent determination of the mayor and council, that no Freeman of Exeter should wear any foreigner's livery, badge, or cognizance without the mayor's license, offended the earl, who immediately impeded the navigation of the river, "flotting, filling, and quitting the same," says Hooker, "with great trees, timber, and ftones, in such fort, that no vessel, or vessels, could passe or repasse." Pre-viously to this occurrence the tides flowed beyond the city; but now they only reach Topsham, a town between three or four miles nearer the sea, the advantage of which was probably the chief object of the earl's measures, as that place was part of his estate, and became exceedingly flourishing in consequence. The river was so completely choked up, that though many attempts were made to restore the navigation, fearfully anything was accomplished till the year 1675, when a canal was cut from Topsham to the city; and about twenty years afterwards the present haven was constructed: and by means of sluices and flood-gates, vessels of 150 tons burthen are now admitted to a good quay, formed near the city walls.

Exeter is situated 170 miles W. from London. The number of inhabitants, as returned under the late act, was 17,588; of houses 2,836. The principal employ of the labouring classes of people arises from the woollen trade; and the city has derived immense profits from the exportation of ferge, kerseys, and other articles, the value of which together has been computed at the average sum of 600,000 per annum: the chief markets were, during peace, Spain, Portugal, Germany, and Italy. About 300 persons are also employed in manufacturing cotton, at a large factory established on the banks of the river. Exeter had anciently a mint, which was granted by King Athelstan; and money has been coined here so late as the reign of William III, the place of coinage being denoted by the letter E under the bust.

This city has been the birth place of several very eminent and learned men. Among the most distinguished are, Josephus Icaneus, whose writings adorned the commencement of the thirteenth century: John Hooker, sir William Petre, and sir Thomas Bodley, who all flourished in the sixteenth century; and sir Peter, afterwards lord King, who held the high office of lord chancellor from 1725 to 1733.

In the vicinity of Exeter are several handsome, and re-

spectable seats, belonging to the nobility and gentry. The principal of these are, Powderham-castle, belonging to Viscount Courteney; Mamhead, the seat of lord Libburne; Haldon-houfe, the seat of sir Lawrence Palk, &c.; Mount-Radford, the seat of John Baring, esq.; Peamore, the seat of Samuel Kekewich, esq.; Cleve, the seat of Thomas Northmore, esq.; Cowick, the seat of James White, esq.; Northmore, the seat of the Rev. John Swete. Polwhele's History of Devonshire, Svo. Jenkins's History and Antiquities of Exeter, 12mo. 1806.

Exeter, a post-town of America, in the county of Rockingham and slate of New Hampshire, and Portsmouth excepted, the most considerable sea port town in the slate. It is situated on the head of the navigation on Swamscot; or Exeter river, a branch of the Pisataqua, 15 miles S.W. of Portsmouth. The tide rises here fourteen feet. This town is well situated for manufactures, and it has already fixed mills, a fulling mill, flitching mill, paper mill, saw-mill, two chocolate and ten grist mills, iron-works, and two printing offices. The candle factories are very considerable. Some few vessels of different burden are built here, and the river is capable of floating three of 500 tons. The situation of Exeter is adapted for an extensive population. The public edifices are, two congregational churches, an elegant building appropriated to the academy, a handsome and capacious court-house, and a gaol. The public offices of the slate are at present kept in this place. It contains 1,727 inhabited houses, the population is of an irregular figure, and about four miles figure. It was incorporated in 1638, before which period it was called Swamscot falls; it lies 50 miles N. of Boston. N. lat. 42° 50'. W. long. 71°. The academy was founded and endowed by the Hon. John Phillips, L.L.D. of Exeter, and incorporated by act of assembly in 1784. It is said to be a respectable institution, under the inspection of a board of trustees, and the immediate government and instruction of a preceptor and an assistant. Its annual income is £800, and the number of students is commonly between 60 and 80. In 1794 a building was erected, which, in point of convenience, and perhaps of elegance, is exceeded by few buildings of the kind in the United States. Morie.

Exeter, the north-westernmost township in Washington county, and slate of Rhode Island, in which the several branches of Wood river unite; containing 2,756 inhabitants, of whom 24 are slaves. Allo, a township in Luzerne county, Pennsylvania, including 737 inhabitants. Allo, a town in New Hanover county, in Wilmington district, North Carolina; situated on the N. E. branch of Cape Fear, about 36 miles from Wilmington.

Exfoliation. This term, in Surgery, denotes the process by which the dead part of a bone separates from the living portion. It is also not uncommon for to be signified, by the word exfoliation, the piece of bone itself that has perished, though this is certainly an abuse of language.

Exfoliation, or the separation of a dead portion of bone from the living, is effected much in the same way as a scab is thrown off from the soft parts. The piece of bone which has perished is not detached by becoming rotten; for, in fact, it possesses considerable firmness, and at first coheres as intimately as ever to the living bone immediately contiguous to it. As Mr. Hunter has accurately observed, if the process of exfoliation were not to take place, the dead piece of bone would remain undetached for years, inasmuch as putrefaction is considered in producing the separation.

The more the pathologist considers the diseases of the bones
bones, the more he will find them resemble those of the soft parts. This fact, indeed, anatomy would lead one to infer, since the texture of the bones is the more similar to the structure of the rest of the body, than an uninformed person would suppose. The chief difference is, that the bones contain lime, which the soft parts do not.

Mr. Hunter describes the process of exfoliation as follows: a dead bone (he says) acts on the system in the same manner as any other extraneous body. It stimulates the adjacent living parts, in consequence of which such a process is begun, as muscle, and is the dead piece being thrown off. The effects of this stimulus are; first, that the living adjacent bone becomes more vascular, a circumstance which always takes place, when a part has more to do than is just sufficient for the support of life. Secondly, that the earth of the living part, when it is in contact with the dead bone, is absorbed. Hence the bone becomes softer, and is now only adherent by the animal matter in its texture. Thirdly, that the living animal part is at last absorbed along the surface of contact. This part of the process begins long before the last is finished. Both of them begin first at the surface, though, in their course, they do not go everywhere where they take place, in an equal degree, at the same time. Fourthly, that, in proportion to the walls made by the last part of the process, a fungus arises from the living surface, and fills up the intermediate space, so as to prevent a vacuum. Mr. Hunter observes, that these different flages, taken together, constitute ulceration. He remarks, that when any part of a bone is once loose, it will be pushed towards the surface of the body, as most other inanimate substances are. This part of the process is partly mechanical, and partly a continuation of ulceration. The same distinguished surgical writer also notices, that a proof of the third flage above mentioned, may be derived from certain cafes, in which people die while exfoliation is going on. A small groove, or worm-eaten canal, may then be discovered, which becomes gradually deeper, and follows the irregularities of the dead and living surfaces. After the application of the trepan, a circular piece of bone is frequently thrown off, which is always less than the space from which it came. This, says Mr. Hunter, could never be the case, if there were not a /loos of substance.

Thus we find that exfoliation, and the process by which it occurs, is frequently detached and close, and in both instances, the matter which forms the bond of connection between the dead and living substances, is absorbed, the dead part is loosen, and is next pushed off by the lifting of the granulations.

The bones, on which exfoliations most frequently occur, are such as are of a firm, solid texture; those which are of a spongy cellular texture, are more subject to the affection called caries.

All the old surgical practitioners and writers used to promote the doctrine, that whenever the surface of a bone was laid bare, and deprived of its periosteum, an exfoliation must inevitably follow. The practice, which was referred to in consequence of this assertion, did really, for the most part, occasion a destruction of a part of the bone, and the progress of the caufe seemed a confirmation of the erroneous opinion, resting on experience itself for its foundation. For it followed almost as a matter of course with the ancient surgeons that since they considered the occurrence of exfoliation unavoidable in the circumstance which we have mentioned, their grand aim was to promote and accelerate the process, so as to shorten, as they conceived, the duration of the case. With this view, they used to put on the uncovered part of the bone stimulating, drying, spirituous applications, and, very often, the actual and potential cautery. Also, fancying that the wound could never heal till the dead piece of bone had come away, they used to avoid laying down the flesh, so as not to leave the surface of the bone a long while exposed, a cautery, of itself, quite adequate to the production of an exfoliation.

However, the fact is, that the mere temporary exposure of part of a bone, such a transient denudation, as need only be permitted in cases of wounds, is not necessarily, or even commonly followed by an exfoliation, when a proper method of treatment is pursued.

We have already remarked that the diseases of the bones are more like those of the soft parts, than many would imagine. The exposed surface of a bone will not die, if it be otherwise free from injury, and the surgeon, immediately he is called, takes care to lay down the detached flesh in the situation in which it previously occupied. Even when the denuded bone, on account of loss of substance, cannot be directly covered again, it will not always exfoliate, provided the surgeon, instead of using the cautery, cautics, spirituous, or any other irritating applications, applies only some plain soft lint, or a pledget of any mild spirituous ointment.

When the soft parts are merely divided, the exposed surface will not slough; but when the wound is complicated, with a violent degree of contusion, laceration, &c. the case is different, and the fibres, vessels, &c. mott injured, will die and be thrown off. These parts may either be killed at once by the violence, or the mischief which they have sustained may give rise to inflammation, which may terminate in sloughing. Things are nearly the same with respect to the bones. We will bring to our consideration a few circumstances relating to the subject of wounds of the head, which are, perhaps, more frequently than any other kind of wounds followed by exfoliations. In these instances, if the soft parts be simply cut, so as to occasion an exposure of the cranium, without the bone itself being violently contused, the wound may be healed by the first intention, and no part of the skull will exfoliate. The same occurrences may happen, together with a detachment of the pericranium, and yet the same consequences will follow.

However, when the external violence has affected the bone, as well as the soft parts, the injured part of the skull will frequently die and exfoliate, notwithstanding the most judicious treatment.

The process by which an exfoliating piece of bone is thrown off, depends almost entirely upon nature, and the surgeon can interfere very little, with any real utility. The milder and less irritating his dressings are, the better. Sometimes, when the dead part of the bone is loose, but is covered with flesh that it cannot come away, the practitioner may greatly expedite the cure, by making a proper opening for the removal of the piece of bone that has exfoliated. Sometimes, when the process of exfoliation is long and tedious, he may render essential aid by occasionally introducing a pair of small forceps into some fissures leading down to the affected bone, and moving the exfoliating portion a little, now and then, so as to accelerate its separation. This latter proceeding, it is obvious, is only admissible when the opening in the soft parts is large enough, and when the dead piece of bone either projects, or is of such a shape as will allow of its being taken hold of with a pair of forceps. Sometimes, when the dead piece of bone is prevented from exfoliating, by being overlapped by new ossific matter at its circumference, the surgeon may properly make some attempt to cut away the portion which is so wedged, that its spontaneous detachment would require an unreasonable length of time. Endeavours of this kind, however, on the part
part of the surfeiture, should be made with great circum-
pection and prudence; and, indeed, they can only be justi-
fiable when the affected bone is sufficiently superficial.

EXFOLIATIVUM, from esfoliis, to flay the skin, an
instrument for flaying e-foliated bones.

EXFREDIARY, in our Old Writers, denotes the
breaking of the peace, or committing open violence. Leg.

Hen. 1, cap. 31.

The word is formed from the Saxon, freeöl, peace.

EX GRAVI QUERELA, in Lactu, a writ that lies for
him to whom any lands or tenements in fee are deviled by
will (within any city, or borough, wherein lands are
devivable by custom), and the heir of the deviser enters, and
detains them from him. (Reg. Orig. 244. Old Nat. Br.
87.) And if a man devises such lands or tenements unto
another in tail, with remainder over in fee, if the tenant in
tail enter, and is foed by force of the entail, and afterwards
dieeth without issue, he in the remainder shall have the writ,
ex gravi querela, to execute that devise. (New Nat.
Br. 441.) Also where a tenant in tail dies without issue
of his body, the heir of the donor, or he who hath the
reversion of the lands, shall have this writ in the nature of a
formation in the receiver. Hall.

If a deviseor's heir be oufled by the devisee, by entry on
the lands, he may not afterwards have this writ, but is to
have it accordingly by the ordinary course of the common
law. (Co. Litt. 111.) If the claimant's title accrues within 20
years, the most eligible method of proceeding, is now by
ejection; which fee.

EXHEREDATION. See Exheredation.

EXHALATION, a fume or steam exhaling or issuing
from a body, and diffusing itself in the atmosphere.

The terms exhalation and vapour are ordinarily ufed in
ifferently, but the more accurate writers distinguish them;
appropriating the term vapour to the moist fumes raised
from water and other liquid bodies; and exhalation to the
dry ones emitted from solid bodies, as earth, fire, minerals,
fülphurs, falt, & c. In this fense, exhalations are dry fob-
tile corporufes, or effuvis, loofened from hard terrestrial
bodies, either by the heat of the sun, or the agitation of the
air, or some other cause, and emitted upwards to a certain
height of the atmosphere, where, mixing with the vapours,
they help to confiftide clouds, and return back again into
dews, milks, rains, &c.

Sir Ifaac Newton takes true and permanent air to be
formed from the exhalations raised from the hardeft and
most compact bodies. See Air, Damp, Evaporation,
and Vapour.

EXHAUSTED Receiver, a glafs, or other vessel,
appled on the plate of an air-pump, and having the air
extracted out of it by the working of the engine. (See Air-
pump.) Things placed in an exhausted receiver, are faid to
be in vacuo. See Vacuum.

EXHAUSTIONS, in Mathematics. Method of ex-
halutions is a way of proving the equality of two magni-
tudes, by a reducito ad abfurdum; shaving, that if one be
 Supposed either greater or lefs than the other, there will
arife a contradiction. The method of exhaustion was of
frequent ufe among the ancient mathematicians, as Euclid,
Archimedes, &c. It is founded on what Euclid lays in his
tenth book, viz. that thofe quantities whose difference is
lefs than any affignable quantity, are equal; for if they were
unequal, the difference ever fo small, yet it may be fo
multiplied, as to become greater than either of them; if not
so, then it is nothing.

This he aflumes in the proof of prop. 1. book v. which
imports, that if, from the greater of two quantities you take
more than its half, and from the remainder more than its
half, and fo continually, there will, at length, remain a
quantity lefs than either of thofe propofed.

On this foundation it is demonstrated, that if a regular
polygon of infinite fides be incribed in, or circumscribed
about a circle, the space, which is the difference between
the circle and the polygon, will by degrees be quite exhausted
and the circle become equal to the polygon.

EXHEBENUM, in Natural History, the name of a
white and smooth fone, ufed by the ancient artificers in
wifhing buildings. It seems to be the fame with the lapis
Sanicus, a small smooth fone which they often found in
the Saxon earth.

EXHEREDATION, Exheredation, in the Civil Law.
with us ordinarily called disinheritance, is the father's
excluding his fon from inheriting his estate.

There are fourteen caufes of exheredation expressed in
Julianus's Novel; without one of which caufe, he
declares the exheredation null, and the testament inofficious,
as the civilians call it.

Indeed, by the ancient Romais law, the father might
 profane exheredation without any caufe; but the rigour
of this law was restrained and moderated by Julianus.

EXHIBIT, in Lactu. When a deed, acquittance, or
other writing is, in a chancery suit, exhibited, to be proved
by witnefs, and the eaminer writes on the back, that it was
shewed to the witnefs at the time of his examination; this
is called an exhibit.

EXHIBITION, a producing or fhewing of titles, au-
torities, and other proofs of a matter in content.

Anciently, they ufed the phrase, exhibiting of a tragedy,
comedy, or the like; but now we fay reprefentation in lieu
thereof.

EXHIBITION, in our Old Writers, is ufed for
an allowance of meat and drink, such as was customary
among the religious appropriorers of churches, who usually
made it to the depending view. The benefactions settled
for the maintaining of scholars in the universities, not de-
pending on the foundation, are also called exhibitions.

EXHORTATION, Hortatio, in Rhetoric, differs
only from fatio, in that the latter principally endeavours
to convince the understanding, and the former to work on
the affections.

EXHUMATION, of ex, cut of, and humus, ground, the
act of digging up a body interred in holy ground, by the
authority of the judge.

In France, the exhumation of a dead body is ordered,
upon prouf that he was killed in a duel. By the French
laws, a parfon has a right to demand the exhumation of
the body of one of his parifhioners, when interred out of the
parifh without his consent.

EXIDEUIL, in Geography, a town of France, in the
department of Dordogne, and chief place of a canton, in
the district of Perigoux; 18 miles N. E. of Perigoux.
The place contains 870, and the canton 8738 inhabitants,
in 15 communes, and on a territorial extent of 190 ki-
ometres.

EXIGENCE, or EXIGENCY, that which a thing re-
quires, or which is expedient and fuitable thereto.

EXIGENT, or Exigium, in Lactu, a writ which
lies where the defendant, in a personal action, cannot be
found, nor any thing of his within the county, whereby to
be attached, or diftrained. It is directed to the sheriff,
ordering him to proclaim and call the party five county-
court days successively, and charge him to appear, under
pain of outlawry.

The
The same writ also lies in an indictment of felony, where the party indicted cannot be found.

It is called an exient, because it is, i.e., exacts, or requires the party to appear, or, by forthcoming, to answer the law. If he appear not at the last day's proclamation, he is liable to be quiaque, or quinto exitium, and then is outlawed. See Outlawry.

EXIGENTES, four officers of the court of common pleas, who make all exients and proclamations, in all actions where the offense is of outlawry.

Anciently, the making writs of supersedes upon such exients as passed in their offices, did likewise belong to them; but this branch of business was taken from them under King James I. and committed to a particular officer in the court of common pleas, created by patent. See Supersedes.

EXILE, Banishment. See Banishment.

Among the Romans, the word exile, exitium, properly signified an interdict or exclusion from water and fire; the necessary concomitance of which was, that the interdicted person must betake himself into some other country, since there was no living without fire and water. Thus Cicero ad Herenn. observes, that the form of the sentence did not express exile, but only aque & igni interdictio. See Interdiction.

The same author remarks, that exile was not properly a punishment, but a voluntary flight, or avoiding the punishment decreed: "Exilium non esse supplicationem, fed pernigritatem, portuque supplicationem." Pro Cæcina.

He adds, that there was no crime among the Romans, as among other nations, punished with exile; but exile was a recourse people flew voluntarily to, in order to avoid chains, ignominy, starving, &c.

The Athenians frequently sent their generals, and great men into exile, out of envy of their merits, or distrust of their too great authority.

Exile is sometimes also used for the relegating a person into a place, whence he is obliged not to stir without leave.

The word is derived from the Latin exitium, or from exul, a banished person; and that, probably, from extra solum, out of his native soil.

Figuratively, we use the phrase, honourable exile, for an office, or employment, which obliges a man to reside in some remote or disagreeable place.

Under the reign of Tiberius, remote employments were a kind of mysterious exiles. A bilocipric, or even a lord-burencancy, in Ireland, has been sometimes deemed a kind of exile. A relegation, or exulancy, in some barbarous country, is also a sort of exile. Accordingly, it is said, that the king cannot be ennobled a man deputy, or lord-burencan of Ireland, nor make one a foreign ambassador against his will, since these in reality might be no more than honourable exiles. 2 Inst. 46.

Exiles, in Geography, a town of France, in the department of the Po, on the river Doria; 5 miles W. S. W. of Suda. This town was fortified, and guarded one of the passages into Piedmont; but by the treaty of peace between the French republic and the king of Sardinia, in 1796, the fortifications were to be razed.

EXILium is when servants are enfranchised, and afterwards unlawfully turned out of their tenements. Tert. lib. i. cap. 11. Stat. Marib. cap. 25.

EXIMNO, ANTONIO, in Biography, a Spanish Ex-Jesuit, who had resided at Rome many years, and published in that city, in 1764, a work, intitled "Dell' Origene e della Regole de' Muffici," in which, too confident of his own powers, he imagined himself capable, with four years study only, intuitively to frame a better system of counterfeit than that upon which so many great musicians had been formed. Puffed of eloquence, fire, and a lively imagination, his book has been called in Italy, "a whimsical romance upon the art of music, in which is discovered a rage for pulling down, without the power of rebuilding."

The author has certainly, with fire, and accuracy, started several difficulties, and pointed out imperfections in the theory and practice of music, as well as in the particular systems of Tartini and Rameau; but his own resources and experience are totally insufficient to the task of correcting the errors of the old system, or forming a new one that is more perfect. He has more eloquence of language than science in music. His reasoning is ingenious and sanguine, even when his data are false; but his examples of composition are below contempt; and yet, they are courageously given as models for students, superior to those of the old great masters of harmony.

When Sig. eximeno calls fugues and canons Gothic compositions, he does not disgrace their structure any more than he would our cathedrals, by calling them Gothic buildings. Let fugues be banished from the theatres and private concerts, if he pleases, and let them remain in the church as a distinct species of composition, where they were first generated, and where they can never become vulgar or obloque. The style being naturally grave, requires musical learning, and will, by the solemnity of the words and place of performance, continue to be reverenced and respected. It is allowed that variety is more wanted in music than in any other art, and by totally excommunicating canons and fugues from the church, the art will lose one capital source of variety, as well as ingenuity; and intelligent hearers will be deprived of a solemn style of music, to be heard no where else.

EXINANITION, the same as evacuation.

EXISTENCE, that whereby a thing has an actual essence, or is laid to be, eff.

The notion of existence is applicable not only to a created, but a created substance; but it must be added, that the existence of created substances, and especially corporeal ones, implies a respect to place, time, and even an efficient cause; whereas the Schoolmen generally define it, that whereby a thing is formally and extrinsically without [extra] its cause, and that here, and now.

Existence and essence come very near the nature of each other; in effect, they only differ in that we have different manners of conceiving the same thing.

For, 1. Essence is usually explained either by the first, noblest, and radical attribute of the thing, e. g., that of body, by extension; that of mind by thinking, &c., or by specifying all the intrinsic attributes, and existence, either by specifying all place and all time, as in that of God; or by specifying some definite place, and time, together with the cause, as in the creatures.

2. The foundation and occasion of this distinction is
this; that essence belongs to the question, What is it? Quid est? but existence to the question, Is it? An est?

3. Existence, necissarily pre-supposes essence, and cannot be conceived without it; but essence may be conceived without existence; in that essence belongs equally to things that are in potentia, and in actu; but existence only to those in actu. Note, however, that this does not obtain in God, about whose nature and essence the mind cannot think without conceiving his existence.

What to me the several ways of arriving at the knowledge of the existence of things. Our own existence we know by intuition; the existence of a God, by demonstration; and that of other things, by intuition.

As for our own existence, we perceive it so plainly, that it neither needs, nor is it capable of any proof. In every act of intuition, reasoning, or thinking, we are conscious to ourselves of our own being, and in this matter come not short of the highest degree of certainty.

As to our knowledge of the existence of a God, though he has given us no innate ideas of himself, yet, having furnished us with faculties of sense, perception, and reason, we can never want a clear proof thereof. See God.

The knowledge of the existence of other things, i.e. of external objects, bodies, a world, &c. we only have by sense; for there being no necessary connection of real existence with any idea a man hath in his memory, nor of any other existence but that of God, with the existence of any particular man; no particular man can know the existence of any other being, but only when, by actually operating upon him, it makes itself be perceived by him. The having the idea of any thing in our mind, no more proves the existence of that thing than the picture of a man evidences his being in the world, or the visions of a dream make a true story. It is, therefore, the actual receiving of ideas from without that gives us notice of the existence of other things, and makes us know that something doth exist at that time without us, which causeth that idea in us, though we neither know nor consider how it doth it.

This notice which we have by our senses of the existence of things without us, though it be not altogether so certain as intuition and demonstration, yet preserves the name of knowledge, if we persuade ourselves that our faculties act and inform us right concerning the existence of those objects that affect them.

Now, besides the assurance of our senses themselves, that they do not err in the information they give us of the existence of things without us, we have other concurrent reasons, as, 1. It is plain these perceptions are produced in us by exterior causes affecting our senses; because those that want the organs of any sense never have the ideas belonging to that sense produced in their minds. 2. Because we find we cannot avoid having those ideas, produced in our minds. When our eyes are shut, we can at pleasure recall to our mind the ideas of light or the sun, which former sensations had lodged in our memories; but if we turn our eyes towards the sun, we cannot avoid the idea which the light or the sun then produces in us, which shews a manifest difference between those ideas laid up in the memory, and such as force themselves upon us, and we cannot avoid having; besides, there is no one who doth not perceive the difference in himself between actually looking upon the sun, and contemplating the idea he has of it in his memory; and therefore he hath certain knowledge, that they are not both memory or fancy. 3. Add to this, that many ideas are produced in us with pain, which we afterwards remember without the least offence; thus, the pain of heat or cold, when the idea of it is received in our mind, gives us no disturbance, which, when felt, was very troublesome; and we remember the pain of hunger, thirst, heat or cold, &c. without any pain at all, which would either never disturb us, or else constantly do it, as often as we thought of it, were there nothing more but ideas floating in our minds, and appearing of themselves, as the real existence of things affecting us from abroad. 4. Our senses, in many cases, bear witness to the truth of each other's report concerning the existence of sensible things without us: he that doubts, when he sees a fire, whether it be real, may feel it too if he pleases; and, by the exquisite pain, may be convinced, that it is not a bare idea or phantom. Such is Mr. Locke's demonstration of the existence of external bodies.

The ingenious Dr. Berkeley has a different system: external bodies, he contends, have no existence, but in a mind perceiving them; that is, they only exist, quatenus, they are perceived; and of this he has given us what he and several others account a demonstration.

In reality, "that neither our thoughts, pulsions, nor ideas formed by the imagination, exist without the mind, he observes, is allowed; and that the various sensations impressed on the mind, whatever objects they compose, cannot exist otherwise than in a mind perceiving them, is not less evident. This magnificent demonstration of the existence of the sensible, when applied to sensible things, without the table I write on, exist, i.e. I see and feel it; and were I out of my study, I should say it existed; i.e. that were I in my study I should see and feel it as before. There was an colour; i.e. I smelt it, &c. but the existence of unthinking beings, without any relation to their being perceived, is unintelligible, their esse is percipi." The notion of bodies, he endeavours to shew, is founded on the doctrine of abstrait ideas: "What are light and colours, heat and cold, extention and figure; in a word, the things we see and feel, but so many sensations, notions, ideas, or impressions on the sense? And is it possible to separate, even in thought, any of these from perception? The several bodies, then, that compose the frame of the world, have not any subsistence without a mind; their esse is to be perceived or known; and as long as they are not perceived by me, nor any other thinking being, they have no shadow of existence at all. The things we perceive are colour, figure, motion, &c. that is, the idea of those things; but has an idea any existence of the mind as to that thing as to perceive; that, therefore, wherein colour, figure, &c. exist, must perceive them. It is evident, therefore, there can be no unthinking subsistence or substratum of those ideas: but you may argue, if the ideas themselves do not exist without the mind, there may be things like them, wherein they are copies or refembances, which exist without the mind; it is answered, an idea can be like nothing but an idea; a colour or figure can be like nothing else but another figure or colour. It may be farther asked, whether those supposed originals, or external things, whereof our ideas are the pictures, be themselves perceivable or not? If they be, they are ideas; if they be not, I appeal to any one, whether it be sense to say, a colour is like somewhat which is invisible; hard or soft, like somewhat intangible, &c. Some distinguish between primary and secondary qualities; the former, viz. extension, solidity, figure, motion, rei, and number, they maintain have a real existence out of the mind; as for the latter, under which come all other sensible qualities, as colours, sounds, tastes, &c. they allow the ideas we have of them are not refembances of any things existing.
EXISTENCE.

existing without the mind, or unperceived, but depend on
the size, texture, motion, &c. of the minute particles of
matter. Now, it is certain, that those primary qualities are
inseparably united with the other secondary ones, and
cannot even in thought be abstracted from them, and therefore
must only exist in the mind. Can any man conceive the exis-
tention and motion of a body without its other sensible qua-
thitics? For my part, I find it impossible to frame an idea of
a body extended and moving, without giving it some colour,
&c. In effect, extension, figure, and motion, abstracted
from all other qualities, are inconceivable; where the others,
therefore, are, there these too must be, i.e. in the mind, and
no where else. Again, great and small, swift and slow, are
allowed to exist nowhere without the mind, being merely
relative and changeable, as the mind is. Now, black and
white, hot and cold, sweet and sour, are qualities of
the mind, therefore, that exist without the mind, is neither
great nor small, the motion neither swift nor slow; i.e. they
are nothing. That number is a character of the mind, is plain
(even though the other qualities were allowed to exist) from this:
that the same thing bears a different denomination of number, as
the mind views it with different aspects; thus, the same
extension is 1, or 3, or 36, as the mind considers it, with reference
to a yard, a foot, or an inch. Nay, many of the modern geometri-
cans, hold, that a finite line may be divided into an infinite
number of parts, and each of these infinitesimals, into an infinity
of others; and so on, in infinitum; so that the same thing is
either unity or infinity, either no number or an infinite
number. In effect, after the same manner as the modern philo-
sophers prove colours, tastes, &c. to have no existence in
matter, or without the mind; the same thing may be proved of all sen-
sible qualities whatsoever: thus, they say, heat and cold are
only the affections of the mind, not at all patterns of
real beings existing in corporeal substances; because the same
body which seems cold to the hand, feels warm to the
other. Now, why may we not as well argue, that figure and
extension are not patterns or resemblances of qualities existing
in matter; because to the same eye, at different stations, or
to eyes of different structure, at the same instant, they
appear various? Again, sweetness, it is proved, does not
exist in the thing itself, because the thing remaining un-
altered, the sweetness is changed to bitterness, as in a fever,
or by an otherwise vitiated palate. Is it not as reasonable
to say, that motion does not exist out of the mind; since, if
the succession of ideas in the mind becomes swifter, the
motion, it is acknowledged, will appear slower, without any
external alteration. Again, were it possible for solid figured
bodies to exist out of the mind, yet it were impossible for us
ever to know it; our senses, indeed, give us sensation of
ideas, but do not tell us that any things exist without the
mind, or unperceived, like those which are perceived: this
the materialists allow. No other way therefore remains, but
that we know them by reason's inferring their existence from
what is immediately perceived by sense. But how should
reason do, if there is not this necessary connection between our
sensations and these bodies? It is evident, from the phenomena of
dreams, phrenses, &c. that we may be affected with the ideas we have now, though
there were no bodies existing without them; nor does the supposition of
external bodies at all forward us, in conceiving
how our ideas should come to be produced. The
materialists own themselves unable to conceive in what manner
body can act on spirit, or how it should imprint any idea on
the mind. To suppose, therefore, bodies existing without the
mind; is little else than to suppose God has created in-
umerable beings entirely ufeless, and serving to no purpose
at all. On the whole it appears, that the existence of bo-
dies out of a mind perceiving them, is not only impossible,
and a contradiction in terms; but, were it possible, why
real, it were impossible we should ever know it. And again,
that supposing that there are no such things, yet we should
have the very same reason to suppose there were that we now
have. Supposes, e.g. an intelligence affected with the
same train of sensations, impressed in the same order, and
with the same vividsness, would it not have all the reason to
believe the existence of bodies represented by his ideas that
we have? All our ideas and sensations are visibly inactive
may, the very being of an idea implies phrenses and inert-
nels; so that it is impossible for an idea to do any thing, or,
in trifles, be the cause of any thing; or, in fact, be the
resemblance or pattern of any active being, unl-
feels, ephebeus can be said to resemble one another. Now,
we find a continual succession of ideas of the mind; but
these, it has been proved, do not depend on any external
body as their cause; it remains, therefore, that their cause
is an incorporeal active subsistence or spirit; for that I am not
the cause of my own ideas, is plain from this, that when I
open my eyes in broad day-light, I cannot help seeing
various objects. Now, the fixed rules or methods wherein
the mind we depend on excites us in the ideas of sense, are
called laws of nature; these we learn by experience, which
teaches us, that such and such ideas are attended with such
and such other ideas in the ordinary course of things. Ideas
are not any how, and at random, produced; there is a cer-
tain order and connection Established among them like that
of cause and effect; and there are several combinations of
them made in a very regular artful manner, which we call
bodies; and the simile of these, the world. In strictness,
however, the connection of ideas does not imply the rela-
tion of cause and effect, but only of a mark or figure; if
the thing signified, the fire I feel, has the cause of the pain I
feel, but the mark that forewarns me of it; the noise I hear
is not the effect of this or that motion or collision of natural
bodies, but the sign thereof. The Cartesian own somewhat
like this: the action of bodies on our organs, say they, is
not the efficient cause of our ideas and perceptions, but only
the occasional cause, which determines God to act on
the mind, according to the laws of the union of the soul
and body." (See Cause.) Dr. Berkeley, indeed, taking away
bodies, takes away what these philosophers account the
occasions of their ideas: "by an occasion, he says, must ei-
ther be meant the agent that produces an effect, or some-
thing observed to accompany or go before it in the ordinary
course of things; but matter is allowed to be passive and
inert, and cannot therefore be an agent or efficient cause;
and this matter primitively, and in itself, is allowed imper-
ceivable, and devoid of all particular sensible qualities; i.e.
it has not this or that particular colour, this or that par-
ticular figure, &c. but has colour in the general, figure in
the abstrait, &c. but an abstrait is no object of sense; neither
the occasion of our ideas in the latter sense." See Berkel, Princ. of Human Knowl. See Ab-
straction.

How far the great argument of the maintainers of a
material world from the impossibility of God's deceiving us,
and from the evidence that he does so, if there be no such
thing, will go against this reasoning, we leave to the reader.
See Stan. Hill. Philosop. part xii. p. 816. where the
objections of the ancient Pyrrhonist to the existence of bodies
are recited.

As to the existence of spirits, Mr. Locke allows, that our
having ideas of them does not make us know that any fuch
things do exist without us; or that there are any finite
spirits, or any other spiritual beings, but God. We have ground
ground from revelation, and other reasons, to believe with assurance, that there are such creatures; but our senses, being not able to discover them, we want the means of knowing their particular existence: for we can no more know that they are inhabited with souls than the idea we have of such beings, than by the ideas any one has of fairies or centaurs, he can come to know that things answering to those ideas do really exist.

EXIT, properly expresses the departure of a player from off the stage, when he has acted his part.

The word is also used in a figurative sense, to express an kind of departure, even death.

EXTERIA, Exteria, in Antiquity, obligations or prayers to any of the gods for a prosperous expedition or journey. There were also feasts under this denomination, which were celebrated by the Greeks, with sacrifices and prayers, when their generals undertook expeditions against any enemy.

EXITURA, from eceos, to come from, in Surgery, an abscess which discharges matter.

EXITUS, Issues, in Law, the yearly rents or profits of lands or tenements. See Issue, &c.

EXLEGALITVS, the fame with an outlawed person.

See EXILIT.

EXLUNGA, in Geography, a town of Spain, in the province of Leon, 13 miles S. E. of Leon.

EX MERO MOTO, in Law, formal words used in the king's charters and letters patent, signifying that he does what is contained therein of his own will and motion, without petition or suggestion of any other.

The effect of these words is to bar all exceptions that might be taken to the instrument, by all-aging that the prince in passing such charter was abased by false suggestions.

EXMES, in Geography, a town of France, in the department of the Orne, and chief place of a canton in the district of Argentan; 9 miles E. of Argentan. The place contains 618, and the canton 7358 inhabitants, in 31 communes, and on a territorial extent of 14,749 kilometres.

EXMOUTH, though a watering place of considerable size and repute, is only a hamlet belonging to the parish of Littleham, in the county of Devon, England. As its name imports, it stands near the mouth of the river Exe. The buildings in general are low, but here are some good houses inhabited by genteel families. The vicinity is highly picturesque: from an eminence, called Chapel-hill, a line of cliffs presents itself, which extends from Exmouth to Berry-head, a distance of about twenty miles. This line is broken by several hills, behind which spring up some bold towering head-lands.

The plantations of Manhead and Powderham-castle heighten the beauty of the prospect; which is additionally embellished by the noble buildings connected with those estates. Holmfield mentions a castle erected here to defend the entrance of the haven; and some flight veltiges of embrasures are still apparent. Exmouth is situated 168 miles W. from London; and contains, including the parish of Littleham, 462 houses, and 1009 inhabitants, of whom 572 are returned as employed in trade or manufacture. Polwhele's Devonshire, vol. ii.

Gen. Ch. General Umbel of many spreading rays; the inner ones gradually shorter; the innermost extremely short; partial of more ray. General involucrum mostly of 12 channelled leaves, with spinous points; partial halved, its intermediate leaf very long, exactly like those of the general involucrum. Perianth scarcely perceptible. Cor. uniform, of five equal, inclosed, heart-shaped petals. Stam. Filaments five, longer than the corolla; anthers roundish. Pfl. Germen inferior, ovate; styles two, short, straight; stigmas simple. Fruit somewhat ovate, flattened, separable into two parts. Seeds two, ovate, convex and flattened on the outside, flat on the inner.

1. E. heterophylla. Billard. Syr. spec. i. 12. Gathered by M. La Billardiere near Nazareth. Root biennial, tap-shaped. Stam. two feet, or more in height, slightly zigzag, branched, round, flattened, leafy, smooth. Leaves pinnate, smooth; leaves one or two pair with an odd one; those of the radical leaves ovate, sharply serrated, often cut; those of the stem-leaves lanceolate, acute, narrow, entire, the odd ones very long. Umbels terminal, solitary, of about 40 rays; the partial ones of about as many, which are equal and crowded. The involucral leaves are very long, prominent, curved downwards, each ending in a sharp spine. Petals white. Anthers yellowish. This plant is akin to the Lechinquera, (see that article,) but differs generally in the want of a perianth, and in having all the flowers perfect and regular, with naked fruit, not imbedded in the involucrum.

Gen. Ch. Cult. Perianth inferior, in five deep roundish, equal segments. Cor. none. Stam. Filaments five, inserted into the calyx between its segments; anthers small, roundish. Pfl. Germen superior, globular; style, short, solitary; stigmas petaloid, orbicular. Peric. none. Seed a roundish nut, of one cell, standing on the top of an elliptical, hollow, fleshy receptacle, about thrice its own size. Some flowers have an abortive germ, others have no flaments, all on the same plant.

E. suprissiformis, the only known species, is an evergreen tree, found in New Holland by M. La Billardiere, as well as by Dr. White. It bears innumerable, compound, pendulous, angular, leaflets branches, at whose extremities are situated the minute greenish flowers, produced in the month of May by the Inner. The fruit is red, not unlike that of the yew in size, form, and colour, but the seed is perfectly exposed to view. This plant has been raised from seed in England, but whether it still remains in the gardens we know not. Its singularity entitles it to notice, and, we believe, it is by no means very tender, if not hardy enough to bear our winters in the open air.

EXOCATACCELUS, in Antiquity, a general denomination, under which were included several grand officers of the church at Constantinople; as, the grand economus, grand facellarius, grand master of the chapel, grand sceophylax, or keeper of the vessels, grand chartophylax, the master of the little chapel, and the procudices, or first advocate of the church.

There are many opinions with respect to the etymology of this term. F. Goar apprehends, that all the inferior priests were called καταστημα, cateciten, q. d. people of a low condition, and that their superiors were called exocaticelli, q. d. people out of the number of cateckeli, or above them. Upon the whole, however, he adheres to the sentiment of G. Corelius, who says, that the patriarchal palace, and the apartments of the syucellerus, and of the monks in the patriarch's
The exocataceli were of great authority in public assemblies; they had the precedence of bishops, and in the patriarchate of Constantinople did the office of deacon; as the cardinals originally did in the church of Rome. Accordingly, in the letter of John IX. to the emperor Basilius, they are called cardinals.

At first they were priests; but some patriarchs of Constantinople, whom Codin does not mention, would have them for the future to be no more than deacons. The reason was, that being priests, each of them had their several churches, wherein they were to officiate on all the grand festival days; so that it unhappily fell out, the patriarch, on the most solemn days, was defeated by all his chief ministers.

EXOCHAS, or ExÔche, from αεωθ, without, and αεωθ, to have, in Surgery, a kind of excrescence on the outside of the anus.

EXOCIONITE, Exociones, in Church Antiquity. The Arians were first called Exocionites, because, when expelled the city by Theodosius the Great, they retired into a place called Exooinion, and there held their assemblies. Justinian gave the orthodox all the churches of the heretics, excepting that of the Exocionites.

The word is derived from ἐκονη, or ἐκοη, the name of the place above mentioned. Codin, in his Origines, says, that the Exoconion was a place encompassed with a wall, built and adorned by Constantinian; and that without the circumference of the wall there was a column, with a statue of that emperor, whence the place took its name, εκοεη, from εκοη, without, and αεωθ, column.

EXOCOETUS, in Ichthyology, a genus of the abdominal kind of fishes; the head is scaly; mouth without teeth; jaws connected at each side, in the gill membrane ten rays; body whitish; abdomen angulated; pectoral fins large, and formed for flying; anterior part of the rays carinated. These are the flying fishes of English authors.

Species.

This is an inhabitant of the American and Red seas, and also those of the warmer parts of Europe; in one or more instances it has been known to appear as far north as Britain. The vastly disproportionate magnitude of the pectoral fins in this genus of fishes affords them extraordinary advantage in effecting their escape when closely pursued by their voracious enemies in the water; but this facility of escape exposes them oftentimes to the attacks of other adversaries, and they not unfrequently elude the pursuit of the bonito, or the gorfpe, in their native element, to become the prey of gulls, corvorants, and other aquatic birds that hover over the water to seize on them in their aerial flight. They remain only for a short time suspended in the air before they again dive into the water, and after a pause of a few moments emerge again at some distance. They often quit the water in flocks, and sometimes alight on board ships in great numbers. The flesh is occasionally eaten.

The colour is silvery, with the back rather blueish; the pectoral fins blueish, edged with yellow; ventral fins and extremity of the tail sometimes reddish.

EXOCHAS, Ventral fin reaching to the tail. Gen. Bloch. See also Echius.

A native of the Mediterranean and Red seas. The colour is silvery, blue on the back, with the fins yellowish at the base, with the extremity blueish. The flesh is in flakes.

MESOGASTER. Ventral fins in the middle of the abdomen. Bloch. Atlantic flying fish.

Native of the Atlantic seas, and was observed by Plinius about the coasts of the Antilles. The fifth is bright silver, with the back and fins blueish. The species is sufficiently distinguished by the situation of the ventral fins.

COMMENSONIORI. Dorasal fin marked with a dark blue spot.

CEPHEUS. Commersonian flying fish, Shaw Gen. Zool.

Described by Commerson as resembling the fifth species, except in having a dark blue spot on that part of the dorsal fin nearest the tail, and the ventral fins placed beyond the middle of the abdomen, their tips reaching to about the middle of the anal fin.

The last mentioned species, we are inclined to believe, may not differ specifically from the fifth described by Bloch under the name of Mesogaster: the evolans and volitans of Linnaeus, according to some writers, constitute but one species; and we should also speak with diffidence of the species denominated exocetus, non volitans by Forcell; is it a variety of volitans, or, as Gmelin considers, rather an error arising from some accidental circumstance?

EXOCRISTU, or Exocristus, from εκοη, without, and αεωθ, the bladder. Writers define this term of surgery a prolapsus of the lining of the bladder. We are probably to understand by the word, a protrusion of the lining outward, between the falciform of the muscular coat of this organ, an occurrence which we know does really sometimes take place. Stones have been found protruded in this manner, carrying along with them a part of the lining of the bladder.

EXODIARY, Exodarius, in the Ancient Roman Tragedy, was a droll, or mime, who appeared on the stage when the tragedy was ended, and performed what they called the exodium, or conclusion of the piece, to divert the company.

EXODIUM, Exoos, in the Ancient Greek Drama, was one of the four parts or divisions of a tragedy. The word is formed from the Greek, εκοεη, going out, degestion, of εκοη and ooe, way, road. Feltus, lib. v. calls it exitus.

The exodium, according to Aristotle, was so much as was rehearsed after the chorus had closed for the last time; so that exodium with them was far from being what the epilogue is with us, as several people have imagined it was.

The exodium was so much of the piece as included the catastrophe and unravelling of the plot; which catastrophe, &c. in pieces regularly composed, always began after the last singing of the chorus, answering nearly to our fourth and fifth acts. M. Dacier’s Comment. on Aristotle’s Poetics, chap. 12. See Catastrophe and Chorus.

Among the Romans the exodium was a different thing; it was pretty nearly what farces are with us. After the tragedy was over, came a pantomime on the stage, called the exodarius, who, by his grimace, jesting, and buffoonery, diverted the people, composed their minds, and wiped away the tears which the tragic spectacle had occasioned to be shed.

Vigilure on T. Livy says, the exodium consisted of certain
tain humorous droning verses, rehearsed by the youth at the end of the fabule attellane, and ansterring to our fares. In another place, the fame author fays, that the exodia were a kind of interludes in the intervals between the acts, partly fable and pleafanfry, partly nufic, &c. to give time both for the spectators and actors to recover breath. The paffage in Livy, whence he takes the notion, is lib. viii. dec. 1. "Ridicula interexa verifius, quae juventus inter fe more antiquo jactare cepit, caque conferta funt fabulis potifium attellanis." See alfso Juvenal.

"Urbius exodio rifiuni movet Atellane Gefibus Autonemos."

EXODIUM, in the Septuagint, signifies the end or conclusion of a feaf. The Hebrew text calls the day נרerglass, which the Seventy render Εξοδιος.

In particular, exodion is used for the eighth day of the feaf of tabernacles, which, it is said, had a special view to the commemoration of the Exodus, or departure out of Egypt, though there is nothing of it exprefled in Scripture. EXODIUM, was also the name of a fong fung at the conclusion of a meal or feaf.

EXODUS, the feccond of the five books of Moies.

The word in its original Greek, Εξοδος, literally imports a going out, or journey; and was applied to this book, becaufe the history of the Israelites' paffage out of Egypt is related therein. Besides this, it contains the story of what was tranfacted in Egypt from the death of Joseph to the delivery of the Jews; as well as what paffed in the wildernes, and particularly at mount Sinai, to the building of the tabernacle.

The Hebrews call it נקדה fmalath, q. d. firm nomina, these are the initial words of the book; for the fame reafon they call Genesis, hereath, q. d. in principis, in the beginning.

EX OFFICIO, in Law, denotes a power which a perfon has in virtue of his office, to do certain things without being applied to; as a judge of peace may not only grant fiety of the peace, at the complaint or requiff of any perfon, but he may demand and take it, ex officio, at diſcretion, &c.

Dalt. 270.

By a branch of flature I Eliz, the queen, by her letters patent, might authorize any perfon exercifing ceffifalifal jurifdiction to administer an oath, ex officio, whereby fupposed offenders were forced to confefs, accuse, or clear themselves of any criminal matter, &c. but this branch relating to this oath is repealed by 17 Car. I. cap. 11.

EX OFFICIO Informations. See Information.

EXOLICETUS, in Natural History, a name used among the writers of the middle ages to exprefs a small flore which had fuch a variety of colours that it dazzled, as they fay, people's eyes in looking at them. It is faid to have been found in Libya. The name is probably only a corruption of the hexaconalibos of Pliny and the older writers; and this seems to have been no other than a name for the opal.

EXOMIS, of εξομις, out of, and χορδα joint, in Antiquity, a straight narrow garment through which the shoulders appeared. It had fomething in common with the tunic, and fomething with the pallium. It was worn by faves, fervants, and the lower claffes of people among the Romans.

EXOMOLOGESIS, εξομολόγος, formed of Εξομολογεια, I confefs, a term little used but in speaking of the ancient ceremonies of repentance, whereof the exomologesis, by us called confession, was a part.

Some of the ancients, and particularly Tertullian, De Penit. cap. 9. use the word in a greater latitude, as comprehending the whole of repentance.

A public exomologesis was never commanded by the church for secret flis, as may be seen in the capitulat of Charlemagne, and the canons of divers councils.

EXONPHALOS, from εξον, out, and ψενδων, the navel, in Surgery, an umbilical hernia, or a diffeafe which conflits of a protrufion of fome of the abdominal vifera at the navel. The subject will be particularly confidered in the article Herina.

EXONCHOMA, from εξον, out, and ψενδων, a tumour, any large prominent fwellings.

EXONEIROSIS, from εξον, out, and ωνης, dream, a nocturnal pollution or emission of the femina in dreams. This, if it happens but rarely, is usually a sign only of redundant vigour; but if it happens frequently, is a sign of weakness of the feminal vessels, which is most frequently the cafe.

EXONERATIONE SeCt., in Laws, a writ that lay for the king's ward, to be freed from all fuit to the county-court, hundred-court, let, &c. during the warfhip. F. N. B. 158.

EXONYCHOS, of εξον, without, and ψενς, a nail, in Botany, a name given by fome of the ancient writers, among whom are Dioscorides and Pliny, to the gromwell or lithopernum. See Exonychus.

EXOPHTHALMIA, from εξον, out, and ψενδων, the eye, in Surgery, a diffeafe confifting of a protrufion, or a preternatural projection of the globe of the eye from the orbit, fo that the part cannot be duly covered by the eye-lids. The diffeafe may proceed either from a morbid enlargement of the eye-ball, or what, perhaps, is a still more common caufe, some tumour which occupies or diminifhes the cavity of the orbit, and confequently displaces the eye.

The affection has feveral other names besides exophthalma; as, for instance, buphthalmus, ophthalmoptosis, prolapfus oculi, ephelimos, melon, &c.

From the few words already delivered on the subject, it is easy to perceive that exophthalma may arise from a variety of caufes, and muft of cofe require very different modes of treatment in different cafes.

One caufe of the diffeafe noticed by writers, is a diffeafe of the fat and cellular fubfiances situated in the orbit, and ferving as a fupport to the eye-ball. In this cafe the furface of the eye appears more moiftened with tears than ufual, and the fat and cellular fubfance becoming thickened and indurated, forces the eye-ball forward out of its focket. As the eye cannot now be properly covered and feltered by the eye-lids, it inflames, and discharges upon its furface, and the patient becomes afflicted with very fevere and deep-feated pain. This forte of caufe is as difficult of removal, when the diffeafe has advanced to a certain extent, as it is difticult of detection at an early period of the cafe. The famous orulif, Saint Yves, pretends, however, to have fometimes dif- fered fuch thickenings of the cellular fubfance in the orbit by perfervering in the exhibition of calomel and purgative medicines. The fame author affures us, that he fuccfefully exhibited the ethiops mineralis to a fevere patient for three months, whole eye-ball protruded to the extent of three lines, by reafon of a morbid thickening of the cellular fubfance, and an enlargement of the lachrymal gland.

When the diffeafe does not yield to any remedies, the fymptoms may become fo urgent as to render the extirpa- tion of the eye indifsipably neceffary, as is proved by the following cafe related by Saint Yves. A woman's eye-ball protruded out of its natural fition, in confequence of a morbid thickening of the fat at the bottom of the orbit. The
EXOPHTHALMIA.

The disease was attended with insupportable pain, and great restlessness. The symptoms were appeased by the employment of general means, and the progress of the affection was for a time retarded. Three years afterwards, the eye having been left in a projectile condition, Saint Yves was requested to visit the patient. She was now labouring under a violent fever, accompanied with feverish headache. The globe of the eye was of a leaden colour, and exceedingly prominent, its coats being swollen, and appearing likely to become gangrenous. The medical practitioners who were in the habit of attending the woman were of opinion that the eye ought to be extirpated. The necessity for performing the operation, indeed, seemed to them so urgent, that the proceeding was immediately adopted. The febrile and all untoward symptoms subsided on the fourth or fifth day, and, in about three weeks, the cure was complete.

Exophthalmia may also be occasioned by some tumour of the surrounding parts, either of those within, or of others on the outside of, the orbit. The celebrated French surgeon, M. Louis, met with a man, 40 years of age, in whom a carcinomatous fungus, situated in the antrum, had destroyed the bony plate which constitutes the bottom of the orbit, and pushed the eye-ball almost entirely on the cheek, so as to produce a great deformity of the countenance. The upper jaw bone was carious, both towards the palate and nose, and the patient suffered from the afflictive complaints, brought on by the carcinomatous ulceration of all the diseased parts. The exophthalmia was the effect of the prodigious size of the tumour, the growth of which could not be effectually resisted by the bones. The protrusion of the eye, says M. Louis, might have been prevented by attacking the first disease at a proper period, on the side towards the mouth. The growth of the carious fungus is represented by this distinguished writer as the effect of a disease of the bone, which latter affection he describes as the consequence of syphils, which had not been skillfully treated.

Raw makes mention of a child whose left eye was completely protruded from the orbit, and as large as one's two fists. The disease, which had only begun a few months before, proved fatal. On opening the cranium, a fungous swelling was discovered, the bale of which was connected with the dura mater over the orbit, without any disease of the cerebrum.

Exophthalmia, however, originates still more frequently from the enlargement of an exofiiosis, which arises within the orbit, and forces the eye-ball out, in proportion as it increases in magnitude. When the bony swelling is situated near the edge of the orbit, the tumour may be attacked with beneficial effects, without meddling with the eye itself. The truth of what has just now been observed is illustrated by the following case. A woman, 30 years of age, had a fistula lachrymalis, for which she had undergone an operation to no purpose. The bones became enlarged, and, fifteen years afterwards, an exofiiosis of the os planum and internal angular process of the os frontis had attained the size of an egg. The globe of the eye, being laterally compressed, was forced out of the orbit, and, in some measure, hung over that part of the cheek which was near the lesser angle. M. Brantiff applied a caustic to the exofiiosis; suppuration ensued, and in the course of three or four months an exfoliation of a considerable portion of the bony swelling took place, the eye refused its natural position, and the cure was completed a short time afterwards.

Exophthalmia is sometimes produced by the formation of a carcinomatous, or fibrous tumour, at the bottom, or sides of the orbit. Trincavelli, Bonnetus, and Saint-Yves, furnish us with several examples of this sort. Here an operation is requisite; but a great deal of patience and dexterity are essential in its performance. As the recital of facts tends to the elucidation both of precept and practice, we shall offer an abridged account of a case, related by Dr. Hope, in the Philosophical Transactions, where every thing respecting the method of treatment is very perspicuously explained. A young woman, eighteen years of age, was affected, when twelve years old, with a distortion of her left eye, towards the temple. This circumstance arose gradually, in consequence of the growth of a tumour between the eye and the orbit. In a few years, the swelling protruded externally, in the form of a hard tumour, which extended from the greater angle nearly to the lesser one, beneath the lower eyelid, and which reached nearly half an inch over the cheek. This tumour had pushed almost the whole eye-ball out of the orbit, so that the pupil was removed more than three inches from its proper place. The eye was also much more prominent than the other, pushed over the temple, and quite motionless, which circumstances, together with the tumour, presented a frightful appearance. The sight, however, was not lost. Dr. Hope, though diffused by Monro, undertook the cure of the patient in the year 1744. Having placed her in a convenient posture, and made the integuments tense, he made an incision about an inch long, from the greater to the lesser angle, following the direction of the fibres of the orbiculares palpebrarum muscle. The lips of the wound being separated, he next passed a crooked needle, armed with some silk; through the middle of the tumour, and, regularly as he cut all the adhesions with a bistoury, he drew outward the whole mass of the disease. Scissors were employed for dividing such connections, as were the most deeply situated. The part which was thus cut out appeared to be furnished with a thick membranous substance, exclusively of the body of the tumour, which was of a regular, spherical, smooth form, and about as large as a small pigeon's egg; the interior was of a flabby structure. In detaching the swelling from its adhesions, several callous indurations were met with, attached to the globe of the eye. The tumour being extirpated, Dr. Hope introduced his finger to the bottom of the orbit, where he felt several hardferences and callousities still remaining; he kept his finger there, and having by this means pressed in a needle and ligature, he drew them through the base of the callousities. Now having directed an assistant to hold up the ligature, he passed in the point of a pair of scissors, on the end of his finger, and made two or three strokes with them, in the place where he felt the roots of the callous hardenesses. Thus he succeeded in cutting away the whole of the indurated parts, so as to leave the bottom of the orbit, as far as he could ascertain, perfectly smooth and free from callosity. All the time that the operation lasted, no hemorrhage of any consequence took place; only a large quantity of dark-coloured gumrous blood was poured out from the various vessels. The wound was closed with some dry lint, which was not removed till the third day. The eyelids and tunica conjunctiva were affected with a flabby kind of swelling, attended with a slight inflammation; pain in the anterior part of the head. The dressings consisted of simple digestive and resolvent applications. The pain in the head, and the tumefaction continued three days, without any formation of matter. Dr. Hope then touched the bottom of the wound with the lapis internalis, and, a few hours afterwards, a large quantity of black blood was discharged. From this period the pain in the head, and the swelling
EXOPHTHALMIA.

The swelling subfided; there was also emitted, during the two succeeding days, a bloody sanguine, which occurrence induced Dr. Hope to make use of some injections of warm water, mixed with a little spirit of wine, and honey of roes. 

After the adoption of this plan of treatment, the pus af- firmed a much more regular appearance. Such, soft, fungous excrescences as arode in the course of the cure, were destroyed by the lapis internalis, and it was not long before the wound was entirely healed. The eye, however, re- mained unalterably immovable; for the abductor muscles had been fo long contracted, while the adductors had been for fo considerable a time stretched and tense, that they had completely lost all power of action.

Finding, that by making rather forcible pressure on the eye-ball, the part could be made to return, in a great de- gree, into the orbit, though it became protruded again as soon as such pressure was discontinued; Dr. Hope con- ceived, that a bandage which would constantly keep up a graduated compression, might be attended with some benefit, and determine the muscles more speedily to resume their proper tone, by maintaining the eye in its natural situation. Conformably to this idea, this gentleman caused a feel bandage to be confructted, with a concave plate proportioned to the convexity of the globe of the eye. This ap- paratus made pressure on the side of the eye-ball next the tempal, by means of a screw. The machine was prized, after gently pulling back the eye into its natural situation, with the hand; and then laying a foil compres between the eye and the plate of copper, Dr. Hope used to make the pressure act on the part by means of the screw, in such a way, that it was impossible for the eye to become displaced outward again, as it usualy was before. With the aid of this bandage, which the patient wore constantly, night and day, and which was gradually tightened more and more, the eye regained its natural position in the space of about twenty days, and did not deviate from it again. At the time when the cafe was publish'd, the eye was capable of motion in every direction, and the patient could fee quite as well with it as the other. The wound got completely well in about a month, and only seven weeks elapsed before the cure was, in every respect, perfect.

Respecting the foregoing cafe, M. Louis observes, that it certainly does honour to the skill and intelligence of the gentleman who undertook the treatment.

Le Drian was equally successfull in the treatment of a form of disease, though certainly it was not so considerable as the preceding. The means made use of, were the actual cautery and alternative medicines. The subject was a young lady, aged eighteen, who, from her infancy, had been subjett to inflammations about her lips, eyes, and ears. She had had a fibrula lachrymatis, and, some time after the usual operation for this complaint, there originated, at the inner angle of the eye, a fungous excrescence, which protruded from the orbit, and had been successively removed with the knife, and touched with the lapis internalis; but in vain, as the tumour always made its appearance again. This plan of treatment was not attended with any greater suc- cess under the hands of Le Drian, and, consequently, he soon made up his mind to attack the excrescence, by intro- ducing the actual cautery into its centre. For this pur- pose, he took a long, large, feewing needle, and had it firmly fixed on a handle. The instrument, having been made red-hot in the flame of a wax-candle, was pushed to the depth of about half an inch into the middle of the swelling. By repeating the application of the cautery three or four times, at intervals of a few days, Le Drian succeeded in destroying the tumour as deeply as its root, the action of the fire having extended beyond the parts ac- tually touched with the heated needle. The consequence was, that the swelling never grew again. To render this cure more certain, Le Drian, for a long while, kept the cauterized part open, and the patient was ordered to take alternative medicines, the chief of which were calomel and arsensio minerals.

The two foregoing examples prove what surgery can ac- complish, when the disease is taken in time. However, when the proper kind of treatment has been deferred too long, the affection of the eye becomes of such a description, as to be irreparable. Nothing now remains to be done except extirpating, not only the tumour, but also the whole of the eye-ball. Even this formidable operation is often impracti- cable, particularly when the parietes of the orbit are diseased. For the bones, in consequence of the pressure made upon them by the swelling, are rendered various, and a very foul ill-conditioned ulcer are produced. In this state there can be but little hope of a recovery, whatever mode of treat- ment is adopted.

One species of exophthalmia, which is indeed uncommon, but not the least worthy of being known, is that which is occasioned by an encysted tumour. In the fourth volume of the Medical Observations and Inquiries, there is an in- stance recorded by Dr. Brodley. A labouring man of the parish of Hedenden, in Surry, had been for several years afflicted with a pain and an obfcurity of sight in one of his eyes. The affection continued, without much attention being paid to it, until, about two or three years afterwards, the man became quite blind on that side. At this period, the globe of the eye was protruded outward in such a manner, that almost the whole of the inner surface of the lower eye-lid was turned out, and hung down over the cheek, fo as to form a true ecticropium.

Several surgeons who were consulted advised the patient not to expose himself to the risk of an operation, fearful that the disease might be converted into one of a cancerous nature. Notwithstanding this counsel, the man did not cease going about to have the advice of all such persons as seemed likely to afford him any assistance. At length, he applied to Mr. Dale Ingram, who, having carefully exa- mined the disease, thought, that on comprething different places, he felt a decided fluctuation below the globe of the eye. He immediately suspected, that the fluid was con- tained in a cyst, and, consequently, that the patient might receive relief from an operation. However, the above gen- tleman would not undertake to do anything without consulting Mr. Bromfield.

The latter surgeon, after a careful examination, was not against the probability of success, and he did the operation in the following manner. After having covered the found eye, by tying a handkerchief round the head, and put the eye-lids of the affected eye as near together as possible, and directed them to be held in this position, Mr. Bromfield made an incision through the lower eye-lid to the conjunctiva, and thus made a sufficient opening for the introduction of his finger behind the globe of the eye. In this way he was enabled to put in a very narrow sharp-pointed knife, for the purpose of puncturing the substance, which was taken to be the eye. Mr. Bromfield was not deceived in his expecta- tion; for, as soon as the opening was made, nearly a glas- ful of a thin transparent fluid was discharged. He now waited a little, both in order to give the patient an oppor- tunity of washing out of his mouth some blood, which had got into it, and for the sake of considering what steps could be taken to extirpate the eye, which had contained the fluid. At last, he determined to proceed as follows: he
passed into the wound a double kind of tenaculum, with which he took hold of the eyelid, and then dissected it entirely away. The wound was filled with soft lint, and the dressings were kept on with a suitable bandage.

In less than four and twenty hours there appeared on the same side of the face a considerable degree of swelling, which soon subsided, however, on a dilatation of the first wound being made, lighter dressings being put on, and the bowels opened. In less than a month the man got quite well, and returned to his home with infinite satisfaction. Dr. Brodley observes, that Mr. Ingram was perfused, before the operation, that the muscles would draw back the eye-ball into the orbit, and that even some degree of vision might return. The doctor could hardly suppose all this possible; but, having an opportunity of seeing the man, about five months afterwards, he could scarcely recognize him. The eye-lids had recovered their original shape, and moved as well as those of the opposite eye. The man also informed Dr. Brodley, that, for about the last month, he had begun to distinguish with the affected eye light from darkness, and that his power of seeing was becoming greater every day. Dr. Brodley remarks, that he could not find any case of this kind related by authors, except one very analogous instance, recorded by Saint Yves in his treatise on the diseases of the eyes.

The last kind of exophthalmia which we have to notice, is that which Sauvages has termed 
traumatic. In this sort of case, the eye is so much protruded from the orbit, that surgeons have frequently been induced to remove the displaced part altogether, and this sometimes has been done too inconsiderately for the unfortunate patient. Covillard informs us, in his Chirurgical Observations, that he was called to see a man, against whose eye a racket-ball had been struck with such violence, that all the circumference of the globe of the eye was separated from the orbit. A relation of the person who was hurt was standing by with a pair of scissors in his hand, ready to cut the rest of the parts which connected the eye with the head. Covillard entered the room in time, and very fortunately, to refit this proceeding, as a complete cure ensued without having recourse to it. Indeed, such was the succour, that the patient's power of seeing suffered no kind of diminution or impression. A similar instance, though arising from a very different cause, occurred to Mr. Benjamin Bell. The eye was almost knocked out of the orbit by the violence with which a pointed piece of iron had entered behind the socket and the eye-ball. The iron had passed through a portion of the orbit, and remained firmly fixed there for about a quarter of an hour. During the whole of this time, the patient suffered insupportable pain. He had completely lost the faculty of seeing, and the eye-ball protruded in such a manner, that there was every reason to fear that the optic nerve was ruptured, and, consequently, great doubt concerning the propriety of replacing the part, or not. However, as a little delay did not seem likely to be dangerous, it was determined to wait a little. On the first removal of the dressings, and after taking away the iron, which could only be done with difficulty, so deeply had it struck, it was with pleasure and satisfaction that the eye was found to return immediately, even before the eye had been replaced. The inflammation which followed was soon appeased by proper remedies, and vision was re-established in its original perfection.

Mr. White makes mention of an analogous example in his book of surgical cases, with this difference, however, that the eye was protruded in a still greater degree.

These two instances confirm the one recorded by Covillard, and weigh against what Maitre Jean has stated, namely, that Covillard's case is not authentic.

In order to convince the truth of the foregoing observations, we have only to recollect the way in which the eye is retained in, and connected with the orbit. The surface of the boundaries of each orbit (says M. Louis, in defending Covillard's case) is oblique, andinclines behind more towards the temple than the nose. The eye-ball is fixed on the side towards the nose, and is set out from beyond the cavity of the orbit. Hence, it is manifest from the lightest examination, that the globe of the eye, in the natural state, is partly situated on the outside of the orbit. When it is also considered that the optic nerve is very heavy, in order to be adapted for readily following, without being at all stretched, all the rotary motions of the eye-ball, produced by the action of the different muscles belonging to this organ, we can then have no difficulty in imagining how the eye may make an immense protrusion outward, in consequence of an inconsiderable swelling, and how it may seem to be quite displaced from its socket, without either the optic nerve or the muscles being torn or lacerated.

EXORCISM, expelling spirits. Prayers or conjurations whereunto to exorcize, i.e. to drive out devils or demons from persons apprehended to be possessed, or to preserve from danger.

The word is derived from the Greek, ἀναφερόμενος, adjurare, conjurare, to adjure, or conjure. In most dictionaries, exorcism and conjuration are used as synonymous; but in reality, conjuration is only a part of the exorcism; and the exorcism the ceremony entire. The conjuration is properly the formula, where the devil is commanded to come forth, &c.

Exorcisms are of great use in the Romish church; their prelates, &c. are frequently exorcising demoniacal persons. The priests make holy water by exorcising common water a certain number of times. In reality, the exorcism is a part in most of their confessions.

Exorcisms had ancienly another and farther purpose; being applied by way of trial or purgation to extort the truth from the accused.

The exorcism, in this sense, was a sort of bread conjured and exorcised for the purpose; and the opinion was, that if the person was criminal he could not swallow the bread.

This, it seems, was a frequent practice in the time of our Edward III. And the bread thus exorcised was said to be confised.

Linderbroek gives instances of exorcisms with barley-bread, and others with chese; and hence, probably, might arise that popular imprecation, "May this bread choke me, if I tell a lie." See Ordeal and Judgment Dei.

EXORCIST, in the Romish Church, a priest, or tonsured clerk, who has received the four lesser orders, one of which is that of exorcist.

The term is likewise applied to a private, or to a priest delegated by a prelate, who actually exorcises a person possessed.

It is a dispute among divines whether ever the Greeks had any such order as that of exorcist. F. Gore, in his Notes on the Greek Exeulogion, has made it probable they had, from several concursing passages in St. Dionysius and St. Ignatius Martyr.

The ordination of exorcists is performed in the time of mass, their principal office being to expel devils. The fourth council of Carthage, can. 7, appoints, that in the ordination of exorcists, the bishop putting the hand of exorcists.
EXO

origins in their hands, shall say these words: "Receive it, and keep it in remembrance, and have power to lay hands on every man, whether baptized or catechumens; which form still obtains."

M. Fleury mentions certain people among the Jews who travelled round the country, making profession of driving out devils by invocations, which, they pretended, had been taught them by Solomon; these were also called exorcists. See Joseph. Antiq. Jud. lib. viii. cap. Origen. Tract. xxxv. in Matt. 35. 63.

EXORDIUM, in Oratory, the preamble or beginning of a discourse or speech, serving to prepare the audience and introduce the matter in hand.

The word is formed from the Latin ordiri, to begin, by a metaphor taken from the weavers, who are said, ordiri telam, to begin, or warp a web, by disposing and ordering the threads in a certain manner for the future work. See Warp.

The exordium, on other occasions, is called the prologue, prelude, and poem.

Cicero defines exordium a part of an oration, whereby the minds of the audience are duly prepared for what remains to be said. The exordium is a part of principal importance, and is to be laboured with extraordinary care; whence Tully calls it "difficultissima pars orationis."

Quintilian mentions three ends, to one or other of which it should be subordinated: viz., "redire auditores benevolent, attentos, dociles." The first end, or that of conciliating the good will of the hearers, may be effected by a selection of topics, in causes at the bar, from the particular situation of the speaker himself, or of his client, or from the character and conduct of his antagonists controlled with his own; on other occasions, from the nature of the subject, as closely connected with the interest of the hearers; and, in general, from the modesty and good intention with which the speaker enters upon his subject. The second end, or that of exciting and engaging the attention of the hearers, may be accomplished by giving them some hints of the importance, dignity, or novelty of the subject; or some favourable view of the clearness and precision with which it is to be treated, and of the brevity with which it is to be digested. In order to effect the third end, or to render the hearers docile, or open to persuasion, the speaker must begin with studying to remove any particular prepossession they may have contracted against the cause, or hide of the argument, which he proposes.

The ancient critics distinguish two kinds of introduction, which they call "Principium," in which the orator plainly and directly professes his aim in speaking; and "Intinitatio," where, preceding the disposition of the audience to be much against the orator, he must gradually reconcile them to hearing him, before he plainly discovers the point which he has in view. Of this latter sort of introduction we have an admirable specimen in Cicero's second oration against Rutilus.

Exordiums are of two kinds; either just and formal, or vehement and abrupt. In the first, the audience is prepared and conducted by due and easy steps; in the second, the orator, as if seized with some sudden passion, breaks out upon his audience at once. - Such is that exordium of Hiaah; "Hear, Oh heavens! and give ear, Oh earth!" Or that of Cicero against Catiline; "Quoniam tamen absur- tere patientia nostra, Catilina?" Abrupt exordiums are most fitful on occasions of extraordinary joy, indignation, or the like; though we have instances of panegyrics of the greatest orators, begun abruptly, without any such occasions. Such is that of Gorgias, who began his eulogy of the city and people of Elis with Hiaah, ovans regum, Els, beata civitas. Abrupt, halting, exordiums, were more to the taste and manner of the Greeks than of the Latins.

Agreeably to the objects which the orator should have in view in this part of his discourse, as we have already stated them, the requisites in an exordium are, 1. Propriety, whereby the exordium appears easy and natural, becomes a piece with the whole discourse, and matches it as a part does the whole; so that it could not be accommodated to any other, or, perhaps, a contrary occasion. The ancient orators were very defective in this point; their exordiums had frequently nothing in common with the subject.

In order to render introductions natural and easy, Dr. Blair suggests that they should not be planned, till the subject of the discourse has been thoroughly digested in the mind. This mode of forming an introduction is conformable to the rule given by Cicero, though not always to his practice. "Omnibus rebus consideratius," says he, "tum demusque id quod primum est dicendum, politreum soleo cognitare, quo utor exordio. Nam si quando id primum inviveri volui pulm mihi occurrit, nidi aut exile, aut nugatorium, aut vulgare; i. e. 'when I have planned and digested all the materials of my discourse, it is my custom to think, in the last place, of the introduction with which I am to begin. For at any time I have endeavoured to invent an introduction first, nothing has ever occurred to me for that purpose, but what wretched, nugatory, and unprofitable.'"

2. Modesty, or an unprecedent bashfulness, which recommends the orator exceedingly to the favour of his audience. This is what Cicero extols so much in L. Crassus, "Fuit enim in L. Crasso pudor quidnam, qui non modo non obesse

The modesty of the orator should discover itself not only in his expressions at the beginning, but in his whole manner; in his looks, in his gestures, and in the tone of his voice. However, the modesty of an introduction should never betray any thing mean or abject. The orator, whilst he exhibits to his hearers modesty and diffidence, real and not affected, should manifest a becoming sense of dignity, arising from a pervasion of the just and importance of the subject of which he is to speak. The modesty of an introduction requires that it should not promise too much. "Non fumum ex fulgere, sed ex uno dare lucem." Horace.

"He does not lavish at a blaze his fire. Sudden to glare, and then in smoke expire; But rises from a cloud of smoke to light, And pours his spicuous miracles to fight." - Francis.

Although, in general, the orator should not put forth his whole strength in the beginning, but gradually, rise as his discourse advances; yet there are cases in which he may be allowed to set out in a high and bold tone; i.e. when he rises to defend some cause which has been much decried by the public. In subjects too of a declamatory nature, and in sermons, where the subject is striking, a magnificent introduction has sometimes a good effect, if it be properly supported in the sequel. Boswell, Flether, and the other celebrated French preachers, very often begin their discourses with laboured and sublime introductions; these raise attention, and throw a luster on the subject; but every speaker should be on his guard against striking a higher note
EXO

at the beginning that he is able to keep up in his progres,
and thus disappointing the expectations which he has excited.
Among English preachers, attempts of this kind are not
always so successful. Variety should be studied in introductions
as much as possible. Explanatory introductions from the
context are the most simple of any, and frequently the best
that can be used; but they should never be long. An
historical introduction has generally a happy effect in running
attention; when one can lay hold upon some noted fact that
is connected with the text or discourse, and by a proper il-
lustration of it, open the way to the subject that is to be
3. Briefly, not amplified or swollen with a detail of cir-
cumstances, or a long circuit of words; and in this respect
it should be accommodated to the length of the discourse;
or should the introduction anticipate any material part of
the subject.

4. The style of the exordium should be judicious, easy, and
pleasing. Quinctilian facetiously compares a faulty exor-
dium to a scarred face, which is presently disfigured, and
very disagreeable. Thus, Cicero, "Videlibai, adinaturque
ad causam facias illustres."
Correctness of expression is peculiarly requisite on account
of the situation of the hearers, who are then more disposed
to criticize than in any other phase of the oration or discou-
urse: because they are as yet unoccupied with the subject
and the arguments, and their attention is chiefly, if not wholly,
directed to the speaker's style and manner. A correct plain-
nes, an elegant simplicity, is the proper character of an in-
trroduction; "ut videamus," says Quinctilian, "accurate
non collidit dicere."

5. Calmness of manner is peculiarly suitable to the exor-
dium. This is seldom the place for vehemence and passion.
Emotions must rise as the discourse advances. The minds
of the hearers must be prepared, before the speaker can
counter on strong and passionat sentiments. To this rule
there are some exceptions, as, for instance, when the sub-
ject is such that the mere mention of it naturally awakens some
passionate emotion, or when the unexpected prominence of some
person or object, in a popular assembly, inflames the speaker,
and makes him break forth with unusual warmth. Either
of these will justify what is called the exordium ab abrupto.
An instance of this kind we have already referred to in
Cicero's first oration against Catiline. However, intro-
ductions of this kind should rarely occur. In the introduc-
tion the speaker should prepare the way for those warm
emotions, which he designs to rouse in the subsequent parts
of his discourse.

The exordium appears an essential part of an oration;
though anciently in the Areopagus, Julius Pollux tells us
they spoke without any exordium, and passions, and any
peroration or epilogue. The like is said to have been done
by Xenophon, who began thus: "Darius et Parthia duos
habueres filios."

EXORMISTOS, in Ichthyology, a name given by some
of the old writers to that species of the petromyzon which
other authors call the lampreta flavilis, and we in Eng-
lish the lampet. This is differentiated by Arcted by the
name of the petromyzon, with only one series of small teeth
in the verge of the mouth, and some large ones, below. See
Mustela, Lampetra, and Pyromyzon.

EXOS, the name by which Rondedelius distinguishes the
scapenifer lufi. See STURGEON.

EXOSTOSIS, from ἐξόσω, out of, and στένον, a bone.
This term, in Surgery, signifies an offensive tumour growing
on a bone. Also, a swelling of the bone itself.

Boyler remarks, that a swelling may take place in bones
as well as other parts of the body. The particular kind of
tumour which occasionally forms on the surface of the bones,
is that to which this writer alligns the appellation of
exostosis. He notices, however, that this name comprehends
different species, which should be considered in a distinct
manner. Thus, eftos-solaris is one peculiar affection; and
there is another species of exostosis, different from all others,
and which confih principally in a thickening of the perioste-
num. Boyler is of opinion, that the disease might be very
properly named periostosis.

In cases of exostosis, the bony swelling acquires, on some
occasions, such a degree of hardness, that no vestiges of a
fibrous texture can be discerned, and it absolutely resembles
ivory. In some instances, the structure of the tumour is
brown; and in others the swelling is composed of a mass of
fibrous and bony matter blended together.

According to Boyler, the bones most frequently affected
with exostosis are the broad bones of the head, the lower
jaw, fternum, humerus, radius, cubitus, the bones of the
cranium, and the femur, and tibia. However, he remarks,
that there is bone, which may not become the seat of the
disease, and the affection may extend to a small, or a con-
siderable portion of it. It is not uncommon to find the
bones of the cranium affected with exostosis over their whole
extent; and Boyler instances the osa parietalia, as sometimes
acquiring an inch in thickness, in consequence of the affec-
tion.

In the majority of cases, an exostosis rises from the surface
of a bone, and appears in the form of a hard round tumour.
It sometimes occurs near the extremities of the long bones,
and, at other times, near the middle portion. It is remarked,
that exostoses, originating from a venereal cause, and com-
monly called nodes, are found, for the most part, on compact
bones, and such of these as are not thickly covered with soft
parts, as, for instance, the bones of the cranium and face,
the internal side of the tibia, &c.

Mr. John Bell has treated of tumours of the bones in the
third volume of his Principles of Surgery. The following
extract will serve to give some of this gentleman's opinions
upon the subject: "Many things conspire (says this author)
to give the tumour proceeding from a bone a peculiar aspect;
it is always irregular and anomalous, never simple. I have
rarely seen a single bony protuberance arising from the head,
or shaft, of a single bone. When a bone falls into disuse,
a large proportion of tendinous and muscular parts of the
and of cellular substance partake of the morbid action.
The bone lies in the centre of the limb, connected by its
larger head with a joint, and by its periosteum with the
tendons, muscles, and ligaments; and all this mass of parts is,
sooner or later, affected; and since every deposition from
vessels appointed for the secretions of bone is solid, and every
increase of such a tumour permanent, it soon attains a great
size; it is ponderous and massive from the proportion of
bony secretion, and from the various structure of these
several parts, it has every irregularity of form and sustance.

When the tumour of a bone has attained a considerable
size, much of the original structure is destroyed, and a new
irregular mass of gelatinous and bony matter is substitued
for it. The bony tumour is firm, bulky, and ponderous, but
not solid; feeling it from without, we can conjecture of what
substance it is composed within; we are sensible that the
part of the bone is covered by a shell, bony in most parts of
its circumference, cartilaginous in some parts, and, throughoult
the whole, yielding and elastic: we are sensible, also, that within
there are irregular points, or spicula traversing the cavities,
or cells, of the hollow tumour; that these are mixed with
the cartilaginous substance, and with irregular collections
of
of matter, partly purulent, but chiefly gelatinous; we are
feltable of such lost cartilaginous and gelatinous parts being
increased and filtered, in the progress of its growth to the tu-
mour, which was, at first, hard and firm; and we find
at fist, by pain and partial ulcerations, and by the increased
of fluctuation and redness at particular points, that ulcer-
ation, the last stage of the disease, approaches. Then the
lump is effectually ruined, and the patient must submit to
amputation, or die of hectic.

"When such tumour is dissected, we find our suspicions
of its internal structure confirmed; we see that foul matter
flows out, when we open into the centre of the tumour,
which we felt but indifferently through its walls; the parts
which appeared the most solid are hollowed out by ulcer-
ation, and full of foul and putrid fancies; while the bone
has been declining into disease, the cancelli and narrow have
degenerated into a sort of fatty mass, with which
much of the cavity of the tumour is filled, and thence such
disease has been very generally derived under the name of

epiplagion. This fatty excretion, occupation the diseased
cavity, is the part which, when the tumour bursts into
an open ulcer, throws out such folicious exudate, growing
apparently from the substance of the bone, and sprouting
up, when amputated, in the course of a few hours. The
solid bone, whether radius, or thigh-bone, is annihilated, and
a mere shell of osseous matter sublimated in its place, and that
in a manner so peculiar, that it must seem to the unintelli-
gent observer as if the main and solid bone had been ex-
pired into an extensive and flat plate of osseous substance,
whereas the process is in truth very simple and very intel-
gible. The bone dies piecemeal of ulceration, what, in tech-
nical language, is termed caries, and is conveyed away by
absoption; but the bone being dead, the surrounding mem-
broes, viz. the periosteum and tendinous expansions, which
once formed a part of its system of circulation, continue fully
alive and ready to secrete new bone; and thus it happens,
that while a carious abscess prefers a large cavity full of
foul matter, the surrounding membranes continue secreting
bone, which, like a shell, thin and expanded, covers this
cavity, and forms the walls of the tumour, of which some part
is composed of thin expanded bone, resembling a cranium,
foam of cartilage, some of thickened membrane; and this
shell is formed in proportion as the original fabric of the
bone is destroyed.

"Bone is destroyed by this internal ulceration, just as it
is by open caries, piecemeal; the process would not be
ulceration, if, while one part were perishing, the other were
not active and secretory new matter; so vigorous is the
general life of the bone, while the internal parts are thus suf-
fereeing, that while one side is wasting with ulcer, the other side
is often secreting bone irregularly and profusely, and shooting
out into fantastic forms among the membranes and surrounding
soft parts, whence the centre of the tumour is cavernous and
cellular, and the walls often rough with spurious and
projecting points. So merely local is the action of arteries in
a tumour, whether osseous or soft, that one side, or part, or
bump of a tumour, grows visibly and protrudes; the features and external form of the tumour gradually changing,
without any sensible cause; and so peculiar is the secretion of
each species of vascular structure, according to the original
definition of the part, that in one part of the tumour the
is generated bone, in another gristle, in another gelatinous
effusion; while in another part, the vascular action is violent
and destructive, and the solid bone, marrow, and surrounding
membranes, are all resolved into a foul and fetid suppuration.
From the periosteum is secreted bone; from the marrow,
this flomatous and solid fat, with much of which the
tumour is filled; to the tendinous and aponeurotic parts,
we can distinctly trace the cartilaginous secretion; and the
gelatinous effusions, we can perceive, even during life, have
their walls thicker, or thinner, according to the degree of
inflammation.

"These are the external characters and internal condi-
tions of a tumour occupying any of the bones. Such tumour
aries often from a bruise, or fracture; sometimes from a
lesion obvious cause, or from internal disease. The radius,
for example, is fractured at the wrist, re-unites and heals;
but heals clumsily, the thickening never subsides, the pain
never ceases, and, though not great, is greater than what
is natural to a fracture. At length, a sensible tumour arises;
at fist it is firm, but in proportion as it increases in size,
becomes somewhat soft and elastic, the thin plate of bone,
of which it is composed, yielding to the detraction from
within. From time to time the tumour changes its form,
full increasing in bulk. On the side of the radius, it is
firm and solid, 1t bends and yields at the parts most distant
from it; it is plainly bony at its base, and as obviously
cartilaginous in the extreme part of its circle; it plainly
contains matter in those other parts, where it yields to the
impression of the finger. Cartilaginous knobs arise, and
sometimes are reddened on the surface; and, at certain
points, the fluctuation is of such a kind, as to imply that
the effusion is in part of a gelatinous nature. Thus the
tumour grows and extends, with various irregularities in form
and consistence; it overhangs the dwindled band, the ule-
or of the joint is lost, and the patient, who might gladly have
been delivered of it at an earlier period, lies, in the end,
to choice left; for, when once it bursts into various ulce-
ration, it never heals, the feto is inconceivably overpowering,
attended with hectic. You are also to remark, that, when
such disease takes place in the hand itself, the joints of each
of the fingers grow out into tumours, at first of a heart-
like form, corresponding with the articulations of the finger
bones; but, in process of time, they grow to globular,
irregular, and almost transparent tumours, still firm, or, at
least, of a cartilaginous firmness. The whole hand de-
gerates into a deformed mass, discoloured, ulcerated, and
fetid; from the individual knobs of which deformed mass,
the points of the respective fingers project like griffin's
claws, with crooked nails of enormous length." Page 58665.

The foregoing passage makes us tolerably well ac-
nquainted with Mr. John Bell's sentiments relative to the
pathology of exostoses, and though we do not ourselves
adopt some of his conclusions, nor think that all bony tu-
mours coincide with his account, yet many cases certainly
answer the description which he has given.

Some exostoses cannot be discovered before the patient's
death. Such was the case referred to by Boyer, of a per-
son whose parietal bone was found after death to be three
times thicker than natural. A similar case is also related in
the memoirs of the academy of Dijon. In the latter ex-
ample, the patient died from an exostosis on the internal
side of the os pubis. The tumour, by pressing on the
neck of the bladder, prevented the passage of the urine,
and the introduction of the catheter.

Boyer notices the possibility of miftaking the head of a
luxated bone for an exostosis. He informs us, that this
happened with a young man, whose clavicle was dislocated
at the end, which is articulated with the sternum. The
mass, formed by the end of the displaced bone, was
mistaken for an exostosis, and was treated as such, of course,
with no benefit.

Boyer also adverts to the liability of miftaking the en-
largements.
EXOSTOSIS.

Largements of the ends of ricketty bones for exostoses. Fun-
gous excrescences of the dura mater might likewise (as the
same author explains) be erroneously conceived to be ex-
ostoses; for, after they have destroyed a part of the bones
of the cranium, they form an external protrusion. Their
real nature, however, may be easily discriminated by at-
tending to their consistence and progress, and particularly
their pulsatory motion, which corresponds with the action
of the arteries in general. We need not here lay more
concerning these swellings, as they are already described in
another part of this Cyclopaedia. See Dura Mater.

Tumours of.

There are certain symptoms which may be said to be
common to all exostoses; such are, a swelling; a sense of
weight; pain, or at least a degree of uneasiness arising from
the morbid action; and deformity.

Another class of symptoms may be called particular,
because they are entirely dependent on the situation of
the tumour. Thus, as Boyer observes, and as we have related
in the article Exophthalma, if an exostosis were to take
place in the orbit, the eye would necessarily be expelled
from that cavity. An exostosis arising from the inner
surface of the clavicle, or sternum, might occasion preasure of
considerable blood-vessels, and on the thoracic vicaera, so
as to induce a train of very dangerous and even fatal con-
fsequences.

An exostosis, arising from the internal side of the os
pubis, may give rise to a fatal retention of urine, as, indeed,
we have already detailed. A similar tumour, similarly
situated, might also render parturition, in the natural way,
impossible.

The generality of surgical writers regard exostosis as
being a caure of exostoses. This statement, however, seems
to rest on no foundation whatever. The swelling of the
joints, when they are affected with exostoses, diappears,
is not produced by an expansion of the bones themselves,
but altogether by a thickening of the soft parts, sometimes
conjoined with a collection of a fluid resembling glair, or of
purulent matter in the capsular ligament. The head of a
bone, really enlarged from exostosis, has never yet been
demonstrated, and cannot be found in any of the collections
of morbid preparations in the various museums. The particular
form of disease, with which exostosis affects the bones,
we shall describe in speaking of the White Swelling.

A scurvy disease is also set down by authors as
sometimes exciting the growth of exostoses: on this point,
we can only profess our ignorance of any rational evidence
in favour of the opinion.

The general disease does undoubtedly occasion one sort
of exostoses, denominated nodes; but, thele we shall dif-
mis from present consideration.

It is painful for us to be obliged to acknowledge, that
we are almost in total ignorance, in regard to the causes of
exostoses; for, excepting contusions and fractures, which
sometimes unprofitably lead to the production of bony
structures, we have no certain knowledge of any others.

Mr. John Bell informs us, that he has seen a woman's
ankle fall into this disease, in consequence of a very trivial
accident; the tibia and fibula grew into a common tumour,
the bones seemed annihilated, and a large offensive shell
appeared to be subtiltuated in their place. In the course of
the disease, the leg became twisted round in a circular
manner, and enlarged to the size of a pillow of a fetter.
The woman died of hectic from the open caries of the
tumour. The same author remarks, that the wrist, which is
more exposed to sprains and fractures, is most liable to
be thus deformed and ruined. He represents the hand
itself as being also particularly subject to similar disorder.
The original injury is some slight blow, or sprain; one
finger is first deformed; joint after joint enlarges; one finger
after another becomes crooked; the nails project like talons,
and force their way into the very flesh of the swollen and
ulcerated hand, which, according to Mr. John Bell, they
sometimes penetrate through and through. At length, the
hand degenerates into an unwieldy and irregular mass,
fluided with knobs and bony tumours. This surgeon tells
us, also, that in consequence of a neglected fracture of the
collar-bone, in a stout young man, he once saw a tumour
produced; partly confining of bone, and partly of carti-
lage, rising to the height of six inches, of round figure,
depressed, moving when the arm was moved; too large,
and too critically situated over the axillary artery, to
admit of extirpation, and which Mr. John Bell doubts not
has by this time become cancerous, and occasioned death.

When exostoses originate from external violence, the ex-
iting cause is involved in no obscurity; but the causes in
most other infusions seem to baffle all human research.

Mr. Samuel Cooper, in his "Dictionary of Practical Sur-
gery," quotes an example of a boy, who came out of Corn-
wall, so excessively afflicted with an apparent propensity to
exostoses, or an exuberant deposition of bony matter, that
a very trifling blow would occasion a bony swelling on any
bone of his body. The ligamentum nuchae was offended,
and prevented the motion of his neck; the margins of the
axile were also converted into bone, so that the poor lad
was, as it were, completely pinioned.

There is one species of exostoses remaining to be noticed,
which is of a very peculiar kind, as it is in its appearance
exceedingly like a bony tumour. A striking influence of such a disease has been recorded by Mr.
Aberforth. The case being highly interesting, we shall
take the liberty of quoting it. The patient, who was
 Resize image
EXO

The ancients, indeed, we might say several of the moderns, have attempted to destroy exostoses with the actual and potential cautery. Sometimes these violent means have fulfilled the object in view; but, frequently; instead of affording relief, they have killed a large portion of the bone, and converted the diæse into the more afflicting one of necrosis, attended with large fleses and abscesses, and often with such debility and hectic symptoms, as have ended in death.

Few good practitioners of the present day, in England, ever have recourse to this plan for the extirpation of exostoses.

When prudence prohibits an endeavour to cut away an exostose, the diæse should never be suffered to expand itself in so great a degree as to deprive the patient of the choice of parting with his limb for the preservation of his life. Amputation should always be performed ere the disorder attains this deplorable state.

We shall conclude the present article with this general observation, that if an attempt is to be made to extirpate an exostose, it be done at an early period of the disease, before its size is very considerable.

EXOSTRA, in the Ancient Theatre, a place where such parts of the play were recited as were not supposed to be acted privately in the house.

Exstra was the Greek name of a warlike engine used in the siege of towns.

EXOTERIC and ESOTERIC, are terms denoting external and internal, and applied to the double doctrine of the ancient philosophers: the one was public or exoteric, the other secret, acroamatic, or efoteric. The first was that which they openly professed and taught to the world; the latter was confined to a small number of chosen disciples.

This method was derived originally from the Egyptians, who, according to the united testimony of Herodotus, Diodorus, Siculus, Strabo, Plutarch, &c. had a two-fold philosophy, one secret and sacred, another public and common.

The fame practice also obtained among the Persian Magi, the Druids of the Gauls, and the Brahmans of India. The Egyptian priests, with whom it originated, sustained the character of judges and magistrates, and probably introduced this distinction with a view to the public welfare, and to serve the purposes of legislation and government.

Clement of Alexandria informs us, that they communicated their mysteries principally to those who were concerned in the administration of the state; and Plutarch confirms the same declaration. However, others have supposed that they invented the fables of their gods and heroes, and the other external ceremonies of their religion, to diffuse and conceal natural and moral truths; but whatever was the motive of their practice, it was certainly applied to political purposes.

See Aristotel.

EXOTIC, Εξωτικός, a term properly signifying foreign, or extraneous, i.e. brought from a remote or strange country. In which sense we sometimes say, exotic, or barbaric terms or words, &c.

The word is derived from the Greek, Εξωτικός, extra, without, on the outside.

Exotic is chiefly applied to plants which are natives of foreign countries, particularly those brought from the East and West Indies, and which do not naturally grow in Europe.

The generality of exotics, or exotic plants, do not thrive in England without some peculiar care and culture; they require the warmth of their own climates, whence the use of hot-houses, glass-frames, green-houses, &c. See Green-house and STOVE.
EXP

. In feeding plants from one country to another, particular cautions are necessary. The plants sent from a hotter country to a colder, should always be put on board in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and on the contrary, those which are sent from a colder country to a hotter, should be sent in the beginning of winter.

The best way of packing up plants for a voyage, if they be such as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as close together as may be; the plants should be set in these boxes three weeks before they are to be put on board; and in good weather they should be set upon the deck, and in bad removed, or covered with a tarpaulin.

If they are going from a hotter country to a cold one, they must have very little moisture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being hoed from the heat of the sun, they will come safe.

Many plants, however, will live out of the earth a great while; as the adonis, euphorbiums, ficoides, and other succulent ones. These need no other care than the packing of them up with moss in a close box, and there should be a little hay put between them, to prevent them from wounding or bruising one another, and holes bored in the boxes to keep them from heating and putrefying. In this manner they will come safe from a voyage of two or three, or even four or five months.

Several trees also will come safely in the same manner, taking them up at a season when they have done growing, and packing them up with moss. Of this sort are oranges, olives, capers, jaffamines, and pomegranate-trees. These, and many others, are annually brought over thus from Italy; and though they are three or four months in the passage, seldom miscarry. And the best way of sending over buds is in their natural hulks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin. Miller.

Dr. Lister has a discourse in the Philosoph. Trans. on Exotic Diseases, i.e. such diseases as are not bred among us, but brought, from time to time, by infection from other countries. Such, according to this author, are, 1. The plague, which is properly a disease of Asia, where it is epidemic. 2. The small-pox, which is an Oriental disease, and not known to Europe, or even Asia Minor or Africa, till a spice-trade was opened to the remotest part of the Indies, whence it originally came, and where it rages more cruelly than among us. 3. The griping of the guts, which he takes for a disease peculiar to the West Indies, and yearly received from thence; for this, he adds, is a quite different disease from the smallpox of the Ancients, and is far more known in the Midland counties, or at least in the north of England.

EXOCUTION, in Church History, a kind of Arian heresies, which maintained that the Son of God was made out of nothing; i.e. Ex νυν ουκ οθαν, supposed by Grotius to be the same with the Exocuon; but his opinion is contradicted by the authority of Theodoret.

EXPAND, in a Military Sense, relates to the exterior of a line or front, either for the purpose of occupying a greater space, or in order to outflank the enemy, thereby to beat in his wings upon his centre.

It is often of the greatest importance to prevent a more extended line of fire, especially if it can be directed towards any particular spot; for instance, when a column is issuing from a besieged city, a detroit, or pafs, the enemy will certainly aim to pour upon its front as heavy a fire as the space may allow.

Thus, he will probably oppose a formidable cannonade thereto, so that the flutes may range along the column, doing great havoc therein, not only among the fowlers, but destroying the cattle, and disabling the artillery. The rest of the field he will generally occupy in affrighted form, presenting a crescent; much the same as that opposed to the immortal Nefius in his last victory! By this means every millet becomes obnoxious, each being levelled at the head of the column.

If we imagine 3,000 men to be drawn up in such a manner as may produce this effect, and that five or six guns are brought to bear as above described, with a certain body of cavalry ready to charge in flank, when the column may have proceeded to contain with the centre of the opposing force, we shall then see how necessary it is for the column to expand with all possible celerity, and not to attempt such an attack before a sufficient front can be formed to make it with effect.

The mode of expanding may be seen under the article DEPLOY, where this particular operation will be found more fully described. We shall in this place remark, that expansion is by no means proper where the enemy can bring a large body of cavalry to act in an open country, unless an equal number of such troops may be at hand to oppose them.

Where a line of intrenchments is to be carried, expansion is not eligible; yet the concentration must be managed with peculiar care whenever the enemy may be able to line their works with artillery, especially howitzers of large calibre, which, by pouring grape among close bodies of men, would soon thin their ranks, and probably occasion, what is delicately called, "a precipitate retreat." The bell authorities instruct us to say, that nine battles in ten are lost by allowing the troops to be too expanded: in such a condition they are every where weak; whereas, when properly concentrated, they are every where formidable.

We may from this collect, that allowing an army to cover too great an expanses in general speaking, expending it to ruin; it enables the enemy to force a line in whichever quarter they may judge proper, and, after forcing it, to cut up the several parts in detail. Hence, blockades are, with few exceptions, extremely dangerous, as may be better understood by reference to environs, which see.

When a column is to expand or deploy, or when an augmentation of front is to be made, such ought to be done with great promptness, and under a heavy fire from each division, to last as it can arrive at its station in the line. By this means, especially if the wind be favourable, the whole may be brought under cover of the smoke, and the enemy may be so rapidly gained upon, as in turn to render it necessary for him to change position; but without great coolness and firmness, nothing will be effected.

EXPANDING RIGGER, or Drum, in Mechanics, is a wheel, or rigger, to receive an endless rope, which can be enlarged or diminished in its diameter, to give a greater or less velocity to the rope passing over it.

The common expanding rigger is a cast-iron wheel with twelve arms, in each of which a groove is formed, extending nearly from the centre to the circumference, as A, B, Fig. 4 Plate XXVI. Mechanics. Against each arm a piece of wood is placed, which has a rebate fitting into the groove, and a screw-bolt passing through both wood and the arm of the wheel; a nut screwed upon the bolt fastens the bolt and wood at any place in the groove: each piece of wood has a groove in it to receive the rope which passes round the wheel.
wheel. The diameter of this rigger can be altered by loosening the nuts, then placing the pieces of wood all in one circle of the proposed diameter, and fastening them there by the nuts. To facilitate the placing of the pieces of wood in one circle, each arm is divided into inches, and numbered from the centre.

Mr. Andrew Flint, of London, lately received a premium of fifty guineas from the Society of Arts, for two expanding band wheels, or riggers. Figs. 5, 6, and 7, are different views of the first of these; A A is a cast metal wheel with twelve arms, each divided by a groove from near the centre to the circumference: these grooves receive rebates on the ends of twelve racks a, a, figs. 6 and 7, which have projecting pieces b, b, with grooves to contain the endless rope d, d. In fig. 5, which is a back view of the wheel c, c, are nuts, which draw up the racks to slide in the grooves without shake, yet freely to and from the centre: the racks are moved all together by means of a circular plate d, d, which has a spiral rib upon it entering the teeth of each rack, so that when the plate is turned round, all the racks move to or from the centre at once: the spiral plate d is screwed to an iron cros, which fits upon the axis f f, and is turned round by a pinion g of fixed teeth, working into a ring of teeth made in the inside of the spiral plate d.

Another method of accomplishing the same object is by means of twelve screws b, b (figs. 8, and 9) pointing to the centre of the wheel; they are all moved together by means of equal bevelled wheels fixed on them; by this means the screws are turned about contrary ways alternately: they must, therefore, be alternately cut right handed and left handed, that they may produce the same effect. The screws are turned, when the diameter of the rigger is to be altered, by a winch put upon any of the three squares b, b, b, on the ends of the screws. In this machine the number of screws must be even.

Figs. 10, 11, and 12, are drawings of an expanding rigger contrived by the author of this article: it consists of two wheels of cast iron, A, A, (figs. 10, 11, and 12,) which have sixteen foliolar apertures marked a, which leave sixteen arms between the wheels and the spaces are exactly equal; and each arm has a triangular piece of wood b d e, (fig. 12,) screwed upon it, by four screws going through the arm into the wood, which is also kept firm and perpendicular to the face of the wheel, by a rib f, (fig. 11,) which projects from each arm, and is let into a groove cut in the wood. The wheels have sockets g, g, (figs. 10 and 12,) which are bored out with a very true cylindrical hole to receive the shaft or spindle B B of the rigger, which is turned in the lathe to fit the sockets without shake, yet at the same time allowing them to move backwards and forwards upon the axis B B. The wheels are put together upon the spindle facing each other, the wooden triangles of one wheel entering the space between the arms of the other, as is shown in figs. 10 and 12; in this manner it is plain that the points, or rather plane, of interjection of the triangles b d e of each wheel, will form a circular groove to receive a rope, which groove can be increased in its diameter by advancing the wheels towards each other, or diminished by letting them farther apart, as in fig. 10. The wheels are prevented from turning on the spindle by means of a fillet, which is inserted partly into a groove cut in the axis, and partly in another groove made in the socket of the wheel. The wheels may be brought nearer together, or thrown farther apart, by two screws h, h, (fig. 12,) which have sockets in one wheel, and are tapped into the other: two equal cog-wheels i, i, are keyed upon the screws, and an intermediate cog-wheel k, placed loosely upon the main axis between them, causes both screws to turn at the same time.

A more simple method of altering the diameter is by pushing the wheels together by hand, and fastening them to the axis by screws e, e, fig. 10.

EXPANSION, in Metaphysics, expresses the idea we have of altering or preferring distance, i.e. of distance, all the parts whereof exist together.

EXPANSION, from the Latin expansio, in Philosophy, denotes the increment of surface or of bulk, of which natural bodies are incapable. With respect to the expansion of surface, see the articles Ductility and Gold Beating.

Bodies of every kind, as far as we are acquainted with them, are expanded in bulk by heat, and are contracted by cold; and to this law there are very few exceptions, which will be noticed in due time. The expansions, or the increments of bulk, are not exactly proportional to the increments of heat in the same body; nor are different bodies expanded alike by the like elevation of temperature. Thus, if a quantity of water be increased one inch in bulk, by the communication of ten degrees of heat, the communication of twice or thrice as much more heat will not cause it to expand two or three inches more. Also, if a rod of gold, and another similar rod of glass, be heated to the same degree, their increments of bulk, arising thereby, will not be equal, the gold expanding more than the glass.

Of the three principal states of natural bodies, viz. solids, liquids, and elastic fluids, the solids are expanded least; the liquids are expanded more than the solids, but the elastic fluids are expanded a vast deal more than the liquids. The knowledge of the precise quantities of these expansions of bodies is of great use in philosophy, in mechanics, and in other scientific subjects; hence no pains have been spared by philosophers to investigate and ascertain them; various instruments have been contrived for that purpose; innumerable experiments have been instituted; and a great many useful results have been obtained. Of these results we shall now endeavour to give a regular and distinct account.

The instruments which have been contrived for the purpose of measuring the expansions of solids arising from an elevation of temperature, are called pyrometers. The objects which must be had in view in the construction of pyrometers, are to form a steady frame, wherein solids of a certain length may be applied either successively, or several of them at the same time, some contrivance by which those metallic bodies may be heated to any required degree, and a mechanism capable of measuring the increase of bulk which is caused by the heat; and this may be accomplished by means of multiplying wheels, by levers, by screws, by a microscopesical micrometer, or otherwise. See Pyrometer.

Some of the first determinations of the expansion of bodies, that may be considered as being sufficiently accurate, were made by Mr. Ellicott with a pyrometer of his contrivance. Mr. Ellicott determined the proportional expansions of several metallic bodies by the same elevation of temperature. They are as follows:

- Gold.
- Silver.
- Brass.
- Copper.
- Iron.
- Steel.
- Lead.

73.
103.
95.
89.
60.
56.
149.

Mr. Smeston contrived a much better pyrometer, and with it he determined the expansions of several solids. Mr. de Luc also contrived a pyrometer of a peculiar construction; but Mr. Ramfled's pyrometer is superior to any other contrivance of the kind.

The following table shews, in parts of an inch, how much one foot length of different substances is expanded by 180° of heat, Fahrenheit's scale, between the freezing and the boiling.
boiling points of water. To the first seven substances, (which were examined in Mr. Raméden's most accurate pyrometer,) there are added the expansions for a single degree of heat. The others were determined by Mr. Smeaton with his pyrometer.

</table>

Iron, instead of being condensed into a smaller bulk, expands in its transition from a fluid to a solid state; so that a quantity of iron occupies more room in the solid form than it does in a fused state.

Dr. Wollaston, in order to form some estimate of the comparative rate of expansion of platinum and palladium, says, "I rivetted together two thin plates of platinum and palladium, and observing that the compound plate, when heated, became concave on the side of the platinum, I ascertained that the expansion of palladium is in some degree the greater of the two. By a similar mode of comparison I found that palladium expands considerably less than steel by heat." Phil. Trans. for 1805.

It must be remarked with respect to the expansion of glass, that sometimes glass tubes are extended more than solid glass rods: their dilatation, however, is not constant; for tubes of different diameters, or of different sorts of glass, are expanded differently by the like degrees of heat.

Wood is not expanded much longitudinally; that is, in the direction of its fibres, by heat, and this is particularly the case with deal and other straight-grained wood. Probably, upon the whole, the longitudinal expansion of wood is less than that of glass. It has been observed, (especially by Dr. Rittenhouf, Trans. of the American Phil. Society) that very dry and seasoned wood, if not exposed to a very high or to a very low temperature, will expand in length pretty regularly; otherwise its expansion by heat, and its contraction by cold, are very irregular; for they seem to depend partly upon the heat, and partly upon the moisture, which the wood acquires in certain circumstances, and is deprived of in others.

It is hardly necessary to mention, that the solids of the preceding table contract their dimensions by cooling as much as they are expanded by heating; thus, for instance, if a yard length of any particular metallic body, by being heated 100° above the actual temperature of the atmosphere, be lengthened one fiftieth part of an inch; afterwards, when cooled down to the temperature of the atmosphere, it will be found to have lost exactly that fiftieth part of an inch which it had acquired by heating.

From the experiments hitherto made on the expansions of solids by heat, no corrspondence has been observed between the expansions and the quantities of caloric they are capable of absorbing. The facility of metals seems to coincide with the dilatations; platinum, the least fusible of the metals, dilates the least; lead dilates most; and the most fusible glass is also the most dilatable. We may therefore conclude with Mr. Berthollet, that bodies are so much the more expansible, the less caloric they require to change their constitution from solid to liquid, and from liquid to gases or vapours.

There is a substance which expands when heated; but do not contract when cooled; and of this singular property Mr. Wedgwood availed himself for the construction of his ingenious thermometer for measuring the highest degrees of heat; viz. those degrees which exceed the scale of the mercurial thermometer. (See Thermometer.) The substance alluded to is the argillaceous earth or clay, and it appears that the above-mentioned property belongs, more or less, to argillaceous bodies of every kind. This property may at first sight appear to be an unaccountable exception from the general law: the difficulty, however, will vanish, if it be considered that bodies of the argillaceous genus contain a considerable quantity of water, and that the contraction of these bodies, when exposed to the action of a strong fire, is great measure due to the escape of the water, and hence they do not contract by subsequent cooling.

The method of measuring the expansions of fluids is to inclose them in a certain vessel, and to measure that part of the cavity of the vessel, which is occupied by the fluid under trial, in different temperatures. It is evident that the substance of the vessel is likewise expanded by the heat, and of course the cavity of the vessel is enlarged. Therefore, when we find that the bulk of the fluid is increased, that increment is only the difference between the enlarged capacity of the vessel and the increased bulk of the fluid. This shows the necessity of forming those vessels of such substances as are least expansible by heat. Indeed glass is the substance which is universally used for such purposes, both on account of its little expansibility, and of its transparency; besides its having other useful properties. A glass vessel, filled to a certain degree with a liquid, for the purpose of showing the expansions of that liquid in different temperatures, or for the purpose of showing the temperature of the corresponding expansion of that liquid, is called a thermometer; viz. a measure of the temperature. See Thermometer.

The proper length for a thermometer is that of a long
EXPANSION.

tube with a narrow bore, having a globular cavity at one end; which, familiarly speaking, may be called a globular glass bottle with a long and narrow neck. The globular cavity, and part of the tube of one of these vessels, is filled with the liquid whose expansion is to be examined, and the vessel is then heated, in consequence of which the liquor, which is contained in it, is expanded, and not being able to extend itself any other way, all the increment of bulk must be manifested in the tube; viz., the surface of the fluid will rise in the tube; or, if cooled, it will descend in it. If the same vessel of the above-mentioned shape be successively filled with different fluids, and with each fluid it be exposed to certain degrees of temperature, (which must be determined by an accurate thermometer,) the proportional expansions of the different fluids may thereby be ascertained. The same object may be obtained by filling several such vessels with the different fluids, that are to be examined, and heating or cooling them all at the same time; but in this case the corresponding capacities of the different vessels must be previously ascertained; which may be done by filling all the vessels with the same kind of fluid, and exposing them all to different degrees of temperature; so that the corresponding elevations of the fluid in the different vessels be marked on the tubes. These vessels are afterwards emptied and filled again with the fluids, &c. Thus the proportional expansions of liquids may be determined; but when the actual or absolute increase of bulk is required, then the capacity of the vessel must be accurately gauged. This measurement of the capacity must be accomplished in the following manner. In the first place weigh the empty glass tube; secondly, fill part of the tube with a convenient fluid, (mercury, for instance, which is the fittest for such purposes); thirdly, measure the length of the tube which is occupied by the mercury, and weigh the instrument a second time; then, by subtracting this second weight from the former, you will have the weight of mercury which fills up a certain length of the cavity of the tube; fourthly, fill the bulk of the vessel entirely with mercury, and weigh the vessel a third time. This weight being subtracted from the first, viz., from that of the empty vessel, will leave the weight of the mercury in the bulb. Now, having the weight of the mercury in the bulb, as well as of that which fills a certain length of the tube, the former to the latter may be easily determined by simple division. Also the absolute quantity in bulk of the former is obtained from the well known specific gravity of mercury, and from the weight of a cubic inch of distilled water, which (when the barometer is at 29.74 inches, and Fahrenheit's thermometer at 66°) is equal to 252.42 grains Troy; one pound Troy being equal to 5550 of those grains. An English cubic inch of mercury of the specific gravity 13.6 weighs 3345.2 English grains. Instead of mercury, some other fluid may be employed for this purpose; but not so conveniently as mercury. The expansions of a fluid, which are caused by different degrees of heat, may likewise be determined by ascertaining the specific gravity of that fluid in different temperatures; for the specific gravity of a fluid decreaseth in proportion as the fluid is expanded, and vice versa; but this method is not capable of as much accuracy as the former.

Liquids differ from each other in regard to their expansibility; some expanding more than others. Also the expansions of the same liquid by equal degrees of heat are not quite regular, and it has been observed that this irregularity is greater when they approach the state of vapour. Upon the whole, mercury has been found to be expanded by heat more regularly that any other fluid; yet its increments of bulk are not perfectly regular. Mr. De Luc, with great care and patience, has endeavored to ascertain the real expansibility of mercury, or rather the real quantities of heat that are required for expanding mercury arithmetically, viz. by equal augmentations. These are expressed in the following table, the first column of which contains the degrees of Reaumur's scale, from five to five, which are equal parts; the second shews the real quantities of heat which are required to raise the mercury to the corresponding degrees, where z is a fict but unknown quantity; and the third column shews the differences of those quantities. De Luc's Recher. fur les Modif. de la Atmosph. 1772, p. 369.

</tbody>
</table>

From the third column it appears, that the differences of heat requisite to make equal and progressive additions to the bulk of the mercury, are not exactly equal, yet are not very far from the ratio of equality. If the bulk of a quantity of mercury, at the temperature of 32° Fahrenheit's scale, be conceived to be divided into 100,000 equal parts, and then be heated as high as the temperature of boiling water; (viz. 212°) its bulk will thereby be increased by 1836 of those parts.

The expansion of water is attended with a singular deviation from the general law; viz. this fluid is expanded by heat from about the 40th degree of Fahrenheit's thermometer upwards; but below 40° its bulk is expanded by a farther decreasse of heat, or increasse of cold; and in fact ice is lighter than water, so as to float upon it; the specific gravity of ice being to that of water nearly as 7 to 8. The bulk of ice is to that of the water, when the ice is melted, as 9 to 8 very nearly. The bulk of water, from its most contracted state at the temperature of 40°, increases continually; but that increase is not very regular; for instance, the increase of bulk from 180° to 212°, is considerably greater than from 45° to 72°. If the bulk of water at 45° be called 1, its bulk at 212° will be 1.5478; Beyond that degree of heat water becomes vapour; viz. an elastic fluid, and the formation of this elastic fluid on the sides of the vessel within the water, forms the bubbles, the escape
The expansion of freezing water is not owing to the extraction of air; for water deprived of air expands like other water in freezing. Mr. Mairan ascribes this property to the tendency of the particles of water to arrange themselves into ranks and lines, which crows one another at angles of 65° and 120°. This tendency seems to begin at the temperature of 4°. The expansion of freezing water has a prodigious force. It is owing to this that in hard fruits timber is burst, phifer is removed from walls, and even iron mortar hells filled with water, and accurately hopped, have been burst by the freezing of the water.

This singular property of water, viz. its expanding from the temperature of 4° downwards, so as to become lighter and lighter in proportion as it becomes colder and colder, is a most striking instance of the wisdom of the Creator, and is a property of immense consequence to the very existence of animals and vegetables. A quantity of water is indispensably necessary to animals and to vegetables at all times of the year. In winter, when the cold air freezes the surface of the water, that effect seldom penetrates lower than two or three feet. Below that depth the water continues fluid, and the crust of ice itself contributes to preserve its fluidity. The heat of the earth, which has been acquired during the summer, undoubtedly prevents the formation of ice below a certain depth. But if water in cooling had continued to increase in specific gravity, and had ice been actually heavier than water, the heat of the earth would not have been sufficient to prevent the total freezing of all the waters of lakes, seas, rivers, &c., "For," says count Rumford, "as the particles of water on being cooled at the surface would, in consequence of the increase of their specific gravity, on parting with a portion of their heat, immediately descend to the bottom, the greatest part of the heat accumulated during the summer in the earth, on which the water repose, would be carried off and lost before the water began to freeze; and when ice was once formed, its thickness would increase with great rapidity, and would continue increasing during the whole winter; and it seems very probable that in climates which are now temperate, the water in the large lakes would be frozen to such a depth, in the course of a few winter, that the heat of the ensuing summer would not be sufficient to thaw them; and should this once happen, the following winter would hardly fail to change the whole mass of its waters to one solid body of ice, which never more could recover its liquid form, but must remain immovable till the end of time." (7th Edit.)

The following table shews the expansions of the principal liquids that have been submitted to such experiments, according to Mr. De Luc's observations. With respect to this table it must be understood that different thermometers (each being filled with a particular fluid, such as is mentioned at the top of each column, and each being divided into 80 equal parts between the freezing and the boiling point of the fluid) were placed with their bulbs in the same vessel full of water, and that the water is gradually heated. Then when the mercurial thermometer stands at 7°, 10°, 15°, &c. the surfaces of the fluids in the other thermometers will be found at the degrees which stand on the same levels; for instance, when the mercurial thermometer stands at 40°, the water thermometer will be found to stand at 20°, 5°, &c. the spirit thermometer will be found to stand at 35°, the oil thermometer at 39°, &c.

</table>

The expansions of elastic fluids, such as common air, the gases, and vapours, are more difficultly ascertained; for the expansions of those fluids are occasioned by a diminution of pressure, as well as by an increase of temperature; and it is difficult to subject any of those fluids to the action of one of these causes only at a time, in order that the effect of each may be duly estimated.

When common air is acted upon by pressure only, independent of any alteration of temperature, its bulk is found to increase and to decrease in the inverse proportion of the pressure; thus, the air close to the surface of the earth is compressed into the bulk which we experience, by the superincumbent atmosphere. If that pressure be increased, the bulk of the lower air will be contracted, which is manifested by an augmentation of its weight; if that pressure be diminished, the bulk of the lower air will be increased, as is manifested by a diminution of its weight. And this expansion and contraction of the air is exactly as inversely proportional to the pressure; so that a double pressure will compress it into half the space, a treble pressure into one third of the original space, &c. The same thing, mutatis mutandis, may be said of the removal of pressure, and of the expansion thereby arising. This elasticity of the air has not been found to be impaired by a long continuance of the pressure; for air has been left during several years very much compressed in proper vessels, wherein there was nothing that could have a chemical action upon it; and afterwards on removing the unusual pressure, and replacing it in the same temperature, the air has been found to recover its original bulk. It is not known how far a quantity of air may be expanded by removing the pressure, nor how much it may be compressed by increasing the pressure; for no experiments have as yet been able to ascertain either limit.

The instrument, in which the expansion of air is tried, has been called manometer (which see.) It is a sort of large air thermometer, consisting of a tube five or six feet long, having a bulb at one end, and being open at the other end. The bore of the tube is about a 20th of an inch in diameter. A small quantity of quicksilver is placed in some part.
part of the cavity of the tube, and the expansion of the air in the bulb, when heated, forces the quicksilver to move towards the open end of the tube. The degree of heat to which the manometer is exposed is measured by means of a thermometer; the quantity of expansion of the air is measured by gauging the manometer, and making marks on the tube, which may indicate parts of the cavity of the tube that are proportional to the capacity of the manometer; as for instance 1000ths, 10000ths, &c. By placing the manometer horizontal or vertical, either with the bulb downwards or upwards, the air in it may either be left of the natural density, or it may be condened, or, lastly, it may be rarefied; for when the manometer itanes horizontal, the quicksilver in the tube does not prefer upon the air in the bulb, nor on that of the atmosphere; when the bulb is downwards, the quicksilver prefers upon the air of the manometer, and when the bulb is upwards, the quicksilver prefers against, and counteracts, in some measure, the gravity of the atmosphere. Hence this prelure, and this expansion of the air within the manometer, may be increased to any required degree by increasing the quantity of quicksilver within the tube; and thus the expansion, or condensation, or rarefied air, may be tried. The expansion of air, by the same degrees of heat, differs according to its density, and to the quantity of moisture it contains; nor are the increments of its bulk proportional to the degrees of temperature.

It appears from Col. Roy’s very numerous experiments (Phil. Trans. vol. 67th) that 1000 parts of the density of the common atmosphere, at 0° of heat, become 1484.21 at 212°; viz. are expanded 484.21, by 212° of heat.

1000 parts of air loaded with 25° atmospheres, are expanded 434 of those parts, by 212° of heat.

1000 parts of air pressed only with 4ths of an atmosphere, are expanded nearly 84 of those parts by 212° of heat.

1000 parts of air pressed with 4th of an atmosphere, are expanded about 14.1 parts by 180° of heat; viz. from the freezing to the boiling point of water.

"From these last experiments," Col. Roy says, "it would seem that the particles of air may be so far removed from each other, by the diminution of pressure, as to lose a very great part of their elastic force."

The above-mentioned expansions of air are by no means regular; viz. they are not proportional to the number of the degrees of heat. The maximum of expansion takes place between 52° and 72°; and the minimum is confinately at the boiling point of water. Moist air expands a great deal more than dry air, especially when it approaches the boiling point of water; so that between 192° and 212°, moist air expands about eight, or nine, times as much as dry air in similar circumstances.

The expansions of gaseous may be tried and determined in the same manner as the expansion of common air. From a long series of experiments, Meffrs. Guyton and Prieur deduced a dilatation peculiar to each gas; but Mr. Guy-Lusae has shown, that all gages, without exception, possess the same expansibility at the same degree of temperature, and that the presence of water in gages occasioned the errors into which his predececssors had fallen. He is led to conclude from his experiments made on gases reduced to the utmost degree of dryness, that 100 parts of each of the permanent gases require an increase of 44, by every degree of the thermometer from 0° to 80 Reaumur’s scale. Vapours, he also thinks, follow the same laws of dilatation as gages, provided the temperature be sufficiently elevated to keep them in the elastic state. Therefore, Mr. Chaptal says, it may be laid down as a principle, that gages and vapours are equally dilatable, and equally compressible; but it will be necessary to be more particular with respect to the expansibility of the vapour of water, upon the elasticity of which numerous natural phenomena, and the action of several important machines, depend.

Mr. Schmidt also made a series of experiments upon the expansibility of air, made as dry as possible by exposure to hot potatoes. He found the expansion of a quantity of air which measured one inch at the freezing point, viz. at the temperature of 0° Reaumur’s thermometer, to expand as below.

This table also shows, by its differing from the results of D’Amontons, De Luce, Lambert, Schuckburgh, Berthollet, and others, that those gentlemen operated upon air more or less charged with moisture. They also took the barometers at different altitudes. In Mr. Schmidt’s experiments the barometer was taken at 29.841 English inches. Thee variations of the rates of expansibility of moist air, faturated at different temperatures, Schmidt attributes to the variations of the degrees of affinity between air and vapour.

Water heated to the 212th degree of Fahrenheit’s thermometer (or thereabout, for the different gravity of the atmosphere occasions a considerable difference) overcomes the ordinary prelure of the atmosphere and becomes fteam, an elastic sublance, the bulk of which at that point is somewhat less than 1800 times the bulk of the water from which it originated. Beyond that point vapour is expansible in a moft astonishing degree; for 30° more of heat (viz. the temperature of 242°) will double the elastic force of steam; 30° more added to that (viz. the temperature of 272°) will render the elastic force of steam nearly equal to four atmospheres; and so forth. This immense expansibility of steam, when the heat which produces it is quickly fupplied, is capable of producing prodigious effects. When water is caufed to boil in a vessel upon a common fire, the heat which is communicated cannot convert all the water at once into steam; but if the quantity of water be small in proportion to the heat which can be communicated in a given time, then the conversion of water into steam is quickened to any degree, and it may be rendered infantaneous; in which case it produces a fudden and violent expansion, or an explosion. A drop of rain in boiling linseed oil, falls to the bottom, is infantly converted into vapour, and occasions dangerous confequences. "It has sometimes," Dr. Black says in his Chemical Lectures, "it happened that a person, by carelessly futting into a copper foundery, has occasioned an explosion that destroyed the whole building." Count Rumford attributes the vaft force of gun-powder to the fudden conversion into vapour of that quantity of water which naturally enters into the composition of that powder; it being a component of the nitre. Phil. Trans. for 1797.

Water
Water at the temperature of 212° is converted entirely into steam, or rather, under the ordinary pressure of the atmosphere, water cannot be heated higher than 212°; but water is gradually converted into steam or vapour at a much lower temperature. Mr. Pictet instituted a series of experiments on the expansibility of pure vapour in low temperatures. He found that a grain of warm water in vacuo evaporates in forty minutes in the temperature of 38° Fahr., under a receiver containing 1452 English cubic inches, but that it did not diffuse itself equally in less than six hours and then raised the hygrometer from 17° to 63°, that is, 46°, and during this whole time the cold under the receiver was constantly decreasing, though slowly: which decrease undoubtedly contributed to the diffusion of the vapour. Effais de Phylique, p. 157.

The best, or most extensive experiments upon the expansive force of the steam of water, and of the steam of alcohol, were made by the Chev. de Bettancourt; and are related by Prony in the second volume of his "Architecture Hydraulique," from which the following compendious sketch is derived.

The fluid with which the experiments were made was confined in a very strong copper boiler, being eight inches at its greatest diameter, and fourteen inches in height. The upper part of it was closed by a cover made of copper, through which passed three tubes. The first served to introduce the fluid into the boiler, and could be closed by means of a screw. The second was occupied by a thermometer, having its bulb about two inches above the bottom of the boiler, and the scale, which was on the outside, contained from 0° to 110° of Réaumur. To the third was adapted a bent barometer tube, having two lines of internal diameter; the ascending branch of which was 110 inches in length. By means of a lateral cock a communication was established between the boiler and an air-pump, which served to make a vacuum before the fire was kindled in the furnace below the apparatus. This circumstance of evaporation in a vacuum forms an essential difference between the experiments of Bettancourt and those made before by Ziegler, and renders them applicable to the theory of the steam-engine, where the vapour acts in a space freed from air.

A vacuum having been made in the boiler, the mercury brought as nearly as possible to a level in the two branches of the barometric tube, and the thermometer reduced to zero by means of ice, the ice was removed, and a fire was kindled, which was excited gently and with much equality, that the thermometer passed over about a degree per minute. One person then stood by to observe the barometer, and another to observe the thermometer, and each kept a register from degree to degree of the pressure and corresponding temperatures; the pressure being expressed by the height, in French inches, of the columns of mercury, which rose above the level in the long branch of the barometer.

These observations of the expansive force of the steam of water furnish 110 results, proceeding from degree to degree of the thermometer, and beginning at zero. These results are contained in the following table, where the degrees of pressure are expressed in French inches of perpendicular height of mercury, and the temperature is denoted according to Réaumur's scale. The experiments on the expansive force of the steam of alcohol were made by the like procès, and with the same apparatus.

The expansive force of the steam of water has also been determined by Mr. Schmidt, with all the accuracy that the experiments seem to admit of: but the results which he has not stated for every degree of the thermometer, do not agree exactly with those of Bettancourt. We deem it therefore necessary to subjoin these results in the following table, wherein the temperature is expressed in degrees of Réaumur's thermometer, as in the preceding table, and the expansive force in French inches of perpendicular altitude of mercury.

Mr. Dalton has likewise endeavoured to determine the expansive force of the vapour of water; but the results of his experiments nearly coincide with those of the preceding tables, which supercedes the necessity of quoting them in the present article. See Evaporation.

From a careful examination of all the experiments made on this subject, Dr. Young has deduced a formula by which the expansive force of steam may be determined for any degree of the thermometer, pretty near the real results of the experiments. The formula is as follows:

Let \( t \) denote the temperature according to Fahrenheit's thermometer, and \( e \) the number of inches in perpendicular height of mercury, which the steam is capable of supporting; then the formula is \( e = \frac{1}{1761} (1 + 0.066) \). The reader might perhaps expect to find in the present article the particulars relative to the expansions of heat, and of electricity; but the uncertain nature of the fluids, to which the effects of heat and of electricity are attributed, besides other considerations, oblige us to refer him to other parts of this Cyclopaedia. See Heat, Caloric, and the articles belonging to electricity.

Dr. Gregory, in his Astron. p. 407, proves, that a globe of our air, of an inch diameter, if it were removed to the distance of a semidiameter of the earth, would expand itself so as to fill all the planetary region as far as, nor, far beyond the sphere of Saturn. See Air.

EXPANSUM FOLIACEUM. See Foliaceum.

Ex Parte, i.e. partly, or of one part, in Law.

A commission ex parte, is that taken out and executed by one part only; where both parties join it is called a joint commission. See Commission.

Ex parte Talis, a writ that lies for a bailiff or receiver, who, having auditors assigned to take his account, cannot obtain of them reasonable allowance, but is cast into prison. The course in this case is to file this writ out of chancery, directed to the sheriff, to take four mainpionors to bring his body before the barons of the exchequer at a certain day, and to warn the lord to appear at the same time. F. N. B. 119.

EXPECTANT FEE, where lands are given to a man and his wife, and the heirs of their bodies; in which sense it differs from fee-simple, where lands are given to a man and his wife in frank marriage, to hold to them and their heirs.

EXPECTANCY, ESTATES IN, are of two sorts; one created by act of the parties, called a remainder; the other by act of law, called a reversion. See these articles; and also Estate and Executory Deeds.

EXPECTATION, in the Doctrine of Chances, is applied to any contingent event, and is capable of being reduced to the rules of computation. Thus, a sum of money in expectation, when a particular event happens, has a determinate value before that event happens; so that if a person is to receive any sum, e. g. 100£. when an event takes place which has an equal probability of happening and failing, the value of the expectation is half that sum, or 50£, and in all cases, the expectation of obtaining any sum is estimated by multiplying the value of the sum expected by the fraction, which represents the probability of obtaining it. The expectation of a person who has three chances in five of obtaining 100£. is equal to \( \frac{3}{5} \times 100 £ = 60 £ \). If the obtaining of any sum requires the happening of several events that are independent on each other, the value of the expectation of that sum is found by multiplying together the several probabilities of happening, and by multiplying the product by the value of the sum expected. E. g. Suppose, that in order to obtain 90£. two events must happen, one of which has three chances to happen and two to fail, and the other has four chances to happen, and five to fail; the value of the expectation is \( \frac{3}{5} \times \frac{4}{5} \times 90 £ = \frac{3}{5} \times 90 £ = \frac{90}{5} £ = 18 £ \). If the first event had actually happened, the value of the expectation depending solely on the second event, would be \( \frac{4}{5} \times 90 £ = 40 £ \). and therefore the happening of the first event is the doubling of obtaining 40£., but the probability of the first happening is \( \frac{4}{5} \times \frac{4}{5} £ = \frac{16}{25} £ \). The rule will be the same if an expectation depends on the happening of one event and the failing of another; and also on the failing of two events; and on the happening or failing of any number of events that may be aligned. It is here supposed that the events are independent, or that the happening of one, neither forwards nor obstructs the happening of the other. But if two events are dependent, i.e. if they are so connected together as that the probability of either's happening is altered by the happening of the other, the probability of their happening is the product of the probability of the happening of one of them by the probability which the other will have of happening, when the first is considered as having happened; and the same rule will extend to the happening of any assigned number of events; thus, in a heap of thirteen cards of the same colour, the probability of taking out the ace is \( \frac{4}{13} \); and the probability of taking the ace out of another heap of the same number is \( \frac{4}{13} \); and the probability of both these independent events happening will be \( \frac{4}{13} \times \frac{4}{13} \) = \( \frac{16}{169} \); but the probability of taking the ace first out of a single heap of thirteen cards is \( \frac{4}{13} \); and that of taking the dence afterwards is \( \frac{3}{12} \); and therefore the probability of both happening is \( \frac{4}{13} \times \frac{3}{12} \) = \( \frac{12}{169} \). If a person has several expectations on several sums, the value of his expectation on the whole is the sum of his expectations on the particulars; thus, let one event be such, that the probability of obtaining any sum, e. g. 90£. in case it happens, may be \( \frac{4}{5} \) in which case the value of the expectation is \( \frac{4}{5} \times 90 £ = 54 £ \). Let the probability of another event, on which depends a second sum of 50£. be \( \frac{3}{4} \); and the value of the expectation in this case be \( \frac{3}{4} \times 50 £ = 37 £ \); and the value of the expectation on the whole \( 54 £ + 37 £ = 91 £ \). But if a person is to receive 90£. once for all for the happening of one or other of the two aforementioned events, then the expectation of the first event being worth \( \frac{3}{4} £ \); as before, yet the expectation of the second will be different; because this depends on the happening of the first, and takes place only in case the first happens to fail, the probability of which is \( \frac{1}{4} \); and
EXPECTATION.

on the supposition of its having failed, the expectation of the second will be $40/1$; therefore $x$ is the measure of the probability of obtaining an expectation worth $40/1$, and consequently the expectation will be worth $x \times 40 = 16l$. and the value of the expectation on the whole will be $54 + 16 = 70l$. See the farther illustration and application of these principles and rules in De Moivre's Doctrine of Chances, ed. 3. 1776. See CHANCES AND GAMING.

**Expectation of Life**, in the *Doctrine of Life Annuities*, denotes, according to the most obvious sense of the term, that particular number of years which a life of a given age has an equal chance of enjoying, or the time which a person of a given age may fairly expect to continue in being. But Mr. Simpson has shown, that this period does not coincide with what the writers on annuities call the expectation of life, except on the supposition of an uniform decrease in the probabilities of life; and Dr. Price adds, that even on this supposition, it does not coincide with what is called the expectation of life, in any case of joint lives: for two lives of 40 have an even chance, according to Mr. De Moivre's hypothesis (see *Complement of Life* of continuing together only $1\frac{1}{2}$ years. According to that hypothesis, the probability that a life aged 40 will continue $1\frac{1}{2}$ years will be expressed by $\frac{225}{46}$; and this fraction multiplied by itself is the probability that two lives of this age shall both continue $1\frac{1}{2}$ years; i.e. $\frac{225}{46} \times \frac{225}{46} = \frac{105625}{2116}$, equal nearly $\frac{6n}{2}$, which represents an even chance; but the expectation of two joint lives being (according to the same hypothesis) always a third of the common complement, will be in this case $1\frac{1}{4}$ years. Therefore, the expectation of life may signify the mean continuance of any given single, joint, or future lives, according to any given table of observations, or the number of years which, taking them one with another, they actually enjoy; so that if 40 persons are alive, all 40 years of age, and one be supped to die every year, according to Mr. De Moivre's hypothesis, till they are all dead in 45 years, half 46 or 23 will be the expectation of life; i.e. the number of years enjoyed by them all will be the same as if every one of them had lived 23 years, and then died; and supposing no interest of money, the value of an annuity payable for life to every single person in such a set, would just be equal to 23 years purchase.

The expectation of life coincides with the sum of the present probabilities, that any given single or joint lives shall attain to the end of the first, second, third, etc. moments, from time to time to the end of their possible existences; or (in the case of survivals) with the sum of the probabilities, that there shall be a survivor at the end of the first, second, third, etc. moments, from the present time to the end of the possible existence of survivorship. From these principles Dr. Price has shown how to deduce the demonstrations of Mr. De Moivre's rules for finding the expectations of lives, which he has omitted, we shall here subjoin them for the information and amusement of our mathematical readers.

Let $x$ stand for a moment of time, and $n$ be the complement of any allied life; then

$$\frac{n-x}{n} \times n = \frac{2 \times n - 3 \times n}{n},$$

will be the present probabilities of its continuing to the end of the first, second, third, etc. moments; and $\frac{n-x}{n}$ the probability of its continuing to the end of $x$ time: therefore,

$$\frac{n-x}{n} \times x$$

will be the fluxion of the sum of the probabilities, or of an area representing this sum, whose ordinates are

Vol. XIII.
**EXPECTATION.**

</table>

Dr. Price has applied his reasoning on this subject to the solution of a curious question in political arithmetic, or to determine the number of inhabitants in any place from a table of observations, or the bills of mortality for that place, on the supposition that the yearly births and burials are equal. For this purpose find by the table the expectation of an infant just born; and this, multiplied by the number of yearly births, will be the number of inhabitants.

Were the bills of mortality constructed with the least regard to truth, and were a regular account kept of all the persons who annually migrate from the country, this rule of Dr. Price might be safely applied towards ascertaining the number of inhabitants in London, but in their present form the London tables are so very incorrect that it can hardly be safe to derive any conclusions from them.

It appears from Tab. I. that though an infant just born in London has not an equal chance (the probability being 376376) of living three years, his expectation is twenty years, and by Tab. II. that though the expectation of such a child in Northampton is twenty-five, it has only an equal chance of living eight years. This difference proceeds from the greater probability of life in the more mature ages, than in the first moments of existence. Were the decrements of life, however, the same through every period of it, these quantities would always be equal; but as this is not the case, neither in the earlier nor the latter ages, the computations founded on such an hypothesis can in general be of very little use. De Moivre's Doctrine of Chances, applied to the Valuation of Annuities, p. 288, &c. Simpson's Select Exercises, p. 253, &c. and particularly Dr. Price's Observations on Reversionary Payments, ch. i. vol. ii. or Phil. Trans, vol. lix. p. 89. See Complement of Life, Life Annuities, Mortality, Survivorship.

**EXPECTATIVE, in the Canon Law, a hope founded on a promise of obtaining the next benefice that shall become vacant, or a right to the reversion of the next. See Benefice.**

**EXPECTATIVE Canons. See Canon.**

**EXPECTATIVE Graves, Gratia Expectativa, called also previsions, were bullly frequently given by the popes or kings for future benefices. The bishops were exceedingly mortified with them, because they encroached on their privileges; besides, that such expectatives are odious, as they induce people to wish for the death of others.**

The use of expectatives is very ancient, though it was not near so frequent in the first ages as afterwards. Originally they were no more than simple requests made on the part of kings or popes, which the bishops comitted to with the more willingly, as they only presented to them persons fit to serve the church: but the frequent exercise of this privilege made it at length be deemed a matter of obligation and necessity.

The council of Trent annulled all expectatives; but the canons relating thereto were never admitted in France, where the right of conferring expectative graces is looked on as one of the regalia.

**EXPECTORANT Medicines, are those which facilitate the excretion of the mucus discharges from the cells and passages of the lungs; or ex pectoris, from the breast.**

This evacuation must be accomplished by more or less of coughing, which the irritation of the collecting mucus excites on occasion. It were, therefore, obviously false and superfluous to give medicines with a view to excite coughing, (if indeed we were acquainted with any substance possessed of such quality,) or to use any external means, as the ancient Caledians are said to have done, for that purpose.

The principal object, in attempting to facilitate the discharge of the contents of the bronchial vessels and cells, must consist in changing the nature of those contents, so as to render them thinner, less tenacious, and more moveable than before. Whether we are possessed of any medicines, however, capable of producing such a direct effect, may admit.
The generality of writers on the materia medica, and of physticians, speak of the utility of such medicines as they have termed attentuatio and indicatia, for this purpose: but we believe, with Dr. Cullen, that their hypothesis on this subject is altogether erroneous, and that no such medicines exist. The only probable explanation of the action of an expiratornt medicine appears to be, that by increasing the secretion from the exhalent arteries in the lungs, the mucus may be diluted and rendered less viscid and the phlegms from the cells may be more fully moistened with a less tenacious fluid. We know that there is a constant and considerable exhalation of moisture from the cavity of the lungs; and there are many reasons for believing that this is an excremenitious secretion, connected with the other excremenitious secretions, particularly with the perspiration from the surface of the body. If, therefore, there are medicines disposed to pass by perspiration, it may be presumed that the same are disposed to pass by the exhalation from the lungs: and this exhalation may not only be increased, but the mucus, produced by the follicles, may also be poured out in a less viscid form, and consequently in a state to be more easily brought up by expectoration.

It would appear, that some such increase of the thinner secretion of the lungs is produced, by sympathy with the lobar, when a condition approaching to succa is induced, and that, therefore, medicines which possess an emetic quality, when used in small doses, operate in some degree as expiratornt; such as the squill, ippecacuana, nicotiana, antimony, &c. A full dose of an emetic seems to produce this effect more completely, and affords considerable relief to those afflmissive complaints, as they are called, in which the lungs are loaded with a quantity of viscid phlegm. Many expiratornt medicines are mentioned by different writers, such as the squill, or colt's foot, enula campana, iris florentina, petalites, &c. which recent experience seems to have rejected, from their failure to answer the expectation which those writers had expected.

Many other medicines which give relief to coughs have been employed under the appellation of expiratornt; but their operation is to be explained upon principles altogether different from that of facilitating expectoration. Among these are ipecacuana, licorice, oil of almonds, and other vegetable and animal oils, various mucilaginous vegetables, such as mallow, horehound, &c. all of which give a temporary alleviation to the irritation about the glottis, and thus appease the cough, but do not in the smallest degree aid the expectoration. See Catarhns.

In the chronic coughs of old people, expectoration appears to be facilitated by the use of the stimulant gums, and of volatile alkali. But perhaps these medicines operate indirectly, by supporting the strength of the patients, and thus enabling them to use greater mucous excretion in the act of coughing.

EXPECTATION, the act of bringing up the mucous and other excretions from the lungs, by coughing, hawking, &c. The word has the same derivation as the preceding.

EXPECTATION, in the Forst-Law, signifies a cutting out the balls of a dog's fore-feet for the preservation of the king's game. Every one that keeps any great dog, not expeditated, forfeits three shillings and four-pence to the king. In mastiffs, not the ball of the feet, but the three claws, are to be cut to the skin. Infl. part. iv. p. 308. "Nillos Dominicos cases abbatis & monachorum expeditari coget." Chart. Hen. III. "Et fin quieti do expeditamentis canum." Ex. Mag. Rot. Pipp. de ann. 9 Ed. 11.

The expedition was to be performed once in every three years, and was done to every man's dog who lived near the forest, and even the dogs of the foresters themselves.

EXPECTATION, the march of an army to some distant place, with a view of forlornness.

Such were the expeditions of Cyrus against Xerxes, of Bacchus, and Alexander to the Indies.

Expectations for the recovery of the Holy Land were called croisades.

The success of an expedition depends on rapid and unexpected movements. An expedition is planned and governed by the following principal maxims, viz., secrecy, if possible, of preparation, and a concealment of design, &c.; a just proportion of the means to the end; a knowledge of the state and situation of the country, which is intended to be the scene of action, and of the place or object that is to be attacked; the appointment of a commander, possessed of those abilities, and of that disposition, which are adapted to the warfare proposed; and the arrangement of the plan of the expedition before it is undertaken or carried into effect. The French use the word expedition to express any particular military quality, which an officer or soldier may possess. Thus, "cet officier est un homme d'expedition," that is, this officer is a man of enterprise, or courageous and daring.

EXPENCES, in Book-keeping. See Book of Expense. EXPENDITORS, in Law, are the persons appointed by commissioners of fevers, to pay, disburse, or expend the money collected by the tax from the repairs of fevers, &c., when paid into their hands by the collectors on the reparations, amendments, and reformation ordered by the commissioners; for which they are to render accounts when required for that purpose.

Thefe officers are mentioned in the statute 37 H. VIII. cap. 11, and other statutes. The Reward who supervises the repair of the banks and water-courses in Romney Marsh is likewise called the expeditor.

EXPENSE Magazine, is a small receptacle for such quantities of ammunition as may be required on emergency, or for the supply of powder, &c. in that ordinary course which enables the proper officers to estimate with correctness what quantity should be kept at hand for the purpose of annual exercise, or for the furnishing the neighbouring camps, posts, or batteries, with such stores as may be necessary for their use. Thus we see, in almost every fortress, various expense-magazines built in commodious and safe situations, for the express purposes of enabling the commissaries, and the ordnance officers, to prevent the defenders of the several works in their view from being a hindrance of want of ammunition. Some of these little stores are occasionally built even upon the terre-plein of the batteries they are to supply; but we have heard this practice censured; for, though it may be true, that owing to their very solid construction they may successfully resist the enemies' shot, still, as they are liable to explode from other accidents, we cannot join an unqualified approval of such positions. We avail ourselves of a suggestion offered to us, in which we think the foregoing objection is greatly diminished, if not totally removed. The suggestion is, that in lieu of allowing any expense-magazines to be built on the terre-plein, a ramp should be thrown up at the back of every fifth or seventh piece of ordnance on the defences, the interior of which should be a magazine of this description. The ramp would serve as a passage for the persons employed in conveying the powder to the gunners, and should have a door at that side left
EXP

Leaf exposed to embalises, or to accidental faults. The entrance might, indeed, be either above or below the ramp; though we are disposed to recommend the latter; as the delay occasioned by ascending would not be of any consequence in ordinary defenses, and would be fully counter-balanced by the safety with which all the expense-magazines might be worked. Possibly, the suggestion might be rather improved if the expense-magazines were to be built partly under the respective ramparts; thereby becoming mines on occasion. (See Plate 1. Tactics, fig. 4.)

Again, works of malony built upon the terre-pleine, we cannot too powerfully inveigh: the immense numbers of soldiers which are generally created by such being sufficient grounds for their condemnation. If, however, it is deemed proper to have small magazines in such situations, (for there may be localities which afford no alternative,) such ought to be sunk so far as to allow the fentinels of their arches to be little more than level with the terre-pleine. Being then covered with foil, and well glazed, (i.e. tarred,) they would become useless, by causing such faults as might be sent over the parapet to throw up, instead of allowing them to tunnel along the terre-pleine. (See Exper.

The entrances of all magazines of this description ought to be towards the back of the battery, and certainly might be rendered safer by making a few steps down upon the inner revetment; so as completely to cover not only the magazine itself, but the persons who might be employed to hand up the cartridges. (See fig. 5.)

EXPENSIS MILITUM LEVANDIS, in Law, was a writ ancieny directed to the sheriff, for levying allowance for the knights of parliament. See Parliament, and Representative.

EXPENSIS MILITIM NON LEVANDIS, &c. an ancient writ to prohibit the sheriff from levying any allowance for knights of the shire upon those that hold lands in ancient demeine. Reg. Otig. 261.

EXPERIENCE, a kind of knowledge acquired by long use without any teacher. Experience confers in the ideas of things we have seen or read, which the judgment has reflected on, to form for itself a rule or method.

Authors make three kinds of experience: the first is the simple use of the external senses, whereby we perceive the phenomenon of natural things, without any direct attention thereto, or making any application thereof.

The second is, when we premeditatedly and designedly make trials of various things, or observe those done by others, attending closely to all effects and circumstances. The third is that preceded by a fore-knowledge, or at least an apprehension of the event, and determines whether the apprehension was true or false; which two latter kinds, especially the third, are of great service in philosophy.

Dr. Campbell, in his "Philosophy of Rhetoric," (vol. i. p. 129, &c.) investigates the nature and origin of experiences and observes, that those fources in our natures which give being to it, and consequently to all those attaintments, moral and intellectual, that are derived from it, are sense and memory. The senses, both external and internal, are the original inlets of perception; and the articles of information exhibited by them are devoloped on the memory. As remembrance infantly succeeds imagination, the memory becomes the sole repertory of the knowledge received from sense; and hence it is the only original voucher of truth; but this endless the evidence of sense.

In order to render the knowledge thus acquired and preserved useful to us, in discovering the nature of things and regulating our conduct, a further process of the mind is necessary; and this is association. This retention and association are called experience. We may here observe, that though memory gives birth to experience, which results from the comparison of facts remembered, the experience, or habitual association, remains, when the individual facts on which it is founded are all forgotten. We cannot pursue the reasoning of this ingenious writer in his illustration of the evidence of experience, which he considers as one species of moral evidence, (analogy and testimony being the two others,) and which, in his opinion, is the criterion, if not the foundation, of all moral reasoning, and the principal organ of truth in all the branches of physiology, in the largest acceptance of the term. See Testimony.

EXPERIMENT, from the Latin experimentum, is a trial, or practical proof of something. In philosophy it means the result of certain applications, dispositions, or combinations, of natural bodies, made with some particular view. Experiments are laid to be mechanical, or chemical, or electrical, or magnetic, &c. according to the subject to which they more immediately belong. The object of making experiments is to ascertain either certain causes or certain phenomena; and for the proper attainment of these objects care must be had to institute experiments that admit of no equivocal result, and so to answer the purpose in the quickest and most direct way. The main object, however, of the inquiry can seldom be determined by a single decisive experiment; hence, in most cafes, it becomes necessary to divide the question into parts, and to ascertain each part separately by one or more appropriate experiments. When the experiment is so prescribed as to decide the question without any possible doubt or equivocation, it has in that case frequently been called experimentum crucis; meaning a capital or decisive experiment; such as supercedes the necessity of instituting more experiments for the same purport. The origin of the expression experimentum crucis has probably been derived from its being a kind of torture, whereby the nature of the question is, as it were, extorted by force. It has been also attributed, though with less apparent probability, to the guide or instruction which it affords, like that of a direction point, which is shaped somewhat like a crook.

It is not practicable to give any instructions for the right performance of experiments in general; for not only every subject, but every particular question belonging to any subject, must be determined by a peculiar mode of investigation. The experimenter can only be instructed by practice. The nature of the subject, a strict attention to every apparent circumstance, an accurate statement of particulars, and an unprejudiced mode of reasoning, will easily suggest a proper train of experiments which the subject in question may admit of. It deserves to be remarke, that though in the investigation of any subject, the philosopher proposes a certain order of investigation, (and it is always proper to propose to oneself some such plan or train of experiments;) yet it is but seldom that the proposed plan can, or deserves to be strictly executed; for the result of the first or second experiment frequently points out a new track for a more promising road; in consequence of which, new and different trials must be instituted; and it is in the study adoption of such plans as may be more fitted to the last indications, that the genius of the philosopher is rendered conspicuous.

Such mode may suffice for the determination of any doubtful point; but when a discovery has been made and is to be explained
explained to other persons; then it is of use to show the same result by different experiments; for it is not only a satisfaction to have several concurrent proofs of the same proposition; but it is also required intelligible to a greater number of readers or hearers; it being seldom the case, that the same experiment conveys an equal degree of conviction and satisfaction to the mind of every body.

EXPERIMENTAL FARM, in Agriculture, that fort of farm establishment which is chiefly applied to, or calculated for, the purpose of making experiments, with the view of ascertaining unknown causes, effects, or results in the various departments of Husbandry. This is a plan which has often been attempted, both individually and collectively, by numbers of persons warmly interested in promoting the improvement of agricultural knowledge; but hitherto, we believe, without that fort of success which might naturally be expected. The caufe of which has probably been the want of a due combination of real practical agricultural information with that of the scientific kind, as without a full comprehension of both the, in persons who have the direction and management of such establishments, it must be utterly impossible that they can be so highly advantageous as they ought to be. But a writer, who has allowed much attention to the subject, seems to prove, that there is much doubt of any real benefit being at all produced in this way; as he considers both experience and experiment the two means by which facts concerning the art may be ascertained as equally liable to objection. The term experience he conceives to denote those deductions which a person draws as the average result of practice continued for a considerable length of time, and which is unquestionably the surest guide that can be followed, where the observations are sufficiently correct; and the circumstances discriminated in so clear a manner as to create no sort of confusion; still where these peculiarities are wanting, the conclusions thus drawn may be extremely fallacious. And what increases the evil in this case, is, that when conclusions have been once drawn in consequence of an imperfect discriminations of circumstances, there is scarcely any chance of eradicating the error; as the mind, when once accustomed to think in a certain way, is apt to proceed in the same way afterwards; and that the same indiscrimination which caused the first error will induce a succession of others of the same fort ad infinitum. Unfortunately, too, it is often difficult to distinguish those things which are capable of affecting the result of a process or operation, are so jumbled and thrown together into one chaotic mass, that it is a matter of extreme difficulty even for the most wise observer to distinguish such as are essential, from those which are merely accidental, consequently extremely easy to mistake one for the other. The inaccuracy likewise, which too much prevails in the operations of the farmer, concerning the actual expense of different processes, as affecting any particular object; and all the difficulty of keeping the different produce of different fields separate, render it, in most cases, almost impossible for the actual farmer to ascertain, with any fort of precision, either the expense or the value of the produce of any one of his fields; consequently the profit or loss of any operation or process is merely gueffed at, not ascertained by the tell of his experience; in consequence of which he is at liberty, and will of course draw the conclusion, which seems most to confirm his own pre-conceived notion on the head, whatever it may be. Under such circumstances experience must, he conceives, be a very fallacious and imperfect guide. It may, indeed, it is supposed, furnish hints or indications of what ought to be pursued or laid aside and avoided; but that un-
E X P E R I M E N T A L.

Economical distribution or arrangement of the necessary business which is to be pursued in the conducting of the work, which is a branch of the art that is of the greatest consequence to be well understood by the real farmer, but that is totally incompatible with the complex arrangements and continually varying operations of the experimental farm.

But however true many of these remarks may be, there can be little doubt, but that the establishment of experimental farms in different parts of the country must, under proper management, be attended with great advantage in throwing additional light on different branches and modes of cultivation, as well as in bringing agriculturalists acquainted with a variety of new and interesting facts.

When conducted under a proper system of management, farms of this kind might readily ascertain the following important questions.

1st. What is the best mode of cultivating arable land?

2d. What is the best system for the management of grass land?

3d. What are the most useful implements of husbandry?

4th. What are the most profitable breed of animals, and the best, and cheapest modes of feeding and fattening them?

5th. What is the best plan for rendering waste or barren land productive?

All these questions are evidently to be considered in relation to the differences of soils, circumstances and situations.

Mr. Arthur Young, in speaking of the establishment of a farm of this nature, as being properly an undertaking only fit for a sovereign, in the fourth volume of his "Annals of Agriculture," remarks, that it would have great effects in promoting agriculture in this country, but in others, where that art is still left under foot, it is absolutely essential to the progress of it. And that if, in some future age, this art, so necessary to the welfare of mankind, should receive an attention that has hitherto been denied it, and a farm of this sort should be established, the following hints may be found of use. It is conceived, that a divided attention to complex questions should be avoided; and that the great leading objects most nearly connected with the deficiencies of the national agriculture demand the first exertions to ascertain. With this view the soil of the farm should regulate the plan of it. If it were a sand one in this country, it should, it is supposing, be thrown into the Norfolk husbandry, and the object of those experiments would be to examine how far that system, by means of carrots, turnip-cabbages, and other new plants, equi-distant drilling, manuring for the roots and grasses instead of the wheat, &c., could be improved. And connected with this inquiry would be the collateral one of the breed of sheep, proper for this soil; with other objects too numerous to recite, which are at present unascertained.

If the soil were of the clayey or loamy kind, too wet for turnips, the great objects would, it is supposing, be, the means of manuring humus fallows, an inquiry of great importance; the culture and use of cabbages; the modes of draining by hollow cuts and arched lands; the best means of converting such lands to meadows, and the proper breed of cattle. And on a loamy soil, strongly inclining neither to clay nor sand, very interesting inquiries are to be pursued. Every plant, common on all other soils, is to be cultivated on this.

The rotations of crops; the culture of potatoes and carrots, and their application to all sorts of cattle; lucerne, and its use in summer feeding a dairy of cows, that are supported in the winter on the roots, &c. are among the numerous inquiries to be prosecuted on this sort of soil. On chalky soils the principal object is, it is supposing, the culture of vines, and the beet means of converting it to corn and turnips preparatory to a renewal.

But on a peat-moor many dubious points are to be ascertained; the beet means of reclaiming, whether by paring and burning, fallow, or mere manuring. The grages proper to lay down with; and the means by roots or cabbages, of furnishing the greatest possible flock of that breed of cattle and sheep, which are found by experiment most proper for the soil; the method of draining, manuring, and giving fertility to bogs, &c. Upon all, or either of these, soils, collateral inquiries would arise in relation to manures, tillage, implements, &c. and a great variety of doubtful points to be decided in the culture and management of all the plants usually raised on any of them.

A small botanical garden of two or three acres, under a botanist, for small experiments upon plants not cultivated but promising; and a laboratory for chemical trials on soils, manures, and vegetables, would, it is suggested, be two necessary additions to such an establishment; and with a smith's and wheelwright's work-shop would render the whole complete.

The great features of such a plan would, it is supposing, be of utility; it would, however, be susceptible of no inconsiderable ornament. The lines of the inclosures might be decorated in any imaginary way, provided the contents of the field applicable to useful grass or corn were traced by rigid lines. Every tract of land, of a considerable extent, has some broken ground, steep slopes, water-courses in glens, or pieces where the plough cannot move with convenience, and where grass is not an equal object with more level spaces; these, by judicious disposition of the ground, might be connected with the margins of the fields, and, by walking being traced through them, might be made highly ornamental and pleasing. It is suggested that one of Brown's winding walks, with its usual accompaniment of shrubs and velvet lawn, surrounding thirty, forty, or more acres of grass, is never less, but it brings to the mind the variety such a space is capable of, by being thrown into experiments that yield a food for the mind as well as the eye. Some delicious spots, it is true, unite to happily in all their parts, melting by an easy gradation into so rich a harmony of distribution, that any change would offend as much as difference in a piece of pleasing music. But such spots are rare; in general, the variety of neat and elegant experiments would not injure the effect at all. The Leaffowers was, it is stated, in all its parts, a farm, and much more agreeable to the eye, than if the whole had been lawn. But in the present system of decorating ground, variety of effect is wanting; something to bring variations to the scene, in which the owner shall be interested: The lawn that was smooth yesterday is smooth to day, and the revolution of the feasons that bids the rose breathe its perfume in June, and wither in November, brings to the eye a succession of the same images which please this year, as they pleased the last, without novelty in the caufe, or increase of pleasure in the effect. The highest decoration of landscape will not give it the power of variety; it will be the same to day as it was the lea; it will be gay in summer; and dreary in December; its forcible effect is for others not yourself; for at every repetition of viewing the colours fade, and what once excited rapture, now brings no other emotion than cold approbation. The beauty of a mere garden-scene is like that of a fine face; it moves admiration at first, and we feel ourselves under the enchantment of a spell that chains all our senses; but let the enchanters speak, and prove herself as pretty...
pretty fool, the insanity of her conversation breaks the spell, and the is from that moment less than a pretty picture, hence no one claims a merit in making her. The beauty of a
garden-scene is much of the same kind; it holds little con-
versation with you; it suggests no new ideas; it furnishes
no food to an inquisitive mind. If a peron be told that he may
contemplate the works of wisdom of God; and hold con-
verse with the vegetable and animal creation, he replies, not
because he is in a garden, for a nettle is as wonderful a
production of divine power as a lily, and the structure of
a toad an object to philosophize on, as much as a night-
shade. Hence the contemplative pleasures of a decorated
scene are not the same as those inspired by the combination
not the combination; and therefore, in this respect, might
as well be combined at all. But when the ornamented
walks lead you to something that offers novel information
with every step, when you are in the pursuit of unknown
facts, to ascertain which is to promote not your own fo-
litary pleasures and contemplations only, but a science in-
timately connected with the prosperity of a nation; when
every inclosure is pregnant with instruction, the field of a
purport, and consequently of a pleasure; in such a cafe,
it is not a question of an arrangement of a lawn, and water,
and shade, that shall please the eye for a time; it is not
the bloom of a flower, or the bend of a walk, but a subjcct
where the renovation of the year brings perennial employment
for the mind: your landscape becomes the source of thought;
the eye may be pleased, but the understanding is satisfied;
and instead of modes of duration that have been repeated to
futility, a novel scene is created, at once the theatre of private
pleasure and public instruction; where useful knowledge
is fought; in vain theories, and indolent speculation,
but in the vigour and activity of experimental exertion.
Compared with such an application of a tract of land, what
are parks and gardens, shrubberies and decorated grounds,
but so many boudoirs to please children; frivoures efforts to
fill the eye, but leave the mind vacant. The prince that
raises palaces, and embellishes the gardens that surround
them, may be commended for his taste, and praised for his
magnificence. Verbaulls was called a creation; but had
Lewis XVI. established such a farm as has been de-
scribed; had the experiments been registred and published
for the benefit of France; how little would the reputation
of that creation now be found, compared with the genuine
and never drying fame that would have sprung from a dif-
derent application of the fame ground. The prince that
rears a palace, does what princes have done before him; but
he who founds an establishment for the instruction of his
people in the most necessary of all arts, does that which
nouve have done before him, and deserves a title more
truly valuable than that of Great, so often ill applied to the
defenders, not the protectors, of humanity; he will enjoy
the title of the "Friend of Mankind." A late writer on modern husbandry, however, seems to
think more favourably of this method of bettering the state
of agriculture than the author mentioned above, as he con-
iders it as a mean by which a general spirit for such
improvements may be the more effectually introduced. It
is a measure, he supposes, which there is every reason to
believe would be attended with good consequences, in regard
to the determining with exactness the proper quantities of
the different sorts of manures that ought to be applied to
the different kinds of soils; the lore best adapted to each; and
the effects they produce when applied singly or in their com-
pound state. But the utility of public experimental farms
in every county, if put under the direction and management
of persons of extensive knowledge and experience, should
not, it is contended, be estimated by a reference to any
particular branch: husbandry, in all its departments, would
be greatly improved in this way; and should the period ever
arrive when the obstacles that stand in its way shall be
removed, and proper means be had recourse to, for difling a
general knowledge of the best methods of conducting the
various operations connected with that science, that which
has been suggested must not be overlooked. It is sup posed
that such sorts of farms would become to many farmers,
at which youth might be instructed in the nature, principles,
and practice of agriculture, and to which the common farmer
might occasionally resort for information, in respect to the
furnaces of experiments made as it were under his own eye,
and on soils, in situations similar to those of his own.
And the author of "Rural Economy of the Midland Coun-
ties," in speaking of the advantages of these sorts of farms, says,
"what man, whether of the superior class of yeomanry or ten-
ants, or of a inferior class of tradesmen or others, who are
now bringing up their sons to husbandry, would not, after his
son had gone through a course of private tuition, and received
the rudiments of instruction from himself or some professional
friend, wish to perfect his education in a public seminary;
where he would have not only an opportunity of seeing practice
in its highest state of improvement, and of conversing
with professional men of the most enlightened understandings;
but where he would be duly initiated in the theory of
rural knowledge, in the method of making, regulating, and
observing the result of experiments; of ascertaining the
inherent qualities, and improving the various breeds of live-
stock; where he would give order and subordination, and
learn the proper treatment of servants; and among a variety
of other branches of useful knowledge, the form and method
of keeping farm accounts, and of ascertaining with accuracy
the profit or loss upon the whole, and every part of his
business; consequently of bringing it, as nearly as in its
nature it is capable of being brought, to a degree of cer-
tainty."

But whatever may be the opinion of some concerning the
utility of public establishments of this nature, we are inclined
to believe that they will be found more beneficial when under
the direction and management of private individuals who are
sufficiently qualified for such undertakings, for though
they may be far less extensive, they will be much more
usefully conducted from their being less subject to those
improper checks and controls, which are continually taking
place when a number of persons are concerned.

Experimental philosophy. Pythagoras is said to have
been the first person who called himself philosopher; viz. a
lover of knowledge or wildom, from the Greek words
phin, a friend or lover, and σύνωθ, knowledge or wisdom,
from which appellation the word philosophy was derived,
meaning the love of general knowledge; and according as
this knowledge relates to the manners, the duties, and the
morals of human beings, constitutes, as it were, the midnight
light, or to the phenomena of natural bodies, so it has been
called either moral philosophy (from the Latin mos or mora,
its plural, which means behaviour or manners) or natural
philosophy.

The philosophers of the primitive ages, among the Greeks,
Romans, &c. in explanation of the phenomena of nature,
such as the motions of the celestial bodies, the rain, snow,
frost, thunder and lightning, the rainbow, the combustion
of fuel, the production of animals and vegetables, and so
forth, generally offered the inadequate speculations of their
imagination, which, though mostly unintelligible, and fre-
quently absurd in the greatest degree, were nevertheless re-
ceived with deference by their scholars, and were propagated
with
EXPERIMENTAL.

with fidelity or diligence from one generation to another. Their acquiescence rested merely on the authority of the teacher. That these explanations were generally inadequate and absurd, is easily evinced by observing that different contemporary philosophers entertained and taught opinions diametrically opposite to each other, though they related to the very same question; and that subsequent philosophers have by actual observations, and unerring demonstrations, flown their fallacy. It may amuse an inquisitive mind to observe, that whilst the exertions of the early mathematicians, whose productions have obtained the admiration of subsequent generations, were strictly rational and correct, the investigations of their contemporary philosophers were conducted in a manner altogether slovenly and superficial. This method of philosophising prevailed for a very long period, and in consequence of it several centuries elapsed, during which the knowledge of nature made no progress deserving of notice, excepting a few rare and accidental discoveries.

The 15th century, which was productive of the greatest events and the most consequential discoveries that history can record, seems to have given a new turn to the subject of natural philosophy. The old tenets began to be doubted, and the energies of the human mind began to manifest their untethered powers. In the next century, the incoherent dogmas of the preceding ages were freely combated; the authority of names and sects was disregarded, and in lieu of opinions, the explanation of natural phenomena was referred to the evidence of actual experiments; and this introduced the appellation of experimental philosophy, meaning the knowledge of natural powers and natural effects, acquired by means of experiments or trials. The light reflection readily shewed the superiority of this new method of philosophising; but, independent of any other consideration, its establishment is principally due to the successes with which it was attended, and which exceeded even the most sanguine expectations of its first promoters; for it was no sooner adopted, than discoveries of importance were made, old-established errors were detected, and the subject of philosophy assumed an entirely new aspect.

It is undoubtedly true, that in this mode of investigation the experiments must be preceded by hypothesis, or supposition; for a man cannot begin to make experiments without the previous formation of a certain plan; but then the plan, the supposition, or the hypothesis goes no farther than to propose something, the confirmation or refutation of which is referred to the result of experiments, affix'd by mathematical calculation.

In the 13th century, the necessary preliminaries for the improvement of natural knowledge began to be made; viz. collections of what then prevailed under the denomination of scientific knowledge, natural knowledge, secrets of nature, and the like; and the abatement of truths, errors, inconsistencies, doubts, and perplexities, which these works contain, is strange indeed. Among the few who officially began to work in the experimental mode of investigation, during that century, is Bacon held the most distinguished place. His desire of information was great; his views extensive; his mind clear and capacious; and he is said to have spent about 2000l. (a sum very considerable at that time) in the performance of his numerous philosophical experiments. Baptista Porta also distinguished himself for similar pursuits in Italy. This inquisitive person lived at Naples, and about the year 1560 formed a society of scientific persons, who met in his own house. The great Galileo, who was born in Italy in the year 1564, became famous as a philosopher and a mathematician towards the latter end of that century and the beginning of the next. His genius, superior to the prejudices of the times, investigated and established several leading propositions in natural philosophy; and his success, his example, and his precepts disseminated an universal ardour for the true mode of investigating the powers and the effects of natural bodies. His successor, Torricelli, was not unworthy of a most distinguished rank amongst the philosophers of the age; and the Torricellian tube, or the barometer, is a magnificent monument of his experimental inquiries.

In England, as we have already mentioned, friar Bacon was the first promoter of true knowledge; but a great part of the work of philosophical reformation was accomplished by another inquisitive genius of the same name. Francis Bacon, lord chancellor of England, gave a fresh and vigorous impulse to the progress of experimental enquiry. He recorded a vast number of facts, proposed and executed a great many experiments, and nothing that related to nature seemed to be below his notice.

These early reformers of philosophy, besides other obvious difficulties, were obliged to struggle against, and the Successes of their labours was much impeded by, the wrong notions which then prevailed, and which had been long rooted in the minds even of the most able persons then living. Galileo was nearly oppressed by the ignorance and prejudices of the clergy. Crichton, who flourished about the latter end of the 16th century, wrote an able book expressly against the vain philosophy of Aristotel, which had long been read in the schools. The two Baco's, and other able writers, frequently allude to, and strenuously endeavour to remove, the wrong notions of their contemporaries, and, in short, the demolition of the old defective fabrics, proved nearly as laborious as the creation of the new structure.

The reform which had been begun by the above-mentioned and other worthy persons was soon after completed by the extraordinary genius of Newton. This truly great man, like a luminous of the first magnitude, illustrated whatever came within the limits of his notice, and his notice was employed in the greatest and most admired works of the creation. His method was to institute experiments, to examine the phenomena with accuracy, and to ground upon them the strictest mathematical reasoning. The conviction which such rational method conveyed, and the numerous discoveries with which it was attended, completely exploded the old tenets, and established the only true method of investigating nature.

The progress of experimental philosophy might have been interrupted by the death of a single individual; for it does but seldom occur that genius, health, opulence, and other opportunities concur in the qualification of an experimental philosopher; but the danger was in great measure averted by the institution of philosophical societies, which, by uniting the efforts of several ingenious labourers, by forming in great measure the means of investigation, and by encouraging improvements, and by recording and propagating the results, have established the progress of knowledge in a regular and permanent channel.

The first society of the kind which we find recorded, is that which we have already mentioned at the house of Baptista Porta in Naples, towards the latter end of the 16th century. It was called 'Academia Secretorum Naturae.' Next to this, and before the end of the same century, the Academy, called of the Lyceum, was founded at Rome, and was rendered famous throughout the world principally by the renown of one of its members, the great Galileo. The Academy del Cimento, and several other associations of scientific persons, were established in the succeeding, viz. the
EXPERIMENTAL.

the 17th century. And amongst those affiliations the first rank must be assigned to the Royal Society of London. This most learned and distinguished society had its origin soon after the accession of the Duke of the 17th century. A few men of learning began to meet at stated times in Wadham college, Oxford; and among those persons there were the following conspicuous characters; viz. Dr. Ward, Robert Boyle, Dr. Wilkins, sir William Petty, Mr. Matthew Wren, Dr. Wallis, Dr. Goddard, Dr. Willis, Dr. Bathurst, Dr. Christopher Wren, and Mr. Rooke. From Oxford this association transferred its meetings to Gresham college in London, which took place in the year 1658. There they increased their number, and soon after the restoration of Charles II. that society received a royal charter, which established it into the form that has been continued ever since; but we must refer the reader to other articles of this Cyclopaedia for the particular account of the Royal Society of London, as well as of other scientific affilations in this and other countries; and at the same time we must proceed to explain the new mode of philosophizing in a manner somewhat more particular.

The objects of the universe, or the natural bodies, which affect our senses, but are known and useful to us by their properties, some of which affect one of our senses, whilst others affect some other sense. Thus we perceive luminous bodies through our eyes, sound through our ears, heat or cold by the touch or feel, &c. Some of these properties are called general, like gravity and extension, because they belong to all bodies; and others, like transparency and fluidity, are called particular, because they belong to certain bodies only. The better we become acquainted with the properties of natural bodies, the more extended the sphere of our powers and of our advantages becomes; and it is for the discovery of these properties, either in simple or in compound bodies, that experimental inquiries are instituted.

In the acquisition of knowledge, the human being has no other assistance besides that of his senses, and of his reasoning faculty. By the first he observes and acquires ideas of self-evident propositions, or properties of natural bodies; such as the human mind cannot differ from without manifest violence; by the second he is led from one of these evident simple propositions, to another first lightly depending upon the first, then to a third lightly depending upon the second, and so on, to the acquisition of some idea more complex, and last apparent at the first announcement.

The constant observations of philosophers, with sir Isaac Newton at their head, and the dictates of plain reasoning, have furnished certain axioms and certain rules of philosophizing, the property of which is too evident to be objected to.

The axioms of philosophy, or the axioms which have been deduced from common and constant experience, are so evident, and so generally known, that it will be sufficient to mention a few of them only.

1. Nothing has no property; hence

2. No substance, or nothing can be produced from nothing.

3. Matter cannot be annihilated, nor reduced to nothing.

The propriety of the last axiom may perhaps be not readily admitted by certain persons observing that a great many things appear to be utterly destroyed by the action of fire, and also that water may be caused to disappear by means of evaporation, and so forth. But it must be observed, that in these cases the substances are not annihilated; they are only diversified, or removed from one place to another, and by being divided into particles very minute, they elude our senses, and escape our immediate notice. Thus, when a piece of wood is placed upon the fire, the greatest part of it disappears, and a few ashes only remain, the weight and bulk of which do not amount to the hundredth part of the weight and bulk of the original piece of wood. In this case the piece of wood is divided into its constituent principles, which the action of the fire drives different ways. The blood part, for instance, becomes steam, the light coaly part either adheres to the chimney, or is dispersed through the air, &c. So that if, after the combustion, the scattered materials were collected, (which may in great measure be accomplished,) the sum of their weights would equal the weight of the original piece of wood.

4. Every effect has, or is produced by, an adequate cause, and is proportionate to it.

It may in general be observed, with respect to these axioms, that we only meant to assert what has been constant-ly true, and confirmed by experience, and is not contradicted either by reasoning or by any known experiment. But we do not mean to assert that they are as evident as the axioms of geometry; nor do we in the least premise to prescribe limits to the agency of the Almighty Creator of every thing in the universe, whose laws are too far removed from the reach of our understandings.

Having stated the principal axioms of philosophy, it is in the next place necessary to mention the rules of philosophizing, which have been formed, after mature consideration, for the purpose of preventing errors as much as possible, and of leading the student of nature along the shortest and safest path to the attainment of true and useful knowledge. These rules are not more than four; viz.

1. We are to admit no more causes of natural things, than such as are both true and sufficient to explain the appearances.

2. Therefore to the same natural effects we must, as far as possible, assign the same cause.

3. Such qualities of bodies as are not capable of increase or of decrease, and which are found to belong to all bodies within the reach of our experience, are to be esteemed the universal qualities of all bodies whatever.

4. In experimental philosophy we are to look upon propositions collected by general induction from phenomena, as absolutely or very nearly true, notwithstanding any contrary hypotheses that may be imagined, till such time as other phenomena occur, by which they may either be corrected, or may be shown to be liable to exceptions.

With respect to the degree of evidence which ought to be expected in natural philosophy, it is but proper to remark that physical matters are not in general capable of such absolute certainty as the branches of mathematics. The propositions of the latter science are clearly deduced from a set of axioms so very simple and evident, as to convey perfect conviction to the mind; nor can any of them be denied without a manifest absurdity. But in natural philosophy we can only say, that because certain particular effects have been constantly produced under certain circumstances, therefore they will most probably continue to be produced as long as the same circumstances exist; and likewise that they do, in all probability, depend upon those circumstances. And this is what we mean by laws of Nature; viz. certain effects which are or have been uniformly produced by certain causes, as the result of our observations reach.

We may, indeed, assume various physical principles, and by reasoning upon them, we may strictly demonstrate the deduction of certain conseqences. But as the demonstration goes no farther than to prove that such consequences must necessarily follow the principles which have been assumed; the
the consequences themselves can have a greater degree of certainty than the principles are possessed of; so that they are true, or false, or probable, according as the principles upon which they depend are true, or false, or probable.

The foundations of experimental philosophy, as we have already observed, are the properties of natural bodies, viz., of all those bodies, either solid or fluid, which in any way affect any of our senses; and since our senses are affected by the properties of these bodies, viz., by their extension, colour, hardness, transparency, &c. we cannot know any more of these bodies than what is manifested to us by such properties only as we are able to perceive. Were we furnished with other senses, we might discover other properties which would make us more intimately acquainted with the nature of such bodies.

Human art has not been able to discover more senses than those which every body knows; but it has, in great measure, improved some of those which we possess, and this alone is sufficient to point out the limited nature of our perceptions. Thus, for instance, the discovery of the microscope, and the telescope, have shown us wonders of which our forefathers were utterly ignorant; and the number and variety of these wonders have increased in proportion as the above-mentioned instruments have been improved. The improvements of these instruments have been suggested by the discoveries that have been made respecting the refrangibility of light, and the properties of transparent bodies, and these have been made in consequence of the innumerable experiments that have been instituted by various intelligent persons.

Thus it appears, that by means of trials and observations new facts are ascertained, which, besides their being immediately useful to the human species, furnish, at the same time, the means of making farther discoveries; and the treasures of the natural world are far, indeed, from a state of exhaustion. Hence the improvements and the discoveries of experimental philosophy proceed in a kind of increasing geometrical progression; unless they be impeded by some extraordinary occurrence.

In contemplating the intimate nature of natural bodies, when our mind goes beyond the bounds of our senses, (and our senses, even with the assistance of instruments and reasoning, are only capable of perceiving a few properties of those bodies;) we wander in the boundless field of probability and conjecture. Two principal hypotheses have been entertained with respect to the primitive component particles of bodies. One is, that the particles of each peculiar species of bodies are different from the particles of another species of bodies. Thus the primitive particles of gold are supposed to be different from the particles of calcareous earth, different from the particles of water, &c. The other hypothesis is, that there is one kind of primitive or original particles of matter, and that from the different arrangement of these ultimate particles, the various bodies arise. Experience shows that certain bodies, which, at first sight, appear to be absolutely different from each other, are, upon further examination, exactly of the same nature. On the other hand, a vast number of bodies are so distinct from each other, that no art has been able to form one of them from the particles of another; thus gold cannot be converted into a diamond, iron cannot be converted into lead, &c. The former of these observations seems to favour the second hypothesis; the latter seems to favour the first hypothesis; but it is not in our power to determine the real state of the matter.

With respect to the number of bodies, which, by our not being able to change one of them into the other, are called elementary, or primitive and distinct, the reader will and sufficient information under the article Elements; but it may be remarked in this place, that new bodies are frequently discovered in proportion as new instruments, and the improvements of science in general, furnish us with the means of discriminating them from others; hence we are naturally led to conclude, that most probably there may exist a vast number of other bodies, of which we at present have not the least suspicion. Some of these may perhaps be discovered hereafter, whilst others may remain utterly unknown to the human species.

The properties of natural bodies, which are the objects of research to the experimental philosopher, are either general, or particular. The general properties, which belong to all kinds of bodies, are, as far as we know, not more than six; viz., extension, divisibility, penetrability, mobility, vis inertiae, and gravitation. We have said that these are the general properties as far as we know, because matter in general may possess other properties that are not yet come to our notice. And the same observation may be made with respect to the universality of these properties: for they are said to be general, because no body was ever found which wanted any one of them. But mankind are not acquainted with all the bodies of the universe, and even several of those which are known to exist, cannot be subjected to experiment.

The peculiar properties, viz., those which belong to certain bodies only, and not to others, are density, rarity, hardness, softness, fluidity, rigidity, flexibility, elasticity, opacity, transparency, the properties of light, the properties of heat, the properties of electricity, the properties of magnetism, and three other kinds of attraction, (independent of gravitation, of electricity, and of magnetism,) viz., the attraction of aggregation, which the homogeneous parts of matter have towards each other, or by which they adhere together; and such is the power by which two small drops of mercury, when placed contiguous to each other, rush, as it were, into each other, and form a single drop; the attraction of cohesion, or that power by which the heterogeneous particles of bodies adhere to each other without any change of their natural properties, such as the adhesion of water to glass, of oil to iron, &c.; and the attraction of composition, or of affinity, which is the tendency that the parts of heterogeneous bodies have towards each other, by which they combine, and form a body, differing more or less from the composition of its components.

It is to be remarked, that of all the properties which we know their excellence is one, and some of the laws upon which they act; but we are otherwise utterly ignorant of their nature and dependence.

The investigation of some of the above-mentioned properties, whether general or particular, has been carried much farther than the investigation of other properties. The results of these investigations have likewise been various, both in point of extent and of application. Some of them are so very extensive and so useful, as to form the foundations of very important branches of science or of art, under peculiar appellations. Thus, upon the mobility and the vis inertiae of bodies, the doctrine of motion, or dynamics, is grounded, which comprehends mechanics, hydrostatics, or the mechanical properties of fluids, pneumatics, &c. Transparency and the properties of light form the fundamental foundation of optics. The attraction of affinity is the foundation of chemistry, as well as of various arts, and for that reason belongs to the properties, or to the extensive subjects that are grounded upon the same. The scientific analyses will be found under the various articles of their peculiar denominations.

The
The phenomena of the universe, are the appearances which take place in consequence of the above-mentioned properties of natural bodies, together (respecting some of them at least) with some original impulse. The phenomena which take place amongst the luminous celestial bodies, properly so called, such as the stars, the planets, &c. are examined by a particular science called astronomy; the meteors, or the phenomena, which take place within the limits of the terrestrial atmosphere, such as shooting stars, northern lights, halos, rain, frost, hail, winds, &c. form the subject of meteorology. The phenomena that take place upon the surface of, or within, the earth, are treated of under the comprehensive denominations of vegetation, earthquakes, volcanoes, conflagration, &c. all which will be found explained under their appropriate articles.

EXPERIMENTUM CRUCIS, denotes a capital, leading, or decisive experiment; thus called, either, because like a cross or direction post, placed in the meeting of several roads, it guides and directs men to the true knowledge of the nature of the thing they are enquiring after; or 'as it is a kind of torture, whereby the nature of the thing is, as it were, extorted by violence.

EXPIATION, the act of suffering the punishments adjudged to a man's crimes, and thus paying off, or discharging the debt or guilt; and it is figuratively applied to the pardon procured for the sins of the penitent by the interposition and death of Christ.

The Romishists hold, that souls after death are sent to purgatory to expiate or atone for their sins. See PURGATORY.

EXPIATION is also applied to sacrifices offered to the Deity, to implore his mercy and forgiveness.

EXPIATION, the Feast of, among the Jews, called by our translators the day of atonement, was held on the tenth day of Tifir, or the seventh month of the Jewish year, answering to part of our September and October. It was instituted by God himself, Lev. xxiii. 27, &c. On that day the high-priest, the figure or type of Jesus Christ, entered into the most holy place, and confessed his sins; and, after several ceremonies, made an atonement for all the people to wash them from their sins. Lev. chap. xvi. See scape-GOAT.

EXPIATION, among the Heathens, denoted a purification used for effacing or abolishing a crime, averting any calamity; and on a thousand other occasions, as purifying towns, temples, and sacred places, and armies, before and after battle.

It was practised with divers ceremonies: the most usual was ablation.

Expiations were performed for whole cities as well as particular persons. After the young Horatius had been abolished by the people for the murder of his father, he was farther purified by several expiations prescribed by the laws of the pontiffs for involuntary murders. Dion. Halicarnass.

EXPIATION, from expiō, I atone, in the Civil Law, the act of withdrawing or diverting something belonging to an inheritance, before any body had declared himself heir thereof.

This made a peculiar species of theft; for there could not properly be a theft in taking a thing not possessed by any body, or before the inheritance was accepted.

For this reason the Roman legislature introduced the act of expiation for the punishment of this crime.

Befide this meaning, it was used in a more special manner to signify a robbery committed by night; whence an expilator was looked upon as a greater criminal than a common thief.

The expilators were so called from their robbing and stripping people of their cloaths.

EXPIRATION, in Physiology, is the act of expelling air from the lungs, produced by a diminution of the cavity of the chest. It is opposed to inspiration, in which air is drawn into the chest. See RESPIRATION.

EXPIRATION is also used figuratively, for the end of a term of time granted, or agreed on, or adjudged.

EXPLEES, in Law, the rents or profits of an estate, &c. See ESPLEES.

EXPLICATION of the Subject of a Discourse, in Fulpius Oratory, and in the composition of sermons, comes in the place of narration at the bar, and should be conducted in a similar manner. It should be concise, clear, and distinct, and in a lively, correct and elegant, rather than highly adorned. To explain the doctrine of the text with propriety, to give a full and periphrastic account of the nature of that virtue or duty which forms the subject of the discourse, is properly the didactic part of preaching; on the right execution of which much depends for all that comes afterward in the way of persuasion. The great art in succeeding in it is, to meditate profoundly on the subject, so as to place it in a clear and strong point of view. Consider what light other passages of scripture throw upon it; consider whether it be a subject nearly related to some other from which it is proper to distinguish it, consider whether it can be illustrated to advantage by comparing it with, or opposing it to, some other thing; by enquiring into causes, or tracing effects; by pointing out examples, or appealing to the feelings of the hearers; that thus a definite, precise, circumstantial view may be afforded of the doctrine to be inculcated. Let the preacher be persuaded, that by such distinct and apt illustrations of the known truths of religion, it may both display great merit in the composition, and what hitherto to consider as far more valuable, render his discourses weighty, instructive, and useful. Blair’s Lectures, vol. ii. p. 297.

EXPLICATIVE Proposition, in Logic. See Complex Proposition.

EXPLICITE, in the Schools, something clear, distinct, formal, and unfolded.

The will or intention is said to be explicite when it is fully explained in proper terms; and implicite, when it is only to be learnt by deductions and confluences.

The Jews had not all an explicite knowledge of Jesus Christ, but they had at least an implicit one.

Such a telfator has declared his will explicite, i.e. in formal terms; there is no need to have recourse to explanations.

EXPLOITS, Bay of, in Geography, a bay of the Atlantic, on the east coast of Newfoundland. N. lat. 49° 45'. W. long. 55° 20'.

EXPLOSION. It is a matter of great moment, in military engineering, to load, and indeed to construct a mine, that it may explode with the greatest precision, and with the maximum effect. A variety of theories has been given upon this subject, but it would be out of place to notice the whole of what appertains thereto in this place; therefore we shall refer our readers to the word Mine for the particular detail of what relates to this subject, contenting ourselves with now offering a few remarks on the manner in which the explosion is usually effected.

It is of the first importance to ascertain, so nearly as may be practicable, what depth, and what weight of foil is to be removed by an explosion. This being done, the mine is formed,
formed, by a gallery leading to the chamber in which the powder was to be deposited in a very strong chest, but into a reces, and firmly secured in every part. Now, it being the nature of the rarified air to escape by that part which may be the weakest, it is evident, that if a mine is made under a rampart, so as to be within six feet of the surface, while all the sides are thicker by far than that measurement, the explosion will be directed towards that part which is thickest, and which from that circumstance is called "the line of least resistance."

But, in order to direct the explosion to that part, it will be necessary to consider whether the foil be every where alike; for if the superincumbent portion should be part of a large stratified rock, while the sides are of a loofe, inadhesive substance, the latter, though measuring more in diameter, will give the line of least resistance, which, in such a case, would follow the intensity, and create a false explosion. Hence explosions may be lateral as well as vertical.

It was formerly supposed, that the diameter of the entonnoir, or explosion, was equal to double the line of least resistance; but we find that for times that line may be exceeded, by allowing a load of 3500 lbs. of gun-powder, duly concentrated, and fired in the middle of the mafs, for every foot of the line of least resistance. We are not to infer from this, that 3500 lbs. will be requisite to lift one foot of foil; far from it; for as a cubic foot of explosion will contain only 17 lbs. of powder, the above quantity (3500 lbs.) would require a space of exactly four cubic feet; the proportion would therefore be preposterous. But when we calculate upon larger masses of foil, such as those prodigious cones thrown out from entonnoirs of great extent, we then find, that, to produce the complete explosion, an immense quantity of powder must be supplied.

It is self-evident, that the power of the powder, according to the above scale, is only computed to that extent which may be necessary towards the ordinary purposes of military devastation; for if we were to contribute, ad infinitum, 3500 lbs. of gunpowder for every foot in the line of least resistance, we should be accumulating power only in a mathematical proportion; while the resistance would be increas- ing in a geometric ratio; of course the power must be in a regular state of comparative diminution, in proportion as the line of least resistance is increased; and this must, after a while, occasion the powder to be inert; or, if there should be no explosion, it could only follow the track of the train; its ignition to be sure might be felt partially, like that of a flight earthquake, but no superfluous effects would be observable.

It has been already related, that the powder must be lodged in bulk; and that it should be ignited at the centre. This may, perhaps, appear superfluous; but all military men know, that much powder is blown out of the muzzles of pieces without ever being ignited; and we have a most remarkable fact, a very recent one indeed, which shews that, unless in bulk, powder is not always sure to be fired in its total. The incident alluded to is as follows.

In the month of March of this year, (1809,) a large ship was proceeding along the new cut, from Paddington, laden with casks of spirits and barrels of gunpowder. One of the crew, it is supposed, allured by the former, bored a hole for the purpose of drawing off a little wherewith to tipple. Unhappily the action of the gimblet set fire to the contents of that barrel, which the dishonest navigator had mislaken for one of spirits. The barrel exploded, and drove eleven other barrels, filled with gunpowder also, to the distance of near a hundred and fifty yards. It is curious, that although the whole of the powder-barrels were together, indeed in contact, only that in giffon exploded.

Vauhan gives us the following scale for exploding foils of various descriptions. He calculates, or perhaps found from experience, that for a cubic fathom (six feet) of foil, measuring in all 216 solid feet, the following proportions of gunpowder were needful.

1. Light earth, mixed with sand, 11 lbs.
2. Common earth 12
3. Strong sand 15
4. Clay, or fat earth 16
5. Old, and good masonry 18
6. Rock 20

In following this calculation, we are to consider the entonnoir to be in diameter equal to only double the line of least resistance; and not according to a maximum explosion.

Explosion, from the Latin explodo, is the act of driving out something with noise and violence. The causes, the report or noise, and the other effects of explosions, however insignificant they may appear at first sight, are nevertheless, when duly considered, of great consequence to the human species, and as such they have been carefully inquired into by divers philosophers. A variety of experiments have been instituted for determining the particulars that relate to them, and numerous conjectures have been offered in explanation of these concomitant circumstances, which have not as yet been thoroughly investigated.

Explosions may be distinguished into natural and artificial. The principal natural explosions are those of the atmospheric thunder, of volcanoes, of earthquakes, and to these there may be added the inferior explosions arising from hogs. The artificial explosions are such as are produced by the force of fired gunpowder in the various engines in which it is used, the explosions produced by other chemical compounds, and the pneumatic explosions; meaning those which are produced by the air rushing into a partial vacuum, by the discharge of air-guns and the like.

Of all these kinds of explosions we shall now briefly treat, not in the order in which they have been enumerated; as this would prove a useless formality; but in a manner which may be more likely to elucidate the most interesting part of the subject; and this undoubtedly is the stupendous force with which effects, in great variety, are produced in certain explosions.

The first thing that strikes the observer is the sudden and violent noise of an explosion. It is hardly necessary to observe that this noise or report is owing to the intermediation of the air between our ears and the cause, whatever that may be, of the percussion which is given to the air. Without that intermediation, or without air, the report could not be heard. But it must be farther observed, that the mere introduction of something into the ambient air is not the principal cause of the report. That effect principally depends upon the sudden replacing or collapsing of the air, after its having been removed or rarified in any particular place. So that in order to account for the immediate cause of the noise in an explosion, we must look out for something which after having been introduced into the atmosphere, whether slowly or quickly, is afterwards suddenly withdrawn or contracted. A few examples will easily illustrate this observation.

Take a common syringe, and open the aperture of it, then draw the plunger entirely out of its other extremity, and at that moment a report is heard, which is occasioned by the replacing of the air within the syringe; for in drawing the plunger out of it, the air within the cavity of the syringe is rarified,
EXPLOSION.

From these facts, and from a vast many more which might here be described, it clearly appears that the sudden introduction of something into the ambient air produces little noise; but that the noise of an explosion is mostly due to the collapsing of the air, which takes place in consequence of the instantaneous contraction of that which has been introduced in it. The noise, *ceteris paribus*, is more or less in proportion as a greater or lesser quantity of air is displaced and replaced, and likewise in proportion to the quickness of that operation.

When more reports than one are heard; these are produced either by an equal number of explosions, or by a reverberation, *viz.* by an echo.

The air thus agitated conveys the sound of an explosion, or propagates its own vibrations, to immense distances. The firing of heavy ordnance has been sometimes heard at the distance of 50 or 60, and even more miles. The explosions of volcanoes, or those which accompany earthquakes, have often been perceived at distances much more considerable; but with respect to the extent of this kind of communication, rate of moving, &c. the reader is referred to the articles Sound, propagation of, and Hearing. We shall, however, in this place, briefly mention an effect of this kind of violent aerial vibration which might be worth being observed if it is at all possible to get a sufficiently exact conception of it. When an apparatus, properly situated, would examine with particular attention. The phenomenon is, that the explosion of cannons, and especially of powder magazines, or powder mills, renders the air considerably electrified, and that it electrifies the glasses of windows.

After the noise, or the report, the next step is to inquire into the cause or causes which produce it: *viz.* into the nature of the elastic fluid which, in coming out of any confinement, displaces the circumspect ambient air, and then suddenly gives way to it. Until very lately the immediate cause of most explosions was principally attributed to the generation or extrication of permanently elastic fluids, *viz.* gases; and this is undoubtedly true in a great many cases; but upon a closer examination of the concomitant particulars, the expulsion of these elastic fluids, even in a state of incandescence, was found inadequate to the effects that were experienced in a variety of cases; hence philosophers began to look out for some other agent more active; and though the force of fumes was known to be concerned in some kinds of explosions; yet it must be acknowledged, that this force is not sufficient to counteract the impact of a body moving with great rapidity on the side of the explosion, and that it is equally insufficient to counteract the resistance of the body, which the latter, and the force of the explosion, have occasion to perform.

An apparatus called an air-pump, and a device of the air, is a subject of great importance in the study of the subject. The apparatus is a cylinder fitted with a pisto, which may be taken out of the cylinder and replaced in it; and the air, when once set in motion, will not contract after its expansion; hence the report is incomparably louder with the former than with the latter.

An electric spark, especially in the discharge of a Leyden phial or battery, is accompanied with a report, in consequence of its suddenly displacing the air from the spot in which it explodes; and of the subsequent collapsing of the air. And that the electric spark really displaces the air, is easily shown by means of an electrical instrument, called "Kinnerley's electrical air thermometer." In this instrument the spark is taken into a glass vellum, which by an annexed narrow tube, partially filled with a liquid, indicates the rarefaction or displacing of the air within the vellum. With this apparatus, whenever a spark or discharge of an electric jar is taken within the glass vellum, the riling and falling of the liquid within the annexed tube shows that the air is suddenly displaced, and is likewise heated in some degree; for the liquid rises suddenly to a certain degree; and as suddenly descends, not quite to its former station, but to a place a little above it, from which afterwards it descends gently to its original situation.
ford says, "the great defideratum, the real measure of the initial expansive force of inflamed gunpowder, so far from being known, has hitherto been rather guessed at than determined; and no argument can be more convincing to shew our total ignorance upon that subject, than the difference in the opinions of the greatest mathematicians of the age, who have undertaken its investigation."

The ingenious Mr. Robins thought, that the force of the elastic fluid, which is generated in the combustion of gunpowder, is 1000 times greater than the mean pressure of the atmosphere. Mr. D. Bernoulli reckoned it equal to 10,000 times that pressure.

Count Rumford, in one of his first experiments, confined gunpowder in a strong iron tube, and burned it by heating part of the tube, or rather of an appendage that had been fixed to it. This was done with a view of confusing the elastic fluid, that was generated in the combustion. "The result," he says, "of this experiment fully answered my expectations. The generated elastic fluid was so completely confused, that no part of it could make its escape. The report of the explosion was so very feeble, as hardly to be audible: indeed it did not by any means deserve the name of a report, and certainly could not have been heard at the distance of twenty paces; it resembled the noise which is occasioned by the breaking of a very small glass tube."

And farther on, he says, "It has generally been believed, after Mr. Robins, that the force of fired gunpowder conflicts in the action of a permanently elastic fluid, similar in many respects to common atmospheric air: which being generated from the powder in combustion, in great abundance, and being, moreover, in a very compressed state, and its elasticity being much augmented by the heat, (which is likewise generated in the combustion,) it escapes with great violence, by every avenue; and produces that loud report, and all those terriblc effects which attend the explosion of gunpowder."

"But though this theory is very plausible, and seems upon a cursory view of the subject to account in a satisfactory manner for all the phenomena, yet a more careful examination will shew it to be defective. There is no doubt but the permanently elastic fluid generated in the combustion of gunpowder, affects in producing those effects which result from its explosion, but it will be found, I believe, upon accurate test, that the real expansive force of fired gunpowder, that this cause, alone, is quite adequate to the effects actually produced: and that, therefore, the agency of some other power must necessarily be called in to its assistance."

This author then proceeds to describe a variety of experiments and calculations which prove, beyond a doubt, that the above-mentioned theory is insufficient to account for the effects which are produced by the inflammation of gunpowder; for he computes, in the amplest manner possible, the force of the gas which is generated even in the heat of red-hot iron, by which elevation of temperature air is known to be expanded not much above four times its ordinary bulk. He endeavoured to measure the force in question by the lifting up of a very great weight, and his ingenious experiments were attended with results sufficiently satisfactory; but we must refer the reader to the above-mentioned paper, if for the detail of these interesting particulars; and we must here only add an abridgment of the latter part of the account, which more immediately relates to the principal object of our present enquiry.

"I will finish," the Count says, "this paper by a computation, which will shew that the force of the elastic fluid generated in the combustion of gunpowder, enormous as it is, may be satisfactorily accounted for upon the supposition that its force depends solely on the calicity of watery vapour or steam."

"It has been shewn by a variety of experiments made in England, and in other countries, that the calicity of steam is redoubled by every addition of temperature equal to 30 degrees of Fahrenheit's thermometer."

"Supposing now a cavity of any dimensions (equal in capacity to one cubic inch for instance) to be filled with gunpowder, and that on the combustion of the powder, and in consequence of it, this space is filled with steam (and I shall presently shew that the water existing in the powder as water is abundantly sufficient for generating this steam); if we know the heat communicated to this item in the combustion of powder, we can compute the calicity it acquires by being fo heated."

"Now it is certain that the heat generated in the combustion of gunpowder cannot possibly be less than that of red-hot iron. It is probably much greater; but we will suppose it to be only equal to 1000 degrees of Fahrenheit's scale, or something less than iron visibly red-hot in day light."

"As the elastic force of steam is just equal to the mean preflure of the atmosphere, when its temperature is equal to that of boiling water, or 212° of Fahrenheit's thermometer, and as its calicity is doubled by every addition of temperature equal to 30 degrees of the same scale, with the heat of 212° + 30° = 242° its calicity will be equal to the preflure of two atmospheres; at the temperature of 242° + 30° = 272° it will be equal to four atmospheres, &c."

"Following up our computations on the principles assumed, (and they are founded on the most incontrovertible experiments,) we shall find that at 692° + 30° = 722°, the calicity will be equal to the preflure of 131,072 atmospheres, which is 130 times greater than the elastic force assigned by Mr. Robins to the fluid generated in the combustion of gunpowder; and about one-sixth part greater than my experiments indicated it to be."

"But even here the heat is still much below that which is most undoubtedly generated in the combustion of gunpowder. That the calicity of steam would actually be increased by heat in the ratio here assumed, can hardly be doubted; it has absolutely been found to increase in this ratio in all the changes of temperature between the point of boiling water, (I may even say of freezing water,) and that of 285° of Fahrenheit's scale, and there does not appear to be any reason why the same law should not hold in higher temperatures."

"A doubt might possibly arise with respect to the existence of a sufficient quantity of water in gunpowder, to fill the space in which the powder is fired, with steam, at the moment of the explosion, but this doubt may easily be removed."

"The bell gunpowder, such as was used in my experiments, is composed of 70 parts (in weight) of nitre, 18 parts of sulphur, and 16 parts of charcoal; hence 100 parts of this powder contain 67 1/7 parts of nitre, 17 2/7 parts of sulphur, and of charcoal 15 3/7 parts."

"Mr. Kirwan has shewn that in 100 parts of nitre there are seven parts of water of crystallization; consequently in 100 parts of gunpowder, as it contains 67 1/7 parts of nitre, there must be 4 1/65 parts of water."

"Now, as one cubic inch of gunpowder, when the powder is well shaken together, weighs exactly as much as one cubic inch of water at the temperature of 55° F. namely 253.175 grains troy; a cubic inch of gunpowder in its dry state must contain at least 10.055 grains of water; for:
for it is 100 to 4,711, as 253,175 to 10,527. But besides
the water of crystallization which exists in the nitre, there
is always a considerable quantity of water in gunpowder,
in that state in which it makes bodies damp or moist. Char-
col exposed to the air has been found to absorb nearly 5th
of its weight of water, and by experiments I have made on
gunpowder, by ascertaining its loss of weight on being
macerated, and its acquiring this lost weight again on being
exposed to the air, I have reason to think that the
power of the charcoal, which enters into the composition
of gunpowder, to absorb water, remains unimpaired, and
that it actually retains as much water in that state as it
would retain were it not mixed with the nitre and the
sulphur.

As there are 15.6 per cent of charcoal in 100 parts of
gunpowder, in one cubic inch of gunpowder, (= 253,175
grains troy,) there must be 38,969 grains of charcoal;
and if we suppose the apparent weight of this charcoal
to be water, this will give 4,875 grains in weight for
the water which exists in the form of moisture in one cu-
bic inch of gunpowder.

If now we compute the quantity of water which
would be sufficient, when reduced to steam under the
mean pressure of the atmosphere, to fill a space equal in ca-
cacity to one cubic inch, we shall find that either that con-
tained in the nitre which enters into the composition of
one cubic inch of gunpowder, as water of crystallization, or
even that small quantity which exists in the powder in the
state of moisture, will be much more than sufficient for
that purpose.

Though the density of steam has not been determined
with that degree of precision that could be wished, yet it
is quite certain that it cannot be less than 2000 times rarer
than water, when both are at the temperature of 212°.
Some have supposed it to be more than 10,000 times rarer
than water, and experiments have been made which seem
to render this opinion not improbable; but we will take
its density at the highest possible estimation, and suppose it
to be only 2000 times rarer than water. As one cubic
inch of water weighs 253,175 grains, the water contained
in one cubic inch of steam at the temperature of 212°
will be 253,175 grains of water.

But we have seen that one cubic inch of gunpowder
contains 10,927 grains of water of crystallization, and
4,875 grains in a state of moisture; consequently the quan-
tity of water of crystallization in gunpowder is 85 times
greater, and the quantity which exists in it in a state of
moisture, is 38 times greater than that which would be
required to form a quantity of steam sufficient to fill com-
pletely the space occupied by the powder.

Hence we may venture to conclude, that the quantity
of water actually existing in gunpowder is much more than
sufficient to generate all the steam that would be necessary
to account for the force displayed in the combustion of
gunpowder, (supposing that force to depend solely on the
action of steam,) even though no water should be generated
in the combustion of gunpowder. It is even very probable
that there is more of it than is wanted, and that the force
of gunpowder would be still greater, could the quantity of
water it contains be diminished.

From this computation it would appear that the diffi-
culty is not to account for the force actually exerted
by fired gunpowder, but to explain the reason why it does
not exert a much greater force.

Besides the common gunpowder, there are several other
chemical compositions which are capable of exploding
with greater or less violence; and the most remarkable of
these compositions are, the gunpowder formed with the
super-oxygenated muriate of soda, instead of nitre; that
preparation of gold which, from its remarkable property, is
called fulminating gold; the fulminating silver, Howard's
mercurial powder, the common fulminating powder, which
confits of nitre, potash, and sulphur, &c. The explo-
sions of almost every one of these chemical compositions is
less than the explosion of an equal quantity of the com-
mon gunpowder; yet when confined in a barrel or other
fit instrument, few of these compositions exert a force, or
produce an effect equal to that of gunpowder. This
which at first sight may appear to be an inexplicable para-
dox, will be easily understood by considering, that the
results of the report depends in great measure on the
quickness of the inflammation or explosion; whereas the
force of the explosion is mostly proportional to the quan-
tity of elastic fluid, be it gas or vapour, which is generated,
and that the abovementioned chemical mixtures exploded
quicker than common gunpowder, may be easily proved.

The explosion of the gunpowder made with the
super-oxygenated muriate of soda, and Howard's mercurial
powder, exert an immense force when fired in barrels or
other like vessels. Fulminating gold and fulminating silver
explode very readily, especially the latter, which, when once
prepared, can no longer be touched; for it will explode,
not only when heated a few degrees above the temperature
of the atmosphere, but even when touched with any cold
body. Yet when either of these preparations is confounded
in a barrel or other like instrument, and is inflamed, the
force which it exerts is by no means equal to that which
one who has heard the noise of their explosions would be
led to expect. It is worthy of remark, that, upon the
whole, no other composition hitherto discovered has been
found preferable to the common gunpowder, for muskets,
cannons, and other instruments of the like nature. Most
of these preparations are considerably more expensive than
the common gunpowder; some of them are not nearly so
manageable as the gunpowder, for they will explode by the
least touch or grinding, even by the friction of the flint
into the neck of the vessel that contains them; but the
principal fault is that very property by which they might
be expected to have a superior power; namely, the quick-
ness of their explosion.

There is a certain time requisite for the motion of the
wadding and bullet from the lower part to the muzzle of
the gun, and the gradual inflammation of the gunpowder,
when used in proportionate quantity, seems to correspond
with that gradual movement of the bullet, wadding, &c.
When the exploding composition goes off much quicker
than the common gunpowder, that force which is exerted
spherically all round, and quicker than the time during
which the wadding, &c. can get along the cavity of the
barrel, frequently breaks the barrel, and endangers the by-
standers. We cannot illustrate this effect better than by
mentioning the common and well-known observation, that
though an open door may be shut by a gentle application
of a child's
EXP

a child's hand, yet if you point a gun, and fire a bullet at it, the latter will make a hole through it without flattening, or closing it in the leaf.

Speaking of the force of explosions, it may naturally be required that we should treat of the force and effects of electrical explosions. But as the nature of such explosions cannot be properly understood without other particulars relative to the subject of electricity, their force and effects will be found described under the articles which belong to that extensive subject; such as Electric Sparks, Lightning, &c.

It is in a manner similar to the effects of gunpowder, that water projected upon red-hot or fused metal, occasions a most powerful, and most dangerous explosion. In both cases the water is instantly reduced into steam, at a high temperature, consequentlly of very high elasticity; hence the force which is exerted is often prodigiously great; and there are instances recorded of whole foundaries having been instantly demolished, in consequence of some persons having inadvertently set upon the liquid metal. If a small quantity of water be poured upon red-hot charcoal, or red-hot glass, a hissing noise is heard; the part which is touched by the water lores its redness, and nothing else remarkable takes place, because the above-mentioned explosions are bad conductors of heat, and it is only that part which is touched by the water that communicates its heat to the water, and this is not sufficient to convert the water suddenly into steam of very great elasticity. But metallic bodies are the best conductors of heat, and fused copper is particularly so; hence, when a small quantity of water happens to fall upon a large quantity of that metal, in a state of fusion, the heat from a great part of the metal rushes to the spot where the water is fallen, and instantly converts it into steam of high elasticity.

The explosion of a mixture of hydrogen and oxygen gases, or of hydrogen gas and common air, does likewise exert a considerable force, but not to be compared with that of gunpowder. These gases, when inflated, expand considerably, but instantly after, they contract into an exceedingly narrow compafs, which occasions the report; for, by the combustion, they are converted principally into water, the bulk of which is less than the ten or twenty thousandth part of the original bulk of the gases.

The last kind of explosion we shall take notice of, is produced not by the generation or contraction of an elastic fluid, but by a sort of mechanical derangement. Those lumps of glass with a long tail, or prolongation, which are well known by the name of Glafs Tears, or Prince Rupert's Drops, are an instance of this kind. If one of these drops be held in the hand, and part of the tail is broke, a smart kind of explosion is heard, and the whole is instantly converted into powder. In order to understand the cause of this phenomenon, it is in the first place necessary to consider how these drops are formed. For this purpose the glass manufacturers take a quantity of the fused glass, (about half an ounce of it,) and green bottle glass is the fittest for it,) and drop it in that state of incandescence into cold water; the consequence of which is, that the external part of the lump of glass is cooled and rendered solid long before the internal part of it. Then when the internal part is cooled, and of course contracts its dimensions, the external part being already cooled and settled, cannot follow it, so that it remains in a state of suspension somewhat like an arch; hence, when part of the lump is broken, the key-stone, as it were, of the arch, is removed, and the whole assemblage of particles is de-ranged. See Glass Tears, for a more detailed explanation of these properties.

Several other subltances explode and are broken upon analogous principles. Such are glass vesseis made for analogous purposes, and especially for electrical machines; also large cast-metal vessels sometimes spontaneously explode and break in the act of cooling. Sir William Hamilton mentions certain volcanic bodies, which he calls volcanic bombs, that explode probably on the same principle. They were large pieces of lava, which burst in pieces like bombs, as they fell to the ground. These were observed in the great eruption of mount Vesuvius, which took place in the year 1779. The cause of volcanic explosions, as well as of those which accompany or precede earthquakes, is possibly attributed to the action of steam; but these kinds of explosions will be found particularly examined under the articles Earthquake and Volcano.

The use to which certain explosions are applied is so well known as not to require any particular description. Every body knows the various uses of shooting with gunpowder, especially in military affairs. The blasting or breaking of rocks, by means of the explosion of gunpowder, is likewise well known. But these uses, together with all the particulars that relate to them, are often mentioned in various other articles of this Cyclopedia; such as Gunnery, Mining, Shooting, &c.

EXPLOITI6N, in Rhetoric, a figure whereby we explain the same thing in different phrascs and expressions, in order to shew it more fully.

Explosion was the favourite figure of Balzac.

EXPONAS VENMDONI. See Venditoni.

EXPONENT, from express, I express, in Arithmetic. Exponent of a power denotes the number which expresses the degree of the power, or which shews how often a given power is to be divided by its root before it be brought down to unity.

Thus, the exponent or index of a square number is 2; of a cube, 3; of the square being a power of the second degree; the cube of a third, &c.

Exponents are commonly written above, and somewhat towards the right-hand of the number or quantity whose power they express. Thus, 3, 4, signify the fifth power of 3, and of a. See Power.

Exponent is also used in the same sense with index or logarithm.

Thus a series of numbers in arithmetical progression being placed under another series in geometrical progression, are called the exponents, indices, or logarithms thereof. E.gr. in the two progressions,

Geom. 1, 2, 4, 8, 16, 32, 64, 128, 256, 512
Arith. 0, 1, 2, 3, 4, 5, 6, 7, 8, 9

0 is the exponent, index, or logarithm of the first term 1; 5 that of the fifth, 32, &c.

Hence, unity is to the exponent of a power as the logarithm of the root to the logarithm of its power; consequently, the logarithm of the power is had by multiplying the logarithm of the root by its exponent; and the logarithm of the root is had by dividing the logarithm of the power by its exponent.

Exponent of a ratio, is the quotient arising upon dividing the antecedent by the consequent.

Thus, in the ratio 3 to 2 the exponent is 1; and the exponent of the ratio 2 to 3 is ।. See Ratio.

Hence, 1. If the consequent be unity, the antecedent is the exponent of the ratio. Thus, 4, the exponent of 4.
the ratio $4$ to $1$ is $4$; and again, the exponent of a ratio is to unity as the antecedent to the consequent.

2. Since in a rational ratio the exponent of a ratio is had by dividing a rational number by another rational, the exponent of a rational ratio is a rational number.

**EXPOSITIONAL CALCULUS.** Calculus exponentialis is a method of differencing exponential quantities, and of summing up the differences of exponentials. See *CALCULUS.*

**EXPOSITIONAL curve** is that which is defined by an exponential equation.

Exponential curves partake both of the nature of algebraic and transcendental ones; of the former, because they consist of a finite number of terms, though those terms themselves are indeterminate; and of the latter, because they cannot be algebraically constructed, or represented by an algebraic equation. Thus $\frac{a^y}{b} = a^y$ is the equation of an algebraic curve; $y = a^y$ is the equation of an exponential curve: this equation $y = a^y$ denotes that any ordinate $y$ is to a constant ordinate affirmed equal to 1, as a constant quantity $a$ raised to a power whose exponent expresses the ratio of the absciss to the line taken for unit or 1, raised to the same exponent. Let $b$ represent the line $= 1$, and the equation

$$y = a^y \left( \text{since } y = \frac{a^x}{b}; \frac{a^x}{b} \right),$$

will become $\frac{a^x}{b} = \frac{a^x}{b}$.

Note, $y = a^y$ is the equation of the logarithmic curve. See *LOGARITHMIC.* See also Curve.

**EXPOSITIONAL equation** is that wherein there is an exponential quantity. See *EQUATION, &c.*

**EXPOSITIONAL quantity** is a power whose exponent is an indeterminate or variable quantity.

Exponential quantities are of several degrees and orders: when the exponent is a simple indeterminate quantity, it is called an exponential of the first or second degree.

When the exponent itself is an exponential of the first degree, then the quantity is an exponential of the second degree. Thus, $a^y$ is an exponential of the first degree, because the quantity $y$ is a simple flowing quantity; but $x^y$ is an exponential quantity of the second degree; because $x^y$ is an exponential of the first degree; so also, $x^y$ is an exponential of the third degree, the exponent $x^y$ being one of the second; and universally, the exponential quantity of any degree has for its exponent, the exponential quantity of the degree next preceding it. See *Bernoulli* Oper. tom.1. p. 182, &c.

**EXPORTATION,** in *Commerce,* the act of sending commodities out of one country into another.

Exportation is a part of foreign commerce (see *Commerce*), distinguished by the appellation *active,* or *selling part,* in opposition to importation, which is called the *passive,* or *buying part.* It is observed, as a general maxim, that commerce, when active, must produce a flow of riches, the balance being received in money; whereas, if it be passive, treasures will be exhausted, as the balance of trade must continually be made good out of the remaining coin. Hence, plenty of money in any place implies, that the quantity of goods exported far exceeds that of goods imported; and wherever money is scarce, it may be concluded that greater quantities of goods have been imported than exported. See *Exchange.*

It has been a principal object of commercial policy in almost every country, to encourage exportation, with the exception of a few articles; that of manufactured goods has been promoted with a view of encouraging the internal industry of the country, and that of foreign produce, as a means of drawing wealth from other countries by the profits of the carrying trade. The excess of the value of goods exported beyond that of the imports has usually been considered as a criterion of the profits which a country derives from foreign trade; but this is a fallacious mode of determining this important point, because advantageous foreign trade might long exist, even if the imports far exceeded the value of the exports. The laws in force relating to exportation confine principally of prohibitory or restrictive regulations concerning bullion, corn, wool, machinery, and tools used in various branches of the manufactures, the exportation of which, it is thought, might diminish the necessary supply of provisions for the consumption of the country, or enable foreigners to rival valuable branches of its manufactures. The acts relative to the exportation of wool, prohibit the exportation, not only of the commodity itself, but also of live sheep, rams, or lambs, from Great Britain, Ireland, Jersey, Guernsey, Alderney, Sark, or Man, on penalty of the forfeiture thereof, and of the ships conveying them; also 3l. for every sheep, &c. and three months' solitary imprisonment of the offender; for a second offence, 5l. for every sheep, &c. and six months' imprisonment; except wether sheep for ships' use, put on board by licence of the port-officer of the customs. A limited quantity of wool, however, is allowed to be exported from the port of Southampton to Jersey, Guernsey, Alderney, and Sark.

The duties on exportation, payable in Great Britain and Ireland, were formerly the principal branch of the revenue derived from foreign trade; but they are now of small amount compared with the duties payable on goods brought into the country.

The official value of all exports from Great Britain, for three years ending the 5th of January 1809, was as follows:

<table>
<thead>
<tr>
<th>British produce and manufactures</th>
<th>Foreign merchandise</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year ending 5th January 1809</td>
<td>£9,124,499</td>
</tr>
<tr>
<td></td>
<td>£2,402,685</td>
</tr>
<tr>
<td></td>
<td>£2,517,422</td>
</tr>
<tr>
<td></td>
<td>£2,692,288</td>
</tr>
<tr>
<td></td>
<td>£7,863,207</td>
</tr>
</tbody>
</table>

The actual value of British produce and manufactures exported from Great Britain, as well as the prices current, and to the declarations of the exporters, was, in the year ending the 5th of January 1809, £25,686,136.

The official value of imports into Great Britain from Europe, Africa, and America, during the same period, is as follows:

| Year ending 5th January 1807    | £2,517,422         |
|                                  | £2,692,288         |
|                                  | £2,692,288         |
|                                  | £7,863,207         |

The real value of Irish produce and manufactures exported from Ireland in the year ending the 5th of January 1809, computed at the average prices current, was £12,497,517.
EXP

102. 11d.  See Customs, and Duty.  See also Com-

mence.

Dr. Smith, in his "Nature and Causes of the Wealth of Nations," states and explains the principles upon which the exportation trade is founded. When the produce of any particular branch of industry exceeds what the demand of the country requires, the surplus must be sent abroad, and exchanged for something for which there is a demand at home. Without such exportation, a part of the productive labour of the country will cease, and the value of its annual produc-
tion diminish. The land and labour of Great Britain pro-
duce generally more corn, woolens, and hard ware, besides some other manufactures, than the demand of the home market requires. The surplus part of them must, therefore, be sent abroad, and exchanged in the manner already men-
tioned. It is only by means of such exportation, that this surplus can acquire a value sufficient to compensate the la-
bour and expense of producing it. The neighbourhood of the sea-coal, and the banks of all navigable rivers, are ad-

vantageous situations for industry, only because they facilitate the exportation and exchange of such surplus: produce for some-thing else, which is more in demand there.

When the foreign goods, which are thus purchased with the surplus produce of domestic industry, exceed the demand of the home market, the surplus part of them must be sent abroad again, and exchanged for something more in demand at home. When the capital stock of any country is increased to such a degree that it cannot be wholly employed in supplying the con-
sumption, and supporting the productive labour of that particular country, the surplus part of it necessarily digresses into the carrying trade, and is employed in performing the trade office to other countries. The carrying trade is the na-
tural effect, and symptom of great national wealth; but it does not seem, says Dr. Smith, to be the natural cause of it.

Holland had formerly the greatest share of the carrying trade of Europe, and in proportion to the extent of its land, and the number of its inhabitants, it was the richest country in Europe. England, now the richest country of Europe, has appropriated to itself the greatest share of this trade. This ingenious writer suggests, that, whether the capital, which carries this surplus produce abroad, be a foreign or a do-

cemone nation, is of very little importance. If the society has not acquired sufficient capital both to cultivate all its lands, and to manufacture in the completest manner the whole of its rude produce, there is even a considerable advantage derived from the exporting of that rude produce by a foreign capital, in order that the whole of the society may be employed to more useful purporses.

Dr. Smith farther observes, in reference to this subject, that with a view of multiplying gold and silver, in which, it has been commonly supposed, the wealth of a country consists, it necessarily became the great object of political economy to dimin-

ish, as much as possible, the importation of foreign goods for home consumption, and to increase, as much as possible, the exportation of the produce of domestic industry; and, there-

fore, its two great engines for enriching the country have been restraints upon importation, and encouragement to exportation. The former were of two kinds, viz. restraints upon the importation of such foreign goods for home con-

sumption as could be produced at home, from whatever country they were imported: and restraints upon the importa-
tions of goods of almost all kinds, from those particular countries, with which the balance of trade was supposed to be disadvantageous. These different restraints conflicted sometimes in high duties, and sometimes in absolute prohi-
bitions. Exportation was encouraged sometimes by draw-
backs, sometimes by bounties, sometimes by advantageous

treaties of commerce, and sometimes by the establishment of colonies in distant countries. Thus it has been intended to increase the quantity of gold and silver in any country by turning the balance of trade in its favour. Our author has particularly examined what are likely to be the effects of these restraints and encouragements upon the annual produce of the industry of a country. According as they tend ei-
ther to increase or diminish the value of this annual produce, they must evidently tend either to increase or diminish the real wealth and revenue of the country. See Exchange, Monopoly, and Balance of Trade. Of the encourage-
ments to exportation above enumerated, those which are called drawbacks (see the article) seem to Dr. Smith to be the most reasonable. Concerning the grant of bounties; see Bounties.

EXPOSING the act of setting a thing to public view.

In the Roman church, the sacrament is laid to be exposed when it is shown in public, uncovered, on festival days, and during the time of plenary indulgences.

EXPOSING is also used with a farther latitude; thus, we say it is prohibited to expose false and clipped money.

Such a house stands very high, and has a delicious pro-

pect; but it is exposed to all the four winds. Such a city being on the frontiers, and not fortified, is exposed to the insulfs of every party of forces.

EXPOSING of Children, a barbarous custom practised by most of the ancients excepting the Thebans, who had an ex-

press law to the contrary, whereby it was made capital to expose children, ordaining at the same time that such as were not in a condition to educate them, should bring them to the magistrates, in order to be brought up at the public expense. (Elian Hist. Var. 1. ii. c. 5.) Amongst the other Greeks, when a child was born, it was laid on the ground; and if the father designed to educate his child, he immediately took it up; but if he forebore to do this, the child was carried away, and exposed. Pitisc. Lex. Ant. in voc. Ex-

positio.

The Lacedemonians, indeed, had a different custom; for with them all new-born children were brought before certain tryers, who were some of the gravest men in their own tribe, by whom the infants were carefully viewed; and if they were found lily and well-favoured, they gave orders for their education, and allotted a certain proportion of land for their maintenance; but if weakly, or deformed, they order-
ed them to be cast into a deep cavern in the earth, near the mountain Taygetus, as thinking it neither for the good of the children themselves, nor for the public interest, that defective children should be brought up. Plutarch takes notice of this law of Lycurgus, and places no censure upon it.

Many persons exposed their children only because they

were not in a condition to educate them, having no intention that they should perish. It was the unhappy fate of
dughters especially to be thus treated, as requiring more

charges to educate and settle them in the world. Likewise,

The parents frequently tied jewels and rings to the chil-
dren they exposed, or any other thing whereby they might

afterwards discover them, if Providence took care of their

safety. Another design, in adorning these infants, was to encourage such as found them to nourish and educate them, if alive; or to give them human burial, if dead.

The places where it was usual to expose children were

such as people frequented most. This was done in order

that they might be found, and taken up by compassionate

persons who were in circumstances to be at the expense of

their education. With this intention the Egyptians and

Romans
Romans chose the banks of rivers, and the Greeks the highways.

Dionysius Halicarn. (Antiq. Rom. I. ii.) informs us, that Romulus obliged the citizens to bring up all their male children, and the eldest of the females. They were allowed therefore to destroy all their female children but the eldest. And even with regard to their male children, if they were deformed or monstrous, he permitted the parents to expose them, after having shown them to five of their nearest neighbours. In Cicero's third book of laws, (cap. 8.) there is a passage, from which it has been concluded, that the law of Romulus, with regard to the exposing and destroying of male children that were remarkably deformed, was confirmed by a constitution of the twelve tables. It appears, from a passage in Terence, that this inhuman custom of exposing and destroying children, especially females, was not uncommon even among parents of the best character. Sentiments of this kind were published with applause on the Roman theatre: and we learn from Seneca (de Ira, I. i. c. 15.) that so late as in his time, it was usual among the Romans to destroy weak and deformed children. "Portentosus factus exitiusimus: liberos quoque, si debiles monstruoque editi sunt, mergimur."

This unnatural practice was preferred and approved even by the more eminent philosophers. Plato (Republ. I. v.) recommends it to be ordered by law that men or women, who are past the age of having strong children, should take care that their offspring, if they should have any, should not come to the birth, or else the light; or if that should happen, that they should expose them without nourishment. Aristotle (Politic. I. vii. c. 16.) expressly says, that it should be a law not to bring up or nourish any child that is weak or mained; and that when the law of the country forbids to expose infants, it is necessary to limit the number of those who should be begotten; and that any one beggets children above the number limited by the law, he advises to procure abortion before the foetus has life and sense. The practice that has long prevailed among the Chinese, and that subsists among them even to this day, is well known.

**EXPOSITION, the act of exposing.** See **Exposition.**

**Exposition** is likewise applied to the interpretation or explanation of an author, or passage therein. See **Exegesis.**

**Exposition of deeds, in Law,** shall be favourable, according to the apparent intent; and be reasonable, and equal, &c. Co. Litt. 313.

**Exposition, exposito, in Rhetoric,** is sometimes used for division. See **Division;* and see also **Exergasia.**

**Exposition, in Gardening.** See **Exposure.**

**EXPOSITIONOR, or EXPOSITORY,** a title which some writers have given to a letter kind of dictionaries or vocabularies, serving to expound or explain the meaning of the obscure or difficult words of a language.

It is also used in the same sense with commentary and paraphrase.

**EX POST FACTO, in Law,** denotes something done after another thing that was committed before. An ellate granted may be made good by matter ex post facto, that was not so at first, by election, &c.

**EXPOSTULATION, EXPOSTULATIO, in Rhetoric,** a complaint addressed to a person from whom we have received some injury. It varies according to circumstances.

**EXPOSURE, or Exposition, in Gardening,** the aspect or situation of a garden wall, building, or the like, with respect to the sun, wind, &c.

There are four regular kinds of exposures, viz. east, west, north, and south; but it must be observed that among gardeners these terms signify just the contrary to what they do among geographers.

The gardeners, in effect, do not give the names east, west, &c. to the places where the sun is, but to those wherein he shines; and they consider the manner wherein he shines, whether as to the whole garden, or some of its parts.

If they find, that the sun at his rising, and during the first half of the day, continues to shine on one side of a garden or wall, they call that an eastern exposure, or east wall, &c. and if the sun begin to shine later, or end sooner, it is not a proper eastern exposure.

For the same reason, they call the wall, the side the sun shines on the latter half of the day; i.e. from noon to night; and accordingly, the south, or southern exposure, is the place whereon he shines from about nine o'clock in the morning till night; or which, in the general, he shines longest on in the whole day; and the part he shines least on is the north, or southern exposure, at what hour forever it begins or end, being usually from eleven o'clock to one.

The eastern and southern exposures are, by common consent of all gardeners, the two principal, and have a considerable advantage above the rest. A west exposure is not much amiss; at least, it is better than a northern one, which is the worst of all; each has its inconveniences.

The eastern, commencing differently at different seasons of the year, and ending about noon, subjects the trees, &c. to the N.E. winds, which wither the leaves and new shoots, blow down the fruit, &c. beside that it has little benefit of rains, which come mostly from the west. Yet does the reverend Mr. Lawrence judge the east better than the west-wall for all kinds of fruit; not that it has more hours of sun, or that there are any peculiar virtues in the eastern rays, but because the early rays of the sun do sooner take off the cold chilly dews of the night.

M. Gentil recommends the eastern exposure as best for all kinds of peaches; adding, that they ripen sooner, grow bigger, are better coloured, and of a finer taste, than in any other; but Mr. Carpenter refrains the rule to the early and middle forts; for the backward, he rather chooses a southern, or south-east exposure, which is best for all late fruits, because the influence of the sun is strongest, and continues longest.

The western, accounted from half an hour past eleven till sun-fet, is backwarder than an eastern one by eight or ten days; but it has this advantage, that it receives little damage from the fruits, which melt before the sun comes to shine upon the fruit, and fall off like dew, without doing any prejudice; so that it may bear apricots, peaches, pears, and plums; but it is incommoded with north west winds in the spring, as also with the autumnal winds, which blow down a great quantity of fruit.

According to Mr. Miller, the best aspect or exposure for walls in England is the point to the eastward of the south; because the sun will enjoy the benefit of the morning sun, and be less exposed to the west and south-west winds, which are very injurious to fruits in England, than those which are creased due south; the next best exposure is due south, and the next to that south-east, which is preferable to the south-west. Other walls, however, may be planted with fruit-trees that suit their several exposures.

The northern exposure is the least favourable of any in England, as having very little benefit from the sun even in the height of summer; therefore can be but of little use, whatever may have been advanced to the contrary. For although many sorts of fruit-trees will thrive and produce fruit
fruit in such positions, yet such fruit can be of little worth, since they are deprived of the kindly warmth of the sun to correct their rude juices, and render them well tawed and wholesome. It is therefore of little purpose to plant fruit-trees against such walls, except it be for fruit intended for baking, &c. in which case the fire will ripen and render those juices wholesome which could not be performed while growing.

In such situations, morrell cherries for preserving may be planted, and white and red currants to come late, after those which were more exposed to the sun are gone; and if the soil be warm and dry, some sorts of summer pears will do tolerably well on such an exposure, and will continue longer in eating than if they were exposed to the sun. But winter pears should by no means be planted in such an aspect, as has been practiced by many ignorant persons, if we find that the best south walls in some bad years are barely warm enough to ripen them. Duke cherries planted against walls exposed to the north will ripen much later in the season; and if the soil be warm, will be well flavoured, and continue a month later than others. Miller.

The southern exposure, accounted from about nine till four, is recommended for peaches, pears, grapes, and plums.

Express, something that is precise in formal terms, or for some particular design. I told him as much in express terms; he gave me a commination express; he had express orders; a courier was dispatched express.

We also say, somewhat abviously, to send an express, meaning a courier.

Express Condition, Contract, Malice, and Warranty. See the substantive.

EXPERIMENT OILS, are such as are procured from bodies only by press- ing; as the oils of olives, almonds, and the like. See Oil.

Expressed Species. See Species.

EXPRESSION, in Algebra, denotes the value of a quantity expressed or represented under an algebraic form: thus, if \( x = \sqrt{a^2 + b^2} \), and \( a \) and \( b \) are known, the value of \( x \) is known. See Equation.

Expression, in Chemistry, Pharmacy, &c. the act of expressing out, or extracting the juices of oils or plants, fruits, or other matters, by squeezing, wringing, or pressling them in a press. This is one of the three modes of obtaining them; the other two being infusion and decoction, which see. The hard fruits should be well bruised, and herbs moderately bruised, before expression. They are then to be inclosed in a hair or other bag, and pressled between wooden plates in the common free-press press, till the juice ceases to run. The expression of oil is performed nearly in the same manner as that of juices, by means of iron plates, or the apparatus of an oil-mill, adapted to this purpose. The impure oils of all unedible seeds are obtained unjured by this operation, if performed without the aid of heat, which, though it may promote the extraction of the oil, gives it an ungrateful flavour. The oils expressed from aromatic substances generally carry with them a portion of their essentail oil.

Expression, in Mytho, is a quality by which a musician manifests his feeling, and executes with energy all the ideas with which he ought to impress the hearer, and all the sentiments which the composer intended to express. There is an expression in composition as well as in its execution, and it is by their concurrence that the most pleasing and agreeable effect results.

To give an expression to his works, a composer ought to seize and compare all the relations which can be found between the features of his object, and the productions of his art; in a musical drama, he ought to know and feel the peculiar cast of all the characters, in order severally to exhibit them exactly as delineated by the poet; for as a good painter does not throw the same light on every figure, neither will the able musician give the same energy to all the sentiments, nor the same force to every figure, but will put each part in its true place, first to give it weight, individually, than to contribute to the effect of the whole.

After having well considered what a character has to say, he meditates how he shall say it; and here begins the application of the precepts of his art, which is to find the particular language in which the actor would wish to make himself understood.

Melody, harmony, movement, choice of instruments and voices, are the elements of the musical language; and melody, by its immediate connection with the grammatical and oratorical accent, is that which gives a character to all the rest. So that it is constantly from melody that the principal expression should be derived, as well in instrumental as vocal music.

What a composer therefore has to express by melody is tone of voice, with which the sentiments can be rendered; and care should be taken not to mimic that of theatrical declamation, which is itself only an imitation, but the voice of nature speaking without affectation and without art.

The composer will therefore at first seek a kind of melody which shall furnish musical inflections the most conformant to the idea of the words, always lowering their expression to the thought, and the thought to the interlocutor's rate of mind; for when we are strongly affected, all that we say in a manner favours the general sentiments which govern us; and we never chide what we love in the same tones as we scold an indifferent person. Our speech is differently accented according to the different passions by which we are agitated; sometimes acute and vehement, sometimes languid and monotonous, sometimes varied and imperious, sometimes smooth and tranquil in its inflections. Thence the musician regulates the choice of keys which he uses in his melody, and the different places in which he employs voice, keeping it down with small intervals to express the languor of sorrow and dejection; and raising it with acute sounds in passion and grief; driving it rapidly through all the intervals of the diapason in the agitation of despair, or the turbulence of distracted passions. Above all it must be remembered, that the charms of music consist not only in imitation, but in an agreeable imitation, and that the declamation (or recitative) itself to have its full effect, should be subordinate to melody; so that there is no painting sentiment without giving it this secret charm inseparable from it, nor touch the heart without pleasing the ear. And this is still very conformable to nature, which gives to the tone of voice of persons of sensibility, certain touching and delicious inflections, which those who feel nothing never possess. Never, therefore, mistake rigorous and severe for expressive, nor harshnesses for energy. Give not a hideous picture of the passion which you wish to paint, nor imitate the performers at the French opera, where the voice of passion resembles a complaint of the colic, more than transports of love.

The natural pleasure which results from harmony, augments in its turn the moral pleasure of imitation, in uniting the agreeable sentations of chords to the expression of the melody, upon the same principle as that just mentioned. But harmony does still more; it enforces even the expression in giving more truth and precision to melodic intervals; it animates their character, and exactly marks their place in the order of the modulation; it calls back the preceding, announces
announces that which ought to follow, and thus connects the phrases in the melody, as ideas are linked together by grammar in a discourse. Harmony, regarded in this light, furnishes the composer with powerful means of expression, which escape him when he seeks expression in harmony alone; for then, instead of animating the accent, he extinguishes it by his chords, and all the intervals, confounded in a continued crowd of combined sounds, offer to the ear only a series of fundamental chords, which have nothing touching or agreeable in their effect, and often not only suffocates the melody, but the sense of the words. What then must the harmonist do to fortify the expression of the melody, and give it more effect? He will carefully avoid covering the principal sound in the combination of chords; he will render all the notes of the accompaniment subservient to the vocal part; he will give relief and energy to it by the concurrence of other parts; he will enforce the effect of certain passages, by the chord of the sharp 7th; he will diffuse others by supposition or suspension, in making no provision for them in the base; he will gain strong expressions by major dissonances; he will reserve the minor, for tender sentiments; sometimes he will unite all his parts by smooth and flowing notes; sometimes he will contrast them with the melody by pointed notes; sometimes he will fill the ear with full harmony, and sometimes enforce the accent by the choice of a single interval. He will render present and sensible the chain of modulation throughout, and will make the base and its harmony serve to determine the place of each passage in the key, in order that no interval or trait of melody shall be heard, without feeling at the same time its relation with the whole.

With respect to rhythm, formerly so powerful as to give force, variety, and ornament to poetical harmony; if modern languages left accentuated and left prolocus have lost this charm, our music can substitute another more independent of speech in the precision of measure, and in the combination of its proportions, whether moving together or separately in each part.

Quantity in language is almost wholly lost in notes of music; and the music, instead of speaking with words, borrow, in some form, from the measure a language apart.

The force of the expression confits in this particular, in the uniting these two languages as much as possible together, in such form, that if the measure and the rhythm speak not in the same manner, they will at least say the same things. Clearness, which gives vivacity to all our movements, ought to do the same in musical measures. Meharchoy locks up the heart, relaxes all our motions, and the same languor is felt in the melodies which it dictates; but when grief is poignant, or great conflicts are passing in the mind, speech is unequal; it moves alternately with the flowers of the spondee and the rapidity of the Pyrrhic, and sometimes suddenly stops short, as in accompanied recitative; it is on this account, that the most expressive music, or at least the most passionate, is commonly that in which the times or portions of each bar, though equal in themselves, are the most unequally divided; whereas the image of sleep, of repose, of peace of mind, require small exertion of voice, and are naturally painted with notes of equal length, which move neither quick nor slow.

There is one observation which the composer ought not to neglect, and which is, that the more studied and extra- neous is the harmony, the flower should be the movement, in order that the mind may have leisure to disentangle the dissonances, and follow the rapid chain of modulation. Nothing but the least degree of fury can permit the union of rapid measures and harsh chords. When the head is distracted, and the actor, by violent agitation, seems not to know what he says, this energetic and terrible confusion may be communicated to the mind of the spectator, and, in like manner, make him lose his reason. But if the composer is not inflamed and sublime, he will only be coarse and cold; if he does not throw the audience into a delirium, he runs a great risk of failure; for he who loses his reason is only mad in the eyes of those who prefer it, and infinity is no longer interesting.

Though the greatest force of expression is derived from the combination of sounds, the quality of their tone is not indifferent in the effect. There are voices so strong and sonorous as to impose by their force; others thin, flexible, and fit for execution; others again so touching and delicate as to penetrate the heart by soothing and pathetic strains. In general, treble voices and acute are fitted to express tender affections and affections; baryes and baritones for interminable passion and choleric; but the Italians have bourned baryes from their solemn operas, as a part, of which the melody is too rude and boisterous for the heroic style, and have substituted in their head tenors, of which the melody has the same character, with a more agreeable effect. They employ baritone voices in the grotesque and ridiculous parts of their comic operas with more propriety.

Instruments have all their familiar expressions, proportional to their quality of tone, force, and compass. The flute is tender, the hautboys cheerful, the trumpet military, the horn sonorous, majestic, and proper for grand expressions. But there is no instrument of more varied expression, and more universally useful, than the violin. This admirable instrument is the foundation of every orchestra, and can furnish a great composer with all the effects which mean musicians vainly seek in a multitude of different instruments. The composer ought to be acquainted with the finger-board of the violin, to consider the shifts, and know how to write arpeggios, by distinguishing the open from the topped strings, and to choose and make use of keys according to the different characters they have upon that instrument.

It is in vain for the composer to attempt to animate his orchestra, if the ardour which ought to reign in it does not inflame the performers. The finger who only fees notes in his part, is not qualified to seize the expression of the composer, nor to give one of his own to what he sings, if he has not well comprehended the sense. He must understand what he reads before he can make it comprehended by others; and it is not enough to be professed in general facility and not particular in expressive in the language we speak. Let him begin therefore by thoroughly understanding the character of the melody which he has to execute, its expression of the words, the distinction of its phrases, the accent which it has in itself, that which it requires in the voice of the singer, the energy which the composer has given to the poet, and that which in his turn he can give to the composer. Let him resign his whole powers, then, to all the enthusiasm which these considerations shall have inspired; he should express every thing as completely as if he were at once the poet, composer, actor, and singer, and he will then have all the animation which it is possible for him to give to the work which he has to execute.

In this manner he will naturally embellish with taste and delicacy airs that are only elegant and graceful; with spirit and fire, such as are animated and gay; with ligths, the tender and pathetic; and with all the agitation of force and piano, such as are expressive of rage and fury. Whenever the musical and oratorical accents are united (as in ari par- lanti), wherever the voice shall be strongly marked, and serve as a guide to the accents of the melody; wherever the ac-
compartment and the voice shall so agree in their effects as to form only one melody, and the hearer, deceived, wholly attributes to the voice the passages which the orchestra embellishes; and, finally, wherever lober ornaments, judiciously applied, manifest the abilities and facility of the singer, without digressing and injuring the melody, the expression will be sweet, agreeable, and animated; the ear will be delighted, and the heart affected; nature and art will be once more in place leading the singer, and there will reign such a coincidence between the words and the music, that the whole shall seem to proceed from one delicious language, which can vary every thing, and always please.

This is more a dissertation than an article of a dictionary, but those are the sentiments of the citizen of Geneva, to which we readily subscribe, as he is ever more reasonable and confident in speaking of that art than on any other subject. His views concerning dramatic music are always fo ingenious, elevated, and refined, that we cannot refrain from translating him. Though we fear that the French, with all their present rage for Italian music and Italian expression, will not adopt them; and the Italians themselves, in their most happy moments of conception, have been successful from instinct and enthusiasm, more than precepts or reflection.

Expression, in Oratory, denotes the manner of delivering or conveying one man's ideas to another. Accordingly it denotes that felicity of discriminative energy in the reader, speaker, or orator, by which the characteristic beauties or peculiarities, whether of language, sentiment, or passion, in a composition or oration, are forcibly and happily illustrated, and the various shades and transitions of style, signification, feeling, and allusion, in such composition or oration, are distinctly and interestingly marked. Expression in this, as in every other art, is one of the chief constituents of excellence; and contrarily distinguishes the eloquentis of taste and genius, from the mere mechanical reader or declaimer. It depends chiefly upon that quickness and vitality of perception which may be regarded, in some degree, as an original gift of nature, and on that prompt and perfect sympathy between the perceptive faculty and the executive organs, which it is the highest glory of art and practical exercise to produce.

Expression is more particularly used for the elocution, diction, and choice of words in a discourse. See Elocution.

It is not enough that a poet or orator have fine thoughts, he must likewise have a happy expression. Defects in the expression ordinarily arise from defects in the imagination: abundance of the beauties of the ancient writers are annexed either to expressions which are peculiar to their language, or to relations, which, not being so familiar to us as to them, do not give us the same pleasure.

Expression, diversifying of, in Rhetoric. See Diversifying.

Expression, in Painting, principally consists in the representation of those attentions of the body, and variations of the countenance of men, which always accompany and denote the immediate influence of the passions of their minds. Besides this more important use of the word, it is used in painting to signify the representation of any object by a mode of execution agreeable to its nature, its character, and the situation it holds in the work. When wrought with just spirit and propriety in these respects, it is said to be well expressed. We will first consider it in the former and more useful sense.

The passions which influence the conduct of men have each a general character of expression, by look or gesture, attached to them in the whole race of mankind; and they are also marked in individuals by peculiarities, arising from the temperament and constitutional habits with which each of them is endowed by nature.

To seize and represent with energy these characteristics of the passions of the mind, and accompany their representation without diminishing its force, with the varieties appropriate to the individual personages introduced into a picture, is the essence, the soul of art. The slightest fuch possession of this quality, acquires an interest unimpaired by, and far above, that excited by the most highly and excellently wrought pictures which are void of it.

Very few painters, amongst the immense numbers of those who lay claim to the name, have been happy enough to obtain a super-eminent degree of expression in their works; indeed it is a task of extreme difficulty to overcome, requiring the founded sense to collect the knowledge of it, and the great ability in art to represent it when understood. The man who aims at it, besides being an ever active observer, should possess great susceptibility of mind to enter into the feelings of others, and this draw, as it were, from himself: yet that susceptibility should be under the regulation of sound discernment, and cool dispassionate judgment, to enable him to discriminate the fictitious representations of passion, from those natural unartificial actions, and looks, dictated by, and arising from, genuine feeling; and in his continued observations upon the actions and aspects of men under their influence, before he should be careful to separate these points which identify a peculiar passion, and distinguish it from others that are nearly allied to it.

Artists endowed with very considerable talents have failed in two different ways in their endeavours to embellish their works with this valuable quality. Some, by an over-anxious desire to give strength and energy to their expression, have carried them into artifice and bombast; others, on the contrary, wishing to unite the beautiful with the pathetic, have only rendered their works infipid and uninteresting in expression; and it appears that he who is obliged to labour to produce it, who does not work from a clear comprehension of the characteristic lines of an expression in its simplest and most undecorated shape, can never effect the representation of it to any degree of perfection, and the beholder of his works will still leave them unimpressed with any portion of the sentiment the real passion is calculated to produce; the only true test of the value of works of art, as far as relates to expression.

"By tedious toil no passions are express'd,\nHe who conceives them strongest paints them best."
EXPRESSION.

Trotta della Pittura, and Le Brun’s Passions. They have pointed out and illustrated those actions of the countenance and figure which most strongly delineate the reigning influence of particular passions.

These rules, however, go only a short way in a general view of the subject; much less do they comprise what is requisite, when the multitudinous varieties of expression in the almost infinitely varying countenances and habits of men of all degrees are taken into consideration. How, indeed, can it be possible to direct the means of obtaining with certainty that which is in itself so infinitely divisible, as the course of the feelings and dictates of the unenforceable heart of man, and his corresponding actions and turns of feature?

It is in having ascertained and established the features of the more strong and leading passions, that these general rules are found useful. We learn from them, that the influence of exquive joy or laughter draws all the features of the face upwards; that grief reverses that order, and draws them downwards. Violent anger distorts them, and enlarges their appearance, particularly the eyes and nostrils; and the action of the body is violent, with quick and short motions.

Defere enforces an eager advancing action towards its object, and the eyes and mouth are somewhat expanded. Acute pain is generally expressed by a mouth somewhat opened and drawn back, the eyes raised, and partly covered by the upper eye-lid, and the eye-brows drawn closely together, wrinkling the forehead. Fear is denoted by expanded eyes and mouth, the eye fixed upon the exciting cause, the hair elevated and thickened, the colour livid, and the figure drawn back as if attempting to retire from the object which caues the alarm. The effects of the sensation of scorn or hatred on the figure and countenance are marked by the mouth being closed firmly, and the lips drawn down at the corners; whilst the elevation of the nostril caues the middle of the upper lip to rife; the forehead is strongly preffed, and the brow falls over the eyes, which express the passion bet when they are turned sideways, towards the object, with the body inverted from it. Awo, or veneration, produces a general inclination of the body, and the head fall more fo, towards the object exciting it.

Under one or other of these passions, and expressions all the feelings of our minds are more or less affected; and of course, we will participate more or less of the indications of them, according to the excitation they meet with: therefore, so far the general rules will be of use in their representation. But mankind, from their various modes of education, their habits, and manners, accompany these sensations, when excited in them, by peculiarities which is of the utmost importance to the painter judiciously to discriminate, and be careful not to give that action to one, which, in propriety, belongs to another; not to attach the vulgar action of an uncultivated clown, to the dignified character of a man of rank and liberal education.

Besides remarking the expressive characters of the stronger passions, great attention is requisite to be paid to the physiognomical expression of the countenance, and of the figure (if one may so speak); the influence of which is daily felt and acknowledged. Though our information upon that subject is much thwarted by the effect of education and reflection, yet its bafa is just and firmly fixed, as evry day’s experience proves. Persons whose features and general forms correspond, are found to be correspondent also in character; that is, in their natural propenities: one of two, thus similarly formed, may have cultivated his mind more than the other, and education and society may have taught him to mask or disguise his inclinations; but nature is still true to herself, and the same general disposition remains. Nay, it goes still further; young persons not naturally addicted to vice, being drawn by accident or early association to continue in the practice of indulgence, acquire, in process of time, a change of feature and expression, in great measure similar to that form usually indicative of the vice or passion indulged in, wherever it is implanted by nature.

In this, therefore, we have a ground of expression which is well worthy, indeed very necessary, to be carefully attended to by those who aim at perfection in the art of painting. They ought to make themselves acquainted with the forms that belong to the peculiar inclinations and different degrees of capacity in mind in the persons they choose to bring forward in their works, of whatever class they may be. They should not put into the face of a man of mild character any of the features indicative of warm passions; in such an one the eye should not have an eager look; the nostrils should not be large, or inflated; all the lines should be smooth, and have little variation of form. And, on the contrary, when the figure of one whose disposition is naturally hot and impetuous is introduced, he should not have a smooth straight forehead; which is indicative of mildness and fuvatity; his nose should not be shrivelled; nor his mouth gently undulating, of a mild pleasing character; though he may not be in the act of exerting his natural impetuosity of character, yet he should have the appearance of one who would be easily roused to that feeling and expression. A man of great sense and intellect should not be represented with the features that characterize imbecility; nor the weak, and undecided character, have the forms denoting sense and intellectual power; and it should be constantly remembered, that though every passion, every sentiment of the mind, has its peculiar expression; every particular person has his peculiar mode of expressing it.

In representations of the passions, 'tis not form alone which is required to perfect the work; though that indeed yields a very strong impression of it, yet its effect is greatly heightened when a proper tone of colour is superadded. By colour we judge of health or sickness, of youth and age, as well as by form: The Painless hue of melancholy is proverbial. It is well known how anger affects the hue of the features; and the person whose countenance is tinged with a violent flushed of blood, and consequent refusal of colour, even almoat to blackness; in others a pallid hue denotes it, or a change from one to the other rapidly succeeding. The malignant passions are generally accompanied in their expressions by a pallid tone of colour: and the more noble sentiments by the reverse. A man performing a benevolent action feels a degree of satisfaction which affects his countenance; his eyes exhibit his sentiments by their liveliness, and his mouth by its gentle curves at the corners, whilst his cheeks bear (what is perfectly underflood so as to be admitted a common phrase) the cheerful glow of humanity flatter upon them. Clearness of complexion, and colour in the cheeks, indicate youth and health; falkness, and the loss of the ruddy hue of colour, sickness and age. The inhabitants of the town, and of the country, exhibit the same distinctions; as also the itiduous man and the sportman. Independent of the individual hue of the character represented, one general tone over the whole picture should prevail, correspondent to the subject. Thus, if it be one of a grave call, the tone of colour should be low, yet rich; and though harmonious not monotonous. If, on the contrary, the subject is gay, the hues of the colouring should be bright and cheerful, and greatly diversified; and every part of the picture should assist in expressing the nature of the subject chosen for representation.

It is attention to this point which gives to painting its real value, its intrinsic worth; and separates it from the more
more vulgar or merely mechanical art. Hence it becomes of moral utility, and its power is not surpassed by the poetical, or other effusions of the pen, in the force and vividness of the impressions it is calculated to produce. Of this there are many notices given to us in history. Alexander is said to have trembled and grown pale on seeing a picture of Palamedes betrayed to death by his friends; it bringing to mind the remembrance of his treachery to Arilonicus. It is also related of an Athenian courtzan, that in the midst of a riotous banquet, calling her eye on the portrait of a philosopher marked with the happy character of virtue and temperance; she was struck with a lively image of her own unworthiness, that the instantly went home and became an example of temperance. In both these cases, to the truth of the expression must be ascribed the force with which the pictures wrought upon the observers; and produced the powerful influence related.

It appears, indeed, to have been the principal object of attention with the ancient Greeks, and very naturally so; for in the beginning of an art, before any rules for regulating its efforts were adopted the artist's attention must of course have been forcibly directed to relating his story; and whatever ascribed to the distortion of that, was preferred to the service. Twofold then are the efforts we are told to be rude in the necessary to explain them: afterwards labels were placed as filling from: the months of figures; and other means of giving the ideas, supposed to occupy their minds, were adopted, till at last the artists arrived at the perfection of imitations of nature; and by giving their figures the actions and expressions appropriate to their situations, caused them to tell their own story, and impress all interest on the beholders, without any extraneous aid. Unhappily, excepting the few pictures found at Herculanenum, and those are of a trivial kind, we have none of their works in this art to judge of the degree of perfection they arrived at in this most important point of it; but we have the testimony of many, authors, some of whom speak as eye-witnesses, by whom we are led to believe, on convincing grounds, that their best pictures were full fraught with this best of good qualities; and there is no reason to doubt the truth of the report, when we see the sculpture of the same period which remains to us, so rich in perfection if.

In their statues, which were principally of gods, a great degree of minuteness of expression does not appear to have been the object of their attention, as far as relates to the passions, the representation of which they seem properly to have regarded as degrading to the dignity of a divinity. A calm unruffled state of mind appears in their countenances, and governs their looks and actions, but each has its appropriate character. What can be more dignified and majestic than the countenance of the Jupiter? Yet the line which its air, partaking somewhat of severity, inspire, is fo blended with mildness, that it produces implicit confidence and reverence. The Apollo Belvedere was also the dignity of the godhead shining in it; but left imparting and overpowering, of a milder character, and the expression of his figure and action is perfect; no one doubts the intent of it for an instinct; and this just discernment, and imprints of character, run through the whole clavus of statues of the primary deities of the Greeks. The Venus, the Bacchus, the Hercules, &c. have each their distinctive line of character without passion, whose influence they are supposed to be excited above, whilst in the lower orders, the face, and symbols, and rural deities, are no less properly marked with characteristic features and actions. In the figure of Laocoon defined with his sons by hermiphs, the authors (who were three) have exhibited a most powerful extent of feeling and power in expression, remaining almost unrivalled in subsequent productions; the agony of pain and ditref of mind are spread over the whole work which chills the beholder with horror.

A correspondent with this powerful effect is that related of and attributed to their pictures. Pliny says of Aritides, "that he infused into his pictures all the passion of the soul." It is said, "that Parthenius, in his picture of Philoctetes, had renewed the pains of the hero, as seen in his parched deep sunk eyes, and the tears which flowed from them;" (Author, lib. 4.) and the epigrammatist concludes with a handsome compliment to the painter, blaming him "for not allowing the sufferings of Philoctetes to end with his life." Philodratus, Vita Apollonii, cap. 10. says, speaking of the Ajax of Timotheus, "we cannot do justice to the picture where Ajax is represented distracted, unless we previously form in our minds the image of his condition. The picture of "Medea contemplating the Murder of her Children," by the same painter, was the subject of numerous epigrams (Anthologia); so that it must have been very powerful to excite so much emulation among the wits to celebrate it. It was said to represent in her face, fury mixed with pity of the innocence of her children, who were represented smiling at the dagger in her hand. Ovid says, "his crime was confessed in her eyes." Pintarch says of Lycurgus the painter, that he was ingenious as well as sublime; that from the slight inclination of the neck natural to Alexander, he invented a sublime expression; making him look up to the heavens with majesty boldness, and commanding majesty. The same author (in Timoleon) praises the paintings of Nicomachus "for their just expression," comparing them "to the poetry of Homer in grace and facility;" and Apelles in this point affirmed himself superior to other painters, though inferior in some others of less importance. It is needful to repeat the well known story of Timanthe's picture of the Sacrifice of Iphigenia, and of his artifice in hiding the face of the father, having exhausted the force of expression in the beholders; commendations and imitations of it are met with everywhere; and of his ingenious contrivance to convey an idea of the immense size of a Cyclops, by drawing some Satyrs measuring his figure with a thyrsus; and Pliny remarks of him on this occasion, that "in all his works there is more understood than is marked, and though his execution be masterly, yet his ideas exceed it." Whatever allowance be made for the zeal and strength of terms with which persons at all times describe those things, than which they are unacquainted with any thing better, and which must have been the case in the early periods of art, the writers not being so learned in it as the painters, who made it their continual study; yet we cannot refuse belief to a wonderful extent of power in rendering expression among the Greek painters, accompanied, as it has been before observed, their descriptions of it are, by the actual effect in sculpture. It is more astonishing that it should ever have been lost sight of, yet that was the case, and on the revival of the art of painting the old original formulæ of labels, &c. were had recourse to, till the gradual advance of learning and propriety of sentiment again restored it in the 15th century to the just imitation of the impulses of nature. Maffeo was among the first who thus advanced it, but it was Lorenzo da Vinci who first perfected its claim to interest over the mind, though in some of his works so completely as in his translation of the Last Supper, painted on the walls of the refactory of the Dominican convent at Milan, where it stood for a period, unrivalled in truth and vigour of expression.
It represents the moment wherein our Saviour has just said to his disciples "One of you shall betray me." Each figure has intelligence beaming from it; each individual exhibits a full report of what passes within his bosom. How tranquilly, yet how fully does our Lord disclose this forerunner of his approaching miseries, that one of those whom he had loved and cherished should become treacherous, and turn his bounty to his ruin; and with what propriety is he thus represented tranquil, yet dignified! So confident with his high character and office! With what eagerness does the impetuous Peter apply to the well deglaciated meek and humble John, to learn the name of the culprit that would betray so good a master! While that conscious culprit, hearing the request, flarts backward with alarm, fearing the consequences of such a disclosure. These are representations so powerful, that it needs but the regard of a moment to comprehend all said, and to be said, to complete the whole interest of the story. The timid hastifying Thomas, at a small distance from Peter, preffes his hand on the other's shoulder, to urge him to make the request his own timidity prevents him from doing himself. The next of the apostles, whose peculiarities history hath not so fully recorded, are represented in great variety of actions and expressions corresponding with, and justly originating in, the incredible circumstance just announced to them. One, with his hands preffed on his bosom, rising, afferts his innocence; another flarts with surpife, and, in the pious conscciusness of sinful weaknesses, seems to demand "Lord, is it I?" One calmly, yet earnestly, lisens to the result of the question urged by Peter; others, in contrast with him, seem to argue together if he be possible such iniquity could dwell with man, and in so doing declare their own innocence.

Anxiety is depicted as disturbing every breath, yet the peculiarities of each are preferred with the most just discrimination; and all appear so impressed with nature, that while it is recognized as the offspring of that great man's genius, the mere imagination of his mind, it has the appearance of a portrait of the actual scene. It is now unfortunately much injured by time and cleaning, being painted in oil, and not, therefore, adhering to the wall so perfectly as fresco.

To become able to produce a work of this surprizing power in exprefion, Leonardo says of himself, that he loit no opportunity which the occasions of life afforded him, of forting up remarks upon the nature of its action in men. He paid much attention to anatomy, and is said to have attended executions, not only to watch the looks and actions of the sufferers, but also to observe how the different persons composing the crowds of spectators were affected.

The common occurrences of life are every day affording the attentive and ingenious artist lessons on this head; and he will succeed, accordingly as he is intelligent and active in observation of them; or if he neglects to improve his mind by them, is inattentive and unfeeling to them, he can never become equal to the task of representing them.

Michael Angelo was also a powerful promoter of this high quality in works of art, but his exprefion is of a grand and more mystic nature than Leonardo's, and it is Raaffelle alone that has approached in his own way the superior excellencies of the work we have above described. "We stand in awe of Michael Angelo," says M. Fufeli, "while we embrace Raaffelle, and follow him wherever he leads us." He has not succeeded well where he has attempted the sublime. His gods are not even heroes, and his heroes are common vulgar men, except in a few instances; but where tenderness, and the amiable qualities of human nature have been his subject, he is not behind his great forerunner. Nor in the relation of his story is he ever deficient; sometimes, indeed, as has been observed on the Cartoon of Ananias struck dead, under the word Energie, in Painting, he combines the part events on which it depends, and the future, to which it leads. His Cartoons of "St. Paul preaching at Athens;" the "Healing the Lame Man at Lythra;" "Elymas struck blind," are intimate with feeling and expression; they are but lightly finifhed, and shew the extreme perfection of Raaffelle's work; however, from the high degree of character to which Raaffelle has carried some of his heads, in his picture of the "Transfiguration," it is fair to suppose he could have perfected these, if the nature of the works (being only examples for tapestry) had required it. In comparing the representation of Raaffelle to Leonardo da Vinci in this respect, it should not be forgotten that he was only 36 years old when he died, and the latter was 49 or 50 when he painted the aforesaid work of the "Laft Supper." Had Raaffelle lived to an advanced age, it is probable he would have surpassed even him. The simplicity and fulness with which he decribes, or effects, the relation of his subject, is beautifully infinced in the Cartoons of "St. Paul and Barnabas healing the lame Man at Lythra," and the consequent adoration paid to them. The apostles are rife upon some fleeps above the crowd, and thus distinguished, as well as by the attention of all being directed to them. The reftored cripple is known from the reft, by his eager demonstrations of gratitude and adoration; by his united and uplifted hands and animated looks, addressed to his restaurer, and by the crutches now become useless, and fallen at his feet to the ground. An aged man bending forwards, lifts with one hand the garments of the healed man, to view the limb now become perfect, and simply by the uplifting of the other, expresses his admiration of the cure so miraculously effected. It is the simplicity of the means Raaffelle uses, which gives so much the appearance of nature to his expreffions: no one, on feeing the works, doubts but that he should have employed the fame means; the art is lost sight of. The effect of the pictures of Raaffelle, in point of expreffion, on the artist who observes them, is much the fame as Garrick's actimg the character of a clown is said to have had upon a countryman, who completely lost fght of the actor, and criticized only the sentiments, in which, by the by, he complimented the author also, by flating that he should have done the fame himself. Yet it is a fact, that no point in art is so difficult to attain as this true simplicity of character with effect. Perhaps the most beautiful piece of expreffion in painting known to the world, is Raaffelle's head of the Madonna della Sedia, now in Paris. The sweetness of sentiment conveyed by the mouth is completely undercrifiable: no picture has been so frequently copied, none so rarely imitated.

Titian has frequently succeeded in rendering expreffion in his works, though it is not his general characteristic. His picture of St. Peter Martyr, before alluded to, (see Execution, in Painting,) is almost perfect in this, as well as in most other points. Indeed, when taken in the whole, we cannot help considering this as the most perfect picture in the world; polleffing more of every good quality than any other we are acquainted with. It has strongly the character of expreffion, both in form, and correspondent tone of colour.

No man of feeling regards it, but with an infinitaneous sentiment of seriousfulness; somewhat, indeed, of horror is inspired by the first view of it; particularly by the figure of the monk who is running away, and who eyes the proffered palm of martyrdom itself with horror. In direct opposition to him is the figure of the faint; who, suffering under the power of the
the adfim, (in whose person nought but the sentiment of brutality prevails,) turns his eyes towards the angels defending with the palm and crown, and hails the vision of future glory. The name of the deified Artist, he has said, is ferious, and it is also rich and deep in colour; 'tis the effect of that hue which prevails at twilight, and is most judiciously chosen as suitable to the affecting nature of the subject. Raffaelle has employed it in his portrait of Leo X. with the cardinals Roffi and Medicé attending him. Here the subject was grand, and its effect is incresced by the deep and serious tone of the colouring.

Poussin has, in several instances, been very happy in the expression of his subject. One of his pictures we will mention as a very excellent model of it; 'tis the Judgment of Solomon, a picture bad in its colour, in its composition, and execution, but fraught with the quality we are now considering. The king is seated upon his throne, surounded by his attendants, and has just given the command to divide the living child. A soldier is proceeding to execute the order, and this gives occasion to the admirable display of diversity of feeling in the bystanders. An old man seems crushingly to reason with himself if the king can intend the performance of so cruel a sentence. Another looks earnestly forward with the vacancy of the countenance of one who is about to pass away her head to avoid the sight, and her child clings to her side alarmed. A soldier regards the scene with a consternation fraught with pity, another turns from it with disgust. Whilst the wicked, abandoned woman, who had slain her own child, seeks the destruction of her neighbour's also; the real mother implores, with an earnestness never to be too much admired, the preservation of her child; rather willing to disown, than to see it destroyed. The expression of the action of the king is completely that of conviction to whom the child belongs; he almost seems to exclaim, now I see the right, now I know to whom to give the award. Poussin has also in this instance added another useful indication of character in the attire of the woman, no less different in mind, than in habit. He has given to the vicious creature that negligence in drefs which is too often indicative of a general habit of idleness and neglect; whilst he has dressed the other with decent care, and propriety.

This great painter has in another picture exhibited the force of an agreeable rendering expression, almost independent of form; 'tis in his picture of the deluge; one of a series of four pictures meant to reprezent the four seasons of the year. It is almost entirely of one hue. The composition consists of little more than a large portion of sky and water; the latter in the lower part of the picture falling in a cataclysm. In the distance is the ark, fearfully discernible through the thickness of the clouds or dens of vapour, through which the sun is with difficulty also seen, of a reddish hue. In the lowest corner of the picture is a family, consisting of a man, his wife, and child, endeavouring to climb from a boat upon a rock, on which the serpents glide along; and a little farther towards the centre are seen the heads of a man and horse joint footing in the water. With these flight materials has Poussin wrought a picture which is completely overpowering in its melancholy effect. It is said that Ronleau would fit enwrapt in silence over it for hours, gratifying with the feebleness it inspired.

Another master, whose attempts to render expressions have been sometimes very successful, is Guido Reni; but he seldom goes farther than the characters of saints in pious contemplations, Magdalens in the moment of contrition, and Ece Homo. Of the latter, there is one of super-excellent perfection, in the poftick of B. Watt, et al. a head only, but full of feeling; purely "never was sorrow like unto his sorrow," may be as truly applied to the painting, as to the sufferings of the divine original. There is an ancient painting of a Satyr's head, now in the Barberin palace at Rome, which is eminently distinguished by expression of nature.

There are but few among the large men of the Italian and French painters who have succeeded in their efforts (to any pre-eminent degree) in giving expression to their works in its more exalted sense. Ludovico Carrache, and Domenichino have sometimes effected it, but rarely, and Annibal Carrache still less frequently, notwithstanding his immense power in execution. Among the Flemings, Jan Steen, and Ofsode, hold the principal places. The former particularly is exceedingly happy in characterizing the aspects and manners of that class of men he undertook to paint, and he does it with great freedom and ease. Ofsode is more laboured in his manner, but perfect in his finish in the confined scale in which he exerted himself. Rubens has sometimes succeeded to a high degree in this quality, but, in general, the expression of his figures in serious subjects are too violent, and upset the model of nature. In the gay scenes, where nymphs and fauns are gracefully indulging their humours, his power is complete; they live and breathe with all their native gayety and animation; and in expressing the characters of the ancients and apostles, his power is unsurpassed. Vandyke rarely appears to have felt it in his historical pictures; but in some of his portraits he is extremely happy. His Cardinal Bentivogio is a perfect instance of expression in this branch of art. His picture of Lord Strafford and his secretary at Wentworth-loune, Yorkshire, is another; but the idea is taken from Titian; whose portraits are masterpieces of identical character and expression, and the prototype of Vandyke's excellence. In this respect, Sir Joshua Reynolds is no less happy than either of them; prints from whose pictures are in too many hands, and so generally known, that it is needless to exemplify the affectation by further remark, yet we cannot decline mentioning the picture of Mrs. Siddons in the character of the Tragic Muse, as a very happy instance of his power.

Rembrandt, though seldom happy in representing the purity of expression in his figures, yet sometimes effects it; but his great characteristic is the truth with which he gives expression in the secondary sense we have affixed to it, as regards the moral and spiritual. The actual expression of the soul was his delight. He seized and expressed, with the greatest truth, the most extraordinary effects of the illumination of objects, and gave it its greatest possible brilliancy and force. In a different line, Neticher and Metsu were highly skilful in the exact expression of the nature of the objects they chose to represent. Silks, furs, carpets, metals, &c. are all expressed by them with the greatest truth, and in a free, broad style of execution, particularly by the former. Teniers, and in short almost all the painters of the Dutch and Flemish schools, have exhibited great ability in expressing the character of natural objects. But to this study they sacrificed attention to expression in its more elevated and useful province.

Not so our inimitable Hogarth. Though he took the common scenes of nature as his field of action; and was not unskilful in imitating the natural effect of objects; yet with him this manner talent was of secondary consideration. By his pencil he inculcates lefsons of morality, and no lectures from the pulpits are more effectually strong and convincing, than those conveyed by his pictures. Witness the Rake's, and the Harlot's Progress; where the evils attendant on vice, and the blessings which a course of virtue is calculated to produce, are so powerfully exemplified. With what force has he satirized pride and luxury in his Marriage-a-la-Mode; bigotry, superstition, and folly, in many of his other works!
and no one has ever expressed identical character more strongly than he has. The figure of the exhausted rake in the breakfast-scene of the Marriage à-la-Mode, has never been surpassed in truth and force. We could enlarge with pleasure upon his value in this point of view, but content ourselves with recommending his works with the excellent comments upon them by Mr. J. Ireland, to the perusal and observation of our readers; and are proud to have so excellent an exemplar of the value of expression in painting as Hogarth, whose talents were native, un indebted to foreign schools, in praise of whom we conclude our observations on this very important point.

EXPROBATION, Exprobatio, in Rhetoric, is the reproaching a person with ingratitude, and unmindfulness of some particular benefit conferred upon him.

EXPUGNATION, in Military Language, the taking of any place by assault.

EXPIALATION, the act of expiating a man by force out of a city, community, or the like. 

Expiation is also used for the act of expiating out a foreign body with violence from the place it was in.

The uterus has the chief office in the expulsion of the fetus; if the expulsion of the fetus happen very soon after conception, it is called a false birth. See Delivery, Foi tus, and Labour.

EXPIRATION, in Astronomy, is used by some authors for that rate or action of the sun, wherein, after having been eclipsed and hid by the interposition of the moon, it begins to appear again.

Later astronomers call this emersion, not expuration.

EXQUINA, in Zoology, the name of a species of monkey common on the coast of Guinea, of which Ray enumerates two or three varieties. See Simia.

EXSIDANIES, in Antiquity, a kind of bidders, who, in the theatre, and other public auditories, used to make a noise with their feet, and even sometimes beat the seats with buttons.

EXSCINATION, formed of ex and succus, dry, in Chemistry, Pharmacy, &c. the act of drying up or evaporating the moisture of a thing. For this purpose two methods are usually employed: in one of which the humidity is evaporated by heat, and in the other it is imbibed or absorbed by substances adapted to the purpose. Bodies combined with, or dissolved in a fluid, require the first mode; and to such as are only superfluous blended with it, the second mode is applicable. Vegetables are commonly excised by the natural warmth of the air, though the assistance of artificial heat is often very useful. By a moderate fire the more tender flowers may be soon dried without any considerable loss, either of their odour or lively colour, which would be injured, if not destroyed, by a more forceful evaporation in the air. Some plants, particularly those of the more acid kind, lose their virtues by this process.

EXSORS PARTICULAR. See Particular.

EXSUCCATIO, a word used by some Chirurgical Writers, to express an enechemosis, or fuggilation.

EXSUFLATION, a ceremony observed in baptism, by which the candidate was supposed to renounce the d. vil. See Baptism.

EXTACY, Efrren, a rapture, or removal of the mind out of its natural state and situation; or a transport, whereby a person is hurried out of himself, and the office of his senses is suspended. See Enthusiasm.

EXTACY, in Medicine. See Ecstasy.

EXTANT, something that still subsists, or is in being. It is but part of the history of Livy, of the writings of Cicero, Caesar, &c. that are extant, the rest are lost. We have nothing extant of Socrates, though he wrote a great deal.

EXTEMPORANEOUS PRESCRIPTION. See Prescription.

EXTEMPORANEOUS Playing, flights in Music, or a harpsichord, or piano forte, have many appellations; as toccata, toccatina, Int. prelude, capriccio. On the organ it is called a voluntary.

There have been organists, whose abilities in un- studied effusions on their instruments have almost amounted to inspiration, such as Sebastian Bach, Handel, Marchand, Couperin, Keelway, Stanley, Worgan, and Keeble, several of whom played better mute extemporaneously than they could write with meditation.

EXTEND, in the Manager. To extend a horse, is an expression used by some to import the same with making a horse go large. See Large.

Extend, in Military Language. When the files of a line, or the divisions of a column, are to occupy a greater space of ground, they are said to extend their front or line. See Extend.

EXTEND'TA DECRA. See Terra.

EXTEND'TA FACIES, in Law, a writ of extent, whereby the value of lands is commanded to be made and levied, &c. Reg. Orig. See Extend.

EXTENDING, in a Legal Sense, signifies the valuation of lands and tenements of one bound by statute, &c. and who hath forfeited his bond at such an indifferent rate, as that by the yearly rent the obligator may in time be fully paid his debt. See Extend.

EXTENSION, in Philosophy, is one of the general and essential properties of matter; the extension of a body being the quantity of space which the body occupies, the extremities of which limit, or circumference, the matter of that body. It is otherwise called the magnitude, or size, or bulk of a body.

A quantity of matter may be very small, or so as to elude the perception of our senses, such as a particle of air, a particle of water, &c.; yet some extension it must have, and it is by the comparison of this extension, that one body is said to be larger than, equal to, or smaller than, another body. The measurement of a body consists in the comparison of the extension of that body with some determined extension, which is assumed as a standard, such as an inch, a foot, a yard, a mile; hence it is said, that a body is a foot long, or three inches long, &c.

The extension of a body is measured three different ways; or a body is said to have length, breadth, and thickness. Thus an ordinary sheet of writing paper is about 16 inches long, about 14 inches broad, and nearly one hundredth part of an inch thick. Either of these dimensions might be called the length, or the breadth, or the thickness; but, by general custom, the greatest extension is called the length, the next is called the breadth, and the shortest is called the thickness. The outside of a body, its boundary, or that which lies contiguous to other bodies that are next to it, is called the surface of that body, and this surface has two dimensions only, viz. length and breadth; but it has no thicknesses, for if it had, it would not be the outside of the body; yet a surface by itself cannot exist. In mathematics, however, surfaces are mentioned, and are reckoned upon, arbitrarily from matter.

But in these cases the surfaces exist in the imagination only, and even then our ideas have a reference to body, for our senses cannot perceive a surface without a body.

As a surface is the outside or boundary of a body, so a
EXTENSION.

Line is the boundary of a finite surface. Suppose, for instance, that a surface is divided into two parts, the common boundary of the two parts is called a line; and this has one extension only, viz. it has length.

The beginning, or the end of a line, or the intersection of two lines which cross each other, is called a points, and this has no dimensions; or, according to the mathematical definition, a point is that which has no parts or magnitude. Thus, if you divide a line into two parts, the division or boundary between the two parts is a point.

Our senses are only capable of perceiving bodies which have three dimensions; or rather the surfaces of bodies, which surfaces have two dimensions, but a surface cannot be represented nor perceived without a body, and of course neither a line nor a point can be perceived without a body. In the study of geometry, and in a variety of other branches, surfaces, lines, and points are represented upon paper, or upon something else; but in those cases, the paper or that something else is the body whose surface we perceive, and the surface of parts is their body. Hence, whatever is not by real lines, but by a narrow slip of surface, which is sufficient to direct our reasoning with respect to the geometrical properties of lines and surfaces. Thus also when points are represented by themselves, the marks are not real points, but very small portions of the surface of a body.

There is a case in which extension is often said to be perceived without the existence of a body, and this is the extension between two bodies. But, upon consideration, it will easily be comprehended, that we may perceive the two bodies, and that they are separate from each other; but we cannot perceive anything positive between them. So that in this case the word extension is used in a figurative manner, as if some other body existed between the two bodies.

The particular extension, whether under the name of inch, foot, yard, metre, league, &c. with which other extensions are compared, or by which they are measured, are established only by the common consent or agreement of persons of a certain nation, or profession, and are used as a standard measuring by them only. Hence, the measures of different nations, though sometimes they have the same name, do, however, differ considerably from each other.

Great endeavours have been made by divers ingenious persons, at different times, for the purpose of determining an unalterable universal standard of measures, but those endeavours, and the successes with which they have been attended, will be found described under the article Standard of Measures.

Extension is usually described as confining in the situation of parts beyond parts, with which some authors extend, maintaining, that we can conceive absolute extension without any relation to parts.

If a man consider the distance between two bodies abstractedly, and without any regard to bodies which may fill that interval, it is called space; and when he considers the distance between the extremes of a solid body, it is called extension.

Extension is frequently confounded with quantity and magnitude, and, for what we can perceive, without much harm, the thing signified by them all appearing to be the same; unless we admit a distinction made by some authors, that the extension of a body is something more absolute, and its quantity and magnitude more respective, or implying a nearer relation to much and little. See Quantity, Magnitude, Mass, and Matter.

The infinite divisibility of extension has been a famous question in all ages. It is not easy to reconcile the doctrine of mathematicians on this head with the tenets of some philosophers. They who hold that all extension and magnitude are compounded of certain minima infinita; and that a line, for instance, cannot increase or decrease, but by certain indivisible increments or decrements only, must, consistently with themselves, affirm, that all lines are commensurable to each other, contrary to the tenth book of Euclid, who demonstrates that the diagonal of a figure is incongruous to its side. But if all lines were composed of certain indivisible elements, it is plain one of those elements must be the common measure of the diagonal and the side. This is a Gordian knot which none of the philosophers have yet thought fit to untie.

Bishop Berkeley observes, that the infinite divisibility of finite extension, though it is not expressly laid down either as an axiom or theorem in the elements of geometry, yet is throughout the same every where supposed, and thought to have so inseparable and essential a connection with the principles and demonstrations in geometry, that mathematicians never admit it into consideration, nor at least question of it. (See Divisibility.) And as this notion is the source from whence do spring all those amusing geometrical paradoxes, which have such a direct repugnancy to the plain common sense of mankind, and are admitted with so much reluctance into a mind not yet debauched by learning: so is it the principal occasion of all that nice and extreme subtlety which renders the study of mathematics so difficult and tedious. Hence, says he, if we can make it appear, that no finite extension contains innumerable parts, or is infinitely divisible, it follows, that we shall at once clear the science of geometry from a great number of difficulties and contradictions which have ever been esteemed a reproach to human reason, and withal make the attainment thereof a business of much less time and pains than it hitherto hath been.

Every particular finite extension, which may possibly be the object of our thought, is an idea existing only in the mind, and consequently each part thereof must be perceived. If therefore, says this author, I cannot perceive innumerable parts in any infinite extension that I consider, or in the least conceivable in it; but it is evident, that I cannot distinguish innumerable parts in any particular line, surface or solid, which I either perceive by sense, or figure to myself in my mind; wherefore, I conclude they are not contained in it. Nothing can be plainer to me than that the extensions I have in view are no other than my own ideas; and it is no less plain, that I cannot resolve any one of my ideas into an infinite number of other ideas; that is, that they are not infinitely divisible. If by an infinite extension I mean something distinct from a finite idea, I declare I do not know what that is, and I cannot affirm or deny any thing of it. But if the terms extension, parts, and the like, are taken in any sense conceivable; that is, for ideas; then to say a finite quantity or extension consists of parts infinite in number, is to manifest a contradiction, that every one at first sight acknowledges it to be so. New Theory of Vision, § 54, 55. Analyst, § 31.

On the other hand, it is observed by an eminent mathematician, that geometers are under no necessities of supposing that a finite quantity or extension consists of parts infinite in number, or that there are any more parts in a given magnitude than they can conceive or expect: it is sufficient that it may be conceived to be divided into a number of parts equal to any given or proposed number; and this is all that is supposed in strict geometry concerning the divisibility of magnitude. It is true, that the number of parts into which a given magnitude may be conceived
to be divided, is not to be fixed or limited, because no given number is so great but a greater than it may be conceived and assigned; but there is not therefore any necessity for supposing that number infinite; and if some may have drawn very abstruse consequences from such suppositions, they are not to be imputed to geometry. Geometricians are under no necessity of supposing a given magnitude to be divided into an infinite number of parts, or to be made up of infinitesimals; nevertheless, they cannot so well avoid supposing it to be divided into a greater number of parts than may be distinguished in it by sense in any particular determinate circumstance. But they find no difficulty in conceiving this; and such a supposition does not appear to be repugnant to the common sense of mankind, but on the contrary to be most agreeable to it, and to be illustrated by common observation. It would seem very unaccountable not to allow them to conceive a given line, of an inch in length for example, viewed at the distance of 10 feet, to be divided into more parts than are discerned in it at that distance; since by bringing it nearer, a greater number of parts is actually perceived in it. Nor is it easy to limit the number of parts that may be perceived in it when it is brought near to the eye, and is seen through a little hole in a thin plate? or, when by any other contrivance it is rendered distinct at small distances from the eye. If we conceive a given line that is the object of sight to be divided into more parts than we perceive in it, it would seem that no good reason can be assigned why we may not conceive tangible magnitude to be divided into more parts than are perceived in it by the touch; or a line of any kind to be divided into any given number of parts, whether in many parts be actually distinguished by sense, or not. In applying the reasonings and demonstrations of geometricians on this subject, it ought to be remembered, that a surface is not considered by them as a body of the least sensible magnitude, but as the termination or boundary of a body; a line is not considered as a surface of the least sensible breadth, but as the termination or limit of a surface; nor is a point considered as the least sensible line, or a moment as the least perceptible time; but a point as a termination of a line, and a moment as a termination of a limit of time. In this sense they conceive clearly what a surface, line, point, and a moment of time is; and the postulate of Euclid being allowed and applied in this sense, the proofs by which, it is shown, that a given magnitude may be conceived to be divided into any given number of parts, appear satisfactory; and if we avoid supposing the parts of a given magnitude to be infinitely small, or to be infinite in number, this seems to be all that the most scrupulous can require. See Macaulay’s Treatise of Fluxions, art. 292, 297.

Dr. Reid, in his “Inquiry into the Human Mind, on the Principles of Common Sense,” endeavours to obviate the difficulties suggested by Berkeley, by overturning the system of ideas established by Mr. Locke. According to his theory, it is absurd to deduce from fenation the first origin of our notions of external existence, of space, motion, and extension, and all the primary qualities of bodies; they have, he says, no resemblance to any sensation, or to any operation of our minds, and therefore they cannot be ideas either of fenation or reflection; nor can he conceive how extension, or any image of extension, can be in an unextended and indivisible subject like the human mind.

Extension, in the Ancient Muses, according to Aristo-
cratus, was one of the four parts of the meleopedia, which consisted in sustaining certain sounds longer than their quantity strictly required. We call these binding-notes, and sometimes perhaps tempo rubato. See Compass.

Extension of Epitrochoid Lines. See Fracture. Extensor, in Anatomy, a name given to those muscles which have the use of extending or making straight those parts to which they are attached.

Extensor brevis digitorum pedis; calcaneo-fus-phalangean common, is a thin and flat muscle, placed on the superior or convex surface of the foot. Poffiling a somewhat quadrilateral figure behind, it divides into four flat tendons in front. It arises from the upper and front part of the os calcis, and from the ligament which connects that bone to the ulnagulus. Thence its fibres are continued obliquely forwards and towards, and divide into four secondary fasciculi, (of which the two innermost are the largest,) giving origin to the same number of tendons; which, in passing over the metatarsus, crosses those of the extensor longus, and terminate in the toes. The fibr, on the inside, is attached to the upper surface of the metatarsal extremity of the first phalanx of the great toe; the three succeeding tendons become intimately attached to the external edge of the corresponding tendons of the extensor longus, and are connected at the first joints of the toes, as well as those of the latter muscle, with the tendons of the lumbricales and interossei. They extend over the second phalanges, and are inserted in the third.

Covered on its external surface by the tendons of the extensor longus and peroneus tertius, and by the aponeurosis of the back of the foot, this muscle lies upon the anterior phalanx of the tarus, upon the metatarsus, and the phalanges.

It extends and elevates all the phalanges of the toes, at the same time turning them rather outwards.

Extensores carpi radiales. See Carpi extensor carpi ulnaris. See Carpi.

Extensor communis digitorum manus; epicondylus-fus-phalangeaetf common; extensive digital; a muscle belonging to the fingers, situated on the posterior or dorsal surface of the forearm, hand, and fingers; elongated, somewhat rounded and fleshy above, and divided into four tendons below.

It arises above, by means of a tendon common to it with the surrounding muscles, from the external condyle of the humerus; is connected internally to a tendinous partition, which separates it from the extensor of the little finger, externally to a shorter septum placed between it and the extensor carpi radialis brevis, and posteriorly to the fals of the forearm. The fibres, uniting together obliquely from these origins, form a muscle, at first thin, and afterwards more considerate, which is divided, towards the middle of the forearm, into four portions, united at first by cellular substance, then separating, and giving origin to the same number of tendons. These at first are connected by a loose cellular substance, pass together with the tendon of the indicator under the annular ligament at the back of the wrist, and in a superficial groove of the radius, surrounded by a bursa mucosa, then diverge towards the fore fingers, and become completely flattened. They are often split longitudinally, and are united to each other, at the back of the hand, by crofs slips of tendon and their aponeuroses. At the first joints of the fingers the broad thin tendons of the extensor communis are joined, on either side by the tendinous expansions of the lumbricales and interossei, and completely cover the articulation. They divide, at their extremities, into three portions, the middle of which are inserted in the second phalanges of the fore-fingers; while the lateral divisions, running along the sides of these phalanges, are inserted close together into the third.

This muscle is covered by the aponeuroses of the forearm,
the annular ligament and skin. It covers the supinator radii brevis, the extensor of the thumb and fore-finger, the carpi, metacarpals, interossei muscles, and posterior surface of the phalanges.

The annular ligament at the back of the forearm consists of a broad, thin, and flat, but strong fibrous expansion, extended from the outer part of the carpal extremity of the radius, over all the extensor tendons at the back of the wrist, and connected to the end of the ulna, and to the os pisiforme. It confines the tendons to the surface of the bones. Those of the common extensor are surrounded, as they pass under it, by a synovial membrane, in which we may distinguish a cavity containing the membranes completely isolated, and a superior and inferior cul de sac, where the membrane is reflected over the tendons. The synovial membranes of the first joints of the fingers are closely connected to the tendons of the extensor communis, where they pass over those joints.

This muscle extends the different joints of the fingers; and afterwards, or if the fingers are bent by their flexors, it extends the wrist upon the forearm. See Indicator.

**Extensor longus digitorum pedis**; peroneo-tibi-fus-phalangettin commun; grand extenseur; is a long, thin muscle, flattened laterally, and placed at the outer and anterior part of the leg, and upper part of the foot. It arises above from the external tuberosity of the tibia, from a small aponeurotic septum which separates it from the tibialis anticus, and from the anterior ligaments of the peroneo-tibiarticular; behind from five or six inches of the upper and anterior part of the fibula; before, at its upper part, from the aponereo of the leg; and externally, from a broad aponeurotic septum, which separates it from the two peronei. The superior fibres descend perpendicularly, the inferior ones more and more obliquely, to end in a common tendon at first concealed in the tubulence, but, from the middle of the leg, occupying the anterior edge of the muscle. It divides into three or four portions, which pass together behind the annular ligament: below which part we always see four separate tendons diverging over the convexity of the foot, assuming a broad and flattened form, and crossing the dorsum of the tendons of the extensor brevis, in their passage to the four smaller toes. At the first joints of the toes these tendons are connected to those of the extensor brevis, and of the lumbricales and interossei, as in the hand, and they have similar insertions to those of the extensor communis digitorum, which see.

In the leg, this muscle, on its inner surface, is separated above by the anterior tibial vessels from the tibialis anticus; lower down it is contiguous, on the same aspect, with the extensor proprius hallucis: externally it is in contact with the peronei; and the aponeurosis of the leg covers it on the front. At the ankle it runs in a peculiar cavity of the strong transverse annular ligament, which binds it firmly down in its place. Here the tendons are surrounded by a synovial membrane. In the foot it is covered by the skin, and covers the extensor brevis and phalanges. This muscle extends the toes, and afterwards bends the ankle joint. If the foot be fixed to the ground, it may either maintain the leg erect upon the foot, or carry it forwards.

**Extensor longus pollicis pedis**; or proprius; peroneo-fus-phalangettin du pouce; thin, elongated and flattened in its form, it lies on the side of the preceding muscle. It arises from the inner and anterior part of the fibula, and neighbouring portion of the interosseous ligament, for a space of five or six inches, beginning about two inches below the upper end of the fibula. Its fibres pass obliquely downwards and forwards, parallel to each other, and of large tendon which runs along their anterior edge, constitute a single penniform muscle. The tendon goes behind the annular ligament, in a peculiar sheath, and falls over the first, terminates in the second phalanx of the great toe. Sometimes a small portion of its tendon is interspersed in the first phalanx.

This muscle is placed between the tibialis anticus, the anterior tibial vessels and nerves being interposed, and the extensor longus digitorum. On the front it is covered by the aponeurosis of the leg, the annular ligament, and the integuments. Its tendons lie on the lower end of the tibia, the tarsus, metatarsus, and phalanges of the great toe, and is closely connected to the synovial membrane of the first joint of that toe.

It extends the two joints of the great toe, and acts upon the foot in the same manner as the preceding muscle.

**Extensor major pollicis.** See **Extensores pollicis**.

**Extensor minor pollicis.** See **Extensores pollicis**.

**Extensor ossis metacarpi.** See **Extensores pollicis**.

**Extensores pollicis.** are three muscles belonging to the three bones of the thumb.

**Extensor primi intermedii; extensor ossis metacarpi pollicis; abductor pollicis longus of Albinus; cubito-radialis metacarpian du pouce; grand abducteur du pouce; is a muscle of an elongated, thin, and flattened form, situated obliquely on the back of the forearm. It arises above from the ulna, below the supinator radii brevis; from the interosseous ligament; and from the radius, below the insertion of the supinator brevis. The flabby fibres unite together from these origins to form a flattenedaddle at first small, but afterwards larger, which crosses the forearm obliquely from above downwards, and from the radial towards the ulnar side. Towards the lower extremity of the radius it terminates in a tendon, which runs in a small groove on the outer side of the carpal extremity of the bone. Here it is surrounded by a hollow sheath, common to it with the tendon of the next muscle. It is inserted, generally by means of joining a tendon in several distinct parts, into the radial side of the carpal end of the first phalanx of the thumb. One of these portions is often connected with the abductor pollicis.

It is covered, in its flabby portion, by the extensor carpi ulnaris, extensor facciuli intermedii, extensor proprius auricularis, and communis digitorum; and it covers the radius, ulna and interosseous ligament. Its tendon is covered by the aponeurosis of the forearm, and covers the extensor carpi, the radius, radial artery, and joint of the wrist.

It extends the first bone of the thumb, when that has been bent towards the palm of the hand. It carries the thumb away from the other fingers; and it may move the whole hand towards the radius.

**Extensor secundi intermedii; extensor minor pollicis; cubito-fus-phalangettin du pouce; is an elongated and slender muscle, situated close to the former, and lying on its ulnar edge. Arising from the interosseous ligament and radius, it crosses the direction of the forearm, like the former, and forms a slender tendon, which closely accompanies that of the preceding muscle. It passes along the first, and is inserted in the second phalanx of the thumb. It is covered by the extensor tertii intermedii, proprius auricularis, and digitorum communis, by the aponeurosis of the forearm, and the integuments. It lies upon the bones of the forearm and the interosseous ligaments, the extensores carpi radiales, the joint.
Joint of the wrist, and the first bone of the thumb. It extends the first and second joints of the thumb, and carries it into the state of abduction. It may draw the whole hand towards the radius.

**Extensor tertii internum;** extensor major pollicis; cubito-fus-phalangetten du pouce; is an elongated and flender muscle, placed close on the ulnar edge of the former, and following the same general direction. It arises from the middle third of the posterior surface of the ulna, and a very little from the interosseous ligament; and crosses the forearm obliquely towards the thumb. Surrounded by a hollow burr, it runs along a peculiar groove of the radius, being placed about an inch on the ulnar side of the preceding tendons. It passes along the ulnar side of the first phalanges of the thumb; is connected with the insertion of the preceding tendon in the second phalanges, and terminates in the third. Situated at its origin between the bones of the forearm and interosseous ligament, and the extensor communis, proprius auriculavis, and carpi ulnaris, it afterwards runs in its peculiar groove; it is then sub-cutaneous, and lies on the extensor carpi, joint of the wrist, and bones of the thumb. It extends all the joints of the thumb, and at the same time rather carries it towards the fingers. It will also act as an extensor of the wrist.

**Extensor proprius auriculavis, or digitii minimi; epicondylus-fus-phalangetten du petit doigt;** is a thin, flender, and elongated muscle, situated in the first or superficial layer of the back of the forearm, and placed close along the ulnar side of the extensor digitorum communis. It arises above by means of the common tendon, from the external condyle of the humerus; on the outside, from a septum, which separates it from the extensor communis; on the inside, from one interposed between it and the flexor carpi ulnaris; and behind, from the aponeurosis of the forearm. It gives origin to a flender tendon, which passes in a separate canal of the annular ligament, and forming the tendon which the little finger receives from the extensor communis, is interposed together with it into that finger. On the forearm, this muscle is covered by the fascia, and covers the supinator brevis, the extensors of the thumb, and the indicator. The extensor communis lies on its outside, and the extensor carpi ulnaris on the inside. Its tendon is surrounded by a tendinous sheath, lined with a synovial membrane, at the wrist; and afterwards is covered by the integuments lying on the latero-carpal bone, and on the phalanges of the little finger. It extends the little finger, and afterwards moves the wrist in the same direction; it will carry the little finger rather in the direction of abduction.

**Extensor propius pollicis pedis.** See **Extensor longus pollicis pedis.**

**Extensor tarsi minor, a name given by Douglas to the plantaris, which see.**

**Extensor tarsi lateralis, or magnus;** a name under which Douglas classifies the gastrocnemius and soleus. See those words.

**Extensio, or Extensus Facias, in law, sometimes denotes a writ or commotion to the sheriff for the valuation of lands and tenements; sometimes the act of the sheriff or other commissioner upon this writ; and sometimes the estimate or valuation of lands, per proprias viros; which, when taken at the unwork value or extent, furnish our extended, or rack-rents.** Fleta. l. h. ii.

This is a species of execution (which see) upon some proceedings given by statute; as in the case of recognizances or debts acknowledged on statutes or statutes by the forfeiture of which, the body, lands, and goods may be all taken at once, to compel the payment of the debt. And by statute 35 Hen. VIII. c. 39 all obligations made to the king shall have the same force, and of consequence the same remedy to recover them, as a statute-fable; though, indeed, before this statute, the king was entitled to sue out execution against the body, lands, and goods of his accountant or debtor. (3 Rep. 17.) And his debt shall, in suing out execution, be preferred to that of every other creditor, who hath not obtained judgment before the king commenced his suit. The king’s judgment also affects all lands, which the king’s debtor hath at or after the time of contracting his debt, or any of his officers, mentioned in the statute 15 Eliz. cap. 4, hath at or after the time of his entering on the office; to that, if such officer of the crown aliens for a valuable consideration, the land shall be liable to the king’s debt, even in the hands of a bond fide purchaser; though the debt due to the king was contracted by the vendor many years after the alienation. (10 Rep. 55, 56.) Whereas judgments between subject and subject reverted, even at common law, no farther back than the first day of the term in which they were recovered, in respect of the hands of the debtor; and did not bind his goods and chattels, but from the date of the writ of the execution; and now, by the statute of frauds, 29 Car. II. c. 3, the judgment shall not bind the land in the hands of a bond fide purchaser, but only from the day of actually filing the same; which is directed by the statute to be punctually entered on the record; nor shall the writ of execution bind the goods in the hand of a stranger, or a purchaser (Skin. 257); but only from the actual delivery of the writ to the sheriff or other officer, who is therefore ordered to endorse on the back of it the day of his receiving the same. Blacki. Comm. book ii.

**Extermination, the act of diminishing or lessening the bulk or substance of a thing, especially of the human body.** FEVERS, agues, long abatements, &c. occasion great extenuations or emaciations.

**Extermination is also a figure in Rhetoric, opposite to the hyperbole.** The Greeks call it **katastasis.**

**Exterior, Polygon, Tactus.** See the substantives.

**Extermination, formed of ex and terminus, boundary, the act of exterminating, or totally destroying a people, race, family, &c.**

The Jews have been exterminated out of Portugal, the Moors out of Spain, the Albigensians out of France, &c. Philip the Fair of France, to be revenged on the Knights Templars, took a resolution, in 1397, to exterminate them.

**Extermination, or Exterminating, in Algebra, is used for taking away. Thus algebraists speak of exterminating words, fractions, and unknown quantities out of equations. See Maclaur. Algeb. part i. chap. 12, where we have some general theorems for the exterminating unknown quantities in given equations. See Equation.**

**External, or Exterior, a term of relation applied to the surface or outside of a body; or that part which appears or presents itself to the eye, touch, &c. In which sense it is opposed to internal or interior.**

The feuds are divided into external, which are those whereby we perceive ideas, or have the perception of external objects; as seeing, hearing, &c. and internal. See Sense.

External is also used to express any thing that is with outside a man, or that is not within him, and particularly in his mind. In which sense we say external objects, &c.

The existence of an external world, i.e. of bodies and objects out of the mind, is a thing which has been greatly
called in question by Dr. Berkeley and others. See Existence, Body, and Quality.

External Angle. See Angle, external.

External Denomination, Ear, Mode, Place. See the substantives.

Externus Auris, in Anatomy. See Ear.

Externus Cubitus. See Cubitus.

Externus Dowsenii, a name given by Douglas to one of the muscles of the ear, called by Cowper and others obligue auris, and by Albini externus mallei. See Ear.

Externus Coformacium, Illiacus. See the substantives.

Externus Mallei. See Ear.

Externus Orbiter, Pterigoideus, Vagus, Rectus Capitis. See the several articles.

EXTINCTION, the act of extinguishing, that is, of putting out, or destroying, fire, flame, or light.

The Aristotelians account for the extinction of fire from the principle of contrariety; thus, say they, water puts out fire, because the qualities of water are contrary to those of fire, the one being cold and moist, and the other hot and dry. But how far this will go, may appear hence, that fire is extinguished by hot water as readily as cold; nay, even by oil, earth, &c.

Some of the moderns offer two more plausible causes of extinction; viz. diffusion, as when the next immediate fluid of the flame is dispered and blown off by too forcible a wind; and suffocation, when it is so comprized, that its free motion cannot be maintained; as happens upon throwing water, &c. thereon. Various preparations and engines have been contrived for extinguishing accidental fires. See Fire.

Boerhaave denies that there is properly any such thing as extinguishing of fire; it is a body sui generis, of an immutable nature, and we can no more extinguish it than we can create it.

Extinction, in Chemistry and Pharmacy, is when a metal, mineral, or the like body, after having been heated red-hot in the fire, is plunged in some fluid, either to soften or temper its secrecy, as tans in rofe-water; or to communicate its virtue to the liqur, as iron or steel to common water; or, flabbly, to give it a temper as, in the extinction of steel in water, or some other preparation.

EXTINGUISHER, self-acting, is a contrivance whereby a candle can be extinguished at any given time after being lighted. There are several ways by which this can be effected. The most simple is placing the candle in a vessel of water, with such a length above the surface as will burn as long as a light is wanted; of course when the candle burns down to the water it will be extinguished.

Figs. 10 and 11, Plate XII. Miscellany, represent two neat mechanical contrivances for the above purpose; in fig. 10, &c. a is a brass clip, formed of two pieces, and jointed together by the pin, b, by means of a flading ring, d; this clip can be closed round the candle so as to fix firmly thereto; the pin, b, has a joint in the upper end to receive a crooked lever, e, which has a conical extinguisher fastened at the other end of it. This extinguisher is held up from falling upon the candle, by means of a small wire, f, which is bent sideways at the end, and thrust into the candle, at the place where it is intended to be put out; as the tallow is consumed, it becomes so soft as to be unable to sustain the pressure of the wire, f, which therefore flies forward, and the extinguisher falls upon the candle. It must be observed that the wire, f, must only be put into the tallow, but not in the wick, as it might not then fall down quickly.

Fig. 11 is another extinguisher, invented by Mr. J. J. Hawkins, and placed in his museum of mechanical inventions.
EXT

Extensively, which are not subject to extinguishment. (6 Rep. t. 155. Co. Litt. 149.) If the lord and another person do purchase the lands out of which he is to have services, they are distinct; also by service of the services a man may be extinguished. Co. Litt. 147. 1 And. 257. See Tenure.

Extirpation of ways. See Extirpation.

Extrication, formed of ex and ipse, root, the act of pulling up, or destroying, a thing to the very roots.

Among the prayers of the Romish Jubilee, there is one for the extirpation of heresy.

Extrication. This word, in Surgery, signifies the eradication of any dis ease, tumour, &c. by some manual operation, whether done with a cutting instrument, with cautic, with a ligature, or any other means.

Thus, the generality of tumours are extirpated with a knife; but some, which clas as excrecences, or warts, are frequently extirpated with cautic, or with the ligature. The extirpation of polypi in the nose is, for the most part, accomplished with forceps, by which such tumours are pulled, or rather twisted off.

The art of extirpating encysted tumours with adroitness consists in deflecting the parts, surrounding the tumour, without wounding the eye. If the latter accident occur, the contents frequently flow out, the cyst collapses, and the continuance of the affection is attended with more difficulty.

It is a great point to remove every particle of the cyst, and, hence, it is satisfactory to take it out entire, that is, without wounding it. When any portion remains behind, the wound will frequently not heal, in consequence of fungous granulations, arising from the diseased part. Unles the swelling be large, a single incision through the skin is sufficient; but, in other instances, it is advantageous to make two cuts in this manner (\(\) ); first, because it facilitates the removal of the tumour; secondly, because it prevents a redundancy of skin, which would take place, if none were removed, and would greatly retard the cicatrization of the wound.

After the operation, the edges of the wound are to be brought together with flocking plaster, and a compress and bandage are to be applied.

When the breast is affected with any dis ease of an incurable nature, the surgeon can sometimes extirpate the malady by cutting away the whole of the diseased parts.

If the disease be of a scirrhous or malignant nature, some particularity in the mode of operating is requisite. The surgeon ought, in this case, not to be content with merely removing parts, which are palpably and visibly diseased, but he should also endeavour to remove a certain quantity of the subsidence, which is in the immediate circumference of the disease. In scirrhous, every surgeon knows the propensity of the skin to be affected, and the frequent extension of white morbid bands into the surrounding adipose subsidence. These facts greatly confirm the propriety of making a free removal of the skin, whenever it is in the least discoloured, puckered, adherent to the swelling beneath, or in any way altered; and of taking away a good deal of the fat, in which scirrhous tumours are sometimes involved. When there are no reasons for supposing the disease of the breast to be any thing else than a mere farcomatous enlargement, the removal of the skin must certainly be considered unnecessary. When cancer recurs, the skin is the first part in which it usually makes its appearance, and the skin of the nipple in particular. Hence, many surgeons always make it a rule to remove the latter part, when it is judged proper to take away any of the integuments.

The operation is usually performed as the patient is in a fitting posture, well supported by pillows and attendants. The pectoral muscle is to be made tense by keeping the arm back, by means of a flick, placed transferably behind the back, in front of the two arms.

If none of the integuments are to be removed, a straight incision is to be made through them; the tumour is to be regularly dissected all round from the circumference parts; and, lastly, its base is to be detached from its connection, from above downward, till the whole is separated.

This is the mode of removing all simple tumours, which are not of a malignant nature, and which are not of an immense size.

When the tumour is of a malignant nature, and adherent to the skin and pectoral muscle beneath, the operator is to remove, at least, an inch or two of the fat on every side of the disease. The portion of the skin intended to be taken away must be included in two semi-circular incisions, which meet thus (\(\) ) at their extremities; and when the base of the tumour is to be detached, the surface of the pectoral muscle, wherever it is adherent to the tumour, is also to be removed.

It is sufficiently obvious, that the advantage of making the incision in the above manner, consists in enabling the surgeon to bring the edges of the wound together after the operation, so as to form a straight line, and unite by the first intention.

The mere magnitude of a tumour frequently renders it highly judicious to take away a portion of the skin in the above method. If some were not removed, the dissection of the tumour would be exceedingly tedious; and, after the operation, the loose undifended skin would lie in folds, and form, as it were, a large pouch for the lodgment of matter.

The tumour being removed, the surgeon should examine the interior of the wound, in order to ascertain that no undurated part is left behind. If any hardness should be felt, it is proper to remove it. The surgeon should also examine the surface of every scirrhous tumour, immediately after it is taken out, for the purpose of knowing whether any of the white bands, shooting into the surrounding fat, have been divided; for, in this case, some portions have been left behind, and ought to be taken away. Their situation may easily be known, by considering the position of the tumour before the operation.

When the dissection of a swelling will occupy a considerable time, it is always judicious practice to tie every large artery as soon as it is divided. This remark is not meant to comprehend vessels of such a diameter, that though they bleed when first cut, they do not emit blood afterwards, so as to require a ligature. It was Duflo’s invariable method, in cutting out tumours, to tie every large artery before he continued the dissection.

When a tumour of the breast has been entirely detached, and the hemorrhage suppressed, the flick confining the arm backward is to be removed. Then if there are any diseased glands in the axilla, it is a very excellent plan to tie the pedicles, by which they are attached on the side towards the axilla, before attempting to cut the tumours completely away. It would be extremely difficult, after taking off the gland, to tie the little short artery which enters the swelling, almost immediately after it has quitted one of the thoracic arteries. The bleeding also, in consequence of the shortness of the vessel, and vicinity of its orifice to the thoracic arteries, would be exceedingly profuse, seeming rather
rather to arise from a wound of the latter vessels than of a small branch.

The celebrated Defaut used to pursue the practice above recommended; and Sir Charles Blicke has long been in the habit of observing the same rule, in the numerous operations which he has performed with the utmost benefit to the afflicted, and well deserved honour to himself.

When the operation is finished, the flux of the wound is to be relaxed, and the edges of the incision brought together with flaps of adhesive plasters. Proper compresses and bandages are next to be applied. Should the operation have been the removal of a disfigured breast, the nearest arm should be kept completely at rest in a sling, as whenever it moves, it occasions a disturbance of the pectoral muscles, and, of course, of the wound. (First lines of the "Practice of Surgery," by Samuel Cooper.)

For the mode of extirpating a diseased testis, see Cæstration.

The method of effecting the extirpation of polypi is to be described in the article Polyposis.

Some observations are offered, under the head Exostoses, on the subject of extirpating tumours of the bones. The way in which a diseased eye ought to be cut out, will be hereafter explained. See Ey. Extirpation of.

For an account of the plan of extirpating certain excrescences, see Excrescence.

EXTIRPATION, in Law, a judicial writ, either before or after judgment, that lies against a person, who, when a verdict is found against him for land, &c. doth maliciously overthrow any house, or extirpate any trees upon it. Reg. Jud. 13. 56.

EXTISPEX, formed of exto, and spicer, of fpieco, or spicer, in view, consider, in Antiquity, an officer who viewed and examined the entrails of victims; in order to draw prefaces from them as to futurity.

This kind of divination, called extispicium, was much in vogue throughout Greece, where there were two families, the Jamidei and Clytitae, consecrated, or set apart, particularly for it.

It appears to have been very ancient, and was probably derived from the ancients. Vitruvius, cap. 4. lib. i. gives the following plausible account of its origin. He says that the ancients inspected the livers of those animals which frequented the places where they intended to build or encamp; and if they commonly found that the liver, to which they attributed fanguiUification, was injured, they concluded that the waters and nourishment collected near such places were not wholesome.

In Italy, the first extispices were the Etrurians or Tuscani; among whom, likewise, the art was in great repute. Lucan gives us a fine description of one of these operations in his first book.

EXTORTION, in Law, denotes generally any oppression under colour of right; and it is usually applied to signify an illegal manner of wresting anything from a man, either by force, menace, or authority: e.g. if an officer, by terrifying another on pretence of his office, or "by colour of his office," takes more than his ordinary fees or dues, he commits, and is indictable for, extortion.

So the exacting of unlawful usury, winning by unlawful game, and, in fine, all taking of more than is justly due, by colour or pretence of right, as excise tolls in mills, excessive prices of ale, bread, victuals, wares, &c. come under extortiott.

Crompton says, that wrong done by any man is properly a trespass, but excessive wrong is extortion; which is most properly applicable to sheriffs, mayors, bailiffs, and other officers, who, by colour of their office, greatly oppress and wound the king's subjects, by taking excessive reward, or fees, for executing their office: and extortiott has been deemed more odious than robbery, because it carries an appearance of truth; and is often accompanied with perjury in officers, &c. by violating their oaths of office.

The distinction between bribery and extortiott seems to be this: the former offence consists in the offering a present, or receiving one if offered; the latter, in demanding a fee, or present, by colour of office. Extortion by the common law is severely punished, on indictment, by fine and imprisonment, and removal of officers from the offices in which the crime was committed. By the flat. 3 Edw. I. inferior officers of justice, &c. guilty of extortion, are to render by c. 26. double, and by c. 20. treble, value, and there are divers other statutes for punishing extortions of sheriffs, bailiffs, gaolers, clerks of the aile, and of the peace, attorneys and solicitors, &c. flats. 23 H. V. i. 7 & 9. 33 H. VIII. c. 24. 29 Eliz. c. 4. 1 Jac. I. c. 10. 9 & 10 W. III. c. 41. 10 & 11 W. III. c. 23. 3 Geo. I. c. 15. 17 Geo. III. c. 26. § 6. In cases of extortion, there must be a positive charge, that the charged person did it extorsio, or colore officii. The place where it was committed must be let down in the declaration; the fun extorted particularly specified, and the indictment or information must state the full particulars by specifying the time, &c. Against attorneys for extortion, action may be brought, and the party aggrieved shall have treble damages and costs; but information will not lie on the flat. 3 Jac. I. c. 7. Sid. 434. 4 Nelf. 825.

EXTRA-Conscriptary Starr. See Sporades.

EXTRA-judicial, something done out of the proper court, or the ordinary course of law. As when judgment is given in a cause, or case, not depending in that court where such judgment is given, or wherein the judge has no jurisdiction.

EXTRA-ordinary space, is the infinite empty void space, which is by some supposed to be extended beyond the bounds of the universe, and consequently in which there is really nothing at all.

EXTRA-parochial, a place out of the bounds of any parish; or privileged and freed from the duties of a parish.

EXTRACT, in Chemistry. The term extract, as used in chemical nomenclature, has been borrowed from the pharmaceutical disputatories, where it has long been applied to a great variety of substances which have little other agreement than in the mode of preparation, which consists in extracting by water, or any other menstruin, the soluble part of certain parts of vegetables, and inquisitively this solution by heat to a thick confection, or sometimes to entire solidity.

The term extract, therefore, in its original and pharmaceutical sense, only refers to the mode of preparation, and not to the nature of the substance prepared; and hence much confusion and uncertainty have prevailed in the attempts of chemists to define the nature of the substance to which this term should in strictness be limited.

All the pharmaceutical extracts are extremely compounded, for being prepared either by water or alcohol, of course every thing soluble in these liquids would be confounded in the general mass. Hence we find in one or other, and sometimes in a single extract, mucilage, sugar, tannin, gallic acid, resin, gluten, several neutral salts, and other ingredients. But along with these there always is found a considerable quantity of a brown tenacious substance, often with a bitter taste, and polluting a number of chemical properties, which entitle it to be considered as a peculiar substance.
The distinguishing properties of this sub stance have been laid down with much ability by Vaquezlin, in his memoir on the extractive principle (Journal de Pharmacie, p. 138) and in his researches on the sap and native juices of trees (Ann. Chem. tom. 31.) and also by Fourcroy in an elaborate and excellent analysis of the cinchona of St. Domingo. Ann. Chem. tom. 8 & 9.

We shall first notice the experiments of Vaquezlin, which being made on the native juices of plants, the extract already in solution, and unaltered by the heat requisite in artificial decoction, is probably in a pure state.

When the sap of any tree is first drawn it is always colourless, or nearly so, but when infusipated by heat, however moderate, it always assumes a brown colour, and in the process of evaporation a certain though small quantity of pulverulent brown insoluble matter falls down. If this is collected separately before the juice is entirely infused, and treated with acetic acid, one portion diffuses with effervescence, and is found to be chiefly carbonat of lime, and an insoluble part remains, which is considered by this excellent chemist as extract altered and oxygenated during the evaporation. If the concentrated sap is now slowly evaporated to dryness, it yields a brown extract, strongly pungent, and of a pungent failure taste. This entire extract is always extremely compound, containing in fact all the soluble ingredients of the original juice. Gallic acid, when preheat, is detected by a solution of iron; tannin, by a solution of tincture of lime; or oxalic acid; fugar, by the tafle, and by its soon acquiring the vinous fermentation. The entire extract also always contains acetic acid, partly in excess and partly united both to lime, potash, and ammonia, and hence when a few drops of strong sulphuric acid are poured upon any extract, copious vapours of pungent acetic acid are given out; and if this is done with large quantities, and in close vessels, acetic acid may be obtained pure. It is probably owing to the presence of these neutral acetates, that all the infusipated native juices attract moisture strongly from the air, and hence too their great disposition to mould and change by keeping.

Ammonia also is detected in most infusipated juices of plants by the pungent vapours of this alkali, that are perceived on the addition of quick-lime, but in the natural state the ammonia is more than neutralized by the acetic acid, as all the foft extract is rendered betimes.

Extractive matter (meaning by this term the pure extract) appears to form a great portion of the colouring matter of vegetables. If to any liquid containing extract a solution of alum be added, a copious coloured insoluble precipitate is produced, confuting chiefly of alumine in intimate combination with extractive matter, and the supernatant liquor remains clear and nearly colourless. The same process takes place in dyeing, the alum being first fixed on the cloth as a mordant, as it is called. The solutions of tin poises this power of precipitating coloured extract as an insoluble powder in a still more flirikening manner. That of the other metallic salts produce a similar precipitate of extract, combined with the metallic oxyd.

The experiments of Fourcroy on the cinchona have been detailed at length under that article, to which we refer our readers. It may be observed in this place, that the facts relative to the subject of extract were, shortly, that the decoction of cinchona during evaporation deposited a quantity of black matter, insoluble in cold water, but which molly was diffused in alcohol, having however a portion of a red powder of a peculiar nature, which the author of the experiments considers as extractive matter, changed by union with oxygen, and thereby rendered insoluble in water or alcohol. The appearance of this powder, and its insolubility in water, might at first lead to the supposition that it was resin, but its equal insolubility in alcohol refutes this idea.

The precise nature of this insoluble matter, which is deposited on the evaporation of all vegetable infusions or decoctions, is hitherto not known, and several objections to the opinion of its being merely oxygenated extract may be reduced, which we have already detailed under the article Cinchona.

On the whole, however, we may safely admit, that there is a peculiar sub stance found in almost all soluble matter of vegetables, and particularly in the common circulating juices, to which the term extract, or pure extractive principle, has been given, and which has the following distinguishing properties.

In its natural state in the sap of trees it is colourless, or nearly so; but when the solution is heated and infusipated, it always acquires a deep colour, which is generally brown or fawn, with various shades, and by the same process its solubility in cold water is diminished.

It is in its natural state equally soluble in alcohol as in water, by which circumstance it is distinguished both from the pure mucilage and resin. This entire extract is insoluble in ether.

It has a very strong affinity with alumine, and with metallic oxides, and when combined with ether it becomes insoluble in water, alcohol, and many other menstrua. By destractive distillation it is resolvable into carbon, oxygen, and hydrogen, and a small proportion of azot.

Much variety is found in the properties of smell, tafle, and colour, in the various extracts, and we are still totally ignorant how far these varieties may depend on other admixtures, or whether there are different species of extract; and in general we may add that this sub stance appears to be one which most easily enters into intimate combination with all the other soluble vegetable principles, and, consequently, can hardly by any known means be obtained pure, as it exists in the vegetable itself, and unchanged by the processes of analysis.

Extract, in Pharmacy. The greater number of pharmaceutical extracts are made by boiling the sub stance (in coarse powder) in water, forming the decoction, boiling it down till it is considerably concentrated, then gently drying the residue in a flove, or flow oven, to the requisite consistence.

A fair of the extracts are made with alcohol instead of water, or with a mixture of the two; the sub stance being first digested with the alcohol, and the tincture, thus prepared, strained off; the residue then boiled with water, and the decoction poured off, and both the decoction and tincture mixed, and evaporated slowly.

The purely spirituous extracts are also called refinés, and are always evaporated to dryness, when they remain hard brittle masses, with a vitreous fracture, resolvable in alcohol, and in all essential characters resembling the natural refinés.

In preparing the extracts by water the decoctions are usually directed to be set aside for some hours, that any sediment may be deposited, which is then rejected. But this is obviously a bad practice, as in many cases much of the medicinal property of the plant resides in this residue which subsides from the hot decoction on cooling.

Another species of extracts is the infusipated juices of plants. Several powerfully medicinal plants, such as the hemlock, are succulent vegetables, which, when strongly expressed,
expressed, yield a large quantity of a green turbid juice, which (after separating the mere fragments of the plant) only requires to be infused by a very gentle heat, to form the extract in the form in which it is used.

All the extracts, except those made by alcohol, are liable to spoil by keeping. This is particularly the case with the infused juice of the succulent plants, being composed of materials all extremely liable to fermentation, and being kept in a conjunct tendency to deliquescence by the neutral acetates which they contain. Therefore they must be kept in close vessels, but with every care the most important of them lose their medicinal quality in no great length of time.

Extract, in Matters of Literature, denotes a short abridgment of a book or paper, or of some of the matters thereof. The journals, newes, bibliothecas, memores, and other monthly reviews, or quarterly accounts of the affairs of learning, contain principally of extracts of the most material passages, doctrines, &c. found in the several books published in that time.

Extract ab Eclefsa. See Restitutio Extradt.

Extract A Curle, in our Old Writers, the issues or profits of holding a court, arising from the customary fees, &c.

Extracion, in Pharmacy and Chymistry, an operation, whereby essences, tinctures, &c. are drawn from natural bodies. See Extract.

Extracion, in Surgery, is the drawing from, or out of the body, any thing fixed in it, as a thorn, or bullet, in the flesh, a tooth from the jaw, &c. Surgeons speak alio of the extraction of a stone from the bladder, a cataract from the eye, foreign bodies from the cæcum, extraneous substances from wounds, &c. For a description of the methods of extracting a stone from the bladder, see Lithotomy.

The operation of extracting the cataract is explained in the article Catarract.

Extration, or D. scent in Genealogy, denotes the flock, or family, which a person is descended from. In some military orders, chapters, &c. a candidate must make proof of the nobility of his extraction before he is admitted.

Extraction of Roots, the method of finding the roots of given numbers, or quantities. See Root.

The square, cube, and other powers of a number, or root, are formed by multiplying the given number into itself a greater or less number of times, as the power required is higher or lower. See Power.

This multiplication compounds the powers; and the extraction of the roots decomposes them again, or reduces them to their principles or roots. So that the extraction of the root is to the multiplication of the power, what the analysis is to the syntheseis.

Thus, 4, multiplied by 4, produces 16; which is the square of 4, or the fuctum of 4, by itself; and 16 multiplied by 4, makes 64, which is the cube of 4, or the fuctum of 4 by its square. Such is the composition of powers.

Again, the square root of 16 is 4, because 4 is the quotient of 16 divided by 4; and the cube root of 64 is likewise 4, as 4 is the quotient of 64 divided by the square of 4. Such is the extraction of roots.

Hence to extract the root out of a given power, is the same thing as to find a number, e. gr. 4, which being mul-

plied a certain number of times into itself, produces the given power, e. gr. 16 or 64.

For the extraction of square and cube roots, it is necessary to have the squares and cubes of all the digits in readiness; as exhibited in the following table.

To extratt the square root out of a given number. — 1. Divide the given number into classes, of two figures each, and include each class between two dots, commencing with the place of units, and proceeding to the left in integers, and to the right in decimals; the root will consist of so many parts or figures as you have classes. By the way observe, it may happen, that for the last class on the left hand there shall be only one figure left.

2. Then the left-hand class being the square of the first figure of the root sought, look in the table of roots for the square root answering to that number; or, if that square number be not precisely there, to the next lesser number; this root write down for the first figure of the quotient; and subtract its square from the left-hand clas; To the remainder bring down the next clas toward the right.

3. Write down the double of the quotient figure under the left-hand figure of the second clas; and seek how oft this double is contained in the figure over it; the quotient gives the second figure of the root.

4. Write the same quotient under the right-hand figure of the same clas, and subtract the product of the whole number underwritten, multiplied by the second figure of the root, from the number over it, as in division.

5. The operation being repeated according to the third and fourth steps, &c. the remainder being still divided by the double of the root as far as extracted; and from the remainder subtract the product of the last divisor, having the last found figure of the quotient added to it, multiplied by this figure, you will have the root required.

E. gr. To extratt the root of 99856, point it after the following manner, 99856: then seek a number, whose square shall equal the first figure 9, vis. 3, and write it in the quotient; then having subtracted from 9, 3 x 3, or 9, there will remain 0; to which let down the figures as far as the next point, viz. 98, for the following operation. Then, taking no notice of the last figure 8, say, How many times is the double of 3, or 6, contained in the first figure 9? Answer 1.

Wherefore, having written 1 in the quotient, subtract the product, of 1 x 61, or 61 from 98, and there will remain 37, to which connect the last figures 56, and you will have the number 3756, in which the work is next to be carried on. Wherefore, also neglecting the last figure of this, viz. 6, say, How many times is the double of 31, or 62, contained in 37 (which may be guessed at from the initial figure 6 and 31, by taking notice how many times 6 is contained 37)? Answer 6; and writing 6 in the quotient, subtract 6 x 626, or 3756, and there will remain 0; whence it appears, that the business is done, the root coming out 316.
EXTRACTION.

Otherwise, with the divisors set down, it will stand thus:

\[ \begin{array}{c|c}
998256 & 3257 \end{array} \]

617
609
88791
84681
411000
376736
2426400
2852649
6057100
5651356
35619400
329566169
72624231

Again, if you were to extract the square root of 22178791:

22178791 (4709, 43637, &c.) If first having pointed it, seek a number, whose square (if it cannot be exactly equaled) shall be the next less square (or nearest) to 22, the figures to the first point, and you will find it to be 4. For 5 \times 5, or 25, is greater than 22; and 4 \times 4, or 16, is less; therefore 4 will be the first figure of the root. This, therefore, being writ in the quotient, from 22 take the square \(4 \times 4\), or 16, and to the remainder 6, adjoin the next figures 17, and you will have 617; from whose division, by the double of 4, you will obtain the second figure of the root, viz. neglecting the left figure 7, say, how many times is 8 contained in 61? Answer, 7; wherefore write 7 in the quotient, and from 617 take the product of 7 into 87, or 609, and there will remain 8, to which join the two next figures 87, and you will have 887; by the division whereof by the double of 47, or 94, you are to obtain the third figure; in order to which, say, how many times is 94 contained in 88? Answer, 0; wherefore write 0 in the quotient, and adjoin the two last figures 91, and you will have 88791, by whose division by the double of 470, or 940, you are to obtain the left figure; viz. say, how many times 940 in 88791? Answer, 9; wherefore write 9 in the quotient, and you will have the root 4709. But since the product \(9 \times 4709\), or 42381, subtracted from 88791, leaves 41100, the number 4709 is not the root of the number 22178791 precisely, but a little less.

If then it be required to have the root approach nearer, carry on the operation in decimals, by adding to the remainder two cyphers in each operation. Thus, the remainder 41100, having two cyphers added to it, becomes 4110000; the division whereof, by the double of 4709, or 9418, will give the first decimal figure 4. Then having writ 4 in the quotient, subtract \(4 \times 45184\), or 376736, from 4110000, and there will remain 34264. And so having added two more cyphers, the work may be carried on at pleasure, the root at length coming out 4709, 43637, &c.

But when the root is carried on half way or above, the rest of the figures may be obtained by division alone: as in this example, if you have a mind to extract the root to nine figures, after the five former 4709, are extracted, the four latter may be had, by dividing the remainder by the double of 4709.

Thus if the root of 326976 were to be extracted to five places, in numbers; after the figures are pointed, write 1 in the quotient, as being the figure of whose square \(1 \times 1\), or 1, is the greatest that is contained in \(3\), the figure to the first point; and having taken the square of 1 from 3, there will remain 2; then having set the first two figures, viz. 32, to it (viz. to 2,) seek how many times the double of 2 is contained in 22, and you will find indeed that it is contained more than ten times; but you are never to take your divisor to times, nor even 9 times in this case; because the product of \(9 \times 29\), or 261, is greater than 229, from which it would be to be taken, or subtracted; wherefore write only 8. And then having written 8 in the quotient, and subtracted \(8 \times 28\), or 224, there will remain 5; and having set down this to the figures 76, seek how many times the double of 18, or 36, is contained in 57, and you will find one, and so write 1 in the quotient; and having subtracted \(1 \times 361\), or 361, from 576, there will remain 215. Lastly, to obtain the remaining figures, divide this number 215, by the double of 81, viz. 162, and you will have the figure, 59, which, being written in the quotient, give the root 181, 59. After the same manner are roots extracted out of decimal numbers. Thus the root of 12975 is 18, 159; and the root of 32,976 is 1, 8159, and the root of 0, 032976, is 0, 181, 59, and so on. But the root of 32976 is 574427; and the root of 32,976 is 574427. And thus the root of 99856 is 3, 16.

To extract the other, or higher root, out of a given number. —The extraction of the cubic root, and all other roots, may be comprehended under one general rule; viz. if the given number is of a third figure, beginning from unity, is first to be pointed, if the root to be extracted be a cubic one; or if every fifth, if it be a quadrato-cubic (or of the fifth power;) and then such a figure is to be writ in the quotient, whose greatest power (that is, whole cube, or whole quadrate-cube, or if it be the fifth power, &c.) shall either be equal to the figure, or figures, before the first point, or next less under them; and then having subtracted that power, the next figure will be found by dividing the remainder augmented by the next figure of the refulved, by the next third power of the quotient multiplied by the index of the power to be extracted, that is, by the triple figure, if the root be a cubic one; or by the quintuple biquadrature, (that is, five times the biquadrate,) if the root be of the fifth power, &c. And having again subtracted the power of the whole quotient from the first refulved, the third figure will be found by dividing that remainder, augmented by the next figure of the refulved, by the next lesser power of the whole quotient, multiplied by the index of the power to be extracted.

Thus, to extract the cube root of 13312053, the number is first to be pointed after this manner, viz. 13312053 then you are to write the figure 2, whose cube is 8, in the first place of the quotient, as that which is the next lesser
EXTRACTION.

If some have called these roots, not cubo-cubic ones but quadrato-cubes. And the same is to be observed in other roots, whose indices are not prime numbers.

To prove the extraction of roots. — 1. For a square root; multiply the root found by itself, and to the product add the remainder, if there were any; if the sum be equal to the number given, the operation is just.

2. For a cube root. Multiply the root found by itself, and the product, again, by the same root. To the last product, add the remainder, if there were any. If the sum come out the number first given, the work is just.

After the like manner may the extraction of the other roots be proved.

To extract the roots of equations, or algebraic quantities. —

The extraction of roots out of simple algebraic quantities, is evident, even from the nature, or marks of notation itself; as that \( \sqrt[n]{a} \) is \( a \), and that \( \sqrt[n]{a + a c + c} \) is \( a + c \), and that \( \sqrt[n]{a + b} = a \).

And also that \( \sqrt[n]{a + b} = \sqrt[n]{a} + \sqrt[n]{b} \), and that \( \sqrt[n]{a + b} = \sqrt[n]{a} \), and that \( \sqrt[n]{a + b} = \sqrt[n]{a} \).

And moreover, that \( \sqrt[n]{a + b} + \sqrt[n]{c} \), or \( \sqrt[n]{a + b} \), is equivalent to \( a + b \), or \( a + b \), and that \( b + \sqrt[n]{a + b} \) is equivalent to \( b + \sqrt[n]{a + b} \).

Therefore all these are evident, because it will appear at first sight, that the propounded quantities are produced, by multiplying the roots into themselves (as \( a + b \) from \( a + b \), \( a + b \) from \( a + b \), \( a + b \) from \( a + b \)), &c.)

The rule is to extract the required root of the numeral coefficient, if there be any, and to divide the exponents of the literal or algebraic quantities by the number that denominates the root required. It is evident from the application of this rule, that any power which has a positive sign may have either a positive or negative root, if the root is denominated by an even number, because \( + \) or \( - \), multiplied into themselves an even number of times will give \( + \). Also, that if a power has a negative sign, no root of it denominated by an even number can be aligned. But if the root to be extracted is denominated by an odd number, the sign of the root will be the same as the sign of the given quantity whose root is required. However, it will often happen, that the number, denoting the required root, will not exactly divide the exponent of the given power, in which case the required root will have a fractional exponent, thus, \( 3^{\frac{1}{2}} \).

Thus, to extract the square root out of a \( + b \); in the first place, write the root of the first term \( a \); viz. \( a \), in the quotient, and having substracted its square \( a \), there will remain \( b \) in the quotient, and having substracted the product of \( b \) into \( a \), or \( b \), there
there will remain nothing; which shews that the work is finished, the root coming out $a + b$.

And thus to extract the square root out of $a^2 + 6aab + 3a^2b = 12a^2b + 4b^2$, first set in the quotient the root of the first term $a^2$, viz. $a$, and having substracted its square $a^2 \times a^2$, or $a^4$, there will remain $6a^2b + 5aab - 12a^2b + 4b^2$; to find the remainder of the root. Say therefore, how many times is $2a$ contained in $6a^2b$? Answer, $3ab$; wherefore write $3ab$ in the quotient; and having substracted the product of $3ab$, into $2a + 3ab$, or $6a^2b + 9aab$, there will yet remain $-4aab - 12a^2b + 4b^2$, to carry on the work. Therefore, say again, how many times is the double of the quotient, viz. $2a + 6a^2$, contained in $-4aab - 12a^2b + 4b^2$? or, which is the same thing, say, how many times is the double of the first term of the quotient, or $2a$, contained in the first term of the remainder $-4aab?\text{ Answer, \(-2b\). Therefore having writ \(-2b\) in the quotient, and substracted the product \(-2b\) into $2a + 6a^2 + 2b$, or \(-4aab - 12a^2b + 4b^2$, there will remain nothing.

Whence it follows, that the root is $a + 3ab - 2b$.

\[
\begin{align*}
6a^2b + 5aab - 12a^2b + 4b^2 \\
o + 6a^2b + 9aab \\
o - 4aab - 12a^2b + 4b^2 \\
-4aab - 12a^2b + 4b^2
\end{align*}
\]

And thus the square root of the quantity $xx - a + \frac{1}{2}aa$ is $x = \frac{1}{2}a$, and the square root of the quantity $16a^2 - 24aax + 9x^2 + 12bbx - 16aab + 4b^2$ is $3x - 4a + 2b$, and the square root of the quantity $y^3 + y^1 + 8y^2 + 8y + 4$ is $y^1 + 2y + 2$; as may appear underneath.

\[
\begin{align*}
xx - a + \frac{1}{2}aa (x = \frac{1}{2}a) \\
o - a + \frac{1}{2}aa \\
o - 24aax + 16a^2 + 16aab \\
o - 24aax - 16aab + 12bbx^2 + 4b^2
\end{align*}
\]

\[
\begin{align*}
y^3 + 4y^1 + 8y^2 + 8y + 4 (y^1 + 2y + 2) \\
y^3 + 4y^1 + 8y^2 + 8y + 4 \\
0 + 4y^1 + 8y^2 + 8y + 4
\end{align*}
\]

If you would extract the cube root out of $a' + 3aab + 3bb + b'$, the operation is performed thus:

\[
\begin{align*}
a'^3 + 3aab + 3abb + b'(a + b) \\
a'^3 \\
3aa \cdot b + 3aab (b) \\
a'^3 + 3aab + 3abb + b^3
\end{align*}
\]

Extract first the cube root of the first term $a'$, viz. $a$, and set it down in the quotient; then substracting its cube $a'^3$, say, how many times is its treble square, or $3a$, contained in the next term of the remainder $3aab$; and there comes out $b$; wherefore write $b$ in the quotient, and substracting the cube of the quotient $a + b$, there will remain $0$; therefore $a + b$ is the root. After the same manner, if the cube root is to be extracted out of $z^0 + 6z^2 - 4z^2 + 96z - 64$, it will come out $2z + 2z + 4$. And so likewise in higher roots.

The general rule for extracting any root out of any given quantity, is as follows. Having ranged the quantity according to the dimensions of its parts, extract the said root out of the first term, and that shall be the first member of the root required; then raise this root to a dimension lower by unit than the number that denominates the root required; and multiply the power that arises by that number itself; divide the second term of the given quantity by the product, and the quotient shall give the second member of the root required. The other members of the root, if there be more than two, are found after the same manner. In some cases the exact root cannot be found in finite terms; thus, the square root of $a^2 + x^1$ is found to be $a + \frac{x^1}{2a}$.

The operation is thus:

\[
\begin{align*}
a' + x^1 (a + \frac{x^1}{2a} = \frac{x^1}{8a} + \frac{x^1}{16a^2}) & & \text{&c.} \\
a'^1 & & \text{&c.}
\end{align*}
\]

\[
\begin{align*}
2a + \frac{x^1}{2a} & \cdot x^1 \\
x^1 & \cdot \frac{x^1}{4a^1} = a^1 + \frac{x^1}{4a^1}
\end{align*}
\]

\[
\begin{align*}
2a + \frac{x^1}{a} - \frac{x^1}{8a^1} & \cdot \frac{x^1}{4a^1} \\
0 & \cdot \frac{x^1}{8a^1} = \frac{x^1}{4a^1} - \frac{x^1}{8a^1} + \frac{x^1}{64a^2}
\end{align*}
\]

In the same manner the cube root of $a^3 + x^1$ will be found to be $a + \frac{x^1}{3a^1} - \frac{x^1}{9a^1} + \frac{5x^1}{81a^2} - \frac{10x^1}{243a^3}$, &c. Thus,

\[
\begin{align*}
a^1 + x^1 (a + \frac{x^1}{3a^1}) \\
3a^1 \cdot x^1
\end{align*}
\]

Then cube $a + \frac{x^1}{3a^1}$, and we shall have $a^3 + x^3 + \frac{x^3}{3a^3} + \frac{x^3}{27a}$, which substracted from the given quantity $a^3 + x^3$, leaves $\frac{x^3}{3a^3} - \frac{x^3}{27a}$ for the next resolvent; and

\[
\begin{align*}
a^3 & + x^3
\end{align*}
\]
this divided by \( 3^3 \) will give \( \frac{x^5}{9a^3} \) for the next term of the quotient, &c. But the roots of quantities of this kind are much more expeditiously obtained by means of the binomial theorem. For the square root of \( a^x + x^3 \) is \( a^\frac{1}{2} + \frac{1}{2} x a^\frac{1}{2} - \frac{1}{8} x^2 + \frac{1}{8} \times \frac{1}{2} \times \frac{1}{2} \times a^\frac{1}{2} \times x^2 \), and \( a^x + x^3 = a^\frac{1}{2} + \frac{1}{2} x a^\frac{1}{2} - \frac{1}{8} x^2 + \frac{1}{8} \times \frac{1}{2} \times \frac{1}{2} \times a^\frac{1}{2} \times x^2 \) &c. \( a^\frac{1}{2} + \frac{1}{2} x a^\frac{1}{2} - \frac{1}{8} x^2 + \frac{1}{8} \times \frac{1}{2} \times \frac{1}{2} \times a^\frac{1}{2} \times x^2 \) &c. &c. = (bringing the powers of a from the numerators to the denominators, by changing the signs of their exponents) \( \frac{a^x}{8} + \frac{x^3}{3} + \frac{x^5}{8^5} \) &c. See Maclaurin’s Algebra, part i. ch. viii.

p. 50, 51. See Root.

EXTRACTOR, in Midwifery, an instrument contrived to extract children in cases of difficult births. We have the description of a forceps for extracting children by the head when lodged low in the pelvis of the mother, in the Medic. Eff. Edinb. vol. iii. art. 20. See also the abridgment of this book, vol. ii. p. 438, where some alteration is mentioned of this instrument from Gilliard’s Midwifery, and an improvement of it by Mr. Freke. See Forceps.

EXTRACTUM CATHARTICUM, a form of medicine in the London Dispensatory, intended as an equivalent for the extractum Rudii, commonly called Rudius’s pill, and which is for many reasons a better composition than that pill. It is now called “extractum colocythisis composatum.” See Colocythis.

EXTRADOS, the outside of a vault.

EXTRANEOUS FOSSILS, in Geology. Adventitious, secondary, or figured fossils, have among them (see Fossils, Extraneous) those remains and exuvia of organized beings, which are found imbedded in the strata of the earth. Since the discovery of Mr. William Smith, that each particular shell, and other organic remain, has its proper and appropriate place in the lamina of some particular stratum, and of which it is often a perfect, and, perhaps, the most unerring test of identity, in most instances, the knowledge and exact differentiation of these numerous animal and vegetable remains has appeared a matter of the first importance to geologists, especially since it has been further ascertained, as it now is, that most, if not every one, of the organic remains, differ essentially from any recent species of the animals and plants, to which former, and too curiously, observations had referred them; while many of them differ altogether and entirely from anything now living or growing; which two points ascertained, have tended irresistibly to show that these organic remains were not entombed by the Mosaic deluge, as most writers had supposed, because they differ entirely from the antediluvian race, of which the present living ones are the descendants and exact representatives, as the Mosaic account informs us, and are not of subsequent creation. Another refutal of the former of these facts has been to show, that the several animals and plants whose fossil remains we meet with in the strata, lived and died on the stratum in which we find them, prior to the deposition, and, perhaps, prior also to the creation of the matter of the lamina which covers them; and that the period of the existence of particular species was in most, if not every instance, limited to that took up in the deposition of the particular stratum in which they are found imbedded, seeming to suggest, that they were created at the period of the stratification, which answers to the lowest lamina in which they are found, and ceased to exist altogether at the period answering to the highest lamina in which they are found; a supposition in no ways inconsistent with the Mosaic account of the creation, if the whole of the fossil race be different from the present race of organized beings, and of a period of time antecedent to the events described by the sacred historian, except in his introductory words, “In the beginning God created the heavens and the earth.” It may, possibly, be urged, against the idea of a temporary duration of the primitive animals and plants, and their becoming after that extinct, that the same kind of organic remains are found again, after large successions of depositions with remains of different beings, in ascending the series of strata, or in very distant parts of the globe; to which it may be answered, that where sufficient discrimination has been made in the specific differences of organic remains resembling each other, but found imbedded in a stratum separated by those of a different kind, and with different kinds of organic beings in them, it has generally, if not always, turned out, that the remains resembling each other, and hitherto supposed identical, are in reality not so, but of perfectly distinct species, their varieties, as some might be disposed to call them, in conformity to the language of the naturalists respecting accidental deviations in forms of the same species, being confin’d, and fixed as properly constituted distinct species in the great families of the primitive creation. Reflecting organic substances found at very distant places on the globe, which, on being brought together and thoroughly examined, appear to be distinct; before any argument is drawn therefrom, against the temporary existence and extinction of their originals in the primitive race which inhabited the waters of this globe, it should be distinctly ascertained that the series of strata and organic remains above and below the two places in the series whence the specimens were brought are really different; or, in other words, that the identical species really do belong to different parts of the series of strata: for if, on the contrary, they belong to the same stratum, however its obvious mineralogical character may appear changed, it is to be expected that the organic remains will be identical, since Mr. Smith has, on tracing the ending or actual out-crop of a stratum for several hundred miles, always found the organic remains the same; as the numerous instances in his collection, marked and brought from the extreme and intermediate points of such examination, do testify.

It is also to be taken into consideration, that the discoveries of Mr. Farey, relative to denuded tracts on our globe, shew the possibility, and, perhaps, the frequent occurrence of such deep excavations being left in the strata of the earth, as to exhibit the edges, and indeed considerable tracts of the planes of strata, at immense depths in the series, below those proper to the general strata on the surface.
face, and having their regular bafett, or ending, on the surface, at great distances from such denuded exposures of them. The immense denudation, for instance, which has laid bare the fourth or lowest limestone rock of Derbyshire and Staffordshire, and the excavation of Dove-dale and other valleys therein, appears to have exposed strata to view, which are from 2 to 2 miles in perpendicular depth beneath the red earth, or gypseous tract, which surrounds them on all sides (except, perhaps, a narrow strip on the north, along the grand ridge, or waterhead of the island,) which lower exposed parts of the fourth lime rock do not, perhaps, anywhere bafett, or come regularly to the surface, within 90 or 100 miles of Dove-dale and other valleys, where the denudation has exposed them. The continents, from the relations of travellers, likely to furnish numerous instances of denudations in the mountain chains, which will be found to expose strata that lie very low indeed in the general series, and at very great distances from the regular or continued line of ending or outcrop of those particular strata; and, without advertizing to which circumstances, the exact identity of organic remains from distant places so circumisenced, might seem to contradic our ideas of their being peculiar to peculiar strata. But after all, should identically the same species of organic remains be found in distant parts of the series of terrestrial strata, what have we to limit the architect of "heaven and earth," from having re-created similar animals or plants during the countless periods of the primitive creation and exislace? Analogy surely cannot be said to do this, when the animals and plants created since he said "Let the waters be gathered together, and let the dry land appears," and which still continue to exit, have so many points of resemblance to some of the primitive and extinct ones, both in forms and habits, that they have for ages passed as identical therewith. Mr. James Parkinson and Mr. W. Martin, having engaged in works intended to collect information on, and more accurately to discriminate, extraneous or organic fossil remains, which work is still in progress, and the results of Mr. W. Smith's labours and thes of his pupils being yet in a great measure unpublished, we shall defer what we have further to add on these highly interesting and curious relics to the article Reliquia, which seems, indeed, their more appropriate title. In the mean time, as the usual names of the several fossil animals and plants, &c. occur, we shall not fail to lay before our readers such facts and particulars as we can collect, and with propriety communicate, concerning the objects of the unpublished researches of the meritorious individuals alluded to; to whose credit it ought to be known, that extended and undisguised communications have all along been made among the circle of their friends, and in consequence of which a spirit of enquiry on the subject has been excited, in various districts of the kingdom, from which the happiest consequences to science may be expected shortly to arise. Extraneous, Extranous, Lat. belonging to nothing, forcing. This word, during the last century, was admitted into the medical tchnica, in speaking of an unusual and irregular change of key, which is called extraneous modulation, or modulating into an unrelated key, as in the key of C natural, D with a sharp 3d, D♭, B♭, and D♭, which are unrelated keys, having so found in common with the chord of C natural. With respect to extraneous modulation, Rousseau says that no composers have frequent recourse to sudden and unusual modulation, but those who are fritty in fancy and invention; and we should believe the assertion well founded, if Eman. Bach, Haydn, and Mozart, were excepted, who cannot be accused of want of invention. It is to the clumsy imitators of these great masters, who, in total want of melody, have recourse to unexpected harmony, that Rousseau's castication seems to attach it. EXTRAORDINARIIL in Roman Antiquity, a body of forces, consisting of a third part of the hostes, and a fifth part of the foot, which was separated from the rest, to prevent any design that might be formed against the natural forces. See Aeblecti. EXTRAORDINARY, something out of the common course. Extraordinary couriers, are those sent express on some urgent occasion. Extraordinary embassador, or envoy, is such a one as is sent to treat or negotiate some special and important affair, as a marriage, a treaty, confederacy, &c. or even on occasion of some ceremony, as condolence, congratulation, &c. See Embassador. A gazette, journal, or other news-paper extraordinary, is that published after some great and notable event, containing the detail or particulars thereof, which are not found in the ordinary papers. Our news-writers generally use postscripts, or supplements, instead of extraordinaries. Extraordinary ulcer. See Culverin. EXTRAVAGANTES, a part of the canon law, containing divers constitutions of the popes, not included in the body of the canon-law, whence the denomination extravagantes: *quasi extra corpus juris vaga.* The extravagantes are divided into two parts: the first contains twenty constitutions of John XXII, and the second other later constitutions of the said John, and his succouers. See Canon-Law, and Decretals. EXTRAVASATION, a term in Surgery, derived from extra, out of, and vafus, the vessel; it signifies an effusion of any fluid from the vessels, viscus, or receptacle, in which such fluid is naturally contained, and the passage of the same into another situation, which is very frequently the interstices of the cellular membrane. In the head, blood is often extravasated, under the cranium, upon the surface of the dura mater, in consequence of the rupture of one of the arteries of this membrane from external violence. The fame fluid is also frequently extravasated on the pia mater, and in the convulsions of the cerebrum, or, more deeply in the ventricles, and very substance of the brain. In cases of wounds of the abdomen, large quantities of blood are occasionally extravasated in the cavity of the peritoneum, or the contents of the stomach, bowels, gall-bladder, or some other injured viscus, may become effused. When the urinary bladder is wounded, or when a slough takes place in a certain part of it, from the distention occasioned by a long protracted, and unrelieved retention of urine, the latter fluid may become extravasated in the abdomen. In the example of flizards, the urethra occasionally ulcerates between the obstruction, and the neck of the bladder, and the urine is consequently extravasated in the cellular membrane of the perineum and ferotum. Sometimes, when a portion of the bowels mortifies, after being returned into the belly, in cases of burns, the intestinal matter escapes from the alimentary canal, through the breach occasioned by the sloughing. In the thorax, surgeons sometimes have opportunities of seeing cafes, in which considerable extravasations of blood arise, in consequence of flabs and gun-shot wounds. In the limbs, and indeed, we might say, in every situation, practitioners frequently meet with extravasations of blood, in cases of wounded arteries, aneurismus, and violent contusions.
EXTRAVASATION.

confusions and blows, which rupture vessels of important size. Bloody swellings, produced in the said-mentioned manner, are technically named ecchymoses, and have already been treated of elsewhere. See ECCHYMOSIS.

Our design, in the present place, is to confider extravasations in a surgical point of view, as they occur in the head, the chest, and the belly; taking occasion, however, to refer the reader for certain parts of the subject to other places in this work.

Extravasation of blood in the head, from external violence.

—After explaining with equal perspicuity and elegance, how the dura mater serves as a pleuroceleum to the internal surface of the bones of the cranium, in the same manner as the perierianium does to the external table, Mr. Pott notices, that by blows, falls, and other shocks, some of the larger of the vessels, which carry on the communication between the dura mater and the skull, may be broken, and a quantity of blood shed upon the surface of that membrane. This, he observes, is one species of bloody extravasation, and, indeed, the only one which can be formed between the skull and dura mater. If the broken vessels be few, and the quantity of blood which is shed, be small, the symptoms are generally slight, and, by proper treatment, disappear: when they are large, or numerous, or the quantity of extravasated fluid considerable, the symptoms are generally urgent in proportion; but, continues Mr. Pott, whether they be slight or severe, whether immediately alarming, or not, they are always, and uniformly, such as indicate pressure made on the brain and nerves, viz. fluidity, drowsiness, diminution, or loss of sense, speech, and voluntary motion.

The shock which the head sometimes receives by falls from on high, or by strokes from ponderous bodies, may likewise occasion a breach in some of the vessels, either of the pia mater, or brain, and thus produce an extravasation of the fluid which should circulate through them.

Mr. Pott remarks, that an extravasation may be the only complaint caused by the accident; or it may be joined with, or added to, a fracture of the skull. But, this is not at all; for it may be produced not only when the cranium is unhurt by the blow, but, even when no violence of any kind has been offered to, or received by the head.

Vertigo, vomiting, fluidity, hemorrhage, lops of sense, and motion, either partial or total, are set down by this celebrated surgical author as the symptoms of an extravasation in the cranium; sometimes one and sometimes others, and sometimes all of them. These symptoms, which are all easily accountable for from extravasation of fluid, and unnatural pressure made on the brain and nerves, are, says Pott, frequently mistaken as indications of a diffuse, which, considered abstracly, can never cause them; he means a simple depressed fracture of the cranium, which may be accompanied by them, but cannot cause them.

The same writer repeats, that when a fluid is extravasated in any considerable quantity within the cavity of the cranium, if any bad symptoms are produced by it at all, they are, and must be, such as indicate pressure made on the brain, and origin of the nerves, occasioning thereby either disturbance, or abolition of the offices of sense and motion; and this in a different degree, according to the quantity, kind, and situation of the pressing fluid.

Mr. Pott seems to have entertained the common notion of hemorrhage from the ears and nose being also symptoms of an extravasation. However, the least reflection must of course make any body perceive, that a bleeding from those parts is only indicative of their having sustained a violent shock in common with the rest of the head. Even the degree of violence is not at all denoted with any certainty by these circumstances; for, with respect to the nose, we know, that, in many perfons, the slightest caufe will make it bleed.

When the above-mentioned symptoms exist, Mr. Pott would opinion, that we might pronounce, in the positive manner, our judgment, that the brain suffers compition; but, says he, to our very frequent mortification, we find there are the only circumstances which, in such case, we can depend upon; every thing else which relates, or belongs to them, being involved in a most perplexing obscurity. We not only have no certain infallible rule whereby to distinguish what the pressing fluid is, or where it is situated; but we are, in many instances, absolutely incapable of knowing whether the symptoms be occasioned by any fluid at all; for, a fragment of bone broken off from the internal table of the cranium, and making an equal degree of pressure, will produce exactly the same complaints.

When a case, attended with the preceding symptoms, occurred, the old surgeons used in general to conclude, that the brain had suffered a concussion, to which all the consequences were imputed.

Mr. Pott observes, that a concussion and an extravasation are very distinct causes of mischief, though not always very distinguished. Mr. Pott, continues, some of the French writers, have made a very sensible and just distinction between that kind and degree of lops of sense, which arises from a mere commotion of the brain, and that which is caused by a mere extravasation, in those instances, in which the time of the attack or appearance of such symptoms, is different, or distinct. The lops of sense, which immediately follows the violence, say they, is most probably owing to a commotion; but, that which comes on after an interval of time is past, is most probably caused by extravasation.

Mr. Pott remarks, that this distinction is certainly just and good, as far as it will go. That degree of abolition, or diminution of sense, which immediately attends, or follows the blow or fall, and goes off again, without the assistance of art, is in all probability occasioned by the sudden shake or temporary derangement of the contents of the head; and the same kind of symptoms recurring again some time after they had ceased, or not coming on until some time has elapsed from the receipt of the violence, are most probably produced, in the body, or worse, from the brain. But, unfortunately, we have it not very often in our power to make this exact distinction. An extravasation is often made so immediately, and so largely, at the instant of the accident, that all sense and motion are instantaneously lost, and never again return. And it also sometimes happens (continues Mr. Pott), that, although an extravasation may possibly not have been made at the moment of the accident, and the first complaints may have been owing to commotion merely, yet a quantity of fluid having been shed from its proper vessels very soon after the accident, and producing its proper symptoms, before those caused by the commotion have had time to go off, the similarity of the effects of each of these different causes is such, as to deprive us of all power of distinguishing between the one and the other, or of determining, with any tolerable precision, to which of them such symptoms as remain are really owing.

Mr. Pott next observes, that the nature and degree of the symptoms, produced by the pressure of an extravasation, are various and different in many persons, though it is to the kind, quantity, and situation of the pressing fluid. Sometimes it is mere fluid blood; sometimes blood in
EXTRAVASATION.

a rate of coagulation; sometimes it is a clear lymph; and, at others, blood and water are found mixed together; each of these is found either simple or mixed in different situations; that is, between the skull and dura mater, between the dura and pia mater, or in the natural cavities of the brain, called its ventricles, and sometimes, in cases of great violence, they are found at the same time in all these different parts. Sometimes, a considerable quantity of blood is immediately at the time of the accident; and sometimes the breach, by which the effusion is made, is so circumstances, both as to nature and situation, that it is at first very small, and increases by fuller or slower degrees. In the former (says Pott), the symptoms are generally immediate and urgent, and the extravasation is of the bloody kind. In the latter, they are frequently flight at first, appear after some little interval of time, increase gradually, till they become urgent, or fatal, and are, in such cases, generally occasioned by extravasated lymph. So that although the immediate appearance of bad symptoms does most certainly imply mischief of some kind or other, yet, on the other hand, no man ought to flippose his patient free from hazard, either because such symptoms do not shew themselves at first, or because they appear to be but flight; those which come on late, or, appearing flight at first, increase gradually, being full as much to be dreaded as to confluence as the more immediately alarming ones; with this material difference between them, that the one may be the consequence of a mere concussion of the brain, and may by means of quietude and evacuation go quite off; whereas, the other being most frequently owing to an extravasation of lymph, (though sometimes of blood also,) within the substance of the brain, are very seldom removed by art. (Pott's Works, vol. i.) It appears from some excellent observations published by Mr. Abernethy on the subject of injuries of the head, that a fracture of the skull is not likely to be followed by an equal degree of extravasation in every part, as the vessels, connecting the dura mater to the cranium, are in most parts of that membrane of a small size. If these are accidentally ruptured, a flight hemorrhage ensues, which soon stops, and only a thin stratum of coagulated blood is found, if the bone be removed. But, says Mr. Abernethy, if the fracture happens in the track of the principal artery of the dura mater; if the trunk, or even a considerable branch of that vessel be torn, the hemorrhage will be profuse, and the operation of the trephine becomes immediately necessary to preserve the life of the patient.

When an interval of some occurs between the blow and the flupor occasioned by the effused blood, the differentiation of the nature of the case is greatly facilitated by that circumstance, as we have already related, because it becomes manifest, that the bad symptoms, which now come on, are not owing to the first mere shock of the external violence on the brain. The patient was most probably fluped by the blow, at the very instant of its occurrence; but he gradually regained his senses, in proportion as the first effects of the shock on the brain subside. However, as some vessel was wounded by the same blow, an hemorrhage continues under the cranium, on, or within, the brain, and as soon as a certain quantity of blood is extravasated, its pressure produces a recurrence of fluporaction.

Unfortunately, great obscurity attends numerous cases, in consequence of patients having no interval of sense, and remaining in a state of complete fluporaction even after the accident. We know not, whether the brain is labouring under concussion, or compression, or both; and even when we do know that the bad symptoms arise from an extravasation, we are frequently unable to say where the effused blood is situated. Now, since the operation of trepanning is not likely to afford affiane, unless the blood be upon the dura mater, so as to allow of being taken away, and since the operation itself is by no means free from danger, we should be very reluctant to put it in practice. Without having good foundation for believing that there will be found immediately under the perforation, which we are about to make in the bone, the extravasated blood, which gives rise to the urgent symptoms. In such cases, however, we are highly indebted to Mr. Abernethy for a suggestion, which promises to be of exceedingly great assistance in directing whether the trephine ought to be used, or not, on a particular part of the head. "Unles one of the large arteries of the dura mater be wounded, (says this gentleman,) the quantity of blood poured out will be inconceivable; and the flight pressure of the brain, which this occasions, may not be attended with any peculiar symptoms; or, perhaps, it may occasion some flupor, or excite an irritation disposing the subjacent parts to become inflamed; but both these effects will gradually abate, nor will any inflammation ensue, if proper means are taken to prevent it. It is indeed highly probable that in many cases, which have done well without an operation, such an extravasation has existed. But, if there be so much blood on the dura mater as materially to derange the functions of the brain, the bone, to a certain extent, will no longer receive blood from within; and by the operation performed for its exposure, the pericranium must have been separated from its outside. I believe, that a bone so circumstances will not be found to bleed; and I am certain it cannot with the fame freedom and celerity, as it does when the dura mater remains connected with it internally."

In some cases, related by Mr. Abernethy, there was not the least hemorrhage, and this gentleman mentions his having twice been able, by attending to the want of hemorrhage from the outside of the cranium, to ascertain the extent to which the dura mater was detached within. Also, when symptoms seemed to require the perforation of the skull, Mr. Abernethy has frequently seen the operation contra-indicated by the hemorrhage from the bone, and rightly, as the event proved.

When the bone has been for some time bare, this criterion may not be so clear; but Mr. Abernethy scraped the surface of a portion of the skull, which had remained some time in a denuded state, and he found that it bled freely enough to denote that the dura mater was adherent to the inner table, and, conseqently, that making a perforation there could be of no service. See Effray on Injuries of the Head, p. 32—33.

We shall now enumerate the symptoms of pressure on the brain, and contrav them with those of concussion. It is to be understood, that the complaints produced are nearly the same, whether the pressure is made by an extravasation, or a fracture of the cranium with depression.

**Symptoms of Pressure.**

1. Patient at first fluped, with cold extremities.
2. Revives, and has an interval of sense, in cases of extravasation, but not in those of a depressed fracture.
3. The quantity of effused blood increasing, he becomes drowsy and stupid.
4. Pulse regular and slow.
5. Patient quite insensible.
6. Pupil dilated.
7. Stertorous respiration.

N.B. When the bleeding is very copious in the first instance,

formed by facts, the most open to observation, and completely exempt from the possibility of mistake. Practicioners saw that the water of dropsies, the pus of abscesses, which had burst into the abdomen, as well as the styyle and feaces, which had escaped through a wound, or other sorts of breach of an intestine, were invariably and universally diffused among the folds of the mesentery and bowels after death.

M. Petit (the son) first questioned the accuracy of the foregoing opinion, in relation to the patient while alive. He suggested that as in the living body the intestines were diffused with feces, alimentary matter and air, while they were also mutually acting against each other, and in a continual state of compression from the alternate contraction of the diaphragm and abdominal muscles, there might be a superior refissance made to the weight of the extravasated fluid, tending to separate the viscera to which we allude. On the contrary, says Petit, it is not possible that, as soon as the patient is dead, and the abovex kind of refissance is taken away, the extravasated fluid may infiltrate itself anywhere without difficulty? M. Petit remarks, that the truth of the preceding suggestion cannot be doubted, when we consider, that certain cures of hernia get well, notwithstanding the burrilling of the gangrenous part of the intestine, after its reduction into the abdomen. In such infances, in fact, the contents of the bowels appear to escape outward through the wound entirely in consequence of the refissance made to their diffusion among the convolutions of the intestines. However it might be objected, that, in cases of hernia, since the bowel is almost always adherent to the edge of the abdominal rigon, the issue of the intestinal matter through the wound is rather to be ascribed to the cure with which this event may happen, than to any refissance made internally by the surrounding viscerse. But M. Petit cites severel cases, which fully confirm, that there is a vast refissance made to the lodgment of extravasated fluids among the convolutions of the bowels, and folds of the mesenbery.

After death, any fluid, extravasated in the abdomen, may by its mere gravity infiltrate itself any where, and become diffused among the various parts, because these parts being without action make no opposition. But in the living state, all the abdominal viscerse reciprocally act upon each other, and forming, as it were, only one body, by reason of such mutual support, the refissance which is made to any extravasated matter will always keep it from becoming widely diffused, in the manner which many have imagined.

Let us next, with M. Petit, reflect upon the inferences to be drawn from such reciprocal action of the abdominal viscerse.

The first consequence is, that an extravasated fluid only infiltrates itself into the cavity of the abdomen, in the same way that a fluid becomes diffused in an external part; that is to say, the extravasation can only spread by degrees, and successively, into such places as offer the least refissance. Blood, when it infiltrates itself into the intertices of the muscles, can only get from one membrause-ceil into another, by the first one being do diffused, that the fluid can more readily get into a second cell, and from this into a third, than increase the diffused state of its first situation. Just so in the abdomen, the blood which escapes from a wounded vessel, is first diffused into a situation near the opening in the vessel, either between the peritoneum and surface formed by the intestines, or more deeply among the convolutions of the bowels, or some of the folds of the mesenbery. In the proportion as the bleeding continues, the blood forces its original boundary, and dilates the place which it occupies, in every direction, until it meets with least refissance in making its way, either upward or downward, or to the right or left. The extravasation continues to dilate the new spaces, which it fills in the same way, until either the first limits are forced, or the effused fluid spreads in some other direction. The extravasation will expand in this manner, till the refissance, made by the viscerse, becomes equal to the impetus, with which the blood issues from the vessel. M. Petit was of opinion, that it was this kind of refissance which put a stop to the hemorrhage, even before any coagulm had been formed in the opening of the vessel. That the blood, while flowing from the vessel and in a fluid state, should only make one mass and be contained in one cavity, till coagulation takes place, is a circumstance which cannot rationally be imputed to any thing else, than the refissance depending upon the mutual action of the viscerse in the living state. It is also equally certain, that it is in consequence of the sudden cessation of such refissance, that extravasated blood, which is fluid after death, becomes diffused among the different convolutions of the bowels, and forms numerous scattered collections.

The second inference which M. Petit mentions, as deducible from the refissance arising from the reciprocal preffure of the abdominal viscerse, is that an extravasation in the cavity of the abdomen cannot so easily happen, as some have fancied. It was once not an uncommon idea, that a breach in a very moderate vessel could occasion a considerable extravasation, because the orifice could not be compressed, like that of a vessel in a more external situation. It is indeed true, that no compression can be directly applied to the opening in an internal vessel; but the refissance which the surrounding viscerse make to the extravasation, operates as a subfstitute. It is even probable, according to Petit, that when blood is exfused in the abdomen, it has a greater refissance to overcome than when extravasated in an external part. This author states, that the refissance of the cellular membrane, the common bond of connection between the muscles, is undoubtedly less than that which depends upon the reciprocal action of the intestines, and reil of the viscerse. The inceffant alternate motion of the abdomen and thorax is in favour of the preceding opinion. The facility also, with which abbeceffer situatd in the abdomen are discharged, through a small, and very frequently not a depending opening, is an additional fact, proving that the abdominal viscerse, by the manner in which they mutually press upon each other, make a greater refissance to an extravasation, than can be made by the cellular substance in other parts of the body.

Swords have often been thrust completely through the body, without giving rise to any dangerous symptoms, or only to such as frequently attend wounds, which do reach into the cavity of the belly. We cannot imagine, contrary to all probability, that, in this case, the weapon has slipped over the intestines, through their intirtices, and by good luck has wounded none of the blood-vessels. We must rather conclude, that an extravasation does not always ensue from a wound of the viscera or blood-vessels, or at least, that the extravasation is not invariably attended with such consequences as former practitioners used to suppose.

For the purpose of rendering the foregoing remarks more intelligible, let us follow M. Petit in his observations, and take notice of the principle which he has laid down in his excellent memoir, viz. that without a particular action in the muscular fibres of the intestine or artery, no extravasation would occur in the abdomen, even were there a breach in such bowel or vessel. Supposing the blood vessels delirious of action, and the place of the opening pressed upon by a force equal to that, which operates upon the rest of their extent, the fluid, which they contain, would never
EXTRAVASATION.

be effused in the abdomen, so as to form an extravasation. Besides its being evident, that this must be the fact, M. Petit mentions his having actually observed it in the body of a man, who died of gangrene in the abdomen, in consequence of a hernia, which was attended for upwards of a fortnight with the most violent symptoms of strangulation. Nearly the whole of the intestinal canal was equally affected with gangreuous mischief, so that it was scarcely possible to handle any of the bowels without occasioning a breach in them. However, although the intestines were filled with very fluid excrement, none of it was extravasated in the peritoneum or other parts; indeed, Petit discovered several little breaches of the intestinal canal, but the fluid had allowed but a little of the excrement to escape, but only just enough to tinge the adjacent parts. Petit acknowledges, at the same time, that round where these holes were situated, some slight adhesions had taken place between the bowels, and these and other parts; but they were so weak, and easily broken, as to be quite incapable of hindering an extravasation. Petit concludes, that in this instance no extravasation happened, because the intestinal canal was everywhere affected with gangrene in nearly the same degree, and the diæse had destroyed the tone and action of the muscular fibres of the intestines.

It is contended by Petit, that the foregoing case affords sufficient proof, that, without a contractile power in the blood vessels and intestines, no extravasation of their contents could be produced in the abdomen, and that such an event would certainly be opposed by the action of the abdominal muscles and diaphragm, which make uniform and equal pressure upon all the viciæa. If this statement be correct, it is obvious, first, that the greater the action of the wounded vessels is, or the greater the obstruction to which they have to propel, the greater will be an extravasation from them; secondly, that no extravasation can arise unless the action of the vessels themselves be capable of overcoming the resistance depending upon the mutual action of the parts. Hence, only wounds of vessels above a certain size can give rise to extravasations, at least, to any of importance. The veins cannot occasion so much extravasation as the arteries; nor are wounds of the intestines so apt to be followed by an effusion of the chyle and feces, as the same injuries of the blood vessels are liable to be attended with an extravasation of blood. Petit was also of opinion, that wounds of the stomach were not so often as those of the bowels the cause of this kind of accident.

The feces cannot be so easily extravasated as blood, not only because the action of the intestines, particularly that of the small ones, upon their contents, is weaker than that of the blood vessels upon the blood, but, principally, because, when there is a breach in one of the bowels, the contents will continue their course through the intestinal canal, without any need of there being a considerable exaction to the occurrence of an effusion. However, Petit admits us not to conclude, from what has been said, that the chyle and feces can never be extravasated in the abdomen. There is no doubt whatever, he observes, that an extravasation may take place, when the wound in the bowel is of ample size, the gut filled with chyle or excrement, and care is not taken to empty the large intestines very often with glysters. The event may also happen, when pain and irritation render the muscular action of the intestines violent, irregular, and convulsive, and when unequal pressure is made upon the abdomen. Under such circumstances, the resistance made to an extravasation, by the reciprocal action of the viciæa, is overcome, and the contents of the bowels will continue to be effused, until the impulse arising from the contractile power of these organs returns to a state of equilibrium with the resistance depending on the mutual action of all the viciæa.

The extravasation of chyle and feces does not take place differently from that of blood; but in wounds of the bowels there is this advantage, that the same opening which has given passage to the extravasated fluid, may also allow it to return and pass off. Petit remarks that we need no further proof of what has been stated, than the great evacuations of blood, which some wounded persons have had with their stools, without being afflicted with any of the symptoms of extravasation. It is highly improbable, that such bleeding could depend upon the injury of any of the vessels ramifying through the intestinal canal, the force of whose fluid is too inconsiderable. We rather believe, that in these cases, some vessels, either of the mesentery, or some other part, have been wounded at the same time as the intestine, and that the blood has insinuated itself into, and taken its course through the bowels, in consequence of the resistance made to its extravasation among the viciæa.

The foregoing remarks, made by Petit (he means, clearly prove not only that an extravasation of feces cannot so easily happen in the abdomen as has been imagined, but also, that it is less dangerous than an effusion of blood, though is, and that it is accompanied with less violent symptoms. When the contents of the bowels are extravasated, adhesions are likewise observed to form more readily, and to limit the effused matter sooner, than when the extravasation consists of blood. After such adhesions have once formed, it is probable that the extravasated matter may be got rid of in the same favourable way, as certain abscesses, which have discharged themselves into the intestinal canal. Blood, however, cannot insinuate itself again into the cavity, from which it has escaped, because a clot blocks up the opening. But a wound in an organ remains continually open, till it is closed by the adhesions which the bowel contracts to the adjacent parts; adhesion, indeed, is the only means by which a wound of this description can be healed.

M. Petit remarks, that among the numerous facts which might be adduced in proof of the difficulty with which a wound of the stomach permits the aliment to be extravasated, the operation of an emetic in this case is a striking one. Petit expresses his belief, that vomiting does not depend upon the action of the muscular fibres of the stomach, but entirely upon the sudden and violent contraction of the abdominal muscles. This author conceives, that, if the particular action of the stomach itself had much concern in the production of vomiting, an extravasation of the alimentary matter would necessarily happen in the abdomen when that viscous is wounded. However, in the instances referred to by Petit, the occurrence did not take place because, notwithstanding the violence with which the abdominal muscles and diaphragm contracted, they made equal and uniform pressure on all the cavity of the stomach. The danger of an extravasation is also less, inasmuch as a wound of the stomach is always much smaller in relation to its cavity, than that of a bowel, in regard to the intestinal canal.

Circumstances are very different, in respect to wounds of the gall and urinary bladders, especially when these receptacles are full. An extravasation is then an inevitable consequence, both on account of the great fluidity of the bile and urine, and of the contractile power with which the parts are endued, and again if which the action of the abdominal muscles makes no sort of resistance. An extravasation of these fluids is extremely dangerous, by reason of their irritating quality with respect to the viciæa. The ca-

...
lies and irregular contractions which such stimulating fluids excite, cause the extravasation to become more widely diffused. The same also, with which the bile and urine mix with the serum, that naturally moistens the surfaces of all the viscera, leads us to suspect, that whenever these fluids are extravasated, they very soon become universally dispersed among all the convolutions of the intestines.

Against these latter extravasations little can be done, and unless they are in small quantity, and their increase can be prevented, the patient's life hardly admits of being saved. Leaving a catheter in the bladder, indeed, is a sure means of hindering the extravasation of urine from augmenting; but not much confidence can be placed in the kind of outlet afforded by the duct of the gall-bladder.

When the extravasated matter is completely encysted and circumscribed, it happens, that at such matter had to overcome the resistance of the parts before it could be effused, no sooner is a passage afforded for its escape, than the reaction of the separated parts necessarily forces out whatever fluid has infiltrated itself between them. This is a third consequence, which is pointed out by Petit as resulting from the resistance, made by the reciprocal action of the abdominal viscera, to extravasations.

The foregoing observations tend to shew, that an extravasation in the abdomen, and especially one of blood, may be as completely discharged as a collection of fluid in the thorax. The evacuation, at least, may always be easily effected, when the extravasation is bounded at any part by the parietes of the abdomen: a circumstance, which must invariably occur, whenever the extravasation is considerable. Indeed Petit informs us, that it was always the case, as far as his experience went even when the effusion was not very copious.

It is not enough to make surgeons understand, that fluids, extravasated in the abdomen, admit of being discharged by an operation; we deem it also necessary to explain the symptoms denoting the caeses in which such a proceeding is proper.

In order to understand this interesting part of the subject, Petit, and most surgical writers after him, have advised us to draw a distinction between the concentric symptoms and the primary ones, or those which attend the wound from the first, and are, strictly speaking, proper to it, because they depend essentially upon the division of the injured parts. Such breach of continuity occasions, from the first, pain, irritation, tension, convulsions, and swelling and inflammation of the abdomen, affections naturally leading to other concentric symptoms, which vary according to the injured parts, and the degree of inflammation. Of the latter clafs are, biliousness, vomiting, confinement, suppression, or retention of the bile and urine, a great deal of fever generally at first, and, after the inflammation has attained a certain pitch, a concentration and flaking of the paffage, considerable prostration of strength, and cold sweats.

If when the first train of symptoms has been relieved, and after an interval of from four to eight days or more, the symptoms recur, or become exaited, without any apparent cause, we may infer that such concentric complaints depend upon an extravasation.

It may at first seem extraordinary, that the symptoms of an extravasation of blood should be concentric; for, as the effusion takes place at the moment, when the wound first happens, why do not the symptoms commence at the same time?

Petit has referred the reason to the following circumstances: blood, extravasated in the abdomen, does not give rise to any complaints, either by the pressure which it makes, or by its quality, and whenever any symptoms are occasioned on the first occurrence of the effusion, they are those of weakness, depending on the loss of blood to the circulation. The extravasation afterwards becomes entirely circumscribed by the adhesions, which are produced by the inflammation around. An additional quantity of fluid continues to be secreted from the vessels into the circumscribed cavity of the effused blood, and consequently pain, inflammation, &c. are occasioned by the increasing diffusion, now produced.

We shall not stop to enquire into the accuracy of the latter part of the foregoing statement, as the fact, that the symptoms of an extravasation are concentric, is a piece of information highly important to the practitioner, while the theory of the subject is a subordinate consideration.

The remainder of the remarks, respecting extravasations in the abdomen, and their treatment, will be found in the article WOUNDS. Some observations will also be offered, when we speak of HERNIA.

Extravasation is a term sometimes likewise used by the gardeners in speaking of gums, juices, &c. which usually out of their trees either spontaneously, or at incisions.

Extrasm, or Extreme, is applied to the last and outermost part of any thing; or that which finishes and terminates it on that side.

The extremes of a line are points. There is no passing out of one extreme into the other, without going through the middle. Extremities must only be had recourse to in extreme necessity.

Some anatomists apply the denomination extremes, or extremities, to the arms and legs. See Extremities.

Extrasm in Logic, denote the two extreme terms of the conclusion of a syllogism, viz. the predicate and subject.

They are called extremes, from their relation to another term, which is a medium or mean between them.

The predicate, as being likewise had in the first proposition, is called the major extreme, greater extremity, and the subject, as being put in the second, or minor proposition, is called the minor extreme, lesser extremity.

Thus, in the syllogism, man is an animal: Peter is a man, therefore Peter is an animal; the word animal is the greater extremity, Peter the less extremity, and the man the medium. See Syllogism.

Extrem and Mean Proportion, in Geometry, is when a line is so divided, that the whole line is to the greater segment, as that segment is to the other.

Or, as Euclid expresseth it, when the line is so divided, that the rectangle under the whole line, and the lesser segment, is equal to the square of the greater segment.

The invention of this division is thus: let the given line be AB = a (Plate VII. Geometry. fig 87.) and for the greater segment put x, the lesser will be a − x. Then, by the hypothesis, a : x :: x : a − x. Therefore, a = a − x = x, consequently a = a + x + x. And, adding $\frac{1}{2} a$ on each side, to make $x + a + \frac{1}{2} a$, a complete square, the equation will stand thus, $\frac{1}{2} a = x + a + \frac{1}{2} a$.

Now, since the latter is exactly a square, its root $x + \frac{1}{2} a = \sqrt{\frac{1}{2} a}$, and by transposition it will be $\frac{1}{2} a = \frac{1}{2} a - x$, which last equation is a canon for finding x.

For at the foot of $AB = a$, set at right angles $CB = \frac{1}{2} a$; then draw $CA$, the square of which is equal $AB \cdot BQ + CB \cdot CQ = \frac{1}{2} a a$. And therefore $AC = \sqrt{\frac{1}{2} a a}$; make $CD = CA$. From whence $CD = \frac{1}{2} a$ being taken at the case
with regard to those in health, it is a real sacrament to those that are sick.

In their great churches they have a lamp, wherein oil for the sick is preferred; this lamp they call αὐθήδομα τον ὀνείρου, that is, the lamp of oil joined with prayer; for what the Latins call extrema unction, the Greeks call οὐσίδομα, or ὀξυν αἰεγεῖ, that is, oil with prayer, or holy oil.

**Extreme, in Music**, is applied to such intervals as deviate as much as possible from the true chord of the same name, without changing their names; generally when the term extreme is added to the prefix diminished or superfluous (which denote a minor femitone), its effect is to double that diminishing or superfluous effect, or to make 1\(\frac{1}{2}\)\(\times\) = 7\(\frac{1}{2}\)\(\times\) + 2\(\frac{1}{2}\)\(\times\) + 2\(\frac{1}{2}\)\(\times\) + 6\(\frac{1}{2}\)\(\times\); but sometimes we find Mr. Gravend applying a major comma and a minor femitone as the effect of his term extreme, or \(\frac{1}{5}\)\(\times\) = 4\(\frac{1}{5}\)\(\times\) + 4\(\frac{1}{5}\)\(\times\) = the medius femitone; at other times we find extreme, when added to other prefixes, to have different effects, as extreme sharp intervals, for instance, are sometimes found a minor femitone above the intervals respectively, or \(\frac{1}{5}\)\(\times\) = 36\(\frac{1}{5}\)\(\times\) + 3\(\frac{1}{5}\)\(\times\); but in other inferences the same prefix signifies a major comma more, or \(\frac{1}{5}\)\(\times\) = 47\(\frac{1}{5}\)\(\times\) + 4\(\frac{1}{5}\)\(\times\) = the medius femitone. It were much to be wished that these various applications of terms, so perplexing to a reader, could be got rid of, and a confiderable nomenclature in harmonies adopted.

**EXTREMITIES, in Anatomy**, is a term applied to the limbs, as distinguishing them from the other divisions of the animal body, the head, and trunk. They are immediately connected with the latter by one end, and totally free in all other parts. The numerous varieties of their form depend partly on the bones, which enter into their composition; but, in a material degree also, on the soft parts, which surround them, and which give to the limbs that roundness and elegance of figure, in which beauty is united with activity and strength. The extremities, being essentially concerned in all the functions of animal life, and containing the great agents of locomotion, are composed of organs especially defined for these purposes.

Their volume is formed by bones and muscles, supplied by numerous vessels, and communicating with the common centre of sensibility, the brain, by nerves distributed most extensively; producing, in one part, the most important sense of touch, and giving the feeling in all to rapid and varied motions.

The extremities are four in number, divided in man into upper and lower; in other animals into anterior and posterior. Each extremity is divided into four parts, the upper into the shoulder, the arm, the fore-arm, and the hand; the lower into the hip, the thigh, the leg, and the foot. In treating of these, both separately and generally, we shall consider only the bones, and the connections between them. On these depend all the motions of the limbs, the direction and extent of action of the muscles being wholly dependent on the bony points to which they are attached, and on the form and mode of junction of the bones on which they exert their power. The parts of the muscles will be considered in the detailed description of each, and may be easily applied to the subject immediately before us.

Our present plan is to offer, first, some general observations on the external figure of the bones of the extremities, as far as it relates to their uses; on their modes of articulation and their motions. We shall next examine separately and in detail each division of the bones of the upper extremity, the ligaments connecting them, the mechanism of their articulations, and their individual motions; afterwards the combined movements of the several parts, and the powers of the members, as resulting from this construction, both in the

\[ \text{EXT} \]

vol. X13.
In body being rendered the forming. Thefe In general emi-

ing moving number, and In This the for the their external surfaces, necessary for their reciprocal articulations and for the infervation of the connecting ligaments. Nothing can be more irregular than their figure, which, in addition to their comparative smallness and number, has given rise to much ambiguity of defcription. By confidering them under the fame aspects as the other bones, and by carefally noticing their relations to thefe, all confusion may be avoided. The fhort bones, in general, continue longer in a cartilaginous flate than the others, refembling, in the phene-

nomena of their iffiffion, the epiphysis, or extremities of the long bones.

There dill remain fome small bones, found only in the extremities, which can hardly be included in either of the above classes, and are diftinguifhed by the epithet of scaphoid. They poffefs this peculiarity, that they are formed, not in common cartilage, but in the middle of a tendon, or fiffament, and that no trace of them can be obferved in early life. Of their use we fhall fpeak hereafter.

There are fome general characters belonging to all the above-mentioned classes of bones. We obferve in all emi-

nences and hollows, either giving attachment to muscles, or ligaments, or forming surfaces for articulation. The eminences difigned for the former poffefion are very nume-

rous in the bones of the extremities, and vary greatly in figure. They fometimes appear only as fuperficies impreffed in the midit of a smooth furface, giving origin to a number of diftinct aponeurotic fibres; fometimes as prominence or tubercles more or lefs elevated and rough, giving infervation to one or more tendons; or, laftly, as a continued raised line. In general these eminences are proportioned to the muscles which are fixed to them; fo that under which-ever form they appear, there is an equality of space allowed for the tendinous infertions of muscles of equal bulk. They are in general lefs strongly marked in the female than in the male; in the infant than in the adult; in feeble ani-

mals than in the carnivorous tribes, which live by preying on others. Their prominence is indicative of vigour and acti-

vity of motion; being more develope as the muscles are more powerful. This is likewife exemplified by a compa-

rition of the bones of a well made and muscular man, where the outline of each muscle might be traced with energy and precision through the skin, with thofe of a weak and ill pro-

portioned male, whole rounded and faintly marked limbs, refeembling thofe of the female, betray a total want of vigour or address. The ufe of these eminences may be clearly traced to their removing the infertions of muscles farther from the centre, or axis of the bone, and confe-

quently increafing their power of moving it. The emi-

nences, which give attachment to ligaments, poffefs the advan-

tage of removing the ligament farther from the joint, and thereby facilitating, and giving greater extent to its mo-

tions. These eminences are given in different names, ac-

cording to their fitation, their direffion, or figure, as we fhall fea more particularly hereafter.

The hollows obferved on the external surfaces of the bones, (with the exception of articular cavities, of which we fhall fpeak below,) are defigned either for the attach-

ments of muscles, or for giving paffage to their tendons. The firft of thofe have the evident advantage of increafing the furface, without augmenting the bulk of the bone;
In all these articulations we find a smooth and polished crust, of an elastic substance, called cartilage, on the surface of the corresponding bones, the immediate means of their motions on each other. It is supposed to obviate by its elasticity the dangers resulting from sudden and violent shocks. The two corresponding cartilages of opposite bones are so disposed as to touch at all points in some positions of the limb, whereas in others they clip each other more or less, and are found opposite the soft parts surrounding the articulation. They are moulded into the form of the bone to which they adhere, preserving its general figure. But in some cases the cartilage is thicker in its middle than at the edges, thereby increasing the convexity; in others the concave, may be observed, and the hollow of the articular surface is proportionally increased. Both occur in the hip and shoulder: the first in the heads of the thigh and arm bones, the last in the cavities which receive them, and in this manner the uniformity of contact is preferred. In the other articulations the cartilaginous crusts are nearly of equal thickness throughout.

The contact of the articular surfaces is secured by ligaments defined immediately for this purpose, and by the muscles which pass from one bone to another, supporting the joint either by the muscular fibres, or their tendons. The ligaments are formed by very strong fibres, a little elastic, disposed in parallel lines, or interlaced in various directions. Their great resistance incurs, at all times, more particularly when the limb is at rest, the relations between the opposite bones; their situation limits in a great degree their inordinate motions. We observe them under many forms, and named either from these, or from their situation. Among the first are capsule ligaments, which are found surrounding some of the joints like cylindrical bags, embracing the opposite bones by the circumference of the two ends. Of this we have examples in the hip and shoulder, and nowhere else perhaps in the extremities. The ligamentous fibres are here interwoven and strengthened by the adherence of the surrounding tendons, lest at a trinity in the periodont, to which they are firmly united. The reason why capsule ligaments are found only in these articulations will be readily understood. They enjoy motion at every nearly alike, and require on all sides an equal degree of resilience. Wherefrom, from the form of the articular surfaces, the motions are confined to narrower bounds, ligaments are necessary only in particular situations in order to regulate them. We find them in the other joints generally on the sides, from which the name of lateral ligaments. These are sometimes rounded, sometimes flat, interwoven with the periosteum at each extremity, formed of fibres lying in parallel lines, or diverging at either end. There are other ligaments, not directly concerned in the joint, which fulfil strength and regulate its motions, as may be remarked particularly in the shoulder. Besides these we observe many irregular slips, or pads of ligaments, different in texture and there over the joint separated by fat and cellular tissue from the neighbouring parts. The ligaments, of whatever description, unite the opposite surfaces of bones, prevent their displacement, and yet allow of easy and rapid motions; a double advantage arising from their firmness on one part, from their flexibility on the other. They sometimes give attachment to muscles.

The muscles surrounding the joints of the extremities are very powerful agents in securing their contact, and the more so as their power increases in proportion as the chance of displacement is greater. The most vigorous efforts at displacement are made during violent and extended motions; at such times the muscles passing from bone to bone, and
EXTREMITIES.

crossing the articulation, are strongly contracted, are firm in their contractions, and powerfully oppose the tendency which the extremities of the bones may have to abandon each other. In repose, when the muscles are relaxed, and offer but little resistance, the chances of luxation are few, but if they occur, the probability of its taking place is exceedingly increased.

In some joints of the extremities we find a subsistence of a somewhat cartilaginous structure, occupying the interval between the cartilaginous surfaces, and called for this reason inter-articular cartilage. Such bodies are sometimes movable, as in the knee, corresponding to the varying want of uniformity in the articular extremities, or fixed more firmly to the end of the bone, or the neighbouring ligaments. They are elastic and highly flexible, refashioning cartilage in the first quality, the fibrous ligaments in the second. This peculiarity of structure has given rise to the name of articular fibro-cartilages, a term hallowed on them in recent times by the French anatomist Bichat.

These surfaces are all moistened by a fluid, called synovia, on the composition of which we shall not dwell here. It is secreted by a delicate membrane which completely envelopes the structure of the joint, by lining every part of its surfaces, whatever be the figure of the cartilage, or the ligaments, from both of which it is distinct, it adheres closely to them. It forms a film without an opening spread over the whole organ, reflected from the cartilages to the ligaments or tendons; so that whatever it embraces is, in reality, without the articular cavity as it is termed, though projecting into it. To the whole it gives that smooth, polished surface so necessary for the easy and rapid movements the articulations enjoy, at the same time secreteting the fluid which facilitates them; it gives to the joint also its peculiar shining character.

The most simple motion of articular surfaces, common to them all, is gliding on each other in opposite directions; it is often so obscure as to be scarcely perceptible. As we ascend we find it multiplied in a variety of ways. The limb can be considerably bent, or extended; it can be removed from, or brought nearer to the axis of the trunk: the first of these motions is called abduction, the latter adduction; in some cases, as in the shoulder, they are termed elevation, or depression. The motions of some joints are confined to any two of these, as in the knee, although the hip has an elevation and the whole, and all the intermediate degrees, as in the thigh. The union of these different movements, as exhibited in the arm or thigh, has been called circumduction. In this case the bone, instead of being moved in one direction, and back again to the opposite, is carried successively through all, describmg by its extremity a circle, or the base of a cone, the apex of which is in the articulation above. Rotation, or rolling, is very different from this. In circumduction the bone is moved from its prior situation to a more distant one; in rotation it remains in the same place, it turns only on its axis, as may be observed in simply rolling the arm.

From this cursory review of the external characters of the bones of the extremities, of their modes of connection and motions, we proceed to the detailed description of each. It will be necessary to premise, that in our terms of position and aspect, we shall always suppose the body erect, the arms depending, and the hands supine, so that the little finger is in contact, or at least next to the external side of the thigh. In this situation we shall foppose a vertical plane dividing the body into two halves, from before backward. With a clear impression of this idea we shall find no difficulty or confusion in the terms anterior and posterior, superior and inferior, external and internal, as applied to the different aspects or surfaces of bones; by the latter, internal, we always mean the surface next the imaginary middle plane above-mentioned. These arbitrary terms, though applicable only to one determined position of the body, are yet necessary to give tolerable precision to anatomical description; when by their assistance we have made ourselves familiar with the objects they are designed to illustrate, they may be disinterestedly as easily as they have been adopted; our ideas of the relative situation of parts will be distinct, and may be applied readily to every possible variety of posture. In order to obviate all ambiguity, we shall introduce also the nomenclature of Chauffier, as conveying exact and precise notions of the relations of opposite bones to each other. The terms are generally simple, and always petitionable as applied to the present subject.

The upper extremity is divided into four parts; the shoulder, the arm, the fore-arm, and the hand, each of which will be separately considered.

The shoulder is the division of the upper extremity attached immediately to the superior and lateral parts of the trunk; it is formed by two bones, one broad, placed vertically behind, called the scapula, or shoulder blade, the other long, situated horizontally before, called the clavicle, or collar bone. The disposition of these bones gives the broad form and character to the upper part of the chest, which is in itself very considerably contracted at this part, its apparent breadth and magnitude being derived from the lateral apposition of the shoulders. Generally, also, there is a proportion between these and the dimensions of the chest; they are large, and strongly developed, when the latter is well formed; contracted and narrow when it is small or badly shaped. The height of the shoulder depends on the situation of the scapula; it is lower proportionately in the female, and in males of a feeble body, than in individuals of the opposite character. In the latter case, though the bones form the outline, it is the brawny muscles which fill it up, constituting, by their well-defined and masy forms, the distingullishing character of the sex in man, and other animals.

The scapula, shoulder blade, or omoplate, is a bone of an irregularly triangular figure, seated on the upper and back part of the trunk. It is connected by muscles to the head, the vertebra, and the ribs, by articulation to the clavicle and humerus. The scapula has such a latitude of motion as to make it difficult to align precisely its situation on the trunk. But when the arm is at rest, it covers the space between the first and eighth ribs, with its base or posterior margin at a small distance from the vertebral column, to which it approaches nearer above than it does below. At this line the scapula lies pretty close on the ribs; forwards, we find it receding considerably from the opposite surface of the trunk, in which situation it is constantly preserved by its connection with the clavicle.

For convenience of description, we divide the scapula into two surfaces, the dorso or exterior, and the costal or interior; into three margins or colles, the superior, the posterior, or base, and the inferior, or external cöllis. The rounded points at which these edges meet are usually called angles, and are named, from their several situations, the superior, the inferior, and the anterior angles of the scapula.

The dorso surface, the dorso, or back of the scapula, is divided into two very unequal portions by a strong and solid process of bone projecting from it transversely, called the spine of the scapula. It commences at the posterior margin, about one-fourth part of the whole length below the superior angle, increases gradually in depth as it advances.
EXTREMITIES.

Vances obliquely forward towards the anterior angle, beyond which it projects in the form of a broad, flat process, called the acromion. The spine is connected with the whole breadth of the dorsum, with the exception of that portion of it called the neck; its anterior edge is smooth, rounded, and concave, and is gradually loft in the under surface of the arch of the acromion. The posterior, or projecting ridge of the spine, is broad and flattened, varying however in breadth in different parts. At its commencement is a smooth, triangular, flat, upon which passes a part of the tendon of the trapezius. Further on it is rough, the upper margin of the crista giving attachment to this muscle, the lower to the posterior half of the deltoit. The acromion is flattened in a direction contrary to that of the spine of which it is a continuation, is of considerable breadth, rough and somewhat convex above, concave and smooth below. On the internal edge, which is continuous with the superior crista of the spine, is a smooth oval surface for articulation with the clavicle. The external edge is rough and irregular, giving attachment to the middle part of the deltoid. The summit of the acromion is rounded, and marked by the attachment of a ligament which connects it with the coracoid process. Towards the anterior part of the basis of the spine, near the neck, we observe holes for the admission of the nutrient vessels. The upper surface of the spine is hollow, forming a portion of the supraspi- nal fossa, the name given to that portion of the dorsum situated above the spine, and which gives lodgment to the supraspinatus muscle. The lower surface is also concave, though irregularly so, and contributes to the formation of the infraspinous fossa, the part of the dorsum lying below the spine, which is occupied by the infraspinatus muscle; the latter portion scarcely defers the name of fossa, being concave in its centre. Towards the inferior part of the dorsum the surface is a ridge running in the direction of the inferior border, for nearly the whole length of its attachment to an aponeurosis, which separates the infraspinatus from the teres major, and teres minor. Towards the inferior angle this ridge is met at a very acute angle by another, originating in the inferior colia. The latter forms the line of division between the two last mentioned muscles, the upper and smaller part giving attachment to the teres minor, the lower and broader to the teres major.

The under or costal surface of the scapula is concave, marked by several converging ridges running from the base towards the anterior angle. They give attachment to the aponeurotic division of the sub-scapularis, its fleshy bundles lying in the intervening hollow depressions. Towards the superior and inferior angles we mark some projecting points, which give attachment to the serratus major anticus, as also more conspicuous evidently a riling line between, designed for the fame purpose.

The superior margin, or colia of the scapula, is the shortest of the three borders. It is this towards the superior angle, because as we trace it forwards to its termination in a strong curved process, called, from its simi- larity to a crow's beak, the coracoid process. At the root of this process we observe a deep notch, crossed by a liga- ment, so to form a circular hole; in many instances the circle is completed by bone. It gives passage to the supra- spinacular nerve, and usually to a branch of the supra-scapu- lary artery and veins. Just behind this notch the omohyoid muscle has its origin. The coracoid process is rather flattened, convex and rough above, where it gives attachment to ligaments connecting it with the under surface of the clavicle, concave and smooth below. Its internal edge gives attachment to the pectoralis minor, its exter- nal to a strong ligament, crossing from it to the acromion, its summit to the united heads of the biceps, and the coraco-brachialis.

The base of the scapula is the longest of the three mar- gins, offering a waving line with an obtuse projection in it, opposite the commencement of the spine; to this, and to the margin below it, the rhomboidal are attached. From its junction with the superior colia refits the superior angle, to which the levator scapulae is partly attached.

The inferior colia is much broader than the other, di- viding at its anterior part into two projecting lines, with a hollow between them. Towards the inferior angle, where it joins the base, the edge is thinner, and convex, giving attachment to the teres major, and occasionally to some fibres of the latissimus dorsi. The outer of the prominent lines gives origin above to the long head of the triceps; below to the teres minor. The inner line, and intervening hollow, is occupied by the sub-scapularis. The inferior colia terminates above, at the anterior angle, towards the coracoid process, in an ovate, slightly hollowed surface, called the glenoid cavity. This surface is at right angles with the plane of the bone, its long diameter perpendicular, and its broader part below. It is covered by cartilage, the edges raised a little by a fibrous ring, which adds some- what to its depth. At the upper end of the brim is at- tached the long head of the biceps. The glenoid cavity is articulated with the head of the humerus; it stands off a little from the body of the bone, supported by a short pro- cies, more contracted than the brim of the cavity, called the neck of the scapula. This narrowing is more particularly observable on the back, under the spine.

The scapula is, in its structure, compact; thin and diapha- nous every where but at its edges and procieses, where the bone is thick and cellular. Its ossification commences at an early period in the fetus, and advances considerably before the latter period, however, the acromion, the coracoid process, and the base, fill exist in the state of car- tilaginous epiphyses.

The clavicle, or collar bone, is placed nearly transverse at the superior and anterior part of the chest, between it and the top of the shoulder. In figure it somewhat re- sembles the italic /; the two thirds next the sternum being of an irregularly cylindrical, or nearly prismatic form, and gently convex anteriorly; the third next the scapula flat- tened horizontally, broad, and with a more considerable convexity directed backwards. It is more slender, and less curved in the female than in the male.

The extremities of the bone are distinguished from their situation by the names of the external or pectoral, and the fcapular, or humeral ends of the clavicle. The frit of these is triangular, presents an irregular articular surface of considerable extent for connection with the sternum; its plane is nearly at right angles to the body of the bone. The fcapular extremity presents also a flat, arterial sur- face, oblong horizontally, accommodated to the opposite one in the acromion. The upper surface is rounded towards the sternum, where the ftermen-clavicular is attached, smooth in its middle portion, flat and broader next the fca- pula. The under side, to which these characters are equally applicable, is marked near the sternal end, by a roughened surface, for the attachment of a ligament connecting the clavicle to the first rib. Towards the middle is a con- siderable longitudinal hollow for the lodgment of the sub- clavicular muscle. Near the fcapular end the face of the bone is unequal, with a rough eminence in it for the infection of ligaments which bind to the coracoid process of the fcapula. Towards the fternum the anterior edge is broad,
EXTREMITIES.

and bends gently forwards, for about one-half of its length, where it gives origin to a portion of the pectoralis major; it then becomes thinner, slopes backwards, and terminates by suddenly turning forwards again towards its junction with the acromion. It gives attachment to the anterior half of the deltoid. The curvatures of the posterior edge are the inverse of the preceding. The bone is rounded, smooth and concave for the two-thirds next the sternum; unequal and convex, towards the scapula, where the trapezius is attached.

The clavicle is in structure like the other long-bones; the medullary cavity is very confined. At the time of birth its form is already strongly marked, and its ossification nearly complete.

The articular surfaces of the shoulder. — The scapula is connected with the trunk by a great number of fibres, which partly support it, and allow of all the various motions of which it is capable. It is closely bound also to the clavicle, which latter bone is immediately articulated with the sternum. We have here only to examine the two last connections, beginning with that between the clavicle and sternum, as forming the union between the shoulder and the trunk.

The sternum end of the clavicle is covered by a cartilaginous crust of considerable thickness, presenting an irregular convex surface. At the upper part of the sternum is an articular cavity, slightly hollowed, of less extent than the opposite articular surface of the clavicle, so that the latter rides considerably above it; a circumstance particularly striking in lean persons.

The ligaments which connect these surfaces are four, an anterior and a posterior, an inter-clavicular, and a costo-clavicular ligament. To complete the joint, we find also an inter-articular cartilage, dividing it into two separable cavities, and a distinct capsular membrane lying each of these.

The anterior ligament covers the front of the joint, lying between the scapula and the sternohyoides without, and the capsule immediately within. It is composed of fibres, which descend obliquely from the upper and anterior edge of the clavicle, diverging as they proceed to be fixed into the upper edge of the articular cavity in the sternum. These ligamentous fibres leave several intervals between them, which are occupied by cellular tissue and vessels.

The posterior ligament is smaller and not so strong as the anterior. It separates the sternohyoides and sternothyoides from the clavicles to which it firmly adheres. It extends from the posterior edge of the clavicle to the opposite part of the sternum. The fibres descend a little in their passage, diverging as they approach the latter bone.

The inter-clavicular ligament is placed between the two clavicles, immediately above the hollow at the upper edge of the sternum, with the integuments only in front, and the sternohyoides and sternothyoides behind. It is attached to the upper edge of the clavicular extremity of each clavicle, the fibres crossing in a flattened form from one to the other, and longer than above. They are separated by intervals filled with cellular tissue.

The costo-clavicular, or rhomboid ligament, passes obliquely upward from the cartilage of the first rib to the internal edge of the under surface of the clavicle, close to its sternum end. It is flat and short, the fibres becoming longer as they recede from the sternum. In front of it lies the subclavian muscle, and immediately behind it the subclavian vein. It has no immediate connection with the articulation, but serves to strengthen it and regulate its motions.

Between the clavicle and sternum we find an intermediate round, flattened piece of fibro-cartilage, its surfaces accom-
EXTREMITIES.

for a similar reason, *trapezoids*. Though scarcely distinct in their origin, they differ so much in figure, and in the direction of their fibres, that we shall consider them as separate ligaments. The posterior ligamentum *scapulo-commune* condones is attached below, from the summit of the cone, to the root of the coracoid processes; above, to the rough tubercle situated on the under side of the humeral end of the clavicle. It is composed of short thick fibres, radiating as they ascend, parallel to, and continuous with those of the anterior ligament, as they approach nearer the acromion. Below, its fibres are often united with those forming the ligament crossing the notch of the *scapula*. The anterior ligament, ligamentum *commune* *trapezoides*, crooks obliquely from the coracoid processes to the clavicle, as a broad flattened band, exceeding the preceding in length. It is fixed below to the posterior part of the upper surface of the coracoid processes, above, to an oblique line proceeding from the tubercle towards the end of the clavicle. The anterior fibres are longer than the posterior; the latter, at the union with the fibres of the posterior ligament, form an angle pointing towards the acromion, and leaving in front an angular cavity which is filled by fat. These ligaments are covered by the subcutaneous in front, by the trapezius behind, leaving an interval of an inch or more towards the *scapula*-clavicular articulation.

The *scapula* has two other ligaments proper to itself, which we shall describe here, although they have no immediate relation with the articulation of the clavicle and *scapula*. One closes the notch in the last-named bone, the other is extended between the coracoid processes and the *scapula*. The first, consisting of a flat, compact band of fibrous shining fibres, crooks from the posterior angle of the notch to the base of the coracoid processes, converting it into an angle, through which the *supra*-capituleary nerve, and frequently also the *scapular* vessels pass.

The ligament placed between the coracoid processes and the acromion is of a triangular form, of considerable surface, thin, and flattened. Its base is attached along the external edge of the coracoid processes, from which it proceeds in two distinct bands, separated by cellular tissue, and converging as they approach in the acromion, into one common fibre. The posterior fibres pass obliquely outwards; the interval between them is crossed by some scattered slips of ligament. Its upper surface is covered by the deltoid and clavicle, its lower side in contact with the *supra-spinatus*. Its anterior edge is not defined, but continuous with a thick and dense layer of cellular membrane, lying between the deltoid and the tendons of the *infra* and *supra-spinatus*. This ligament completes the arch formed by the coracoid processes and acromion over the shoulder-joint.

The mechanism and motions of the shoulder.—The *scapula*, by its muscular connection with the trunk, is capable of powerful and varied motion; the clavicle, on the contrary, can only follow the impulse communicated by the *scapula*, whose motions it regulates and limits under certain circumstances. The *scapula* forms the essential part of the shoulder, the clavicle can be considered only as accessory in man, and some animals who use their anterior extremities for other purposes besides progression. The *scapula* may in some warfare be considered as defending that part of the trunk over which it moves; but its more evident use is to serve as the base of all the motions of the arm, which at the same time it increases most extensively. In this respect it differs from the hip, which is in itself motionless, although affording a point from which the thigh directs all its movements. We shall recur to this difference hereafter; in this place it will be sufficient to notice, that notwithstanding the apparent want of firmness in the shoulde, it is enabled, by means of its numerous and powerful muscles, to offer a solid resistance to the impulse communicated from the arm in any of the violent actions of the upper extremity. The *scapula* plainly accompanies the motions of the arm, forwards and backwards, but in the simple elevation upwards, and in depression of that bone, its movement is scarcely observable. In the former cases it rotates on an imaginary axis, perpendicular to its plane, placed somewhat about the middle of the bone.

In the instance where the arm pales forward from the flat of adduction, the superior angle of the *scapula* is lowered a little, and approaches the vertebral column, whilst the inferior recedes from it, and is at the same time somewhat elevated. Where the arm is carried backwards the converse of this occurs. In these rolling motions the clavicle is concerned but little if at all; the *scapula* turning on it at the joint which unites them, the articular surfaces gliding on each other, and the ligaments above and below becoming alternately stretched or relaxed, as the motions are successively continued. They, however, are not capable of fulfilling alone any violent effort tending to displace the bones in this rotary motion; it is the strong ligaments crossing from the coracoid processes to the tubercle of the clavicle which, by their alternate tension, secure their relations under these circumstances. This articulation is further defended from injury by the mobility of both bones, which would recede before any violent shock.

The clavicle acts as a prop, preventing the shoulder and arm from falling forwards and approaching the breast, either by their weight or by the action of the muscles which move them. It is partly preferred in its situation by muscles which are fixed to it above. Its existence is necessary for many of the motions of the upper extremity, particularly those in which it is carried forward; it favours also the circumference of the arm, by keeping it at a distance from the trunk, and allows the whole limb to describe areas of a sphere, the centre of which is found at its infernal end. We find consequently that animals without clavicles enjoy these motions but imperfectly, in many instances in no degree. Their employment in the case of fractured clavicle is another proof of the utility of the latter in directing the actions of the shoulder.

The combined motions of the *scapula* and clavicle are those of depression, elevation, those in which the shoulder is carried forward, or backward, and the combination of these or circumduction.

When we raise the *shoulde*, the *scapula* pales during its elevation a little obliquely forward. The inferior angle advances, whilst the upper edge or costa recedes from the trunk. The *femoral* end of the clavicle is necessarily also raised, so as to increase the space between it and the first rib, and to diminish somewhat the angle it forms with the acromion, its infernal end pressing more and more on the articular cavity in the *sternum*; the *rhomboid* ligament is stretched, limiting the elevation, and the inter-clavicular ligament relaxed.

In depressing the shoulder the exact inverse of these effects is produced, and requires not therefore a minute detail. We shall observe only that the lower surface of the clavicle must be brought so near to the first rib, as to compress the intervening vessels very considerably, and produce a painful swelling of the arm. The depression is much limited by this contiguity of the rib, which lies pretty close to the clavicle in the most common and easy position of the shoulder.

When the *scapula* advances forwards its anterior angle recedes from the trunk, being kept off by the clavicle, the base at the same time approaching nearer the breast. The clavicle becomes more distant from the first rib in the horizontal
horizontal direction, the inter-clavicular, and the posterior ligaments are rendered tense, the clavicular end pressing inwards and backwards. In this situation luxations have occurred, but the accident is rare, as the shoulder is seldom exposed to any violence under these circumstances, that by its direction would probably effect it.

In carrying the shoulder backward, the anterior angle of the scapula is brought nearer to the chest, and the base approaches the spine. As the scapula has a considerable extent of motion in this direction, and is accompanied by the clavicular end of the clavicle, it will readily be conceived, that if the movement is sudden and violent, the clavicular end will divert its anterior ligament, may rupture it; and become luxated forwards on the sternum. In fact this is the most common mode of displacement.

The shoulder may be moved in any of the intermediate directions to those we have described; and in all we are to consider it as a lever composed of two parts, one horizontal, the other vertical, the clavicular end of the clavicle being the resting point, or the centre of the movements of the lever. The continued succession of all these motions produces the circumduction of the shoulder, a motion in which the clavicle describes a cone, the summit of which will be at its clavicular ligament, and the base traced by its scapular extremity. We are not to confound this motion of the shoulder with that of rotation, described above.

The direction of the shoulder is subject to variations from the slightest motion; in general it is so inclined that the glenoid cavity points outwards, proving most evidently, if any argument were wanting, that the upper extremities are not designed to support the body in the attitude of a quadruped. In fact, in that position, the head of the arm bone would press, not against the glenoid cavity, but on the capsular ligament which surrounds it, and which is utterly incapable of being rendered the effort.

The Arm.—The humerus, the only bone in the arm, is the largest and strongest of those of the upper extremity, and is placed between the shoulder and the forearm. It is nearly straight, bending gently forwards below, "tangam ad melioris amplixem," says Albinus. Of an irregular prismatic form, somewhat rounded at its upper and middle portions, flattened and gradually widening below, so as to be broadest at its lower end where it supports the forearm. It has the appearance of having been twisted in the middle, as if at an early period the upper end had been carried round forcibly outwards, and the lower end in the opposite direction. We divide it into two extremities, a superior or scapular, and an inferior or cubital; and into a middle portion or body.

At the upper end, the most bulky part of the bone, are three eminences; the head, and the great and small tubercle of the humerus. The head of the humerus is rounded, forming nearly the half of a sphere, smooth, covered by cartilage, articulated with the glenoid cavity of the scapula. It stands on a very short process, somewhat more constricted than the articular circumference, called improperly, perhaps, the neck of the humerus. The head and neck are directed obliquely upwards, so that a line drawn in their axes would form an acute angle with the body of the bone; they are also inclined backwards with respect to the plane of the condyles at the lower extremity. From this oblique position of the head with regard to the body of the humerus, the neck is longer, and the contraction more strongly marked below than it is above, where we remark only a shallow groove dividing the head from the tubercles.

The great tubercle is placed externally, opposite to the head. It is rough, broad, and flattened; marked by three distinct surfaces for the attachment of tendons. One, anterior, for the tendon of the supra-spinatus muscle; a middle spot, for that of the infra-spinatus, and one below for the teres minor. The little tubercle, placed in front of the bone, is rough, much smaller but more elevated than the last. It gives attachment to the sub-pecularis. Dividing the tubercles is a deep longitudinal groove, of which we shall speak below.

The body of the humerus, though of a very irregular form, is sufficiently marked for us to divide it into three differently inclined surfaces, and as many projecting lines between them. Owing to the twirled figure of the bone, these angular lines partake rather a spiral than a straight course.

The anterior ridge or spine commences at the inner edge of the great tubercle, and is continued through the middle of the bone to the lower end. It is rough in its upper half, giving attachment above to the pectoralis major, and lower down to a portion of the deltoid; below it is rounded and smooth, giving attachment to and covered by the bicipital ante-brachialis internus. The internal line descending from the small tubercle, gives attachment above to the latissimus dorso, and lower down to the coraco-brachialis and triceps. Towards the anti-brachial extremity it becomes much more prominent, affording attachment to a strong inter-muscular aponeurosis. The external edge begins at the under side of the neck, running obliquely forwards as it descends. It is but faintly marked above where it gives attachment to a portion of the triceps; is interrupted towards the middle, leaving a smooth flat surface, over which the radial nerve and accompanying vessels turn; below it rises again into a slight prominence, and is sometimes ridged, which gives attachment to an inter-muscular ligament, connecting the muscles belonging to the fore-arm. In the internal surface, bounded by the anterior and inner lines, we observe above the bicipital groove, continued between the tubercles and the spine, proceeding from them for some way down the bone, increasing in breadth, and gradually becoming obliterated. It is lined by cartilage, and provided with a synovial membrane, where it lodges the tendon of the long head of the biceps. Towards the lower end of the groove, at its outer side, is a rough line for the insertion of the tendon of the teres major. About the middle of the internal surface the coraco-brachialis has an attachment, and below this the brachialis internus. The external face is larger than the preceding; covered above by the deltoid, strongly marked by a rough prominence intersecting it obliquely for the insertion of this muscle. Immediately below this ridge is a broad shallow oblique depression, along which the radial nerve and some vessels pass. Towards the lower extremity the bone is slightly concave, and gives attachment to the brachialis internus. The posterior surface is smooth and rounded, altering its direction in a considerable degree as we trace it downwards; it gives origin to and is covered by the triceps.

The lower, or anti-brachial extremity of the humerus, is broad and flattened transversely, and advances a little forwards from the axis of the body of bone. In the middle is an articular surface for connection with the forearm, and on either side a projecting point, called tuberosity, or condyle. Of these the internal (polier of Albinus) is the most projecting. It is somewhat flattened, continuous above with the internal spine, marked irregularly below by the attachments of muscles, and the internal lateral ligament of the elbow joint. The external condyle (prior Albinus) is much less prominent, and gives attachment to the external lateral ligament, as well as to several muscles which lie on the radial and dorsal sides of the forearm.
EXTREMITIES.

The articular surface, placed between these two points, descends a little way beyond them. It is marked by several eminences and hollows. Next to the external condyle is a rounded eminence (capitulum of Albinus) adapted to the hollow in the head of the radius, and at its inner side is a groove for the internal projecting edge of that hollow. The remaining division forms the pulley or trochlea (rotula of Albinus) for articulation with the ulna. We observe two prominent eminences and a depression between them. The edge next the radius is not so prominent in front as behind, neither does it rise so high as the edge next the internal condyle, which descends a considerable way below the rest of the articular surface, sloping gradually into the hollow of the pulley on one side, and terminating abruptly by an acute margin on the other. The hollowed part, forming nearly three-fourths of a circle in extent from before backwards, is much broader behind, directed from thence obliquely inwards as we follow it to the front of the bone. Above the middle of the pulley, at its back part, is a deep cavity, oblong transversely, which receives the olecranon, or extremity of the ulna, during the extension of the fore-arm. Opposite to this, at the termination of the pulley in front, is a smaller hollow for the reception of the coronoid processes of the ulna, when the fore-arm is bent. Between these corresponding hollows there remains but a thin plate of bone, in many instances diaphanous.

The humerus refenes in structure the other long bones. Its ossification commences at three points; at the middle and at each end. At the time of birth the scapular extremity of the humerus is entirely cartilaginous, and of greater proportionate bulk. At the lower extremity the capitulum is much larger in comparison with the trochlea than in the adult bone.

The articulation of the humerus with the scapula, forming the shoulder joint.—The head of the humerus is covered by a layer of cartilage, much thicker in the middle than at the circumference. The glenoid cavity of the scapula is lined by cartilage, thinner in the middle than round its edges. The margin of the cavity is further provided with a fibrous elevated border, proceeding above from the tendon of biceps which gives off a bundle on either side; below, from the circumference of the articular cavity. Over the joint is the bridge formed by the acromion, the coracoid process, and the ligament stretched across between them. The head of the humerus moves on the glenoid cavity; but from the small relative size of the latter, the surface of the head of the humerus in contact with it forms but a small part of its articular superficies, the remainder of which is thus out of the cavity, and corresponds to the capsular ligament.

The capsular or orbicular ligament encloses the whole of the joint in the form of an oblong bag, constricting a little at each extremity. The upper edge is fixed round the glenoid cavity of the scapula, beyond the fibrous ring we have just mentioned. In some instances there is an interval left on the inner side, which is then supplied by the tendon of the sub-scapularis. The lower edge is attached round the neck of the humerus; close to the margin of the articular cartilage above, at a greater distance from it below. The attachment is interrupted between the two tubercles, the ligament crossing from one to the other over the bicipital groove. The deficiency occasionally observed on the inner side is supplied as above by the tendon of the sub-scapularis, which may be seen from within the joint covered only by the reflected synovial membrane. The capsular ligament is remarkable for its length, which allows the articular surfaces of the two bones to be separated from each other, by the distance of an inch, on the admission of air into the cavity. It is covered above by a dense ligamentous band passing from the outer edge of the coracooid process, to the anterior part of the larger tubercle, where it unites with the tendon of the supra-scapularis; and so closely joined to the under surface of the capsular ligament, that, for its attachment to the coracoid process, it would be difficult to make any distinction between them. It is this accessory hand which makes the capsular ligament thicker above than in any other part. The shoulder joint is further strengthened by the tendons of the supra-scapularis, infra-scapularis, teres minor, and sub-scapularis, which surround it, and which are firmly united to different parts of the capsular ligament. The latter is in contact also with the deltoid above, and the origin of the long head of the triceps below. It is formed by fibres running in various directions, and crossing each other, is thickest where covered by the infra-scapularis, and teres minor, stronger on the inner and outer sides; apparently insufficient to secure the firmness of the articulation, if not supported by the mufcles proceeding from the scapula. The synovial membrane is spread over its internal surface, and reflected over the articular cartilages. At the edge of the bicipital groove a process goes from it, which descends along the groove, lining it for the space of about an inch. It is then reflected on all sides over the tendon of the long head of the biceps, and continues to give it a covering in its passage through the joint to its attachment above the glenoid cavity. By the reflection of the sheath below, the escape of synovia is prevented, and the tendon may still be said to be exterior to the cavity of the joint.

The mechanism of the shoulder joint as to mobility and resist-ance.—Although motion be the principal office of the upper extremity, there are many accidental circumstances in which firmness of opposition is as necessary as in the lower, and the means nearly as complete.

The motions of the arm are very extensive, generally combined in different degrees with those of the shoulder. Indeed so great is its mobility, that it escapes on that account many injuries it would otherwise be liable to, from the looseness of its articulation with the shoulder. Add to this that the point of support, the glenoid cavity of the scapula, is in itself so moveable, as further to modify and lessen the effects of external impulses. We have before observed that the scapula more particularly accompanies the arm in its motions backwards and forwards, left and in its elevation outward and depression; the clavicle necessarily partsake of the movement, and from this disposition two advantages are derived that the circuit of motion is enlarged, whilst tendency to displacement is diminished by the distribution of the effor over three points instead of one. The arm, and consequently the whole limb, may be elevated, depressed, carried forward, backward, and in all the intermediate directions; it may be rolled also on its axis in any of these conditions.

When the arm is raised, the head of the humerus glides from above downwards in the glenoid cavity, in former measure abundant in, and rests against the lower side of the capsular ligament, which it detains more or less according as the scapula has accompanied it in its movement. If the arm be elevated outwards or abducted, it cannot be much assisted by the scapula; the great tubercle is buried under the arch formed by the acromion, the coracoide process, and the ligament between them, and in this situation the capsule is particularly stretched, is liable to be torn, and the arm luxated downwards. When the arm is thus raised above the horizontal line, at a distance from the trunk, the weight of the body brought to bear with force on the head of the bone, as in the case of falling, tends to pre-
under the skin; concave before, where it forms the upper part of the great sigmoid cavity. The sigmoid procês

The ulna, the largest of the two, is on the inner side.

Irregular in shape, strong, and longer above, lessening gradually in size to its lower end. We divide it into two extremities, an upper or humeral, a lower or carpal; and into a middle portion or body.

The humeral extremity comprises two strongly marked eminences, the olecranon and coronoid processes, and two humated cavities, the largest articulated with the pulley in the lower end of the humerus, the lesser with the head of the radius. The olecranon projects beyond the coronoid processes in a line with the body of the bone; it is strong, somewhat curved, rough above, where it affords attachment to the triceps; smooth behind, where it lies immediately

The ulna is formed from three points of ossification, as the
The radius is situated on the outer side of the fore-arm. It is shorter than the ulna; smaller above than below, and sharply curved in the middle. The upper or humeral extremity, called also the head of the radius, presents a circular articular surface; slightly hollowed in the middle, corresponding to the rounded eminence on the cubital end of the humerus. The smooth articular surface is continued a short way down the bone, and is broadest on the inflex, where it lies in the lateral figid cavity. This division is supported by a narrower portion of bone, cylindrical, and of an inch in length, called the neck of the radius. Immediately below, on the inner side, is an oval protuberance, smooth on its anterior half, over which the tendon of the biceps, separated from it by a bursa mucosa; rough posteriorly, where this tendon is inserted.

The body of the radius is of an irregular prismatic form, which makes a natural division of it into three faces, and as many angular lines. The anterior edge is more prominent above than below. The upper part gives attachment to the long flexor of the thumb, to the flexor sublimis, and to the supinator brevis; its lower to the pronator quadratus. The internal edge or spine, acute in the middle, rounded at each end, gives attachment to the interosseous ligament. The posterior, prominent also in the middle, and disappearing insensibly above and below, gives no muscular attachments. The anterior surface is concave above, where it gives origin to the flexor longus pollicis, a little convex below, where the pronator quadratus is fixed. About its middle is the hole for the nutrient vessels of the bone. The posterior surface, like the former, becomes gradually in breadth from above downwards, is irregular, gives attachment above to the supinator brevis, and lower down to the extensors of the thumb; its inferior part, covered by the extensor communis, the extensor tertii internodii pollicis, and the indicat- or. The external surface is convex throughout. Its upper third gives attachment to the supinator brevis; about its middle is a rough eminence, into which the pronator teres is implanted; below it is covered by the radial extensors of the carpus.

The carpal extremity is larger than the superior, irregularly quadrilateral, the longest side anter.] We observe in it an articular cavity, oblique, slightly hollowed, crossed by a riving line from before backwards, adapted to two of the bones of the carpus; the outer division to the scaphoid, the internal to the semi-lunar. The anterior edge of the cavity is rough; the for the ligaments. The posterior offers two grooves; the internal, broad and superficial, gives passage to the extensor communis and indicator, the outer, narrow and deeper, follows an oblique course from within outwards and downwards: through it pass the extensor tertii internodii pollicis. On the inner margin is a lunated articular surface, corresponding to the capitulum of the ulna. The outer side, divided from the posterior by a riving spine, is marked in a similar manner by two hollows. The anterior offers two grooves for the extensors prini and secundi internodii pollicis; the posterior is marked by the tendons of the radial extensors. At the sharp edge, between this side and the anterior, the supinator longus is implanted. The prominence between the hollows is continued downwards into a blunt process, passing beyond the articular surface, called the fydoid process of the radius. It gives attachment to the external lateral ligament of the wrist.

The elbow joint; the articulation of the ulna and radius with the humerus.—The lower end of the humerus presents an articular surface composed of alternate epineces and depressions, covered by a continued crust of smooth cartilage. The great figid cavity of the ulna is lined by cartilage, interrupted in the middle by a transverse contraction and groove; continued into the lateral figid cavity. The head of the radius is also covered by cartilage, continued over its circular margin for a short way down its cylinder. The humeral end of the ulna corresponds to the pulley, that of the radius to the capitulum at the lower extremity of the humerus. These surfaces are bound together by ligaments, and covered by a synovial membrane reflected from one to another.

The ligaments which more particularly secure the joint are called lateral, one being placed on its outer, the other on its inner side. The interval lateral ligament is fixed above to the internal condyle of the humerus. It radiates as if divided into two portions; the anterior is fixed to the inner side of the coronoid process of the ulna, the posterior, the small of the two, to the olecranon. The anterior division is covered by the tendon common to the muscles proceeding from the internal condyle, and is partially united to it. Immediately under the ligament is the capsular membrane. The external lateral ligament can with difficulty be distinguished from the common tendon of the muscles attached to the external condyle. It is fixed above to this condyle, below it is united to a large portion of the circle of the annular ligament of the radius. It is not so strong, so large, nor so clearly defined as the internal lateral ligament, its fibres diverge considerably, and are in contact with the synovial membrane. In addition to these ligaments we find scattered bands of fibres traversing in different directions, both before and behind the articulation; their irregularity scarcely admits of description. Between them and the synovial membrane lies some cellular tissue and fat. This synovial membrane is reflected from the humerus close at the margin of the articular cartilage, and is continued under the ligaments to the opposite surfaces of the ulna and radius, lining the figid cavities of the flexor, and spread over the head of the bone. It continues therefore to the articulations of the fore-arm with the arm, and of the bones of the fore-arm between themselves. This joint is strengthened also in a remarkable degree by the numerous muscles which are attached round it, and which cover it on every side.

The motions of the fore-arm on the arm—are confined to flexion and extension, the ulna executing the principal part, the radius necessarily following the same direction. In a state of complete flexion the coronoid process of the ulna and the prominent margin of the head of the radius are found corresponding to the opposite hollows in front of the humerus, the olecranon below the condyles, having moved a considerable distance from the internal one. At this time the lateral ligaments are relaxed; the posterior half of the trochlea of the humerus in contact with the capsular membrane, reflected from it to the olecranon, and protected by the triceps. Under these relations the joint is secure; displacement in any direction would be almost impossible, without some fracture of bone. In the intermediate states between flexion and extension the articulation has not the same appearance of security; but from the great mobility of the lower end of the humerus; from its receding easily
before every shock when the fore-arm is in such situation, we seldom meet with a dislocation of the latter under these circumstances. In the extension of the fore-arm on the arm, the radius and ulna glide backwards over the articular surface of the humerus, until stopped by the olecranon becoming locked in the cavity adapted for its reception in the latter bone. At this time the lateral ligaments are tightened as well as the capsule in front of the joint. It is in the state of complete extension that luxations most usually occur, the humerus passing downward in front of the bones of the fore-arm. This frequently happens in a violent fall on the hands. The whole weight of the body is carried forwards with considerable impetus on the arms which are stretched out to face the head from coming to the ground. In this case the fore-arm is fixed, and the humerus, following the impulsion of the body, ruptures the ligaments, and is thrust forwards, the olecranon opposing itself to all displacement backwards. It would appear also, that a dislocation might occur from lifting a heavy weight with the arm fully extended; but here the effort is voluntary, and the pain felt in the bend of the elbow is a sufficient warning to deflect. When the fore-arm is extended it forms an obtuse angle with the arm, and when bent it is not found in the same line with the humerus, but slants a little inwards towards the breast. Both these circumstances depend on the obliquity of the pulley at the lower end of the humerus. This direction of the fore-arm, and consequently in the hand in the state of flexion, is particularly obsequious in man, and necessarily requires the existence of a clavicle, without which the fore-arm, when bent, would be carried to the opposite shoulder. Thus in the different ranks of animals the existence of a clavicle, and the motion of pronation, are found generally connected with this obliquity in the flexion of the fore-arm. In the state of demiflexion we may observe a slight lateral motion of the fore-arm on the arm, which cannot take place in the latter state of complete flexion, or extension.

The articulations of the radius with the ulna.—These bones are in immediate contact at their humeral and carpal extremities. Between these points there is a vacancy occupied by a flat interosseous ligament. Above, the head of the radius is received into the lesser sigmoid cavity of the ulna; below, it offers a shallow articular surface, which revolves on the capitulum at the carpal end of that bone. First we shall examine the articulation at the humeral ends. It is lined by the synovial membrane common to it, and to the articulation of the fore-arm with the arm, and secured by a strong flat circular band of fibres, called the annular or orbicular ligament of the radius. This ligament forms three-fourths of a circle, which is completed by the lesser sigmoid cavity, and in which the head of the radius turns. It is about three lines in breadth, fixed before and behind to the ends of the lesser sigmoid cavity, fast infensibly above over the surface of the synovial capsule, to which it is firmly united, terminating by a more defined edge below. It is composed of parallel circular fibres, into which the external lateral ligament is fixed from above, as also some oblique fibres proceeding from the olecranon, the ligamentum adductor or Weitbrecht. This circular ligament is of a dense compact texture, frequently cartilaginous in advanced age. It lies immediately over the synovial membrane, but is no where connected in any degree with the radius. It is covered by muscles.

The space between the upper and lower articulations is filled by the intervention of ligamentous fibres, which further secure the relations between the radius and ulna. A portion of these has obtained the name of the oblique ligament, or chorda transversalis; the remainder is included under the general term of Interosseous ligament. The oblique ligament, a small and flat band of fibres, passes obliquely from the inner edge of the coronoid process below the lesser sigmoid cavity to be inserted into the radius at a point which lies just below its tubercle. In this course it accompanies the inner edge of the tendon of the biceps, its direction being opposite to the fibres of the interosseous ligament, and in a plane anterior to them. Between this ligament and the head of the radius there is left a triangular space filled by cellular tissue, in which the tubercle of that bone revolves. The interosseous ligament commences below the tubercle attached to the inner ridge or spine of the radius, from which the fibres pass obliquely downwards and inwards to be attached to the opposite spine of the ulna. It is composed of flat parallel fibres, leaving various intervals for the passage of vessels. It is covered on both its surfaces by the deep seated muscles of the fore-arm, to which it affords attachments. It is more delicate above, insensibly losing its sinuous appearance, and interrupted by a large vacuity, which gives passage to the posterior interosseous vessels; stronger below, where we find another opening for the passage of the anterior interosseous vessels. On the posterior surface of this ligament, and more especially at the upper end, we often find flat bands of fibres decussating it; they have been described under the name of the posterior transversal chord.

The inferior articulation between the radius and ulna, or that at the carpal ends of these bones, is provided with a synovial capsule, and a triangular fibro-cartilage interposed between the ulna and the bones of the carpus, and filling the vacancy observed between them in the skeleton.

This triangular cartilage is fixed by its base to the prominent edge which divides the articular cavity at the bottom of the radius, from that which receives the capitulum of the ulna. It is attached by its summit to the groove between the capitulum and the styloid processes. Its edges are united to the synovial membranes of both articulations, the radio-carpal and the radio-ulna. Its upper and lower surfaces are concave and smooth, the superior corresponding to the lower surface of the ulna. It is occasionally incomplete at the base, allowing of the contact of the two capular membranes just mentioned.

The capular membrane is loose, so as not to impede the extended rotation of the radius. It is continued from the upper surface of the inter-articular cartilage over the articular surfaces of the radius and ulna. It is sometimes covered here and there by a few scattered ligamentous fibres, which are in many instances feebly observable.

The motions of the bones of the fore-arm, between themselves and their powers of resistance.—We have hitherto considered the fore-arm only in its relation to the arm, in which the ulna was more essentially concerned; the movements in the present case depend chiefly, and almost exclusively, on the radius, and are necessarily communicated to the hand with which it is articulated below, the ulna concerning but little in the construction of the joint of the wrist. These bones are thus disposed with regard to importance in the joints of the elbow and wrist; above, the ulna plays the principal part, the radius being accessory only; whereas below, the ulna is of comparatively little importance, the radius of the greatest. Their form is accommodated to the different use of each: the ulna large above and small below; the radius of little volume at its upper extremity, broad and solid at its lower, where it supports the hand. This double opposition in the form of the bones is not only accommodated to their functions, but renders the solidity of the fore-arm nearly equal throughout.
The radius, however, from its more direct connection with the hand, more immediately furnishes any effort impressed on the latter, as in pushing violently, or falling, and is often fractured under such circumstances. Still the result of the general mechanism will be, that the same bone, not having to support the motions of the two joints, the elbow and wrist, motions which are often simultaneous, fractures and dislocations are the less likely to occur.

The radius may be rolled on the ulna inwards and outwards. In the former case, supposing the radius to be horizontal, the palm of the hand is turned downwards, and the motion called on that account pronation; in the latter it is turned upwards, and the motion called supination. In pronation, which is the commonest position, the humeral end of the radius turns on its axis in the loop formed for it by the lefser ligament cavity and the annular ligament, while the carpal extremity rolls over the lower end of the ulna, tracing an arc of a circle. In this state the relative situations of the bones are changed; the radius crossing the ulna, and diminishing the space between them. If pronation be carried forcibly too far, a dislocation may take place in either articulation; more readily in the lower, on account of the greater extent of motion, and less strength of restraining ligaments; in the upper, the radius does not quit its situation, and is secured by a very strong ligament, besides the powerful support of the muscles attached round it. In supination the radius moves in the contrary direction, until it becomes parallel to the ulna, beyond which it cannot go. If it is forced beyond these limits a dislocation of one of the articulations must ensue, most probably of the lower.

A great obstacle to luxations of this joint, either in pronation or supination, is found in the triangular fibro-cartilage at the lower end of the bones, which is very strong, and which must necessarily be torn.

Although at first sight one might be disposed to imagine the ulna an inmoveable fulcrum, round which the radius rolls, it is certain that in pronation the carpal end of the ulna paffes outwards, in supination in the contrary direction, so that it traces arcs of a circle in a contrary way to the carpal end of the radius. Of this any one will be effectually convinced by any observation or experiment. But as the ulna cannot roll on the lower end of the humerus it necessarily involves the latter bone in the execution of these motions, which it thus afflicts by its powers of rotation. Pronation and supination then depend not only on the rotation of the radius, but on the opposite motion of the ulna, and the rotation of the arm. The latter of these is very much more sensible if the motions take place when the forearm is extended on the arm, than when it is bent: in the former case, from the disposition of the bones and ligaments, any rotatory motion of the ulna is impossible, in the latter it may exist in a slight degree.

We have observed that the disposition of the bones of the forearm is such as to offer the best possible resistance to external efforts; nor is their position as to these motions less favorable, the head of the radius lying a little before the ulna, and the breadth of its carpal extremity removing its axis from the lower end of the ulna, so as to increase and facilitate the pronation and supination of the hand, offering at the same time a broad basis for its support.

The hand—forms the fourth and last division of the superior extremity; it is articulated with the lower end of the forearm. It varies considerably in size and form in different individuals: most commonly it is comparatively smaller in females. We distinguish in it two surfaces, a dorsal and a palmar; two edges, a radial and ulnar; and also an upper or anti-brachial, and a lower or digital end. It is composed of twenty-seven bones, which have been arranged under the different titles of carpus, metacarpus, and fingers.

The Carpus.—The carpus, or wrist, is oval transversely, convex on its dorsal, hollowed on its palmar surface, where it gives passage to the flexor tendons. This hollow is bounded laterally by four eminences resulting from different bones of the carpus, which give attachment to a strong ligament confining the tendons in their situation. It is convex at the edge next the fore-arm, offering a number of irregular articular surfaces at the border next the metacarpus. It is formed by two rows of small irregularly shaped bones, the upper range called anti-brachial, the lower metacarpal. Each of these rows is composed of four bones: the anti-brachial row, commencing from the radial edge, are the scaphoides, lunare, cuneiforme and pisiforme; in the metacarpal row the trapezium, trapezoides, magnum and unciforme. Although varying much in figure, they have common characters in common, which allow of our describing them with tolerable precision, without rendering confused or obscure our ideas of their mutual relations.

We distinguish in each bone six surfaces, or sides; an upper or anti-brachial, a lower or metacarpal, an anterior or palmar, a posterior or dorsal, an outer or radial, and an inner or ulnar.

The scaphoides, so called from a supposed resemblance to a boat, is the largest bone of the first row. It is somewhat oval in figure, the long axis being directed obliquely from above outwards and downwards. The upper surface is convex, triangular, articulated with the radius; the lower is also convex, corresponding to the opposite surfaces of the trapezium and trapezoides. The posterior narrow, and grooved by the insertion of ligaments; the anterior long and contractred, concave towards the fore-arm, convex and projecting below, forming one of the eminences before mentioned. The outer, or radial side, is rough for the attachment of the external lateral ligament of the wrist; the internal presenting a double articular surface, the upper narrow and convex, connected with the os lunare; the lower broad and concave, forming part of the articular cavity for the reception of the os magnum of the second row.

The lunare, or semi-lunare, has obtained its name from the figure of one of its articular surfaces, which resembles a crescent. It is not so elongated in form as the last bone; convex and triangular above when articulated with the radius; concave below, narrowell in its transverse diameter, articulated with the os magnum, and in a small degree with the unciforme; rough and unequal on the anterior and posterior surfaces for the attachment of ligaments, the anterior side the smallest; the outer face narrow, smooth, in the form of a crescent, with the convexity upwards in contact with the scaphoides; the inner also smooth, plane, articulated with the cuneiforme.

The os cuneiforme (triquetrum of Albinus) lies in volume between the preceding, oblong and somewhat pyramidal in shape, its base next the os lunare, its apex directed obliquely inwards and downwards. The upper surface is convex, articulated with the bottom of the ulna by the intervention of the triangular fibro-cartilage before mentioned; the lower oblique, concave, articulated with the unciforme; the anterior presents on its inner side a flat circular articular facet articulated with the pisiforme, on its outer it is rough for the attachment of ligaments; the posterior and internal are also unequal and rough for similar purposes; the external or radial surface is plane and smooth, articulated with the lunare.

The os pisiforme (labrum of Albinus) has obtained its
its name from its rounded figure. It is the smallest of the bones of the carpus. On its posterior surface we observe a slightly hollowed articular surface, where it rests on the flat described bone, “affident petellae in modum, ut fcemoides,” (Alb.) With this exception the bone is convex on all sides, projecting beyond the plane of the other carpal bones, rough, and unequal, giving attachment above to the flexor carpi ulnaris, below to the abductor of the little finger, and before to the annular ligament of the wrist. It encomples one of the four prominent points of the palmar side of the carpus.

The trapezium (multangulum major, Alb.) is the first bone on the radial side of the second range of carpal bones, and lies somewhat anterior to them. Above it offers a concave articular surface, semi-circular, opposed to the scaphoid; below another, convex antero-porteriorly, concave transversely, articulated with the metacarpal bone of the thumb; on the front rough, with a deep groove at the upper end for the passage of the flexor carpi radialis; the outer edge of the groove giving attachment to the annular or transverse ligament, and forming one of the eminences already mentioned; on the back and outer sides rough and unequal for attachment of ligaments; on the inner side are two articular surfaces; the upper, large and concave, connected with the trapezoides; the lower, narrow and plane, for the metacarpal bone of the fore-finger.

The trapezoïdes (multangulum minus, Alb.) is very irregularly placed like a wedge between the last and the following bones, the base of it being posterior, the point towards the palm. The upper surface is concave, quadrilateral, and articulated with the scaphoids; the lower divided by a convex line running from before backwards, adapted to the hollow of the metacarpal bone of the fore-finger; the dorsal or posterior, convex, rough and broad; the anterior poffering the former characters, but much smaller; the external, convex articulated with the trapezium; the internal or ulnar, smaller and concave, smooth anteriorly where articulated with the following bone, rough behind for ligamentous attachments.

The os magnum (capitatum, Alb.) is the largest of the eight; longest in its vertical axis, rounded into an articular head above, (from whence it derives its name,) of a quadrilateral form below. The upper articular surface is convex, divided by a prominent line into two portions, one for the scaphoids, the other for the lunare; the lower is divided into three facets, the external articulated with the second bone of the metacarpus, the middle the largest of the three, concave; supporting the third, the internal or posterior very small, plane, opposed to the inner edge of the fourth; the latter the largest of the two, the external narrow, articulated with the trapezoïdes; the internal of greater extent than any of the preceding, smooth above where contiguous to the unciforme, rough below, giving attachments to ligaments.

The unciforme (os hamatum; cuneiforme Alb.) completes the second row of carpal bones, being the last on the ulnar side. Above is a rounded angle opposed to the lunare; below a smooth surface, convex transversely, the outer surface supporting the fourth, the inner the fifth metacarpal bone; on the anterior side we observe, below, a curved process projecting forward, to which the annular ligament is attached, as also some muscles of the little finger; it forms the lbf of the four eminences referred to before; the inferior part of this surface is narrow, unequal, but smooth, giving attachment to ligaments; the posterior surface is broad, triangular, and rough; the external offers an articular surface above, in contact with the os magnum, is rough below for ligamentary connections; the internal is directed obliquely, presenting a curved, oblong, articular facet, and a rough line below it; the former opposed to the cuneiforme, the latter serving for attachments to ligaments.

The bones of the carpus resemble each other in structure; composed of a cellular or spongy substance, externally covered by a thin layer of compact bone. They are developed from single points of unfication, which do not commence till after birth. At that period they are entirely cartilaginous, distinct, well marked, and not at all proportionally larger when fully ossified, and on this account differing from the cartilaginous extremities of the long bones.

The articulation of the fore-arm with the carpus, or joint of the carpi.—The superior surfaces of the scaphoides, lunare, and cuneiforme, form by their union a common convex surface, oblong transversally; each bone is covered by its proper cartilage, firmly united to the next by an intervening band of a fibro-cartilaginous structure, which separates this joint from the articulations of the carpal bones between themselves. The lower extremity of the radius, and the triangular cartilage at the bottom of the ulna, form an elliptical concave surface, which receives the opposite convexity of the carpus, so that the scaphoides and lunare are opposed to the radius, and the cuneiforme to the inter-articular cartilage which separates it from the ulna. The joint is strengthened by ligaments on each side, and also before and behind, and lined by a synovial membrane.

The external lateral ligament is attached above to the styloid process of the radius; it advances forward a little as it descends, and is fixed on the outer side of the scaphoides. The fibres of which it is composed diverge below, and become continuous with the anterior ligament; we can often trace them on to the trapezium. Its form is irregular, and by no means defined, the edges being variously connected with the parts around it. The internal lateral ligament proceeds from the styloid process of the ulna, and is attached below to the inner side of the os cuneiforme. It is implanted also by some of its anterior fibres into the annular ligament, and pisiforme bone.

The anterior ligament is broad, and flat; fixed above to the anterior part of the styloid process of the radius, and the whole anterior edge of the articular cavity; from hence the fibres descend obliquely inwards, and are fixed below in an irregular line to the scaphoides, lunare, and cuneiforme; some fibres go to the pisiforme, the greatest number are attached to the lunare. The flexor tendons lie in front, the synovial membrane immediately behind it. The posterior ligament is not so broad as the preceding, and more evidently fibrous; its direction is nearly the same, being fixed above to the posterior border of the articular hollow of the radius, below the lunare, and cuneiforme; it is covered by the extensor tendons. These ligaments are in no wise connected with the ulna, so that they cannot in any situation impede the rotation of the radius on that bone. The synovial membrane is spread over the articular surfaces of the radius, and triangular cartilage above, and the three bones of the carpus below; it is reflected between them under the ligaments, appearing in the intervals between their fibres in several spots. The joint of the wrist is strengthened on every side by strong and numerous tendons, some of which are inserted in its vicinity, others closely bound to its surface by strong transverse ligaments as they pass from the forearm to the hand and fingers. The security derived from this construction must be very great, without it the joint would readily yield to the many violent impulses it has to
EXTREMITIES.

The motions of the carpus on the fore-arm—are those of flexion, extension, lateral inclinations or abduction, and adduction, and circumduction. From the close connection of the carpal bones between themselves, and with the rest of the hand, these motions of the carpus may be considered at the same time as general motions of the hand. Those of pronation and supination depend on the motions of the bones of the fore-arm, and are in no wise dependent on this joint.

In flexion the articular convexity of the carpus glides from before backwards in the corresponding cavity of the fore-arm, and the poltter ligament and extensor tendons are stretched; it may be carried to nearly a right angle without violence; an effort precluding beyond this point would strain, and might certainly dislocate the bones.

In extension an opposite succession of phenomena occurs, it is the anterior part of the joint which has the effort to sustain. This motion is not confined to the bringing the carpus and hand into the same straight line with the fore-arm, but may be continued in the opposite direction to some extent, so as to make them form a considerable angle with it on the dorsal aspect. The freedom of motion enjoyed by the carpus in this sense is subservient to many of the important uses of the hand, and is not to be found in other analogous joints, where the power of flexion is greater, and that of extension limited to bringing the opposite bones into the same axis, as in the elbow, knee, &c. The lateral motions, those of abduction and adduction, are more confined, especially the latter. The lateral ligaments are alternately stretched and relaxed, preventing their too great extent. Circumduction is also confined to narrow bounds, more particularly so when pronation and supination are not concerned in producing it.

The articulations between the carpal bones—all communicate together, being lined by a continuous synovial membrane. The bones lie in close apposition, and are bound firmly by ligaments on the palmar and dorsal surfaces, some by ligaments passing deeply between them. The three first bones of the upper row are in contact by nearly plane surfaces covered by cartilage, the scaphoid bone being connected with the lunare, the outer with the scrotiforme. The palmar ligaments uniting them lie deep under the anterior ligament of the wrist, the fibres of each passing transversely from bone to bone. The dorsal ligaments are more distinct, the fibres longer as they are more superficial, they have the same direction as the former. The superior, or interosseous ligaments, have been already mentioned in speaking of the joint of the wrist, as separating it from the articulations of the carpus. They are of close condened texture, passing between the bones from before backwards, one joining the scaphoid bone to the lunare, the other last bone to the scrotiforme. They are very narrow, the upper side smooth, covered by synovial membrane forming a polished surface with the convexity of these bones, with the edges of whose cartilages they are continuous. The os pisiforme is placed without the ranks of the carpal bones, and has no communication with the common joint between them. It rests by a slightly concave articular surface on a corresponding convexity of the scrotiforme; the joint is lined by a synovial membrane reflected from one to the other, strengthened by beamed ligamentous fibres. Two bands of these, of considerable size and strength, pass from the lower side of the bone, one to the root of the metacarpal bone of the little finger; the other to the os scrotiforme. The pisiform bone is retained in its situation by these, and, in some measure, also by the abductor muscle of the little finger, to which it gives attachment. Above we observe some ligamentous fibres passing from it to the ulna, and the insertion of the flexor carpi ulnaris. It performs the office of a patella, or ischial bone, for this latter muscle "poistum porrectumque inter eunjs tendinem, ligamentumque ad os metacarpi digitii auriculares pertinent." Its motions are very limited; it forms, together with its connections above and below, a large portion of the channel through which the flexor tendons glide.

To form the articulation between the first and second row we find the scaphoides touching the trapezium and trapezoides, forming, in conjunction with the lunare, a cavity for the reception of the head of the os magnum, and the scrotiforme bone supporting the unciforme. The respective articular surfaces are covered by a thin crust of cartilage, and preferred in their situations by palmar, dorsal, and lateral ligaments. The palmar ligaments are short and strong, formed by fibrous bands, passing from one row to the other in different directions; the most superficial are contoured with the anterior ligament of the wrist. The dorsal ligaments resemble them in their passing from the upper row to the lower, but are too irregular in size and direction to allow of specific descriptions. Indeed they are both mixed with the surrounding ligamentous fibres as scarcely to admit of distinction. Of the lateral ligaments, the external is the shortest and strongest, passing from the scaphoides to the trapezoides; the internal stretched between the scrotiforme and unciforme.

The bones of the second row are in contact by cartilaginous surfaces, and connected by ligaments, as those of the first. The dorsal tranverse ligaments, are very distinct, one between every two corresponding bones; the palmar are not so well defined, the fibres of each being shorter and more numerous, as they are more deeply seated. We can observe one band, passing from the trapezoides to the os magnum in front of the trapezoides, independent of those between the contiguous bones. Between the unciforme and os magnum is a strong collection of fibres passing from side to side through the depth of the carpus, adhering firmly to such parts of the corresponding bones as are not covered by cartilage. A similar connection exists also between the os magnum and unciforme.

The synovial membrane is continued from one articular facet to another, lining the ligaments we have described, appearing in many places between their fibres. Nor does it form a continued surface only between the carpal bones, it is extended below into the joints, between the carpus and metacarpus; not always, however, into those formed above by the os magnum and unciforme. Owing to this general communication, diffusel of one articular surface is presently propagated to the whole; in this respect it must be considered only as a single joint.

The pisiform bone is in no wise concerned in the mechanism of the carpus; its uses have been mentioned above. So closely are the bones of each row bound one to another, that they allow of scarcely any perceptible gliding motion. The articulations between the two rows allow of a more sensible movement; though this is confined to narrow limits; it resembles somewhat that observed in the joint of the wrist; they can be bent, and extended a little on each other, as well as inclined laterally; the drift of these is the most evident. The little motion they possess is produced principally by the articulation of the head of the os magnum, which has the greatest effort to sustain, and has been sometimes luxated backwards. Notwithstanding the obscurity of movement in the carpal bones, it co-operates in increasing the mobility of the hand, whilst at the same time, by the num-
number of articulating surfaces, impulses may be to a certain degree weakened.

Before we enter on the latter point, it will be proper to take some notice of another ligament, materially affecting the solidity of the carpus, though defined but in a secondary way for this purpose, its first office being to confine the flexor tendons in their passage to the fingers. The annular ligament in front of the wrist, (ligamentum armillare, ligamentum carpi proprium,) passes from the eminences formed by the pisiform and unciform bones to the opposite ones of the scaphoides and trapezium, completing the canal for the flexor tendons. It is composed of very strong and thick fibres, becoming gradually thinner above and below; rough superficially, lined behind by a synovial-bur. It gives attachment to several muscles of the thumb and little finger. The fibres are all transverse, numerous and compact, secur- ing, in addition to its other uses, the arch formed by the carpal bones. The carpus then derives its firmness from the large surface of the articulating facets in comparison with the smallness of the bones, from their number, from the numerous ligaments, and from the arched form resulting from the connection of the whole. It is further strengthened by numerous tendons, the flexors in front, the extensors on the back.

Another cause of the solidity of the carpus is, that the articulations between the two ranks are not in the same transverse line, the unciforme, and more especially the head of the os magnum, mounting far beyond the level of the trapezium and trapezoides, so that any impulse would not act on all at once, and cause a general displacement, the effort and the injury must be partial, confined to the articulations between one or two of the bones.

The metacarpus (die mittelhand, Germ.) - is composed of five bones, reposing on the carpus above, giving support to the thumb and four fingers below. They are strong, those supporting the fingers parallel to each other, the other a little anterior, and capable of altering its position. The intervals between them are filled by muscles so as to form a broad and solid body. The anterior face of the metacarpus is concave, constituting the palm of the hand, the posterior convex, and forms the back. The bones are distinguished from the connections below, into the metacarpal bones of the thumb, the fore, the middle, the ring, and the little fingers, or we class them numerically, begin- ning on the radial side with the metacarpal bone supporting the thumb. Of these divisions we shall adopt the latter. The first metacarpal is the largest, and shortest of the whole; the second and third are nearly of the same length; the fourth and fifth are successively shorter and smaller. They are all somewhat concave before, and flat behind, presenting several more or less acute angles; larger at each extremity, the upper angular and unequal, the lower forming a convex head, compressed laterally, with an articular surface terminating on the palmar side in two prominent points; smallest in the middle of the body of the bone, increasing gradually in size above and below. In considering the distinguishing characters of each metacarpal bone, we shall observe them as seen on the carpal extremities, the bodies, and the digital extremities of each suc- cessively, and not tire the reader by a separate description of the several bones, in which it would be impossible to avoid repetition, and which must necessarily be of greater length.

At the upper or carpal end of the first metacarpal bone, we observe an articular surface convex transversely, slightly concave in the opposite direction, opposed to the trapezium. It is surrounded by ligaments, and gives attachment on the outer side to the extensor off metacarpal pollicis.

In the second are three articular surfaces, the middle concave, corresponding to the prominence of the trapezoides; the external small and flat, articulated with the trapezium; the internal divided into two portions, the upper articulated with the os magnum, the lower with the following bone. The circumference of this extremity is rough, and gives attachment to ligaments. On the palmar side is a smooth spot, which gives attachment to the flexor carpi radialis; on the dorsal a tubercle, into which the exten- for carpi radialis longior is inserted.

In the third a quadrilateral articular surface opposite to the os magnum, bounded before and behind by inequalities, giving attachment to ligaments; on the outside by a smooth facet articulated with the preceding bone; on the inside by two small round articular surfaces, separated by a hollow con- tinuous to the following bone. At the external dorsal angle is a pyramidal eminence (proc. synovialis), and close on the inner side the insertion of the extensor carpi radialis bre- vior.

In the fourth, at the top, a double articular surface, ac- commodated to those of the os magnum and unciforme, surmounted before and behind by rough points for liga- mentous attachments, on the outside by two small ar- ticular surfaces, corresponding to those of the first bone; on the inside by a slightly concave surface articulated with the following.

In the fifth, a broad articular surface, convex from before backwards, concave transversely; flattening outwards and upwards, opposed to the unciforme, bounded before and behind by rough surfaces for ligaments, on the outside by a small articular facet connected with the base bone, on the inside by a tubercle which gives attachment to the tendon of the extensor carpi ulnaris.

The bodies of the metacarpal bones are all concave an- teriorly, and slightly convex on their dorsal surface. Although rather irregular in figure we can distinguish in them four sides, an anterior, a posterior, an internal, and external. In the first the palmar surface is broad; in the next we observe above a prominent line running lengthwise, which soon bifurcates, forming the lateral boundaries of a flat tri- angular surface, the breadth of which increases as it ap- proaches the digital extremity; in the last an angular line, running diagonally from the inner side of its carpal end to the outside of its lower extremity. In all of them the palmar surface is covered by the extensor tendons.

The anterior or palmar surface presents also a longitudi- nal rising line, generally more prominent towards the lower end. It separates the attachments of the interossei muscles, and has somewhat different directions in the several bones. In the first rounded, covered by the opponens, and flexor brevis pollicis; in the third giving attachment above to the latter muscle, below to the adductor pollicis. The lateral surfaces of these bones are broad, inclined obliquely in various directions, giving attachment to muscles. In the first they are compressed and rounded, the outer side giving attachment to the opponens, the inner to the first external interosseus (the abductor indicis of Albinius). In the last the inner or ulnar side gives attachment to the adductor of the metacarpi minimi digitii; the outer side, as well both sides of the other metacarpal bones, give attachment to and are covered by the external and internal interosseus muscles.

The digital extremities are in all convex, and nearly alike in figure. On the palmar side of the first we observe two flight depressions corresponding to the flexor digitorum bones in front of the joint; on the sides of the articular surfaces of each deep hollows for ligaments, which secure the articula- tions between these bones and the fingers.

The metacarpal bones referable in structure and formation
EXTREMITIES.

The other long bones. At the period of birth the extremities are cartilaginous, ossification commencing in the body of the bone in the embryo of three months.

In the preceding description we have reckoned five metacarpal bones, according to the plan followed by the most eminent anatomists. By many the first metacarpal bone has been omitted, and described as the first bone of the thumb, which they consider as composed of three bones, like the fingers. By Albinus the metacarpus is divided into two portions, one, comprising the four last bones, he calls the metacarpus manus; the other, the metacarpus pollicis.

The articulations between the bones of the carpus and metacarpus are nearly similar in all but the first. The articular surface at the upper end of the metacarpal bone of the thumb is convex and concave in opposite directions, adapted to the corresponding surface of the trapezium. The joint is surrounded by ligamentous fibres passing from one bone to another, amongst which the external and dorsal are the most strongly marked, and the most in number, the internal and anterior are continued on to the annular ligament. It is lined by a distinct synovial membrane. The disposition of the ligamentous fibres is such as to form a capsule round the articulation, like that observed in the shoulder joint, but not so loose. The whole is supported by the muscles and tendons of the thumb. The second metacarpal bone is articulated with the trapezium, the trapezoids, and the os magnum; the third with the latter only; the fourth with it and the unciforme; the fifth with the last alone. The surfaces are covered by cartilages continuous with those forming the joints between the metacarpal bones themselves, and lined by a common synovial membrane with occasional exceptions, as mentioned when speaking of the carpus. The ligaments on the dorsal surface pass in different directions from the lower row of carpal bones, to the upper end of those of the metacarpus. There are two for the second of these, one from the trapezium, the other from the trapezoids; the third has but one from the os magnum; the fourth two, passing from this bone and the unciforme; the fifth a single band from the latter. They are all short, flat, and compact. The palmar ligaments are less distinct, being confounded with those around them. The most evident are, a band passing from the trapezium to the third and fourth metacarpals, confining in its pannage the tendon of the flexor carpi radialis; and a band between the trapezium and first metacarpal.

The articulations of the metacarpal bones between themselves. — The metacarpal bones, with the exception of the first, touch at both ends by lateral articular facets, which have been already described. The synovial membrane lining those at the carpal extremity is open above, forming a free communication with the carpus. They are secured in their relations by transverse ligaments at both ends. At the carpal end there are found on the palmar and dorsal surfaces; on the first of these the superficial ligaments form a continued layer, passing from the second to the last, the more deeply seated passing from bone to bone. The dorsal ligaments pass across between each bone. Besides these, we find immediately below the articulations strong ligaments passing deeply between the bones, uniting them most firmly together. At the digital end is a strong transverse ligament on the palmar side, the superficial fibres passing from the first bone to the last, those more deeply seated between each individual bone. It is covered in front by tendons and vessels, behind it supports the interosseous muscles, and is united to the ligaments connecting the metacarpus with the fingers.

Among the bones of the metacarpus, the first enjoys very extensive motions in every direction. The most important motion is that which brings the thumb in opposition to the fingers, and enables us to grasp the object before us; an office which made Albinus bewail on it the emphatic name of "manus parva majori adjutrix." The freedom of this motion depends on the extent and obliquity of the articular surfaces, between it and the trapezium, and is favoured also by their being on a plane anterior to the rest of the hand.

Circumduction of the thumb is very free towards the palm, very much less so in the opposite direction. The interval between this and the other metacarpal bones is highly advantageous in allowing of all its motions. The four last bones of the metacarpus are bound so closely together, as to allow of much individual motion. They can be brought closer together, and bent a little forwards, so as to increase the hollow of the hand; this motion is most evident in the two last, those of the ring, and little fingers.

The four last bones of the metacarpus hold a middle rank, as to motion and solidity, between the carpus and fingers; above they partake of the firmness of the carpus, below approach nearer the mobility of the fingers.

The fingers, including the thumb, are five in number. They are either reckoned numerically from the radial to the ulnar side, or distinguished by proper names. The latter are in common acceptance. We count, therefore, the thumb as the first; the fore-finger or index as the second; the middle finger as the third; the ring finger as the fourth; and the little finger as the fifth. By this arrangement we can immediately compare their relations to the metacarpal bones, which have been described also in a similar numerical order.

The fingers are composed of rows of long bones, placed vertically one beyond another, called phalanges; of these we find three in the fingers, properly so called, and two only in the thumb, the middle phalanx being wanting. They are distinguished by the names of the first or metacarpal phalanx, the second or middle, and the third or ungual. As the corresponding bones of the several rows are essentially alike in all, we shall include them in one description, noticing the peculiarities of each. We divide them into two extremities, and a body.

The first, or metacarpal phalanges, — are the largest, and longest of the three; of different lengths and size, the third being the longest, and all diminishing successively in volume from the first to the last. They are convex on the dorsal surface, the transverse convexity forming nearly half a circle; concave anteriorly, with sharp angular edges laterally.

At the superior extremity we observe an articular surface, oblong transversely, slightly hollowed, articulated with the corresponding bone of the metacarpus; a broad tubercle on each side giving attachment to lateral ligaments, divided anteriorly by a depression, in which the flexor tendons pass. In the thumb this extremity gives attachment to the abductor, the flexor brevis, and the adductor. The bodies of the phalanges are convex posteriorly, covered by the extensor tendons; concave on the palmar side with projecting edges, so as to form a kind of gutter, in which the flexor tendons are partly lodged; the edges give attachment to ligamentous sheaths confining the tendons in their situation. The lower extremity offers an articular pulley, extended further and much broader on the palmar side than on the opposite, and the edges diverging considerably from behind forwards. On each side are depressions, which give attachment to lateral ligaments.

The second, or middle phalanges, — are smaller and shorter than the first, which they resemble much in general figure. The thumb possesses none. As to individual comparison, they differ but little, that of the middle finger is the longest, the last belonging to the little finger the shortest and smallest.
EXTREMITIES.

The upper extremity offers an articular surface closed antero-posteriorly by a rising line, corresponding to the opposite pulley of the first phalanx; on each side are tubercles giving attachment to ligaments. The body resembles that of the metacarpal phalanx. About the middle of the anterior surface are two rough prominences, giving attachment to the divided tendon of the flexor sublimis, and to a fibrous sheath, which crofles over it from side to side, containing also the tendon of the flexor profundus. Its posterior surface gives attachment to a portion of the tendon of the extensor communis. The lower extremity resembles that of the first.

The third, or ungual phalanges—are found, in all, five, diminifhing in fize from the thumb to the little finger, that of the former being by far the largest of the whole. The upper extremity or base, from a comparison of the bone to a pyramid with its apex downwards, forms an articular surface, oval transversely, with a convex line crofing from before backwards, accommodated to the pulley of the middle phalanx; is tuberculated for ligaments on each side, giving attachment behind to extenfor tendons. The body is confocted; on its anterior surface the flexor profundus is fixed in the fingers, and flexor longus in the thumb. The lower extremity, or point, is fiat, rounded, broader than the body, feafrous at the edges and on the anterior fide, fmoother behind, where it supports the nail.

The bones of the fingers have nothing peculiar in ftructure or formation: the first and fefcond phalanges are formed from three oflifying points, the third from only two. At the time of birth, their figure is well marked, and their formation very conferderably advanced.

The articulations of the thumb and fingers with the metacarpus.—The convex heads of the metacarpal bones are covered by articular cartilages, in contact with those lining the concave surfaces of the fift digital phalans. They are bou?d together by lateral ligaments, and strengthened in front by the sheaths of the flexor tendons, behind by the expansion of the extenfors, on each fide by the interofi muscles. The lateral ligaments are attached above to the fides of the lower end of the metacarpal bones, and divide as they descend into two dilatf bands, which are fixed to the fides of the correéponding bones of the fift phalanx. They are strong, fom? of parallel fibres, lined on the inner furface by the fynovial membrane. In front of the joint we find the tranverfe ligament of the lower end of the metacarpus, which has been already defcribed. The fynovial membrane is loose, particularly before lining the extenfor tendon in its paftage behind over the joint, and appearing between the ligaments, which it also covers in front and on the fides. In front of the joint of the thumb we find two fefamos fide bones developed in the tendons of the flexor brevis, leaving a fawrow between them, in which the tendon of the flexor longus pafes. They roll on the head of the meta
carpal bone, gliding up or down, as the joint is bent or extended. They are fometimes found in the articulations be
tween the metacarpus and fingers. The motions enjoyed by this joint are thofe of flexion, extenfor, abduction, and addu?tion; of thofe the firt is by far the moft confiderable, the thumb poififling it in the lead, the little finger in the moft exfefive degree.

The articulations between the phalanges are alike in all; the condyles, at the lower extremities of the fift and fefcond phalans, are covered by cartilage, and correépond to the little hollows at the upper ends of the fcond and third. They are covered by a fynovial membrane, and connected by lateral ligaments, which pass from bone to bone, refem?bling thofe of the preceding articulation. The fynovial membrane is supported by thofe, as also by the extenfor and fefcor tendons. It is fо closely united to the extenfor tendons, at the upper end of the fcond and third phalans, that it is almoft impoffible to separate them. It is continued much further down on the bone on the palm, than on the dorsal furface, forming a little bag in front of the joint. The thumb has but one of these articulations, which is in every refpect similar to the joints between the phalanges of the fingers.

In this laft part of the hand we observe an evident decrease of firmnefs, when compared with the metacarpus and carpus, and a proportionate increafe of facility and extent of motion. The shortnefs of the bones, however, fearely offering a refifting point to external impulfes, fecures their relations, and lefens the chance of fracture, though the fingers are more immediately within the action of surrounding bodies, and more expoed to injuries than any other part of the limb. The joints of the phalanges of the thumb and fingers allow only of flexion and extenfor; the latter cannot be carried beyond the fhght line, the former is very free; an effect which depends on the continuation of the articular fufces in front, far beyond their extent on the dorsal furface, and which is provided for by a correéponding laxity of the fynovial membrane. The advantages of this disposition, for the important functions of the fingers, is fo confpicuous as to require no comment. In opening the hand, the fingers cannot be extended beyond the plane of the hand; from this situation they may be bent in various degrees, until their points touch the lower end of the meta
carpus. This general flexibility, derived from the fuccelfive rows of bone, and their peculiar modes of articulation, allows of the fingers being applied accurately to any body whose qualities we wish to examine, whatever be its figure. The decreasing length and fize of the feveral phalanges permit us to feize objects conveniently and firmly, to retain them, however small. The power we poifefs of moving them fingly, or in different degrees, of touching the palm of the hand at any point of its furface, of fpreading them laterally, of separating one from another, &c. enables us to adapt their position to every poiffible ufe. In all the actions of the hand, the thumb holds a confpicuous rank. Alone, it oppofes the efforts of the other fingers, which are much longer, and bend, as it were, to meet the thumb, whenever we clofe them on the object. With regard to the different lengths of the thumb, and feveral fingers, we may observe, that when seperated most widely from each other, by gently bending the points they may be brought to defcribe nearly a circle on a plane furface, forming with the hollow of the palm a concave hemisphere; from which situation they may be further contracted, till the feveral points meet: from this conftruction they are fuited to grasp equably and firmly bodies of a rounded form. The fefne of touch owes, in a great measure, its delicacy and perfection to the readinefs and prep?ftion with which the fingers can be applied to the object whose qualities we wish to examine. It would be abfolute enuilefs to defcribe the different motions of which they are fupecible; they are fo rapid in fuccefsion, fo varied in di?rection, extent, and power, fo exquisitely adapted to the in?numerable offices they have to perform, as to confitute an inexhaus?ible, not to fay an inexplicable fubjeft for difcuf?fion.

We conclude our history of the upper extremity, by fome remarks on its powers of reflation and fancifibility of motion, as a complete member, enjoying the affembly of all the properties we have defcribed as refulting from the mechanism of each division.

The cafes in which the upper extremities are required to support
EXTREMITIES.

Support great efforts, or to oppose a powerful impulse, are by no means so numerous or so frequent as in the lower limbs, where considerable exertion and resistance are necessary, to support the body in the ordinary attitudes. In the action of pushing, the hand is applied to an object, the forearm and arm extended between it and the trunk forming a straight lever, which conveys the weight of the latter on the body to be pushed. In this motion, the hand being inflected backwards on the forearm, the joint of the wrist is soon fatigued by the dilatation and pressure in front; the sigmoid cavity of the ulna bears directly against the lower end of the humerus, the latter rests on the glenoid cavity of the scapula, which is fixed firmly by its muscles and the clavicle.

It is only, however, when the arm is directed outwards, that it bears directly on the glenoid cavity: if it be turned forwards or backwards, the capsular ligament and the surrounding muscles sustain the effort. The wrist is most favourable to insects and continued resistance; and we may observe, that when at liberty to choose our attitude in pushing with one arm, we always place it in such a direction as to bring it to bear directly on that cavity. For instance, if the object be in front, we turn ourselves so as to bring the side of the body corresponding to the limb we are about to exert opposite to the object. In pushing downwards, in rolling on the arm, &c. the mechanism is nearly the same, as far as regards the hand, which is so much extended on the forearm as to form an angle with it behind, while the forearm is placed in the same line with the arm, the joint of the elbow being fixed and immovable. The difference depends only on the change of situation which takes place in the joint of the shoulder, the head of the humerus preffing more or less advantageously, as the direction of the prefiure varies from the relative position of the object on which the limb rests.

The belt possible direction is where the arm is extended laterally, so as to bear on the glenoid cavity, the scapula being at the same time supported directly by the clavicle. It is understood that in every case the position of the limb is preserved by muscles, which are called on to act more or less, as that position is more or less favourable for sustaining the effort, and become tired in the same proportion. This observation is more particularly applicable to the cafe in which the upper extremities have to sustain the whole weight of the body, as in the instance of tumblers, when the hands are placed on the ground, and the body raised into the air, the upper exerting for a time the functions of the lower extremities. This attitude is both difficult and painful, from the want of sufficient muscles to maintain it, and from the small extent of the articular surfaces. The wrist suffers more particularly, as in marching on all-fours, because these surfaces do not bear on each other, but on the front of the joint; the elbow is not so much dis tended from the contraction of the articulation; the shoulder-joint suffers almost equally with the wrist, from the prefiure on its capsule.

The upper extremities are articulated with the trunk in a plane posterior to the lower; the line of gravity in the attitude above described is anterior to the support, and we find, consequently, that to preserve the balance, to counteract the tendency to fall forwards, the lower extremities are thrown consider-ably backwards.

The motions of the upper extremity are so numerous and varied, as scarcely to admit of classification; they are so familiar as not to require description. The mechanism by which they are performed has been considered in treating of the several articulations, and may readily be applied to any case; we shall now only briefly recapitulate the more material points. The shoulder is the centre of motion of the whole limb: the arm gives the general movement, the parts below those which are more partial. The motions of the shoulder affect the whole limb; as we descend, the actions are more and more confined. A finger may be employed if the latter is motionless; if the latter is moved, all below must partake of the motion. It is from the combination of the several partial motions that the increase and variety of the whole are derived, and these are multiplied the lower we go. The hand enjoys the individual motions of its component parts; a general motion from the joint of the wrist; a more general still from the connection of the bones of the forearm and the elbow, which is increased to a still greater extent by the shoulder joint and shoulder. The motions then may be more compound as we descend, as well as more partial, because each part enjoys the motion resulting from its proper articulation, in conjunction with all those above it. This general action of the parts of the upper extremity is observable in seizing or grasping any body, or in embracing, where all the articulations are bent, or in the opposite actions of spreading the arms, or extending the whole limb in different directions, &c. It is more commonly seen under cafes where the different joints are inflected purposely at the same time, or others bent, these motions being often alternate. All these modifications of action may be observed in pulling, pushing, climbing, grasping a distant object, swimming, striking, &c. &c. In short, in all the familiar exercises of the upper extremity we are constantly in the habit of performing. We cannot conclude without hinting at those impetuous actions of the upper extremity, which form a mute language employed most emphatically in aiding the expression of our passions, or our will; it is enough to say, they are as numerous and varied as the feelings which bring them into play.

The lower extremity is divided, as the upper, into four parts, viz. the hip, the thigh, the leg, and the foot, each of which has a more or less striking analogy with the corresponding divisions of the upper extremity. We shall examine their points of resemblance and difference more minutely hereafter; at present, we would observe only, that the bones, which form the basis of the lower extremity, are more malleable and solid in their forms, and are hence adapted to their functions, as organs by which the seat of the body is supported and moved. Their prominent character is solidity and firmness; in the upper extremity every thing is constructed for variety and quickness of motion.

The lower extremity is connected with the trunk by the articulation of the hip bone with the basis of the vertebral column, the sacrum; through which the whole weight of the body is transmitted to the bones of the hip. The connections of the two hip bones with the sacrum behind, and with each other in front, form a bony cavity called the pelvis, the principal uses of which are, to contain some important viscera, to offer a basis of support to the trunk above, and two fixed points for the motions of the limbs below. It is in the last functions only that we shall have occasion to notice the pelvis here; we shall not, therefore, enter into a description of it as a whole, but attend to those of its parts which bear on the present subject, and correspond to analogous portions of the upper extremity.

The os coxa, os innominatum, hip, or hames bone, is the largest of the broad bones, placed laterally at the lower end of the trunk, connected with its fellow in front, by means of cartilage, and separated from the opposite bone behind by the intervention of the sacrum. The hip-bone is very irregular in figure, broad and flattened above, con- fracted
tracted and mafly in the middle, and apparently more slender in the anterior and lower portions: it is curved so as to have its flat surfaces in almost opposite directions; the upper division is flattened from side to side, the lower from back to front, the change of direction taking place in the middle portion. In young subjects this bone is formed of three separate pieces; a superior, called the ilium, an anterior, the pubes, and an inferior, the ischium. In the adult they are intimately united, that we can with difficulty trace their former line of separation. We can see therefore no reason for describing as distinct, what in its perfect state forms but one solid bone. We shall consider it as such; but, not to devote too much from common usage, shall notice the different divisions as we proceed, and afterwards particularly describe their lines of union. We distinguish in the os innominatum two surfaces; an internal or pelvic, an external or femoral, and a circumference or border, which is again subdivided into several parts.

The external surface looks outward above, and forwards below; it is covered by strong and numerous muscles. The outside of the broad upper division, the furrow of the ilium, is convex and concave in different parts; at the posterior and superior part is a rough eminence, which gives attachment to the gluteus maximus; below this a surface, concave and broad behind, convex and gradually narrowing in front, gives attachment to the fibres of the gluteus medius; it is bounded by the eminence just mentioned, by the upper edge or crista of the ilium, and below by a semi-circular line, with the convexity upwards, passing forwards from a deep notch behind, (the great facrofictic,) and terminating in the crista of the ilium in front. The space comprised between this curved line and the deep articular cavity below, gives origin to the gluteus minimus; it is concave behind, and gibbous in front. At the anterior part, immediately above this cavity, is a rough impression, where the curved tendon of the rectus urinis is fixed. The portion of the external surface, which is directed downwards and forwards, is very irregular in figure. Above is a deep and large cavity, called the acetabulum or cotyloid cavity; it forms nearly the half of a sphere, lined by cartilage in its upper two thirds, the lower part a little deeper, lodging some cellular tissue, and the strong ligament passing to the head of the thigh-bone. The margin of the cavity is irregular and waving, more prominent above than below, surmounted by a ligamentous ring, which makes the acetabulum still deeper, interrupted towards the inner side by a notch, completed by a ligament which leaves a small opening for the passage of the articular vessels; it gives attachment to the capsular ligament of the hip joint. The bone surrounding the cotyloid cavity is thick and mafly, especially at the upper and outer sides; the cavity itself is directed obliquely downwards, and forwards. Below, and on the inner side of this cavity, is a large hole, of an oval shape, the foramen ovale, obturatorium, or thyroideum. Its long diameter is from above downwards, its edges are acute and rough, except at the upper part, where there is a smooth gutter directed obliquely from above inwards and downwards, in which the obturator nerve and vessels are lodged. The groove is formed by the internal and external edges of the circumference crossing each other at the top of the oval, the latter passing in front to a point called the spine of the pubes, leaving the oblique hollow between itself and the internal margin which paffes up in the opposite direction. The foramen ovale is closed by a ligament attached to its edges every where but at the groove just mentioned, where it leaves a vacancy for the passage of the obturator vessels, &c. In the female this foramen is smaller than in the male, and of a triangular figure. On the inner side of the foramen is a rough and unequal surface, broader above and below than in the middle, giving attachment to portions of the triceps, and the external obturator muscle.

The internal or pelvic surface is concave, corresponding in its direction to the external or femoral, covered by muscles which arise from it. The anterior part of the upper division, the os iliaca, is occupied by the iliacus internus muscle; the posterior is very scabrés and unequal, divided into two portions, of which the anterior is covered by cartilage, and articulated with the acetum, forming the sacro-iliac symphysis, resembling somewhat in outline the human car, the posterior is convex and very rough, giving attachment to the strong and numerous ligamentous fibres which connect this bone with the acetum above. Below the iliac fossa, crouling from the articular surface to the anterior angle of the bone, is a prominent angular line, forming a part of the superior aperture of the pelvis, separating the upper division from the lower. The latter presents a plane surface behind, broader above than below, giving attachment to the obturator internus and levator ani; in front of this is the obturator foramen, and in the inside of the latter a narrower surface corresponding to the bladder above, giving origin to a part of the obturator internus below.

The circumference of the os innominatum is exceedingly irregular, with alternate prominences and hollows, and is divided into four portions, viz. a superior, an inferior, a posterior, and an anterior. The superior margin bears the name of the crista of the ilium; is convex, narrower in the middle than at the ends, and inclined outwards. The inner edge, or labium, gives attachment to the transversalis abdominis, and quadratus lumborum; the external to the obturator externus, the latissimus dorsi, and the fascia of the thigh; the middle convex portion to the obliquus internus. The anterior margin is concave, and its lower half nearly horizontal. Its union with the crista forms the anterior superior spine of the ilium, which gives attachment to the tenor vaginai seminis, the sartorius, and the upper end of that part of the tendon of the external oblique, called Poupart's ligament. Below this point is a slight notch, rising again into another eminence, the anterior inferior spine of the ilium, from which the rectus urinis arises. This is succeeded by a smooth hollow, over which pas the ploas magnus, and iliacus, bounded by a protuberance called eminentia ileo-pectinea, into which the tendon of the ploas parvus is implanted, when it exits. On the inside of this there is an oblique surface, concave, triangular, with the base outwards, and the point inwards, bounded in front by a line which is continued from the external margin of the obturator foramen, behind by a sharp ridge, the crista of the pubes, which is continued from the transverse line described as crossing the pelvic surface. Over this concave space pass the crural vessels. The anterior margin terminates by uniting with the inferior, at a right angle, called the angle of the pubes. A little before its end we observe on it a projecting point, the spine of the pubes, giving attachment to the pyramidalis, and the external pillar of the abdominal ring, formed by the tendon of the external oblique. The inferior margin is the shortell, projecting above a perpendicular oblong surface, forming with the opposite bone, by the intervention of cartilage, the symphysis pubis; below this the edge is thinner, forming with the opposite one the arch of the pubis, affording attachment to the gracili, to portions of the triceps, to the corpus cavernosum, the transversalis perinei, and the erector penis, or clitoris. The upper half of this bony plate is called the descending ramus of the pubis, the lower the ascending ramus.
the extremities.

must of the ilium. The posterior margin is the most irregular in its outline. Beginning from above we observe the angle formed by its junction with the superior margin, the superior posterior spine of the ilium, an hollow separating it from the eminence below, the inferior posterior spine; a deep notch forming part of the facet-sacral notch; and a prominent prominence, the spine of the ischium, giving attachment to the inferior gemellus, the coccygeus, and the latticer sacro-sciatic ligament; a smooth concave surface, over which the tendon of the obturator internus plays; and a broad eminence where it joins the inferior margin, the tuberosity of the ischium giving-attachment, externally, to the quadratus femoris, and the great head of the trochanter; within to the great facet-sacral ligament, and the inferior gemellus, in the interface to the ischios, the semi-tendinosus, and semimembranosus.

The os innominatum is in structure like the other flat bones; the two compact tables, enclosing the more cellular parts, touch each other in the middle of the iliac fossa, and again at the depression in the acetabulum. It is developed from three points of ossification, at the angle of the pubis, the tuberosity of the ischium, and the middle of the upper division, or ilium. The union of the bony plates proceeding from these points takes place between the ilium and pubes at the eminentia ileo-pubic line: between the latter and the ischium, in the middle of the branch which forms the inner side of the foramen ovale, and the half of the arch of the pubes; between the ischium and ilium at the great facet-sacral notch. The junction of the three takes place in the acetabulum, which forms the principal point of union; the ilium makes the upper part of the cavity, the pubes the anterior, the ischium contributing the principal share, and completing it at the inferior and posterior portions. The part which either bone takes in forming any of the principal features of the os innominatum will be immediately seen, by observing their lines of union with each other. At the time of birth the acetabulum, being far removed from the centres of ossification, is wholly cartilaginous, are also the different eminences, the spines, and the crista. It is not till the time of puberty that all traces of cartilage are obliterated. The os innominatum is articulated with the acetabulum, by the iliacum symphysis; with its fellow, by the symphyses pubis; and with the thigh-bone by means of the cotyloid cavity. We shall say nothing of the two former of these connections, but that they are exceedingly strong, and the bones bound to closely together, as not to allow of any perceptible motion; we shall describe the last having gone through the history of the thigh bone.

In commenting on the mechanism of the shoulder, we had to notice its articulation with the trunk, and the motions resulting from its peculiar mode of connection; in the present instance we find an immovable adherence of surfaces, which allows of no deviation from one determined position. In consequence of this total want of motion, we shall not enter on the detail of the connections of the hip bone with the trunk, or with its fellow; they can influence the functions of the lower extremity no farther than by transmitting to it the weight of the body.

The oblique direction of the articular surfaces of the acetabulum, which gives it the form of a wedge driven between the two osa innominata, is well adapted to the purpose of transmitting securely the weight of the trunk to the latter bones: the stronger the depression imparts, the more closely the surfaces are brought together; the shock must be violent indeed, which can in anywise loosen their connection. It is then through the medium of the acetabulum that every effort is propagated to the two hip bones, which in some positions are the immediate base of support, while in others they continue the impulse to the limb below. In the common attitude of sitting, the trunk is supported on the tuberosities of the ischia; in progression, or in standing, on the cotyloid cavities. These being at a distance from each other, facilitate the motions of the thighs, and increace their extent, the pubes executing one of the offices of the clavicle, in keeping the hip joints far apart, as the clavicle does those of the shoulder. It will be seen, from the description of the hip bone, that its surfaces and circumference give attachment to numerous and powerful muscles, by far the greater number of which are destined to regulate, or to give vigour and effect to the motions of the thigh and leg, and to balance the varying weight above them.

The thigh—is the division of the lower extremity between the hip and the leg. It is formed by a single bone, called the femur, or thigh bone.

The femur is the longest bone of the body, the largest in volume, and the strongest. It has a considerable curve forwards, is contracted in the middle, wider and more bulky at each extremity, one of which is called the upper, or iliac, the other the lower, or tubial.

The upper extremity includes three remarkable eminences: the head, supported by a long neck, and the great and little trochanters. The rounded head of the femur is received into the cotyloid cavity of the os innominatum; it forms more than half of a sphere, directed upwards, inwards, and a little forwards; so that the greatest part of its convexity is above, and its axis the same as that of the neck, which furthers it. The convex surface is smooth, except just below the centre, where we find an hollow, which gives attachment to an inter-articular ligament; it extends further in front than behind, above than below, and terminates in a wavy line at the neck. The latter contracts immediately below the head, and becomes a little flattened vertically, the upper edge remaining the widest; it is longer below and behind, on which aspect it is also hollowed, than above and in front; joined by a broad basis to the body of the bone, from which it stands off in a direction slanting upwards and inwards, advancing at the same time a little forwards, forming with it an angle more or less obtuse. The length and obliquity of the neck vary considerably in different subjects, being in some nearly horizontal. The great trochanter is on the outer side, directed a little backwards, below the level of the head, rising above the hollow of the neck, quadrilateral, convex on the outside, and excessively rough for the attachment of strong tendons, the tendon of the gluteus maximus passing over the smooth surface at the posterior part; hollow, and of much less extent on the inside, giving attachment above to the tendons of the gemellus, the obturator internus, and the pyramidalis below, and towards the back part to the obturator internus. It has rough and irregular borders; to the anterior is fixed the tendon of the gluteus minimus; to the lower part of the posterior the quadratus; to the upper the gluteus medius; to the lower the vastus externus. The attachments of these muscles are hardly, however, confined to the edges of the trochanter; their tendons are implanted also to a greater or less extent over the outer surface, for which purpose its roughness, as mentioned above, seems particularly designed. The little trochanter is placed at the internal and posterior part of the base of the neck, oblong and somewhat pyramidal in shape, its rough summit giving attachment to the united tendon of the psoas magnus and iliacus. From its base we trace two prominent lines proceeding obliquely upwards to the great trochanter, one uniting them
EXTREMITIES.

...them in front, the other behind. These, in conjunction with the two trochanters, mark the circumference of the basis of the neck, and give attachment, more especially the anterior, to the capular ligament of the hip joint. The body of the thigh bone is convex forwards, and hollowed behind, appearing nearly cylindrical when viewed in front, but almost triangular above, and flattened transversely towards the lower end. It has been divided in descriptions into three surfaces and as many angular lines; these characters, however, are not strongly marked; the surfaces are universally smooth, the dividing lines blunt and rounded, if we except the pectineal ridge formed by the union of the internal and external surfaces, called with great propriety the linea aspera, or spina femoris. This is formed by two converging rough lines, commencing from each trochanter above; that which proceeds from the trochanter major is the most prominent and rough, giving attachment to the gluteus maximus; the pectineus is affixed to the other; and the interspace is occupied by the quadratus and a portion of the triceps. The double ridge, formed by the approach of the two rough lines, is continued down the bone, when it again divides into two less remarkable lines, which terminate in the condyles at the lower extremity. The whole middle of the linea aspera gives attachment to the triceps; a portion of the biceps has its origin at the lower part, which is continued along the line diverging towards the external condyle; the line going to the internal condyle is fearfully observable for a little way below the point of bifurcation. These two branches of the linea aspera leave a triangular interval between them, smooth and somewhat concave, corresponding to the popliteal vessels. Bifides the malleoli fixed to different parts of the linea aspera, the vaflus externus is attached to almost the whole extent of the line, proceeding from the great trochanter to the external condyle; and the vaflus internus is connected in a similar manner to the line from the little trochanter to the internal condyle. The surfaces of the body of the femur are covered by these malleoli, and by the crureus, which cover the bone at every point, excepting towards the lower end, and the space intercepted between the bifurcation of the linea aspera. The nutrient arteries of the body of the bone are found in the course of the linea aspera; the principal one about the point of convergence above.

The lower extremity much exceeds the upper in volume, and presents two eminences called condyles, the internal and external. They are both convex, project more behind than in front, are smooth below for articulation with the tibia, this surface being terminated behind by two hollows, which give origin to the heads of the gastrocnemius. They diverge behind, leaving a deep notch between them, where the crucial ligaments of the knee joint are fixed; on the front they are joined by a continued articular surface, which is hollowed to receive the knee-pan or patella; the edge of the pulley formed by the outer condyle being more elevated than the opposite one. The articular surface terminates abruptly in the lateral direction, in the perpendicular rough sides of the condyles; in front it is continued a little way up the bone, ending in a slightly prominent edge. The internal condyle gives attachment on the inner side to a lateral ligament, and to the tendon of the triceps. The external surface of the outer condyle is marked by a depression to which the popliteus is attached, and by an eminence for the external lateral ligament of the knee. The articular surface of this condyle is broader than that of the internal, and not so convex, the anterior part being nearly plane; and it is continued much higher up in the front than on the opposite side. The internal condyle, when the thigh bone is placed perpendicularly, appears to defend much lower than the external; but in the natural oblique direction of the femur, the bottom of the two condyles will be found nearly in the same horizontal plane, the internal full exceeding a little.

The femur is compact in its structure in the middle part, recticular and pungy at the extremities, which are yet cartilaginous at the time of birth. Ossification commences in the middle of the bone, and it is not till after this has reached the extremities that we observe three centres of ossification above, in the great, the little trochanter, and the middle of the head, and two below, one for each condyle. The cartilages between them and the body of the bone gradually decrease in thickness, and they become united, the two trochanters the fifth, then the head, and last of all the conjoined condyle. It is not till the bone has nearly arrived at its complete and adult form that the line of separation is entirely obliterated. In infancy the neck of the bone is nearer at right angles to the body than at any after period; as the age advances the angle becomes more and more obtuse in the majority of subjects; in some few it fearfully alters its direction. This alteration, from an horizontal to an oblique line, is a proof among many others how little the functions or growth of the animal body are subject to physical laws; we see the neck of the thigh bone rising, as it were, in direct opposition to the weight of the superincumbent body. This portion of the femur is also proportionally shorter than in the adult, and wholly cartilaginous. The body of the bone is freight, instead of being curved forwards, as in the adult; and the inferior extremity is comparatively of larger dimensions. These characters of the infantile bone are lost as it gradually becomes developed, and acquires its remarkable density and firmness. The thigh bone is articulated above with the os innominatum, below with the tibia and patella.

The articulation of the femur with the os innominatum, the hip joint.—The surface of the cotyloid cavity of the hip bone is lined by an articular cartilage, of which the central parts are thinner than the circumference. It terminates at the edge of the depression observed at the inner and lower parts of the cavity, which is filled up by a fatty cellular tissue, supplied by numerous vessels. The bony margin of the cavity is completed by a ligament crossing the notch, and the whole rim of the acetabulum is surmounted by a circular cartilage, called the cotyloid ligament, which much increases its depth. In this round articular cup, or acetabulum, the head of the thigh bone is lodged. The latter is covered by cartilage thinner at the circumference than towards the centre, where it is partially interrupted by the insertion of a ligament, and accommodated exactly to the opposite surface of the acetabulum; the cartilaginous head, however, is so deep as not to be wholly embraced by this cavity in any position; and hence some part of its margin always appears exposed on turning back the enveloping ligament. The contiguous surfaces are secured in their relations by a very strong capsular ligament, supported by fibres from the neighbouring parts, and surrounded on all sides by malleoli; and by an inter-articular ligament. The opposed surfaces are covered by a synovial membrane.

The cotyloid ligament adheres firmly to the edge of the acetabulum at every point, excepting the great notch which it crosses. It is thick at the border next the bone, thin at the opposite prominent margin, broader above, and externally thin in the contrary directions, and partially broader wherever there is any depression in the osseous rim, so that the unconnected margin of the ligament is exactly plane throughout. It is formed by ligamentous fibres arising from
from the edges of the cavity without, inclining gently towards it in their progress, and inserted again into the sides of the margin within a greater or less distance from their point of origin. These fibres receive an addition above from the curved tendon of the rectus cruris; below they are confluent with the fibres of another ligament, completing the great notch. The latter is formed by two crescentic plates of fibres passing from one edge to the other; they decussate each other in their course, one band corresponding to the surface of the joint, the other to the edge of the obturator foramen, from the ligament occupying which it partly takes its origin. They leave a vacuity below for the passage of vessels into the joint; towards the brim of the cavity they are continuous with the cotyloid ligament in the manner above-mentioned; they give a partial attachment also to the ligamentous capsule. The cotyloid ligament, in conjunction with these bands, completes the figure of the acetabulum, and by increasing its depth secures the joint without in any degree diminishing the motions of the head of the femur, to the prejudice of which it readily yields. They are both lined towards the joint by the synovial membrane, which is continued over the edge of the cotyloid ligament a little way down the opposite surface, before it is reflected to the capsular ligament. These two last are opposed to each other in part by its intervention; towards their mutual attachment to the brim of the cavity they are intimately united. Into the articular hollow thus constituted, the head of the femur is received, and secured by an orbicular and internal ligament.

The capsular ligament of the hip joint, (l. orbiculare, membrana capsularis femoris, Soemm,) extends from the circumference of the acetabulum to the base of the neck of the femur. It is fixed to the bony margin of the former from the line of insertion of the cotyloid ligament, to a short space beyond it, so as to surround the latter, which projects freely into the joint. Its insertion extends further beyond the cotyloid ligament in front and on the outer side than it does internally, where it may be almost said to arise from its very edge. From this circular attachment the capsule descends, enveloping in its course the chief part of the neck of the femur, to the circumference of whole base it is finally fixed. In front it reaches the oblique line between the trochanters, the linea inter-trochantérica; behind, some of its fibres only reach so far, the greater number are implanted into the neck between the posterior oblique line and its middle; above, it is fixed to the root of the great trochanter; below, it extends nearly to the little. The capsular ligament is in general very thick, and of a close and condensed texture; it is thinnest internally and behind, thicker externally, and most decidedly so in front, where it is strengthened by a layer of longitudinal fibres arising from the anterior margin of the os innominatum, and from the anterior inferior spine, and fixed below to the anterior line inter-trochantérica. In other parts of the ligament the course of the fibres is less distinctly marked; from the margin of the acetabulum they follow different directions, decussating each other, and leaving occasional intervals, more especially below, through which vessels pass to the synovial membrane. This last is occasionally exposed and bare on the side next the obturator foramen. The capsular ligament is covered in front by the rectus cruris, psoas magnus, and iliaceus internus, a synovial bursa lying between them; on the internal side, by the obturator internus and pectineus; behind, by the quadratus femoris, the gemelli, the tendon of the obturator internus, and the pyramidalis; above and without, by the glutæus minimus, which is more closely connected with it than any other of these muscles.

The interior, or round ligament, (ligamentum internum, internus) is entitled to almost any name rather than round; it is flattened, and of a triangular figure, the base towards the acetabulum, the summit next the head of the femur. It is fixed at one end to the extremities or corners of the great notch of the cotyloid cavity, and to the posterior edge of the transverse ligament occupying the vacancy; from thence it mounts obliquely backwards, and is attached to the depression noticed towards the centre of the head of the thigh bone. It appears as if composed of two bands of fibres, one arising from the superior, the other from the inferior extremity of the great cotyloid notch, which approach each other towards their opposite insertion. The upper of these is by far the weakest; in many cases it appears only as a duplicature of the synovial membrane, enclosing only a small number of ligamentous fibres. It must restrain the head of the femur from quitting the cavity upwards and outwards, and must be partially, if not entirely, ruptured in the luxations in those directions; in the displacement towards the obturator foramen it would not apparently suffer much injury.

The synovial membrane lines the cotyloid cavity; it spreads over the fatty cellular tissue, occupying the sinus at its bottom, is reflected from thence over the internal ligament, which it wholly encases, adhering to it more or less intimately in different parts; it covers the articular cartilage of the head of the femur, is continued over the periphery of the neck, which appears through it as if formed of parallel fibres; at the base of the neck it turns back over the inner surface of the capsular ligament, lines it to its attachment round the brim of the acetabulum, and from thence passes over the cotyloid ligament. The hip joint is very much strengthened by the surrounding muscles, especially by those which immediately cover it.

The motions which take place in the hip joint resemble those in the shoulder; they are, however, with the exception of rotation, less extensive, owing to the immobility of the cotyloid cavity, its great depth, and the comparative tightness of its capsular ligament. The femur can be bent on the hip bone, extended, brought nearer to, or removed further from, the mctial plane, moved between these directions, or carried round in a circular direction (circumduction), and rolled inwards and outwards. In the most common position, with the thigh in the same line as the body, the summit of the great trochanter, which can be always felt externally under the integuments, is in the same horizontal line with the spine of the pubis, and about the middle of an oblique line extended between the superior anterior spine of the ilium, and the tuberosity of the ischiium. By a previous knowledge of the relative position of this eminence to points which can be easily felt, we shall be competent to decide on accidental displacement, as well as to follow the alteration of position in the different motions of the femur.

When the thigh is bent, the head rolls in the acetabulum in the axis of the neck, the summit of the trochanter recedes from the spine of the ilium, and approaches the tuber of the ischiium, and the lower end of the bone is advanced. In moderate flexion there is but little alteration in the relations of the articular surfaces; when carried to its greatest degree, a portion of the head of the femur quits the acetabulum, and rests on the posterior part of the capsular ligament, which undergoes considerable dilatation. Extension of the thigh is the replacement of the limb in its former state, from the position of flexion. The very close manner in which the head of the bone is covered in front by the strong ligamentous fibres, which proceed from the anterior and inferior spine...
of the ilium, and the neighbouring anterior portion of the cotyloid line, entirely prevent us from carrying the limb backwards beyond a perpendicular line drawn from the pelvis downwards, if the latter part be preferred immovable. The degree of motion in this direction, if it exist at all, is very trilling, supposing the trunk to be erect, and the pelvis fixed; the apparent freedom of motion in the direction of extension arises from the pelvis being ordinarily moved in the opposite direction.

In abduction, or removing the thigh from its fellow, the great trochanter rises towards the fossa of the ilium, which it touches, if the motion be continued as far as possible, and thereby limits the extent of that motion. The internal surface of the head abandons the acetabulum, while the external sinks deeper into it; the capular ligament is made very tense on the inner side, where it supports the head and opposes its tendency to any displacement in that direction. In abduction nothing remarkable occurs; it is merely the return of the thigh from the lateral position to its natural one; the limb may, however, be carried, in this direction, across the opposite one. Besides these four motions in opposite lines, it will be readily understood that the femur can be moved through all of the intermediate points. Circumduction is not so free as in the shoulder joint, as may be gathered from the preceding observations; rotation is, on the contrary, less confined, on account of the length and obliquity of the neck of the femur, strikingly different from that of the humerus. In the latter rotation is nearly in the axis of the bone, on account of the extreme shortness of the neck; in the femur, where the axis of the bone is so far removed from the centre of motion, this motion pales round a line extended from the upper part of the head to the middle point or interval between the condyles. In rotation inwards, which is more confined than that outwards, the great trochanter describes the arc of a circle from behind forwards, and the head of the bone is buried deeper in the cavity; the motion of the trochanter is more feeble and more extensive as the neck is proportionally longer. In rolling the thigh outwards the great trochanter sinks under the muscles, and the head of the bone deflects the capsule somewhat in front. In its most natural position the thigh is turned a little outwards, which contributes, with the direction given to the foot by the construction of the ankle joint, to point the toes moderately outwards. As the leg and foot needfully follow the rolling motions of the thigh, and more perfectly so when the leg is extended on the latter, it will be seen that the rotation of this bone inwards and outwards will imply a corresponding alteration in the position of the foot; and the great power we enjoy of turning the toes outwards, and the narrow limits to which we are confined in directing them inwards, will be found to result from the difference observed in the powers of rotation of the thigh.

The motions of the hip bone on the thigh, when the latter is the fixed point, will require no particular detail after the preceding remarks. It is sufficient to say they may be made in every direction, and with tolerable facility, particularly lateral inclination, in which one hip bone is lowered, and the opposite one elevated, and rotation; motions executed with promptness and to a great extent in the pirouettes of our stage dancers. We shall have occasion to speak at length of the flexion and extension of the hip bones on the thigh, when we examine the mechanism of the whole in the attitude of standing.

The leg—is the part of the lower extremity placed between the thigh and the foot; the bones which it contains are the tibia, the fibula, and the patella. The tibia, the largest of the three, alone supports the weight placed on the leg from above; it comes next to the femur in size, is larger above than below, nearly triangular throughout, divided into an upper, femoral extremity, or head, a middle part or body, and a lower or tarsal extremity.

The upper extremity is nearly oval, with the long diameter transverse, large, and spreading.

The vertex or top presents two articular hollows or funnels; of which the internal is oblong from before backwards, and deeper than the external, which is nearly circular. They correspond to the condyles of the femur by the intervention of movable cartilages; and are divided from each other by a middle eminence, terminating in a rough depression before and behind, which completes the separation. This protruberance, placed nearest to the posterior edge of the head, is not much elevated; it flanks into the articular surfaces at the base, and is bifid at the summit, with a rough groove in the interval. The rough depression in front is larger than that behind; they both give attachment to the semi-lunar inter-articular cartilages of the knee, and to the crucial ligaments of the joint. In front of the upper extremity is a broad, flat, triangular surface, with the base upwards, corresponding to the ligament of the patella. The lateral parts have been called the tuberofities; they project considerably by a convex edge, separated in front by the flat space just mentioned, behind by a notch varying much in depth. The internal protuberance is the largest, and is marked by the attachment of the femoral and membranous behind, the external presents in the same agent a rounded articular surface inclined downwards, for connection with the fibula.

The body of the tibia is slightly curved outwards above, and inwards below, diminishing in bulk as we trace it from the upper extremity till about one-third from its lower end, from which point its size gradually increases again downwards. It is of a prismatic form, with strongly marked edges. The anterior of these, the crista or spine, commences above at a rough eminence, called the anterior tuberosity of the tibia, into which the inferior ligament of the patella is fixed in front, and the tendons of the extensor, gracilis, and semi-tendinosus internally; it is sharp above and in the middle, in the latter of which portions it projects a little, and becomes insensibly low below; it forms by its course a waving line, which gives attachment to the aponeurosis enveloping the muscles of the leg. The internal edge is flattened above, and more angular below; in the first portion it gives attachment to the popliteus, for the lower two-thirds to the long flexor of the toes. To the external edge, the least prominent of the three, the interosseous ligament is fixed; below it bifurcates and is continued into the edges of the articular cavity, which receives the lower end of the fibula. Of the surfaces between these edges, the internal or the thin is the largest; smooth, slightly convex above, and covered by the tendons of the extensor, gracilis, and semi-tendinosus; throughout the rest of its extent it lies immediately under the skin. The outer surface is hollowed longitudinally above, and convex below, where it turns a little forward; its upper half is covered by the tibialis anticus, to which it gives attachment, and lower down the tendon of this muscle, with those of the extensor of the great toe, and the common long extensor of the toes, passes over. The posterior surface is crooked obliquely by a line passing downwards and inwards from the articular surface, at the back of the external tuberosity; above this the popliteus is attached; below, the tibialis posticus, and long flexor of the toes; to the line itself these muscles are fixed, as also the flexor.
is towards the upper end of the posterior surface that we find the hole which gives passage to the nutrient vessels.

The lower extremity is much less in volume than the femoral or upper; it is nearly quadrilateral with an articular cavity of the same form at the bottom, which rests on the foot. Of the four sides, the anterior and posterior are straight, transversely and nearly parallel, giving attachment at their edges to ligamentous fibres; the latter presents also a groove for the passage of the long flexor of the great toe. The internal is prolonged downwards below the level of the others, forming a broad and strong process, called the malleolus internus. This eminence does not correspond exactly to the inner tuberosity of the femoral end, but is situated a little more forwards from the slightly twisted form of the bone. The circumference of its anterior and lowest parts gives attachment to ligaments; the posterior has a broad and superficial hollow, over which pass the tendons of the tibialis anticus, and the long flexor of the toes; the inner surface is convex, and covered by the skin, the external is smooth, presenting a vertical articular surface, joining above the large articular cavity, the depth of which it considerably increases. On the outer side of the tarsal extremity is a triangular hollow with the summit upwards, smooth below, and covered by cartilage, where it receives the fibula, rough above for the attachment of strong and ligamentous fibres, which secure the connection: the edges of the cavity are continued above into the external spine of the body of the bone, and give attachment to ligaments which pass to the fibula. The articular surface at the bottom is a little concave, quadrilateral, narrow and deep, towards the inner side, crossed antero-posteriorly by a broad gently rising eminence; it corresponds to the upper surface of the astragalus, the highest of the bones of the tarso.

The structure and formation of the tibia resemble those of the other long bones. At birth the extremities are cartilaginous, and are not completely ossified and united to the body till a late period; the bony spines in the latter are already very prominent, and better marked than in any other bone. The tibia is articulated with the femur, the fibula, and astragalus.

The patella, rotula, or knee-pan (kniecheibe, Germ.) is situated in front of the knee-joint, or articulation between the femur and tibia, varying as the leg is bent or extended, in its relative position with regard to the femur. It is flattened, of a triangular form, with the base upwards, the upper angles rounded, the lower more acute. The anterior surface is convex, pierced by numerous longitudinal openings, covered by a tendinous extension from the extensors of the leg, which is partially attached to it, and by the skin. The posterior articular surface is oblong, transversely divided by a blunt elevated line, passing rather obliquely from the upper edge to the lower angle, into two differently inclined concave faces, of which the external is the largest and deepest; they both correspond to the condyles of the femur on which they play. It is terminated below by a rough depression, into which a portion of the ligament of this bone is fixed. Of its circumference, the upper edge is thick, and gives attachment to the tendon of the extensors, the lateral borders more clearly convex, to the common aponeurosis of those muscles. In the lower angle the long anterior ligament which connects the patella to the tibia in front of the tibia is firmly implanted.

The substance of the patella is spongy in the middle, covered by a thin crust of compact bone. It is formed in the thickest of the tendon of the extensors, and always preserves the appearance of longitudinal fibres. It is not till some years after birth that bony matter is deposited in room of the cartilaginous substance at first observable, and it is a later period still before it is fully developed. The patella is articulated with the femur, and connected with the tibia by means of a ligament, of which we shall speak below.

The knee joint, or articulation of the femur with the tibia and patella.—This joint, one of the most complicated in the body, results from the contact of the condyles of the thigh bone with the head of the tibia and the posterior surface of the patella. The lart of the knee, as well as the articular pulley formed by their union in front, are covered by cartilage, which is thicker in the middle of the condyles than at their circumference; the cartilage covering the patella is particularly thick, it is thinner on the hollows of the tibia, particularly in their centres. The forms of the articular surfaces of the femur are accommodated to those of the patella and tibia; but in the latter case the correspondence is further maintained by means of two inter-articular semi-lunar fibro-cartilages, interpolated between the femur and tibia in such a manner, that a small portion only of the latter bone comes into actual contact with the condyles of the former. The relations between these parts are secured by muscles, and their tendons, by the ligament of the patella, two lateral, and the same number of cruciate or oblique ligaments, a posterior ligament, and by a synovial membrane spread over the whole.

The ligament of the patella, which may be regarded as the termination of the tendons of the extensor muscles, consists of a very strong flat band of fibres attached above to the lower angle of that bone, and to the depression on its posterior surface, from which point it extends about two inches in length, and half as much in breadth to the anterior tuberosity of the tibia. It is covered on the front by the skin and an aponeurotic expansion. The posterior surface corresponds above to some fat and cellular tissue lying between it and the synovial membrane, below to a small synovial capsule placed between it and the tibia, a smooth portion of which it covers, just above the insertion of the ligament. The edges are continuous, with an aponeurosis proceeding laterally to the tibia. It is composed of parallel, shining, tendinous fibres, of which the anterior or most superficial are continued in front of the patella to be identified with those of the immediate tendons of the extensors. It is exceedingly strong, and capable of fulfilling the strongest efforts of those muscles.

The internal lateral ligament is flat and thin, attached above to the internal condyle of the femur, it becomes broader as it descends, part of its fibres is inserted into the edge of the internal semi-lunar cartilage, and into the edge of the head of the tibia, the greater portion contracted in breadth is continued further down, and becomes fixed at the commencement of the body of the bone to the internal edge, where it joins the aponeurotic insertion of the popliteus. It is covered by an aponeurosis descending from the fascia lata of the thigh, and below by the tendons of the sartorius, gracilis, and semi-tendinosus: it lies over the synovial membrane, the internal semi-lunar cartilage, and a small part of the tibia. The external lateral ligament is placed between the external condyle of the femur, and the fibula, in the form of a long, round, shining cord, covered nearly throughout by the tendons of the biceps. Immediately under it are the inferior articular vessels. It is fixed to the condyle above the attachment of the tendon of the popliteus, and rather behind it; to the fibula on the outside of its upper extremity, adhering to the outer semi-lunar cartilage in its passage. The posterior ligament is nothing but a tendinous expansion given off from the tendon of the semi-membranosus, which mounts obliquely upwards.
wards and outwards behind the crucial ligaments, from which it is separated by cellular tissue and the middle articular vessels. It is attached above to the external condyle, and is confined with the tendon of the outer head of the gastrocnemius. Independent of this band, which is very irregular in its form and size, we find other fibrous parcels crossing in different directions above it.

The crucial ligaments are more deeply seated, but may fill be considered as external to the joint as they are covered only in front, and on the sides by the synovial membrane, and are really without the fasc which it forms. They are strong fibrous bands crossing each other in their course, from which they derive their name. The anterior paves from the posterior and upper part of the hollow between the condyles, and from the interior side of the external condyle; obliquely downwards and forwards, narrowing as it descends, to be fixed in the rough surface, in front of the spine at the head of the tibia, behind the attachment of the internal femoral cartilage, and on the inside of the external, being partially united to both. The posterior crucial ligament is attached above to the anterior part of the shaft between the condyles, and the outer side of the internal condyle. It descends backwards and inwards, becomes broader, and divides into two large distinct bands, of which the largest is inserted into the depression behind the spine, the other joins the external semi-lunar cartilage. These two ligaments are separated from each other by cellular tissue, and by the bone means from the posterior ligament behind; they adhere firmly to the synovial membrane, invetting them on the anterior and lateral surfaces.

The semi-lunar cartilages, as they are termed, lie on the articular surfaces of the tibia, between them and the corresponding condyles, occupying only the circumference, the femur and tibia touching in the centre of each. They are thick at the convex margin, and become gradually thinner, terminating in a delicate concave edge, increasing thereby the depth of the cavities which receive the gibbous condyles of the femur. The internal is broadest behind, the external in front; the first represents a portion of an oval, of which the short diameter is transverse; the latter forms nearly a circle, corresponding, in this respect, to the figure of the two articular surfaces of the tibia. The upper surface of each cartilage is concave, accommodated to the convexity of the condyles, the lower is nearly flat. The convex margins are united to the ligaments which cross them in their course, especially to the lateral; that of the external has an oblique depression in it behind, where it is contiguous but not adherent to the tendon of the popliteus. The concave edges are free, thin, and sharp. The anterior extremity of the internal cartilage paves in front of the anterior crucial ligament, and is inserted on the outer side of the depression which gives attachment to it; the posterior is attached behind the spine, before the insertion of the posterior crucial ligament. The anterior extremity of the external semi-lunar cartilage is adhered to the depression in front of the spine, but much behind the attachment of the internal, and united in part with the anterior crucial ligament; behind it is implanted into the posterior depression, and is connected with a portion of the posterior crucial ligament. We have called these cartilages, not to depart too much from established language, though they are of a fibrous texture. They are formed of curved concentric fibres, which are particularly evident at their extremities and convex margins, less so in the middle, where they are more analogous in their appearance to cartilage. They are sometimes immediately joined by a short transverse ligament, continued from the convex borders in front. The internal appears more fixed in its situation than the external, which has a gliding motion backwards and forwards on the tibia.

The synovial membrane, if we trace it from above, is reflected from the condyles of the femur, some way above the termination of the cartilage to the circumference of the patella. In this part it is loose, covered above by loose fat and by the cruciate, to the tendon of which it adheres most firmly, and laterally by an aponeurotic expansion, from the extensors passing from the edges of the patella to the tibia and femur. After lining the posterior surface of the patella, it paves on to the upper edge of the tibia in front, lying under the ligament of the former bone, and a large quantity of fat and cellular tissue placed underneath it, and keeping them at a considerable distance. From this part a duplication of it paves backwards through the joint, and is attached to the anterior and external part of the sinus between the condyles. It has been called the ligamentum alare by Weitbrecht, or l. musculorum, fun adiposum; all names equally unapplicable to it. Laterally, also, it descends towards the tibia, invetting the upper surfaces, and concave edge, and the under surfaces of the semi-lunar cartilages; after which it is continued downwards, covers the articular cartilages at the head of the bone, and is reflected upwards over the cruciate ligaments in the middle, lining behind the tendons of the gastrocnemius on their anterior surface, and enveloping the tendon of the popliteus. It thus reaches the condyles behind, to the edges of which it is attached, leaving the sinuses between them without the bag, and paves over the cartilages to the point from which we set out. It is covered in front by the extensors and their tendon; by their aponeurosis laterally, as also on the inside by the tendons of the tibialis, gracilis, and semi-tendinosus, and by the internal lateral ligament with which it is in contact; on the outside by the tendon of the biceps and the external lateral ligament, behind by the semi-membranous and its lateral tendon, by the gastrocnemius and popliteus. After all, we should have a very imperfect idea of the knee joint, if we considered it in this abstract state. It is most strongly supported by the muscular powers attached to the tendons we have mentioned, the latter being numerous, and of great strength, and the muscles naffy and exceedingly powerful, securing most effectually, when in action, the relations of the opposite bones.

The motions of the leg on the thigh—are those of flexion, extension, and under particular circumstances of rotation. In flexion, the tibia and semi-lunar cartilages glide backwards on the condyles of the femur; the patella quits the articular pulley, and descends in front of the joint, so as to be opposite to the sinuses between the condyles: the tendon of the extensors occupies its place, and is much dilated if the flexion be carried far back, as is also the ligament of the patella; and the crucial and oblique ligaments, as well as the posterior, are relaxed. In extension, the tibia glides forwards again, and the semi-lunar cartilages are brought opposite to the inferior instead of the posterior cartilages of the condyles, which, in this position, rest against the heads of the gastrocnemius; the patella mounts again, and, in complete extension, if the muscles are in action, paves up a little way above the articular pulley; if the muscles are quiescent, the tendon of the patella is relaxed; this bone is loofe and may be moved in all directions; the posterior crucial and lateral ligaments are stretched, and prevent this motion from being carried beyond the point which brings the femur and tibia in the same line. The great strength of the crucial ligaments, which are essentially dilated at this time, is a powerful obstacle to the luxation, which would throw the head of the tibia backward. When the leg is near the middle state, between
between complete flexion and extension, it can be rotated slightly inwards and outwards; a motion, of which the foot necessarily partakes, and which carries the toes in corresponding directions. In rotation the articular surfaces of the tibia glide in opposite curves in the rounded surfaces of the condyles; not, however, in equal degrees, the most evident motion occurring on the outer condyle. In rotation inwards the posterior cruciate ligament is brought to cross the anterior more directly, and is much tightened, so as effectively to limit it. In rotation outwards, which, on account of the disposition of these ligaments, is more extensive, we find them scarcely affected. In both cases the lateral ligaments are rendered tense; the semi-lunar cartilages undergo little change of position, excepting that in rotation inwards, the external one, from its connection with the posterior cruciate ligament, is drawn a little aside. When the leg is bent, the motions by which the toes are carried alternately inwards or outwards take place in the knee joint; when it is extended, they are effected in the hip, and depend on the rotation of the femur. The patella favours extension, by removing the power further from the centre of motion, besides which it glides more readily over the pulley of the flexor tendons, it could have done, and protects materially the front of the joint in flexion, for instance in kneeling. It scarcely moves in rotation inwards or outwards.

The fibula—Placed on the external side of the leg, obliquely with regard to the tibia, being behind it above, and immediately on the outside below. It is a slender bone, nearly equal in length to the tibia, but very much smaller, divided into an upper or tibial, or lower or tarsofibular, and a middle portion or body.

The upper extremity is very irregular; we remark in it above, and a little on the inside, an oblique, slightly hollowed, articular surface, corresponding to one on the outer tuberosity of the head of the tibia. In every other aspect the surface is rough and unequal, giving attachment to ligaments which connect it with the tibia, to the external lateral ligament of the knee, and to the tendon of the biceps.

The body of the fibula is of an irregular prismatic figure, somewhat twisted, and curved a little, so as to approach nearer the tibia in the middle of the angles, the anterior rises gradually from above, is sharp and prominent in the middle, and bifurcates below, where it is covered only by the skin. It gives origin, in the greatest part of its extent, to an aponeurosis, which separates the peronei muscles from the extensor commissure of the toes. The external edge is spiral in its course, running backwards as it descends. It gives attachment to an aponeurosis, which divides the peronei from the long flexor of the great toe and the soleus. The internal edge becomes anterior as it descends; it is very prominent in the middle, and gradually lost above and below. The upper two-thirds give origin to the flexor of the great toe, and the tibialis posterior, the lower third to the interosseous ligament. Of the surfaces between these borders, the external alters its aspect, becoming posterior below; it is covered by the peronei, which are fixed to the two upper thirds. The internal surface looks rather backwards above, and forwards below; it is divided into two unequal portions by a fine extending from the upper part of the anterior angle to the lower part of the internal angle, and which gives attachment to the interosseous ligament. Of these two planes the posterior is covered by, and gives origin to, the extensor of the great and of the other toes, and to the peroneus tertius; the posterior, which is hollowed longitudinally, to the tibialis posterior. The direction of this spine varies very considerably, as also its length. The posterior face is inclined outwards above, where the soleus has its attachment; below it turns inwards, giving attachment by nearly its lower two-thirds to the long flexor of the great toe. About the middle, the opening for the nutrient artery directed longitudinally downwards. It widens towards the lower extremity, where it terminates in a rough convex surface, connected with the tibia.

The lower or tarsofibular part is oblong, flattened transversely, thicker behind than in front; it forms the outer malleolus, which descends rather lower, and is more pointed than the inner. The external surface is convex, and covered only by skin; the internal presents, at its anterior part, a smooth articular surface convex from above downwards, articulated with the external side of the talus, and behind this a rough depression for ligamentous attachments. The posterior border has in it a superficial groove for the passage of the peronei; the anterior, as well as the angle below, give attachment to ligaments.

The fibula is in structure like the other long bones. It is formed from three points of ossification, one for the body and one for each extremity. The latter are still cartilaginous at birth.

The articulation between the tibia and fibula—is by actual contact at the two extremities, and by means of an interosseous ligament in the intervening space. The superior articulation results from the contact of two flat cartilaginous surfaces, secured by ligaments in front and behind, and covered by synovial membrane. The anterior ligament palises from the fore part of the upper end of the fibula to the anterior part of the external tuberosity of the tibia. The fibres are transverse, the superior ones the longest, and divided into several parcels, with intervening cellular tissue. It is strengthened by a portion of the tendon of the biceps, which embraces the external lateral ligament of the knee, and palises over this anterior ligament before it is fixed to the tibia. The posterior ligament is also transverse, but not so strong, or so well marked as the preceding; it is continued above with some ligamentous fibres found in the back of the knee-joist; it is covered by the popliteus. Besides these two ligaments, we find a few other scattered bands below, which help to secure the articulation. The synovial membrane lines these ligaments, and the cartilaginous surface is separated from the tendon of the biceps by cellular tissue, and is contiguous behind to the synovial membrane of the knee. The middle connection is preserved by means of an interosseous ligament, analogous to the one we have described in the forearm. It is thin, composed of parallel fibres depending obliquely from the external edge of the tibia to the ridge dividing the internal surface of the fibula, and below to the internal edge of this bone. It is broadest at the upper part, and terminates in a point beneath, where the bones begin to touch each other. It is pierced by many openings for the passage of vessels; of these the most remarkable are, one above, near the edge of the fibula, for the passage of the anterior tibial veins; and another below for a branch from the peroneal artery. The anterior surface serves for attachment to the tibialis anticus, the extensors of the great and other toes, and to the peroneus tertius, and supports the anterior tibial vessels. To the posterior surface—the tibialis posterior and long flexor of the great toe are fixed. The inferior articulation is composed of the contact of two cartilaginous surfaces below, a convex for the fibula, and a corresponding concave one for the tibia, lined by a continuation of the synovial membrane from the ankle joint. The relations are secured by ligaments before, behind, and between.
EXTREMITIES.

tween the bones. The anterior ligament is broad, attached to the anterior edge of the tarsal end of the fibula; in crossing to the tibia it mounts a little upwards, widening in its progress, its fibres divided by intervals filled with cellular tissue, the superior long, and is fixed to the neighbouring parts of the tibia. It is covered by the peroneus tertius, aponeurosis of the leg and the shin; its lower end is confluent with ligamentous fibres passing from the fibula to the astragalus. The posterior ligament resembles it in direction, but it is not so large, and the lowermost fibres are the longest. It passes immediately from the posterior part of this end of the fibula to be fixed to the tibia behind the cavity which lodges that bone, is confluent with the surrounding ligaments below, covered behind by the two lateral peroneal muscles. In addition to these ligaments we observe, between the opposite surfaces of the two bones, just above their cartilaginous contact, a fibrous sublamine passing from one to the other, occupying a considerable space, interrupted here and there by cellular tissue, and continuous above with the interosseous ligament. It materially secures the articulation.

The motions of the fibula on the tibia are excessively limited, very different in this respect from those between the bones of the fore-arm. The upper end of the fibula may glide a little backwards and forwards; the lower is nearly motionless from the disposition of the ligaments, a structure necessary for the stability of the articulation of the leg with the foot, as refuting the tendency to lateral displacement.

The foot—forms the last division of the lower extremity; it has some characters in common with the hand, but is distinguished from it in a remarkable manner by its great depth and firmness, by the preponderance of its solid over its moveable parts, the reverse of which is so strikingly seen in the hand. It varies much in size, in general is proportionally smaller in the female than in the male, is elongated in form, broad and flat anteriorly, thick and narrower behind. It is convex on the upper surface, which is called the back of the foot, concave on the lower, called the sole, thin on the outer edge, deeper and longer internally, with a projection behind, named the heel, and terminated by the points of the toes in front. We divide it, as we did the hand, into three portions; the tarus behind, the metatarsus in the middle, and the toes before.

The tarus (oberfus, Ger.) forms about the posterior half of the foot; it is composed of seven bones, viz. the astragalus, the os calcis, naviculare, cuboides, and three cuneiform bones.

The astragalus, (talus of Albinus,) occupies the upper part of the tarus, rising far above the level of the other bones; it is of a very irregular form, convex above, hollowed below, flattened at the sides, and running out into a strong process before, termed the cervix or neck of the bone. It is placed half between the two bones of the leg, the heel bone, and the os naviculare. On the upper surface, anteriorly, is a rough, transverse depression, forming part of what has been called the neck of the bone, for insertion of ligaments; behind this is a large articular surface, broader than the bone, convex in those directions, rather concave from side to side, fo as to form a superficial pulley, suited to the opposite surface of the tibia. Below we have two articular surfaces, which rest on the os calcis, separated by a deep groove, running obliquely from within outwards, widening much in its course, and rough for ligamentous attachments. The posterior articular surface, which is external, is the largest, concave, and oblong obliquely; the anterior is small, oval, and nearly flat. The posterior side is narrowed horizontally, and presents the commencement of an oblique groove, in which the tendon of the long flexor of the great toe glides. In front is a convex rounded articular surface, which has been called the head of the bone; it rests against the os naviculare, and by a small surface on the os calcis. On the outside a triangular articular surface, concave vertically, corresponding to the lower end of the fibula. On the inside another articular surface, flat, elongated horizontally, adapted to the descending malleolar internus; below this a rough irregular surface for ligaments. These two articular surfaces are continuous with that on the upper surface, and form part of the ankle joint. It is developed from two points of ossification, which are just appearing at birth.

The os calcis (calcaneus of Albinus,) is situated at the posterior part of the tarus, where it forms the heel. It is the largest of the seven bones; its greatest extent is from behind forwards, its next is in the depth, and it is narrowed transversely. On the superior surface we observe posteriorly a concave part occupied by the flat and cellular tissue in front of the tendo Achillis; next we have a large, convex, oblique articular face, adapted to one in the astragalus; on the inside of this a groove, which divides it from another smaller oval, flat articular face, corresponding also to the astragalus. This last is placed on a lateral process of the bone, ("fulcetaculum cervicis tali, Alb.") and is rather anterior to the tibia. It is sometimes continuous with another small articular surface in front of it, though generally separated by a narrow groove. The rest of the upper surface is flat and rough for ligaments. The under surface is long, much contracted transversely, terminated behind by two tubercles which give attachment to some muscles of the toes; the internal is the largest. There are also other eminences further in front to which ligaments are fixed. The posterior surface is bulging and convex, and forms properly the heel; at the upper part it is smooth, where it is separated from the tendo Achillis by a synovial bursa, and rough below for its insertion. The anterior surface is the smallest of the whole; it is articulated with the os cuboides, and is slightly concave. The outside is flat, much broader behind than before, and marked by two superficial grooves for the long and short peroneal muscles. The inside is large and hollowed deeply, to lodge the nerves and vessels going to the sole of the foot, and also the tendons of the tibialis posticus, the long extensor of the toes, and the long extensor of the great toe, which plays in a peculiar groove observed at its upper part. The malleolus accessorius has its origin from this surface, towards the back part. The os calcis is formed from two points of ossification, which are visible at birth. The two bones we have been describing have been considered as the first row of tarsal bones; the remaining five as the second.

The os naviculare is situated in the middle of the tarus, of an oval figure, with its longest diameter transversely; its circumference is rough for ligamentous attachments; broad and convex above, concave below, pointed and projecting internally where the tibialis posticus is inserted, and narrowed on the outer side, on which we generally find a flat articular facet opposed to the cuboides. The anterior surface is convex, divided into three articular planes for the three cuneiform bones; of these the internal is broadest below, and the two external above. The posterior surface is concave, articulated with the astragalus.

The os cuboides, (cubiforme, Alb.) is placed at the external and anterior part of the tarus, and resembles somewhat a cube in figure. Above is a rough, slightly convex surface, with four unequal sides; below posteriorly an emi-
rence for ligaments, a superficial hollow, and a more marked protuberance for the same purpose, in front of which is a deep groove, which gives passage to the tendon of the peroneus longus, as it crosses the foot. Anteriorly an oblique articular surface nearly plane, supporting the two outer metatarsal bones. Behind a concave smooth surface, still more oblique, articulated with the os calcis. Externally, a narrow border, in which we observe the commencement of the curvature of the navicular bone, and the termination of the posterior longus; internally, a small articular facet behind, in contact with the os naviculare: a larger one in the middle for the third cuneiform bone; the rest of the surface is rough for ligaments.

The first cuneiform bone (majus five internum) lies at the inner and anterior part of the tarus, and is the largest of the three; it is deeper than it is broad, with the base of the wedge below, and the narrower border upwards, of a rhomboid figure viewed laterally. The upper side is oblique, and gives attachment to ligaments; the inferior is convex, and gives attachment before to the tibialis anticus, behind to a part of the tibialis posticus, as well as to ligaments. The posterior surface, articulated with the naviculare, is concave and pointed above; the anterior, by which it rests on the first metatarsal bone, is longer, and of an oblong, or rather semi-lunar figure. Internally, it is convex, rough, and sub-cutaneous; externally concave, with a small articular facet near the upper edge, in contact with the second bone of the metatarsus, and another near the posterior edge, which touches the following bone. The second cuneiform bone (minus five medium) is the smallest of the three, and of all the bones of the tarus; it well deserves its name both from its figure and situation. The base of the wedge forms the upper surface which is quadrilateral, with the short diameter transverse, and rough for ligaments. The edge of the wedge below is sharp, and serves the same purposes; behind it is articulated by a concave surface, with the middle plane in the front of the os naviculare; before, by a convex one, with the second metatarsal bone. Of the two four-cornered sides the internal is nearly plane, with an articular facet near the upper edge, and another at the posterior, joined to the last bone; the external has a concave articular facet for connection with the third cuneiform bone towards the upper and posterior angle; they are both rough on the remainder of their surfaces for fibrous attachments.

The third cuneiform bone (externum, or medium, Alb.) is rather larger than the preceding, and longer from before backwards; it resembles in much in figure and position. The base, which is above, and the edge below, give attachment to ligaments. Behind is a triangular articular surface, corresponding to one of the planes in front of the naviculare; before an oblong flat one in contact with the third metatarsal bone. The internal surface is marked by two articular facets; separated by a rough depression for ligaments, of which the anterior corresponds to the second metatarsal bone, the posterior to the second cuneiform. The external side is rough anteriorly, and has a plane articular facet towards the upper and posterior angle, in contact with a corresponding one on the inner side of the cuboides.

The last five bones of the tarus are wholly cartilaginous at birth, and are gradually and solely developed from single points of ossification. They are not proportionably larger in this stage than when in their perfect osseous forms, in which respect they refer ble the carpus.

The articulation of the leg with the foot, the ankle joint.—To form this joint, the upper articular surface of the astragalus, nearly all the outer side, and the narrow cartilaginous facet on the inside, are received into the cavity formed by the lower end of the tibia and fibula, and embraced closely by the two ankles. The corresponding surfaces are covered by cartilage, and united by several ligaments, the most efficient of which are placed at the sides; the connection is much strengthened by the numerous tendons which pass over or near it to be attached to different bones of the foot.

The internal ligament (l. deltoides) is of considerableness breadth; attached above to a part of the circumference of the internal malleolus, more especially to its point, it descends a little obliquely backwards, and is fixed to the inner surface of the astragalus, and the neighbouring parts of the os calcis. It is composed of a considerable quantity of longitudinal fibres, of which the anterior and the most superficial are the longest. On the outside is a straight rounded and thick ligament (l. medium perpendicular) which descends from the lower extremity of the fibula a little obliquely backwards, passing under the tendon of the peroneus longus, and is attached to the outer side of the os calcis; it is formed of compact, longitudinal fibres. In front of this is another ligament (l. anterius malleoli externi), which passes from the anterior part of the point of the outer malleolus, forming a strong flat band of fibres, frequently divided into two or more portions of considerable strength, and is fixed to the astragalus in a depression before the external articular surface. The front of the joint is strengthened also by a collection of irregular fibrous bands, which descends from the anterior part of the lower extremity of the tibia, amidst much cellular tissue and fat, and are inserted partly into the astragalus close to the termination of the articular pulley, and are partly continuous with the ligaments passing from this bone to the naviculare. Towards the back of the joint, we have arising from the fibula a strong ligament (l. posterius malleoli externi) passing nearly transversely inwards, and fixed to the edge of the articular pulley at the back of the astragulus, close to the outer margin of the groove for the tendon of the long flexor of the great toe. It is stronger than any of the preceding ligaments, and composed of numerous distinct packets of fibres. Immediately above this, and connected intimately with it, at its origin from the back of the external malleolus, is a transverse band of fibres passing directly forwards, or mounting a little obliquely, to be attached to the posterior border of the articular surface of the tibia, and to the inner ankle. It increases a little the depth of the articular cavity behind, and might be regarded properly as one of the posterior ligaments connecting the tibia and fibula. The synovial membrane is distributed as usual, lining all the cartilaginous surfaces and the ligaments; lining also the narrow articular facets between the tibia and fibula, making this little joint communicate with that between these bones and the astragalus. It is loose in front, where we find a considerable quantity of cellular tissue and fat; covered in this aspect by the tendons of the tibialis anticus, the long extensors of the great, and other toes, and the peroneus tertius; behind by the tendons of the tibialis posticus, the flexors of the toes, and the peronei; partly in these situations, and on the sides by the ligaments just described. In addition to the many tendons enumerated, this articulation is further strengthened by the tendon Achilles behind, a powerful agent in preserving its relations.

The motions which take place between the leg and foot are chiefly those of flexion and extension; the lateral in
External flexions are extremely limited. In flexion, which is more confined than the opposite motion, on account of the disposition of the articular pulley of the astragalus, this bone glides backwards on the lower end of the tibia, regulated by the two malleoli lying close on either side; the posterior ligament is stretched, the others undergo but little change; and luxation rarely occurs. In extension the motion may be continued, so as to make the foot form a very obtuse angle with the leg; the external anterior ligament is dispersed considerably, the others less so, the posterior is relaxed. In falling on the toes this position is maintained by muscular efforts, particularly by means of the tendo Achillli; the tibia rests on the posterior part of the pulley of the astragalus, and transmits the principal weight to the navicular, instead of the os calcis, as in ordinary standing. The lateral inclinations of the foot on the leg, as far as this joint only is concerned, are extremely confined, owing to the lateral defect of the malleoli; in which respect they differ much from the lateral motions of the carpus on the forearm. The lateral ligaments are here reciprocally stretched or relaxed, as the foot is turned inwards or outwards. Diflocations to either side occur more frequently than we might at first imagine from the apparent security afforded by the malleoli. Luxation outwards is the most frequent; the fibula breaking two or three inches above its lower end, so as to allow of the eversion of the foot; it is generally the consequence of sudden violence, as in jumping, or in falling on the foot from any height.

The articulations between the bones of the tarsus.—The astragalus is articulated by two, sometimes three cartilaginous planes on its inferior surface, with corresponding ones on the upper surface of the os calcis. These surfaces are preferred in contact by a strong collection of ligamentous fibres, passing directly upwards from the whole length of the oblique groove, between the articular facets on the upper surface of the os calcis to a similar deprefion on the under side of the astragalus, where it is attached to every point not occupied by articulating cartilage. The internal fibres lie deep between the bones, and are short; the external ones are longer, and more in quantity, buried in the cellular tissue and fat which contribute to fill the vacancy observed in this part. Behind there are some parallel fibres passing down from the back of the astragalus to the os calcis, which converge in forming the sheath for the tendon of the long flexor of the great toe; they are not numerous. This articulation is also strengthened by the lateral ligaments of the ankle joint, especially by the external, which passes immediately from the fibula to the os calcis. The synovial membranes offer nothing remarkable. The motions which have place here are always combined with others, and will be considered farther on.

The anterior convex articular surface of the astragalus is received into a cavity formed by the concave surface of the os naviculare, a small spot of the os calcis, and completed below by ligaments passing between these two bones. We observe above a dorsal ligament, thin and flat, composed of fibres passing from the depressor called the neck of the astragalus to the upper rough surface of the naviculare; they sometimes reach to the articular bone. It is covered by the extensors of the toes. Below is a very strong ligament, passing from the anterior and internal parts of the os calcis obliquely forwards and inwards to be attached to the hollow in the lower surface of the naviculare. It is covered on the inside by the tendon of the tibialis posterior: above it is lined by synovial membrane, and forms the lower part of the cavity which lodges the head of the astragalus, to the far part of which it eminently contributes. It is very dense in its structure. There is also a short and very firm band passing from the anterior part of the os calcis to the outside of the naviculare, completing the cavity externally.

This joint is lined by a synovial membrane, which communicates with the anterior articulation between the astragalus and os calcis, as before mentioned. It is spread over the corresponding surfaces and ligaments we have been describing.

From what we have said, it appears that the os calcis is firmly connected with the naviculare, though in contact only by a very narrow spot; the ligaments cross the head of the astragalus in their course, and their apparent use is to support the latter, at a point which appears too deficient, when examining the mechanism in the dry skeleton. The os calcis is more extensively articulated with the cuboïdes by cartilaginous surfaces slightly concave and convex in opposite fenest. The joint is secured by two ligaments, a superior or dorsal, an inferior or plantar. The tibis is broad and thin, composed of short parallel fibres passing rather obliquely forwards from the upper and external parts of the os calcis, to the superior rough surface of the cuboïdes. It is often formed into two separate longitudinal bands. It lies under the peroneus tertius. The inferior ligament is the longest, and strongest of all the ligaments of the tarsus. It is attached behind to the middle of the inferior surface of the calcis, passes horizontally forwards, and is fixed principally into the oblique protuberance observed on the lower surface of the cuboïdes. It is formed of a great number of fibres, divided into several bundles, which diverge rather as they approach the cuboïdes. The inferior ones, or the most superficial, are much longer than those more deeply seated, and are continued under the tendon of the peroneus longus, part of whose sheath they form, to the posterior extremities of the first and second metatarsal bones. The upper plane is shorter in its course, and fixed behind to the groove for the peroneus longus. The ligament is covered below by several muscles of the foot, which have partly their origin from it. It should be remembered that this joint is in the same transverse line with the one between the astragalus and naviculare.

For the articulation between the naviculare and cuboïform bones we have in the tibis a cartilaginous surface divided into three planes, in the latter corresponding surfaces covered by articular cartilages continued laterally into their mutual articulations. It is secured by three dorsal ligaments, attached to the upper and lateral portions of the circumference of the naviculare, passing one internally to the first cuboïform, another in the middle to the second, and a third more externally to the outer cuboïform bone. They leave intervals filled by cellular tissue; the internal is the largest; and thicker at its inferior edge. The plantar ligaments have been described as three also, but they are too irregular for distinction, appearing as fibrous bundles passing between the opposite bones, confounded at their attachment to the naviculare. This joint is strengthened internally by an elongation of the tendon of the tibialis posterior, which is attached to the base of the first cuboïform bone, and continuous with the more internal of the ligaments we have been describing.

The articulation of the naviculare with the cuboid is formed by the contact of two small plane cartilaginous surfaces, lined by their proper synovial membrane, and secured by numerous short ligamentous fibres passing from bone to bone, occupying the remaining space; they are very close and compact. There is also a plantar ligament rounded in form, passing obliquely from the inferior and external part of the naviculare to the opposite point of the cuboid; and a dorsal transverse band, crossing from one to the other, covered by the extensors.
EXTREMITIES:

The cuneiform bones are articulated with each other by cartilaginous facets connected by ligaments passing from bone to bone, deeply as well as superficially. The dorsal ligaments are transverse, and form really but a single band, continued over the three, and attached in its course to each. The plantar ligaments are also transverse, but not so marked; the one which goes from the first to the secon is the strongest: they are covered by an extension of the tendon of the tibialis posticus, one part of which is fixed to the second cuneiform, another to the secon metatarsal bone; there are distinguished from the ligaments by the opposite direction of their fibres. We find also many short ligamentous fibres passing between these bones, as between many others of the tarsus, attached to the parts not occupied by cartilage; they add much to the strength of union.

We have here a synovial membrane common to these joints, and that with the os naviculare above described. It is spread over the anterior surface of the latter, over the connecting ligaments, and dips between the cuneiform bones, lining their articulation throughout.

The articulation of the third cuneiform with the cuboides is by means of plane cartilaginous surfaces, provided with their distinct synovial capsule, and secured by ligaments. Of these the dorsal is oblique, small and thin, uniting the opposite edges of bone; the plantar is considerably thicker, and more directly transverse. Here also are many interosseous ligamentous fibres, fixed to the parts not covered by cartilage, or where the bones are not in immediate contact.

Motions of the tarsal bones on each other.—The motions which take place between the tarsal bones are very limited, if we except those between the astragalus, and the os calcis and scaphoides. By this chiefly the foot is turned inwards and outwards; the lateral inflexions of the ankle joint affording the motion but little. In the movement which carries the point of the foot a little outwards, which depresses its internal and elevates its external edge, the navicular glides on the head of the astragalus, and the os calcis on its lower articulating surfaces; the latter bones approach each other more closely, the interosseous ligament, and the external lateral one of the ankle joint are relaxed, the internal lateral ligament is stretched, especially those fibres which pass to the calcaneum. In the opposite motion of twisting the foot inwards, and bringing the sole to face the other, the bones move in the contrary direction, the inner border of the foot is raised, and the external becomes inferior; the interosseous, and external lateral ligaments are distended. These motions, which are very sensible, may be accidentally forced beyond their natural limits, and give rise to injuries which are too generally referred to the joint of the ankle. The navicular and cuboides may be moved up and down on the astragalus and os calcis, and the cuneiform bones have gliding motions on the navicular, the cuboides, and between themselves, by which the concavity of the foot may be a little increased or diminished. The utility of these numerous articulations in enabling the foot to refract the heels it must often necessarily suffer, and in giving grace and ease to the motions of the lower extremity in progression needs scarcely be inferred on: their great relative size and the very powerful ligaments sublervent to them make displacement of more rare occurrence than we might at first imagine, on considering the efforts they have to sustain.

The metatarsus (mittelfuss, Germ.)—is composed of five long bones placed horizontally and nearly parallel to each other, so as to form a gently convex surface above, and a concavity below. It is situated between the tarsus and the toes, and is analogous in many points to the metacarpus. The individual bones are distinguished numerically, beginning from the inside. The first metatarsal bone, that of the great toe, is by much the largest in volume, though rather shorter than the rest; the second is of the greatest length; the third comes next to it, the two last differ but little: the four latter differ very little in size. They all contract a little in the middle, and swell at each end, particularly towards the tarsus, and are divided into two extremities and a body.

The tarsal, or posterior extremity of the first, is oblong vertically, with a semi-circular articular cavity behind, refitting on the first cuneiform bone. The inner edge of the circumference, which is convex, gives attachment about its middle to a part of the tendon of the tibialis anticus; below is a blunt projecting process, to which the tendon of the peroneus longus is fixed; and on the outer concave edge a small smooth spot, which is in contact with the second metatarsal bone.

The tarsal bones are much larger than the digital extremities of the other four, angular, and in close opposition with each other. That of the second is placed farther back than the first, is triangular, with the base upwards; it is wedged between the cuneiform bones, refitting on the second by a concave triangular articular surface behind; on the first by a small spot on the inside, and on the third by one on its outer side. In the left aspect there are two other articular facets in front of the left joined to the third metatarsal bone, surrounded by apertures for ligaments: the edge above, and the point below are also rough, for the same purposes. The tarsal end of the third is triangular in the same direction as the preceding, articulated by a plane surface behind, with the third cuneiform bone. On the inside are two small facets contiguous to corresponding ones in the second metatarsal; on the outside a smooth spot above, articulated with the following bone, and a rough depression beneath for ligaments. It is rough also above and below. In the fourth, the tarsal extremity is more quadrilateral; behind it is articulated with the front of the cuboides; on the inside with the same bone, and with the third; on the outside with the left metatarsal. Below, and in front of these articular spots, the bone is rough for ligamentous attachments. The tarsal end of the fifth or left metacarpal bone is larger than those of the preceding. It presents behind an oblique triangular articular surface for the cuboides; above and below rough and unequal borders, the former giving attachment to the peroneus tertius, and both to ligaments; on the inside a small articular facet in contact with the fourth; and on the outside a rough eminence projecting backwards, to which the peroneus brevis is fixed, and a portion of the abductor of the little toe.

The bodies of the metatarsal bones are concave from before backwards below, and gibbous above, very irregular in form, and scarcely admitting of regular divisions into surfaces. That of the first is of a triangular prismatic form, with the upper surface convex, and inclined a little inwards; the interior concave, covered by the flexor brevis of the great toe; the external flat and large, corresponding to the muscles which lie between these bones. The bodies of the rest may be regarded in four aspects; the dorsal presents in each a blunt rising line, which divides the attachment of the interosseus; the plantar offers a smooth surface for muscular attachments; the internal and external exhibit variously inclined surfaces, of different breadths, continuous with the two former, smooth, and covered by the muscles which arise from them, and fill the interstices. In the fifth the body is curved a little from within outwards, and its external side, or rather edge, gives origin in part to the
the abductor of the little toe; the dorsif surface is inclined considerably outwards, and terminates on the side by a prominent line; the plantar surface is covered partly by the flexor brevis of the same toe. In all the dorsal surface is covered by the tendons of the long and short extensors, by vessels and nerves, and the plantar by the deep-seated muscles and tendons in the sole of the foot, by ligaments, and by larger blood vessels and nerves.

The digital, or anterior extremity, is very similar in all. It presents a rounded articular surface, called the head, supporting the first phalanx of the toe; this extends further from above below than transversely, in which direction it is compressed. The circumference is rough, offering above a fencible groove for ligaments, and on each side a hollow, in which the lateral ligaments are fixed. The articular surface is prolonged further below, than the dorsal aspect, and terminates on each side by projecting tubercles. In the first this lower surface is divided by a prominent line into two pulleys, on which the sesamoid bones glide, which are placed below this joint of the great toe. In this bone also the articular surface has a much greater proportional breadth.

The metatarsal bones resemble in structure and formation the other long bones, with this exception only, that the smaller ones are sometimes developed from two points of ossification, one for the tarsal extremity, and body, another for the digital; in the first there are always three.

The articulations of the metatarsal with the tarsus.—The first bone of the metatarsus is articulated with the anterior surface of the first cuneiform; the second with the three cuneiform bones; the third with the corresponding cuneiform; the fourth and fifth with the cuboidei. The opposite articular surfaces are covered by thin cartilage, and their relations preserved by ligaments above and below; they are all lined by synovial membranes common in general to these joints, and to the articulations of the metatarsal bones between themselves.

The dorsal ligaments pass from each metatarsal bone to those bones of the tarsus with which they are articulated. From the first there pass a broad and thin band to the first cuneiform, attached to the superior surface of each. From the second, which is let in between the three cuneiform bones, we find three ligaments crossing, one internally to the first, another in the middle to the second, a third externally to the third cuneiform: the first and last are oblique in their course, the second passes directly from before backwards. The dorsal ligament of the third is short, and goes straight to the third cuneiform; those of the third and fourth are attached to the upper surface of the cuboidei; they are more or less oblique, and by no means constant in their forms or situation, the dorsal ligament of the fourth being often attached to the third cuneiform. They are all covered by the extensor tendons.

Of the plantar ligaments, which are analogous in direction and attachment to the dorsal, that passing from the first metatarsal is very strong, and the joint is strengthened also by an extension of the tendon of the tibialis anterior, which is fixed to the side of the tarsal end of that bone. The plantar ligaments of the second are similar to those above. That which passes from the first cuneiform is thicker, and larger than the other, reaching to the base of the third metatarsal; the other two are covered and strengthened by a portion from the tendon of the tibialis posterior. The inferior ligaments of the others are small, yet distinct, and of various lengths. The plantar ligaments are much strengthened by the numerous tendinous sheaths which are found in the sole of the foot, and particularly by that of the peroneus longus, which crosses most of them as it passes along to reach the first metatarsal bone. The ligaments, both above and below, are composed of short and close parallel fibres, following longitudinal, oblique, or transverse directions, according to the relations between the points to which they are fixed. They are separated by intervals filled with cellular tissue, and giving passage to veins. The synovial membrane, lining the joint between the first metatarsal and cuneiform bones, is distinct, and offers nothing remarkable in its distribution. That lining the triple articulation, formed by the second with the three cuneiform bones, is continuous with the synovial membrane, lining the articulation between the two first of these bones. A separate one is found spread over the joint of the third metatarsal and cuneiform, and sending off two small lateral elongations, which dip between the articulations of the third with the second, and fourth metatarsals. It often communicates with the former at the point where they are in contact. Another synovial membrane belongs to the articulation of the two last metatarsals with the cuboidei, common also to that between the two former of these bones.

The articulations between the metatarsal bones, are formed behind by the contact of lateral articular facets, with the exception only of the first, which touches the second without being articulated with it. These two bones are united by short ligamentous fibres passing from one to the other, of considerable strength; the others are connected by dorsal, plantar, and interosseous ligaments. The dorsal are transverse, and three in number, passing from one bone to the next, irregular in form, and attachment, appearing in some subjects as a single transverse band. The plantar are similar in number and direction, but in addition we find several small slips passing from the fifth to the three next metatarsals, separated by cellular tissue. The interosseous ligaments between the posterior ends of these bones are formed by numerous short fibres, occupying the parts not covered by cartilage, and tending very materially to secure their relations. The anterior extremities of the metatarsal bones are not in absolute contact, but they are firmly connected together by a transverse ligament passing below them, and attached to each bone, resembling the ligament described as passing between the distal ends of the metacarpal bones in its form and direction. The metatarsal bones have but an obscure motion on the tarsus, on which they may be slightly elevated and depressed. They may be moved also so as to approach each other in front, and augment the depth of the concavity of the sole; this effect is produced chiefly by the motion of the first and last towards the long axis of the foot, and is in consequence of muscular action; when the foot is flattened by pressure they are forced farther apart mechanically.

The toes, forming the last division of the foot, are five in number, placed horizontally side by side, composed of rows of small bones extending longitudinally one beyond another. We reckon them numerically, beginning from within. The first and last are known also by the names of the great and little toe. The second is rather longer than the first, the other three diminish successively in length. We find three bones, named phalanges, in all, excepting the first, which has only two; these are termed, from their situation, the first or metatarsal phalanx, the second or middle, and the third or ungual, in the great toe the bone of the middle phalanx is deficient. The two bones of this last are very strong, and exceed very much in volume the different rows of the other toes which are slender in form, and comparatively weak. The bones of the first phalanx are the longest; those of the second are very short, as also the third. They all
all swell considerably at the extremities, and are contrasted in the middle part or body. They resemble the fingers very nearly in the material points of their formation, differing from them chiefly in size and mobility.

The first phalanges are by much the longest, and the bones are more rounded than the corresponding ones in the fingers. They are hollowed below, particularly near the extremities, where the flexor tendons lie, the edges giving attachment to the sheaths which confine them. The posterior extremities are concave for the heads of the metatarsal bones, the anterior have condyles, and a middle depression for the second phalanges. The two opposite articulating surfaces between these bones and the corresponding ones of the metatarsus, are cradited by cartilage, and secured by lateral ligaments, as in the fingers. These are thick and strong, paffing from the end of one bone to the opposite. The joint is strengthened below by a transferve ligament, covering it from side to side, contributing to the sheath of the flexor tendons; and is further supported by the ligaments by the extensors, and the smaller muscles which surround them. The synovial membrane is loose and extensile; in the joint of the great toe it lines the two sesamoid bones. These small bones are unequal in size; the internal is the largest, oblong, gibbous below, concave longitudinally above, and a little convex transversely, covered in the latter aspect by cartilage, and resting on the head of the metacarpal bone in the two hollows already mentioned, so as to be separated by a small inter space. They are connected by ligaments to the first bone of the great toe, as the patella is to the tibia, and glide backwards and forwards in the different motions of the joint, defending it effectually below, giving an advantageous purchase to the muscles which are fixed to them, and preventing from pressure the tendon of the long flexor, which runs between them. These bones are rarely met with in the other articulations. The motions between these bones and the metatarsus may be effected in every direction, except rotation, and are in general more limited than in the fingers. The toes, however, can be inflected backwards, or extended on the metatarsus to a greater degree than they can be bent. The advantages of this mechanism, so widely different from what we noticed in the hand, may be particularly noticed in standing on the toes, and in progression, and will be examined hereafter.

The second phalanges of the four lesser toes are so short and compressed longitudinally, as to have fearfully the usual characters of the long bones. This is a distinguishing point, in comparing them with the second phalanges of the fingers, which they otherwise resemble in miniature, giving attachments in a similar manner to flexor and extensor tendons, and to the fibrous sheaths of the former. The articulations are also analogous; the motions, which are those only of flexion and extension, are more limited.

The last, or ungual phalanges, five in number, resemble those of the fingers both in structure and formation. That of the great toe is strong and broad; the others are more than proportionally small. This last difference is the principal one between them and the fingers; the articulations and motions are very nearly the same; the latter may be a little more limited. In children they are very movable: this mobility diminishes as we grow up, and is often completely destroyed in advanced age, owing most probably to the confinement of our shoes. The metatarsal rows have three points of ossification, the others have two, and very frequently only one.

From the allomagl of the bones we have been describing, there results a long, broad, and partly vaulted basis, for the support of the weight above, secured by numerous and strong ligaments binding the arch beneath. The principal points of bearing are on the lower part of the heel bone; the outer face of the foot in nearly its whole length, especially the posterior end of the metatarsal bone of the little toe; the anterior ends of all the metatarsal bones, and most conspicuously that of the great toe, which is proportionally strong. When the heel is elevated from the ground, the whole pressure is on the last mentioned points, and on the toes, which compensate, by their augmented breadth, their comparative want of solidity. The vaulted form gives a space in which the vessels and nerves can pass free from compression; and the number of the articulations, by distributing the shock over numerous slightly yielding surfaces, prevents the injurious effects which might otherwise arise from leaps, or falls on the feet.

Mechanism of the lower extremities.—In supporting the trunk, the hip bones are placed between two opposite efforts; viz. the weight of the body transmitted by the facrum; and the resistance offered by the limb below in the direction of the cotyloid cavity. The depressing impulse acts in a plane posterior to that of support, tending to make the hip bones move backwards on the thighs, if they were not counterbalanced by muscular efforts. The base of support, as far as regards the osa innominata, is contained between the plane of the vertebral column behind, and that of the thigh bones in front; a space which varies in different individuals, and which is comparatively narrow in infancy, from the more oblique direction of the hip-bones, which brings the thighs more immediately under the vertebral column. As the osa innominata become more horizontal, the base of support is rendered wider, and the muscles being at the same time more fully developed, give it additional security. This is one source of the difference in gait in manhood and infancy. Another is found in the disposition of the cotyloid cavities. As they are at a distance from the points of offlection, they are almost wholly cartilaginous for some time after birth; and therefore can offer but a feeble resistance to the thighs, quite insufficient for standing or progression, until the place of cartilage is supplied by bone. Add to this, that the two joints are comparatively nearer to each other; which circumstance, though it give facility, must necessarily diminish firmness.

The greater proportional distance in the adult throws the thighs further apart above. In females this distance is greater than in the male, which gives a peculiarity to their walk, a more observable rolling of the hip in the successive advancement of each limb. This is not to be seen in the infant female, where the position and form of the hip bones differ but very little from those of the male of the same age.

The femur, which is the only bone in the thigh, is curved considerably forwards in the middle; hence a larger space is left behind for muscles and the base of support, afforded by this bone to the trunk, is directed forwards, so that the latter is sustained in the direction, in which it has the greatest tendency to fall. The neck of the bone, besides increasing the extent of rotation, enlarges transversely the base of support; gives the body a greater firmness in standing, without impeding progression, since the head of the bone, and not the body, is the centre of motion. If the thigh bones possessed no neck, but were kept equally far apart, by increasing the distance between the cotyloid cavities, the attitude of standing would be equally secure, the transverse base of support being still the same; but progression would be impeded, as it actually is in the female, from the greater transverse diameter of the pelvis. The head of the femur, sunk into a deep cavity, is forced, in supporting
supporting the trunk, against the most resisting part of this cavity, &c. under the anterior spines. The strong ligamentous bands which strengthen the capsule in front and above, are fo disposed as to augment the resistance to any effort of the thigh-bone in that direction, and to restrain any part of the head which may not be contained in the acetabulum. The interior ligament also adds to the firmness of the joint; preventing, by its tension, the displacement of the articular surfaces in every effort which forces the head upwards; an effort which, from the prehure of the trunk, is almost constantly operating. In the infant, the body of the bone is nearly straight, a conformity unfavourable to standing, according to the reasons above alluded: the neck is shorter, and consequently the base of support diminished; it is cartilaginous, and therefore less able to endure, for any time, an attitude which demands solidity in the supporting parts. These are other reasons for the insecurity of the station and progression of young children, and they by contrast the advantages of the form of the adult bone.

In the knee, we are struck with the extent of the articular surfaces, and the number and strength of the ligaments which connect them, so well adapted to sustain the weight transmitted by the thighs; the crucial ligaments limiting and maintaining the extension of the leg, preventing it from passing in this direction beyond the axis of the thigh; the patella in some measure restraining its flexion, protecting the joint; and more particularly favouring the action of the extensor muscles, which play so important a part in the functions of the lower extremity. The perpendicular direction of the leg is very advantageous in giving firmness; to this end also the immobility of the two bones which compose it seems directed. The tibia, solid and broad at either end, alone receives the pressure and continues it to the foot; the fibula serves principally to afford attachments to muscles. This disposition, so different from that observed in the analogous part of the upper extremity, bears an obvious relation to its different function. In infancy the patella is scarcely perceptible; its absence must be unfavourable to the power of the extensors, and may be one cause of the feebleness observable at that period; and further, its want is felt in kneeling.

The foot is admirably adapted to its office of sustaining every effort continued from above. It is articulated at right angles with the leg, through which it receives the weight of the body in a perpendicular direction, bearing directly on the upper surface of the allagrus, the whole length of the foot resting on the ground. The articulation is situated nearer to the posterior than to the anterior part of the feet, which gives to the base of support a greater extent forwards, a direction towards which the line of gravity naturally inclines. The lateral extensile of the malleoli materially secures the firmness of the ankle joint. The breadth of the foot, increasing gradually towards the front, the length of the metatarsal bones, the direction of that which sustains the great toe, its situation and want of mobility, are other circumstances marking the distinction between the hand and foot, and adapted to increase the solidity and extent of base afforded by the latter. The functions of the foot are affiliated also by its concave form, which enables it to gain a kind of hold of the bodies on which it rests, and to accommodate itself to unequal surfaces, an advantage almost destroyed by the use of shoes, but eminently conspicuous in those people whose feet are not cramped by artificial means of defence. In its posterior half nearly it rests on the ground by its outer side, composed of the solid bone of the heel, and the os cuboidei, the inner side representing an arch, and placed at a distance from the plane below; in the anterior half the weight is principally supported by the inner side, where we find the solid bones of the great toe very little affiled by the external edge.

Every thing in this structure of man evinces that he is designed by nature for the erect posture: we shall notice here those proofs only which are deducible from the framing of the extremities. One of the most obvious is the great disproportion in the respective lengths of the upper and lower limbs, and the greater comparative strength of the lower. Other marks are found in the width and direction of the hip bones, in that of the neck of the femur, in the articulation of the leg at right angles with the foot, in the size and length of the latter, and the predominance of its solid over its moveable parts. We may remark also the flattened chest, and the shoulders set off by long eavicles, so very different from the construction of these parts in quadrupeds, where the chest is compressed laterally, and the anterior extremities approach each other in front for the better support of the body. The form of the hand, and the modes of articulation between the several bones of the upper extremity, are among the numerous and evident arguments that the erect posture is natural to man, and we believe we may add, peculiar to him. In all the postions, produced by different motions, this posture is more or less preferred; so that, before we enter on progressive movements, it will be well to consider separately the simple act of supporting the body, which they necessarily include.

Station—or the act of standing, in man, as far as the lower extremities are concerned, will be the first point for our observation. In this attitude it is necessary that the perpendicular line, which passes through the centre of gravity of the whole body, should fall somewhere in the space intercepted between the two feet, or on the sole of the foot itself, if we are supporting ourselves on one only. This centre of gravity, when the body is erect, has been proved by Borelli to be placed between the hip bones, "inter nates et pubens," in the human subject. To favour this disposition, we find a vertebral column curved alternately in opposite directions, and placed obliquely with regard to the direction of the osa innominata, by which means the distribution of the foot parts is more easily managed, the balance preferred, and permanent slant much facilitated. If this obliquity did not exist, and the vertebral column had been straight, it would approach too nearly the line of direction of the leg and thigh, a disproportionate quantity of the mass of the body would be placed in front of the line passing through the centre of gravity, which would continually tend to make the body fall forwards in prolonged station, or progression. In the orang-outang the angle, which the vertebral column raised perpendicularly makes with the hip bones, is much more obtuse than in man, and the equilibrium is preferred by the length of the arms; the same may be observed of the gibbons, the simia lar of Linneaus. In quadrupeds this angle, under similar circumstances, is still more obtuse, and the efforts they make to remain upright on the hinder feet are continued with difficulty, more especially if not assisted by some other peculiar advantages of construction, as in the bear, for instance, by the length of the heel. In man, the hip bones united to the sacrum form a circular support, by means of which the columns below are not inclined to the trunk, but sustain it in perpendicular lines. If they had converged above, they would have formed an angular support, not so capable of resisting the prehure, and requiring a constant and powerful exertion on the part of the adductor muscles. As it is, the columns are press'd on perpendicularly by the transverse width of the hip bones,
EXTREMITIES.

so that the pressure may be said to render them more firm and steady. The long bones of the lower extremity in man are placed nearly vertically on each other, and on the foot. And we may just remark, that even in fliation a succession of columns of the same size is probably more advantageous than a single one, equal in bulk and length to the whole: this has been demonstrated in the case where the weight is upheld by columns supposed to be flexible. The direction of the head and neck of the femur has been already mentioned as increasing the bafe of support, and we may add that the oblique position of the latter decomposes, in some measure, the pressure of the trunk from above, and renders it less sensible than if it had been vertical; avoiding at the same time the disadvantages arising from an inclined position of the whole column, as mentioned above. By the arch of the necks also the thigh bones are projected from under the hips, and sustain the trunk with greater conftancy and freedom than if they had been placed vertically beneath it during its different inclinations. The thighs, charged with the weight above, transmit it to the leg at the knee joint; somewhat differently, however, in the adult, and in the aged. In the latter the spine is bent forwards, and to preserve the balance the thighs are necessarily also bent, and press obliquely on the leg, a disadvantageous bearing, as requiring greater muscular efforts, and soon becoming on this account wearisome. It is through the tibia alone that the pressure is communicated to the foot, which finally supports the whole weight. The arch of the latter is ferviceable to fliation only inasmuch as it favours the adaptation of the fole to inequalities of surface. In procifion it may give care and grace, but the long and somewhat flattened foot is probably best suited to firmness of fliation. The concavity is lessened by the prefure, which acts more fensibly on the anterior and more moveable part: it is very evident, when the foot comes with force to the ground, and it may be proved also by the others and meafures performed by wearing fhort fhoes, which impede the elongation of the foot.

A question has arisen concerning the most advantageous bafe of support, or what opening between the two feet is best fuitable to security of fliation. An answer equally applicable to every cafe cannot readily be found; the nearer it approaches a square, including the feet, the better. Still different individuals must require different bases as suited to their own form. In every cafe, if the separation be too wide, the limbs lose their perpendicular bearing, and become inclined to the trunk. The smaller the angle made by two lines produced backwards in the direction of the feet, the better: it leems, indeed, that a parallel direction of the two feet is the moft natural, as we fee it in children and in the greater number of adults, especially of those who have not been inftucted by art. The body has a tendency to fall forwards, which is partly counteracted by the length of the foot; increasing the bafe of support in the anterior direction. Now if the foot be turned much outwards, the bafe is necessarily shortened towards the front; and, as in flation, the trunk has no disposition to fall laterally, what the bafe gains in that direction is in no degree equivalent to what is taken away from the other. The fame observation applies to turning the toes inwards; but as this never takes place to any considerable degree, an abuse of it is lefs to be apprehended. The unnatural position, in which education teaches us to place our feet, with the heels forming an obtufc angle behind, is contrary to the whole mechanism of the limbs, is uneasy, and infecure. In different gymnastic exercises the feet are placed thus to offer the greatest possible resistance to the probable direction of the effort they will have to withstand. In wrestling, where the force in the first inference is generally applied latetally, we obferve the feet parallel, and at a considerable distance from each other. Constant attention, however, is absolutely necessary to change this bafe, if any unexpected impulse be made in a contrary line. A deficiency in this respect is the reason why inexperienced wrestlers are so readily pulled down forwards, or thrown on their backs, their exertions being uniformly directed to oppose the expected ones of their adversaries; if these be suddenly altered, there is no adequate power of refiftance. In boxing, the bafe is increafed from before backwards, the feet are placed nearly at right angles and far apart, the knees are bent a little, and the trunk lowered. Here the impulse is expected in front, and the attention is particularly directed to oppose it in that point. This, in short, is one of the great principles observed not only in these exercises, but in every laboursome exertion, as in pushing or pulling, where the line of opposition does not vary. Whatever be the direction or distance of the feet from each other, no muscular effort can prevent the fall of the body, whenever the perpendicular line from the centre of gravity falls without the quadrilateral space intercepted between the feet. And a man can support a weight much heavier than himself, provided that the line from the centre of gravity of such body fall within the bafe of support.

Our observations hitherto are principally applicable to fliation, with the trunk erect. Let us now fuppofe the feet fixed securely on the ground, and the trunk moving in different directions by means of the articulations of the hip with the thighbones. In bending forwards, if the motion be prolonged considerably, the centre of gravity is no longer supported, and a fall is the immediate and necessary consequence. We have before remarked, that the articulation of the ilium with the subpubis is in a plane parallel to that of the feet. Now, if in bending forwards, the hipbones move on the thighs, as to bring the two bafes into the same plane, the centre of gravity is easily thrown forwards beyond them, and a fall is the refult. To counteract this, when the trunk is bent much forwards, we at the same time carry the upper part of the lower extremities backwards, the feet remain advanced, the leg and thigh are inclined backwards, so as to form an angle with the body. In extending the body on the thighs, and carrying it back beyond the perpendicular, as there is no extended bafe of support behind, analogous to that formed by the feet in front, we are obliged to bend the knees, in order to bring the centre of gravity within the space occupied by the feet. If the lower extremities are maintained in an upright position, while the trunk falls behind the perpendicular line, a fall is inevitable. Lateral inclinations of the trunk on the thighs are necessarily confined; since, in order to lower it on one fide, the opposite limb must be proportionally raised; when both feet touch the ground, it is almost completely prevented, so that the lateral balance is seldom lost, especially as we can at pleasure widen the bafe of support.

The power of standing on the toes results from the mode of their articulation with the metatarsus, which allows of extension or inflection upwards, beyond the axis of the latter. By this mechanism we rest on the whole length of the toes, not merely on their points, which would be utterly incapable of supporting the weight; here too the femoral bones are essentially useful, the preflure bearing directly on them, as it does on the patella in kneeling. In this attitude the feet are extended on the legs, and form an obtufc angle with the toes, which constitute the bafes of support; the legs and thighs are in the same straight line, and the trunk is projected a little forwards by the elevation, so that the centre of gravity
gravity is brought over the contracted plane, which now forms the base of support, heightened very much in length posteriorly by the loss of the tarsus and metatarsus. The same difficulties occur if we stand on any pointed, or narrow body, and for the same reason, viz. the diminution of the space in which the vertical line from the centre of gravity must fall, in order to preserve the equilibrium. This applies also, and more forcibly, to the cafes in which we stand on the toes, or heel of one foot only. In the last instance the foot is bent, the sole elevated, the rounded heel alone touches the ground by a very limited surface, great muscular exertion is required to keep the line of gravity vertical, the body vibrates on every side, and the attitude is necessarily soon lost or discontinued. We have not so much difficulty in standing on the heels of both feet, though this is far less easily than on the toes, on account of the points on which the weight rests. Standing on a single foot, with the whole sole on the ground, is an attitude more easily maintained, on account of the greater length of contact, and the less muscular exertion necessary to incline or erect the trunk so as to bring the line of gravity within it. In this position the body is more or less inclined on the limb which supports it, and may be moved with facility in every direction by means of the joint at the hip. The long neck of the thigh-bone is here eminently useful, by widening the base of support afforded above to the trunk; and the position cannot for an infant be maintained by animals, who, besides other obstacles, have a very short neck to the femur. It is obvious that flaton on one foot must be more difficult than on two, as in the last case it is not only the feet, but the plane intercepted by them, which form the base, and much less exertion is required to keep the line from the centre of gravity within it. We must have observed also, that when in flaton on one foot, the trunk is much inclined in any direction, we throw out the other limb in the opposite one, in order to keep the centre of gravity vertical to the base: and if we stand on the toes or heel of one foot, not only the other leg, but the arms also, are called into action to preserve the equilibrium, which is peremptorily lost and regained by the tottering trunk, and flapping base. A fixed stability is utterly prevented by the difficulty of keeping the balance even under the greatest muscular exertions.

In sitting, the support is afforded by the tuberosities of the ischia, the thighs and the interval between them, and by the legs also, if we sit on the ground with them extended. This is a firm position, easily continued, especially if the body is inclined a little forwards over the base; if it is inclined backwards a fall may easily take place. On this account we have generally backs to our seats, to allow the trunk to recline, when the muscles are fatigued by supporting it in its position of inclination forwards. The legs and thighs are concerned only in a secondary way in this posture, as the principal support is afforded by the tuberosities of the ischia resting immediately on the surface below.

Kneeling is another attitude in which the lower extremities are employed, but the base of support is extended posteriorly, consisting of the space included by the legs, which are projected backwards under the trunk. Hence the body, if erect, is disposed to fall forwards; we require a resting place in front, as we throw the hips backwards, to bring the line of gravity over the legs. This posture is far from an easy one, since it requires a constant and unfavourable exertion of muscular force. The use of the patella has been already explained.

The importance of the general law, by which it is necessary that a vertical line passing through the centre of gravity should fall on some point within the base of support, is strikingly exemplified by the following observations. If we stand with our back and feet touching a wall, and then make a profound bow forwards, we inevitably fall, as the vertical line from the centre of gravity over-reaches the base of support. Again, when fitting with the trunk and legs perpendicular to a horizontal plane, we cannot rise from our seat; because the centre of gravity of the trunk fails far behind the feet: we are obliged concomitantly either to incline the trunk very much forwards, or draw the feet backwards under it, in the first case changing the centre of gravity, in the latter the base of support; and then by muscular efforts the thighs are easily extended on the legs, the trunk suspended, and the whole body erected; operations extremely difficult, if not impossible, supposing the original position had been preferred. Our notions of flatton would be very imperfect if we did not take muscular exertions into the account; it is in vain that we place a dead body so as to bring the centre of gravity over the base of support; the bony columns are not longer regulated by the varied efforts of numerous muscles, as in the living subject; the machine is incomplete, and inertly gives way to the pressure. The same phenomena occur if sitting comes on in the erect posture; the head and neck incline forwards, as also the trunk; the bones bend on the thighs, the latter on the legs, and these again on the feet. We must not therefore confine our attention to the idea of bony columns preffing vertically on each other, but recollect that they have highly moveable articulations, which require some strong external efforts to give them positive stability. These exertions are more or less powerful as the bones depart more or less from a vertical bearing on each other. Hence the anterior extremities of quadrupeds pollies fewer and less powerful muscles than the posterior: as, in the first instance, the bones are directly extended on each other, and press vertically on the ground; in the last, they form angles more or less open, which can be preferred only by a constant exertion of muscular force. The elephant is an illative exception to this observation; his hind limbs are nearly vertical columns; a mechanism which so ailuishes the equality of the two sides is necessary to support his enormous bulk. In insects, on the other hand, the joints are bent at very acute angles; a structure less inconvenient than we might at first suppose, as on account of the smallness of their body, the weight is diminished in a sub-duplicate ratio to their size. In birds who sleep perched on trees there is a peculiar construction, by which the more cession of muscular action, the allowing the body to sink, and the knees to bend, induces a mechanical contraction of the toes, which grasp firmly the body on which they rest, and secures their position when at roost. In the grallae tribe, in the fork for instance, who stands motionless for hours waiting for his prey, there is a particular construction in the articulation of the knee, which enables him to stand without much muscular exertion.

Progression—may be effected in many different ways, of which we shall examine only the most ordinary and simple. In walking, the action, which carries the body forwards, backwards, or to either side, consists in alternate motions of the lower extremities, in which each of them becomes, in its turn, the fixed point on which the whole weight of the body is supported; the limb which moves, giving in its elevation an impulse to the trunk by means of the hip bone. Each of these motions is called a step, and a sustained succession of them constitutes progression: and in order to understand the latter, we shall examine the mechanism of the step under different conditions. In walking, if we suppose
EXTREMITIES.

Both feet to be on the same transverse line, the limb (by the left) which makes the first step, is raised from the ground and advanced, by bending the hip joint; it is then extended, and lastly, the foot preserving its advanced position, is fixed on a different spot; so that the centre of gravity of the body which, during the advance of the left leg, was sustained by the right, is moved forwards by a simultaneous movement of the trunk; and the line of gravity falls between the two feet. If the step is short, the hip and trunk move but little; if it be long, and the left leg carried far beyond the right, there is an evident rotation of the right hip, and consequently of the trunk on the corresponding thigh. By this horizontal rotation, which carries the left side of the body obliquely onwards, the extnt of the step is greater than it would have been by the simple bending of the thigh; and we feel it in fact most evidendy in long strides, where the rotation is so great, as to bring the shoulder of the advanced side immediately in front, the hip moving through the quarter of a circle, giving thereby an additional impulse to the limb below. The step is shorter, this lateral rotation is left observable, till in some cases it can be no longer noticed. It is more evident in the female, from the greater transverse diameter of the pelvis; and is particularly striking in individuals who have a stiff, or ankyloped hip joint, where the limb cannot be advanced by bending the thigh. The short step is effected, on the contrary, chiefly by the alternate flexions and extensions of the joints of one extremity, uninfluenced by any movement of the trunk on the other.

If the feet are not in the same transverse line at the commencement, the limb, which is behind, and inclined to the trunk, is the one to be moved forwards. Here the foot rises, each part quitting the ground successively, from the heel to the toes, by a kind of circular motion. The limb is thus elevated and advanced, and the centre of gravity is carried in the same direction, which latter is effected with greater facility, as the body at the same time leans a little forwards. When this impulse is carried to its full extent, the toes are detached from the ground by the thigh being suddenly bent on the hip, which has been moved forwards, and the limb is carried on as in the former case, the other remaining fixed as the temporary support. The hip and knee joints are then extended, and the foot bent on the leg. The foot touches the ground first by the heel: this is succeeded by a circular motion of the anterior part of the foot round this fixed point, and a corresponding motion of the leg in the same direction, which brings it to a vertical line at the time that the toes begin to bear on the plane below. In these circular motions the foot is feebly elongated, and its concavity lengthened by the pressure, its vaulted form, and the number and mode of its articulations imparting a degree of ease and grace to the whole motion which we look for in vain, where the foot is flat and stiff, and the whole foot quits, or reaches the ground at the same instant. There is, in this case, an awkwardness of gait, and a real inability of walking with promptitude and vigour. This step we have been describing takes place successively in each limb in progression; and differs from the preceding in being more extensive, and depending more importantly on the foot. The impulse which its elevation communicates to the trunk will be influenced however materially by the knee: if this is kept in proportion as the foot rises, the limb lores in one action what it gains by another; the impulse will be stronger as the knee is kept more extended. And when the foot is detached at once, without this rotation, no impulse will be given to the hip by the limb in motion: if the pelvis roll on the thigh which is fixed, it must be by an independent muscular action, as in the former case. In every case, as soon as the foot has left the ground, the trunk supports the limbs; and carries it forwards. The mechanism of the step backwards will be easily understood from what has been said: we observe only that the foot is raised more immediately by bending the knee; and that when the step is prolonged, there is an evident horizontal rotation of the trunk in the same direction. The side step is produced by gently bending the knee to detach the foot from the ground, and then abducting the thigh; or by lifting the whole limb by a lateral inclination of the trunk on the opposite one, and then separating them, the knee being all the while extended.

Walking is a succession of these motions, and requires for its regularity an equal length of both limbs; a shortness of either limb induces a sinking and relative inclination of the whole trunk to the corresponding side, every time that the deficient extremity touches the ground. In the most natural mode of walking, one foot does not quit the ground entirely, until the other touches it wholly, or in a great part of its length: the latter begins to fix itself while the former Still rests on its point; the vertical line from the centre of gravity, which fell on one foot during the transportation of the other, being carried forward, and dropping at this time between the two. When the advanced foot is firmly fixed, we throw on it the centre of gravity; the same motion necessarily projects the whole body forwards, and a succession of similar phenomena takes place. At each step the impulse given to the trunk by the limb which has just quitted the ground produces an undulatory motion up and down, and at the same time an horizontal rotation alternating from one side to the other. It is the latter which, from not being sustained equally, produces the deviation from the straight line in walking forwards, so constantly observed if we walk with blind folded, where consequently we cannot correct incidental errors by the light. The whole of walking is a succession of steps, in this case is by taking very short steps, and for the reasons intimated above. In fact, the centre of gravity is not, when we carefully endeavour to attain it, moved forward in the same straight line, but varies more or less between the lines described by the feet at every step, in a degree proportionate to the extent of each. This is scarcely noticed, but is evident from this simple experiment. If we stand at any distance from a small perpendicular rod, and fix our eyes on any point some way behind it, and in the same straight line, we shall, as we advance to the rod, find this point alternately to the right and left of it, as we move each limb. A proof that the trunk is not carried as in a straight line, but describes a tortuous one, winding from one side to the other. Another consequence of this rolling of the trunk on the opposite limbs in succession, is a swinging motion communicated to the upper extremities: these move, most commonly, in an opposite way to the feet; that is, the right arm moves on the same instant that the left leg propels the trunk. The use of this cross motion of the arms is supposed to be that of correcting the lateral impulse given to the trunk by the leg in its elevation. In every case of progression there must be a regulated degree of flexions and extensions, which is in some instances provided for by the mechanism of the bones, and their ligaments, but in all depends principally on an uniform succession of sustained muscular actions. The greater difficulty and fatigue experienced in walking up an ascending plane depends upon the greater degree of flexion necessary to raise the limb from the ground; this must be increased as the plane becomes more vertical; the heel is at the same time lower than the toes, and must pass through more
more space in each elevation than in the ordinary case of walking on plain ground. Walking down hill is for the same reason less difficult; there is less occasion for extensive muscular action. The object is to regulate the impulse which the trunk easily acquires, and to keep the centre of gravity over the feet, by throwing the trunk a little backwards, instead of leaning forwards, as in the preceding case. In ascending also we have each time to elevate the weight of the body by muscular powers; in descending we have only to prevent it from sinking too fast. Mounting steps, or a ladder, or descending either, are still more difficult, as the reasons above given apply more strongly.

Running differs from walking chiefly in the rapidity and force with which the motions of the lower extremities are executed. The mechanism by which they are produced is nearly similar; the remarkable differences are, that the toes only touch the ground, and the whole trunk is inclined very considerably forwards. In consequence of the first circumstance, a small surface only is in contact with the ground; and this can be more rapidly applied and detached, while the extent of the foot upon the leg adds to the length of the limb. From this small extent of the base of support arise the frequent falls in running from tripping obstacles, or flight lateral impulses; and hence, in this mode of progression, we should constantly endeavour to preserve the balance, by preventing the centre of gravity from being removed too quickly from the leg behind, or from being thrown too soon on the one in advance. Running is also infecund from the short time allowed for fixing the point of support; and hence, the economy of strength is lessened inerterly as the necessity for it is increased by the quick transition of the centre of gravity from point to point. At each step the trunk is suddenly and violently carried forwards by the limb which has just left the ground, and which must be immediately and considerably advanced to support the centre of gravity. In running very fast, especially on a declivity, so powerful an impulse is communicated to the trunk, that it is almost impossible to stop suddenly; we gradually slacken our pace, still projecting the limbs to support the trunk till the impulse is weakened. In running up an acclivity we always bend forwards, to assist the propulsion of the centre of gravity, which is effected under many difficulties; we generally do so in running on plain ground, though, when we run carefully, the head and shoulders are thrown back to counterbalance the impulse below. When from fear, or inability to continue the muscular exertions necessary to maintain this posture, the trunk is neither thrown back, nor even kept vertical to the horizon, the runner appears to yield entirely to the impulse, to commit himself almost to chance: his only endeavours being to throw his legs out rapidly and to the greatest extent, to sustain the increasing velocity with which the centre of gravity is carried onwards: the ground covered at each step is really immense, the power of balancing is totally lost, and the slightest inequality of surface is sufficient to overturn him with the roughest violence. If he be steady enough to reach the bottom in safety, he continues his course a very considerable way before the impulse is detained, and the power of regulating his movements recovered. In running, the lateral rotation of the hip and trunk on the thigh is extensive, from the length of the steps; and the same cause produces an equally great and rapid motion of the opposite arm to preserve the equilibrium, which is more easily lost than in walking.

In leaping, the body may be raised vertically, or with any degree of obliquity. The joints of the lower extremities are first closely bent, and then suddenly extended, so as to propel the trunk; for the ground effectually refits the impulse, which must be entirely spent on the moveable parts above. The alternate angles, formed by the ankles, knees, and hips, depress the centre of gravity, without altering its bearing on the feet; and the same mechanism enables us to elevate the trunk nearly in a vertical line, the circular motions in opposite directions executed with almost infinitesimal velocity, acting in a straight line intermediate to them all. If the flexions were all made in the same direction, subsequent extension would be more laborious, and a perpendicular impulse, such as produces the vertical leap, would be impossible. The mechanism of leaping may be illustrated by comparing it with other motions. The muscular powers being the same, the leap will be more considerable as the levers are longer, and more inclined on each other. Hence animals, whose hind limbs appear disproportionately long, can make the most extensive bounds; we need fearlessly trust the kangaroo, hare, squirrel, or grasshopper.

The elevation of the body in a vertical leap is continued to long as the communicated impulse exceeds the power of gravitation; as the former diminishes, the latter again begins to operate, and the body descends in the same line with that in which it had been elevated. It is incapable, while in the air, of altering the general direction derived from the first impulse; although many motions of the extremities may be produced, as we observe in dancing. The ground, from its want of elasticity, communicates no impulse to the body at the moment of elevation. A certain reliance to the action of the muscles on the moveable levers is required. If the ground be soft or sandy, it yields too readily to the impulse of the feet, and leaping is impeded; on the contrary, if the point from which the jumper springs be elastic, as in the case of a flexible board, or a tight rope, there is an evident re-action, considerably increasing the impulse communicated by the exertion of the lower limbs. In jumping forwards the trunk is inclined, and projected in the same direction by the extension of the thigh on the leg. This latter motion is counterpoised or varied, according to circumstances; but it is so essential in every case, that we cannot leap if the knees are kept extended, no muscular action or exertion could then raise the body from the ground. The chief effort is to turn the thigh and trunk balanced on it forwards on the tibia; and the impulse thus given predominates over the others; in leaping backwards, the tibia is the more moveable division of the lever by a variation in the combined action of the muscles employed, determinable by the will. In the vertical leap the body moves up and down in the same line; but if the impulse be given in a line inclined to the horizon at oblique angles, the line described by the centre of gravity will be a parabolic curve, compounded of the uniform straight motion of projection, and the force of gravity, as in other projectiles. While the first predominates over the last, the body ascends; when they are in equal power, the elevation is the greatest; from this point, it descends, the force of gravity acting with increasing effect as the impulse is weakened. The impulse, in this case, may be considerably increased by a previous motion given to the body by running: the impetus is somewhat altered in direction by the violent extension of the extremities, but it acts with almost undiminished force in projecting the body: there are here two causes acting in opposition to gravitation. This kind of leap is facilitated by inclining the body forwards; and, in order to afford a point of support to the centre of gravity, we always find, before the body is elevated from the ground, that one of the legs, generally the right, is much before the other; this position is preferred throughout, for the same reason, or the two legs are brought into parallel obliquely inclined lines, before we reach the ground.
THE EXTREMITIES.

ground at the end of the leap. If we jump with the feet together, we cannot incline the body much forwards, without losing the balance. In this case, to all the impulsive force, we lifting the arms backwards and forwards before we make the spring, endeavouring to give some degree of horizontal impetus to the trunk, which must however always be inferior to that obtained by even a short run. The body comes in contact with the ground, at the end of the leap, impressed by a double force, viz.; the projectile impetus, and that acquired by gravitation in the descent. We extend the feet on the legs, so as to touch the ground first by the toes; we then yield somewhat to the force, and allow the joints to be bent gradually, so as to weaken and finally destroy the shock. In order to destroy the impulsive force given to the centre of gravity, we throw back the head and shoulders, and slacken our pace by degrees, till the power of balancing is restored.

The action of dancing, which consists in a rapid change, in various manners and directions, of the lower extremities, principally resembles, in some respects, the run, in many others the leap. We omit the detail of those extraordinary and amazing feats of agility, which astonish us in the stage dancer, or the tumble; as they depend, not on any peculiar circumstances, but on the powerful, long sustained, or rapid actions of muscles, educated to the task, and performed by constant exercise, in the highest possible state of energy. Hopping is a succession of leaps on one leg alone; the actions are otherwise analogous. Skating is a simple motion; the mechanism of which may be readily conceived after the observations we have made: the centre of gravity is brought alternately over the opposite feet, as each glides on the plane beneath, and the balance is preserved by muscular actions. Swimming is a more complex action of both upper and lower extremities, involving in its discussion many interesting questions, independent of their functions, and which consequently cannot properly be considered here.

For a detailed information on the subject of animal mechanics, we refer the reader to Borelli, de Motu Animalium; Haller, Element. Physiol. tom. iv.; Barthéz, Nouvelle Mécanique de l'Homme; see Jour. des Scavans 1782-1783. Bichat, Anatomic Descriptive, tom. i. Cuvier, Lécons d'Anatomie comparée; tom i. for la fin. There is a catalogue of authors on this subject in Dr. Young's Natural Philosophy v. ii. p. 164.

Comparison of the upper and lower extremities. — A review of the differences in the construction of the upper and lower limbs will illustrate the mechanism of their component parts. There is a general resemblance of form throughout; and the essential varieties may be all referred to the principle of mobility in the upper, and that of firmness in the lower. In man, the extremities are nearly parallel to the long diameter of the trunk; and consequently they must be parallel to each other; but they are not in the same vertical plane. A line drawn from the glenoid cavity of the scapula to the acetabulum, will be very oblique from above downwards and forwards, because the plane in which the former lies is posterior to that in which the latter is found. Hence the arm drops necessarily behind the thigh. The advantage of such a disposition in the upper extremities is, that the principal motions, which are those in the anterior direction, have a greater range than if the glenoid cavity had been seated nearer to the front of the trunk. The extremities differ also in the space, by which they are separated from each other. If we judged only by the intervals between the right and left glenoid and cotyloid cavities respectively, we should suppose the difference to be great; the long clavicles keeping the first at a greater distance than the pubal portions of the hip bones do the second. This, however, is compensated by the length and obliquity of the necks of the thigh bones, which throw the axes of these bones far without the cotyloid cavities. We have here supposed the legs to be extended, and the arms lying in their natural direction by the sides of the trunk; if the knee and elbow be bent in this position, we shall find the angles are formed in nearly opposite directions, that of the knee backwards, and the elbow forwards. These are the only joints in which the articulations are directly inverse in their modes of action; in quadrupeds, this condition prevails from the shoulder and hip to the feet in a very striking manner. The lower extremities are nearer together below than above; while the upper are kept amlber by the intervening body. The lower extremities are rather longer than the upper, in consequence of the great length of the thigh and leg, when compared with the arm and fore arm. For the latter, by the long axis of the hand being in the same line with their length, gain much more than the lower extremity does by the mere thicknees of the foot. When the arm hangs easily extended by the side, the points of the fingers reach to about the middle of the thigh; whereas there are many varieties in this respect. The form, and the distribution of the surface of the lower, are strikingly contraltered with the flender make and narrow articulations of the upper; the first bearing a marked relation to their principal function of sustaining the body, the latter to their distinguishing character of mobility. At the time of birth the upper extremities are more advanced in formation than the lower. This feature is, however, more remarkable, the nearer we mount to the first development of the embryo; it is gradually lost after birth, and the structure of both is completed nearly about the same period. The different nature of their functions, those of the upper commencing almost immediately, and those of the lower not until a considerable interval after the birth of the child, explains, in some measure, the reason of this disposition.

The bones of the hip and shoulder differ more in their form and connections than any other parts of the extremities. The scapula are bounded by muscles, allowing a greater cavity of motion, and are kept apart by the two moveable clavicles in front; the hip bones are bound firmly to the spine, and the articular cavities separated from each other by an immovable medium. The space between the cotyloid cavities is proportionally greater in the female than in the male. The same excess may be observed in the shoulders, where it arises from the greater comparative length of the clavicle. The breadth of the scapula increases in the male the transverse diameter of the shoulders, which on this account is particularly striking from behind; in front they are not proportionably so wide as in the female. It is therefore the proportional excess of width in the hips, and not any decrease in the breadth of the shoulders, which gives to the female figure one of its most prominent features; this distinguishes it from the male, in whom the strong, though narrow, hips are opposed to the comparatively broad articular shoulders. These circumstances are sufficiently evident in examining the disposition of the bones; but they become still more striking, by the addition of the soft parts, in the complete subject, where the strongly marked and muscular form of the shoulders, and the contracted outline of the hips in the male, is finely contrasted with the delicacy of the first, and the swelling roundness of the back in the female. The hip bone exceeds the scapula and clavicle in volume, as well as in the firmness of its articulation; it further gives a fixed point of motion to the thigh, by a deep
deep articular cavity, whereas the scapula offers a shallow and easily moveable one, yielding to a slight impulse.

The femur exceeds the humerus very much in size, and length, (this last being nearly in the ratio of 4:6 to 3;), and in the extent of its articular surfaces. Although their motions are for the most part analogous, some differences may be pointed out. The movements of circumduction and rotation exist in an inverse ratio to each other. In the thigh bone, the length of the neck, which is the lever of rotation, gives great extent to this motion, and thus supplies the want in the leg of the motions corresponding to the pronation and supination of the forearm, so that all rolling of the foot out and in, when the limb is extended, arises from a motion of the whole limb. The short neck of the humerus, on the contrary, by bringing the axis of the bone nearer the centre of motion, limits rotation; which is less essential, insomuch as the hand is moved by the pronation and supination of the forearm. Circumduction is more confined in the thigh by this very length of the neck, which makes an angular lever of this bone, differing much from the nearly rectilinear one of the humerus. In the first case the axis of motion is not in the long axis of the bone; in the latter, it is nearly so; and the difficulty of this motion is proportional to the difference between the two axes, while its facility is greater as they approach each other more nearly. The advantages of this disposition, in giving mobility to the upper, and firmness to the lower extremities, may be readily perceived.

The leg exceeds the forearm in size and length of the bones, the proportions being as 39 to 26. In the orang-outang the ratio of the thigh to the arm is as 9 to 10, and that of the forearm to the leg as 9 to 11; which proportions are very different from those of the human subject.

The excess of length in the lower extremity of man is seen most evidently when he attempts to move on all fours, as we express it. To correct this disproportion he is obliged to bend the joints of the lower extremities, or to throw them out very obliquely behind the trunk, whilst the upper are perpendicular to it. The leg and forearm resemble each other less than the thigh and arm; in the forearm the parts are arranged favourably to mobility; in the leg the object is to procure a firm and solid support, which can transport the centre of gravity with ease and safety from one point to another. Of the two bones of the forearm, which are nearly equal in every respect, one rolls easily over the other, and the hand is articulated with the moveable bone. In the lower extremity these rolling motions would have been dangerous; to give it firmness, the foot is articulated with the tibia, which corresponds to the ulna, and not with the fibula; the latter possesses no perceptible power of motion.

The hand and foot resemble each other most closely in the structure and number of the phalanges, and of the bones which support them; the principal differences occur in the carpus and tarsus, which are the most solid portions. That part of the hand in which its strength resides is less developed, and has far less volume than the analogous parts of the foot, on which the whole weight of the body in station finally rests. The moveable phalanges, which are the principal agents in executing the functions of the hand, are much longer, and larger than those of the toes, which are not so essential to station or progression. The foot and hand are disposed inversely as to form; the posterior part of the former, and the anterior part of the latter, is the most important, the long-, and pollex, the most striking characters. The functions of the hand render it necessary that its plane should be nearly continuous with that of the forearm; otherwise the radius could not guide it so precisely over the objects in view. In the foot, the articulation is so disposed that its posterior part offers a powerful lever for muscular agents, and a solid support for the mass above; it is formed by a single bone of the foot, which necessarily adds to its solidity. The metacarpus and metatarsus have a much greater similarity to each other; the latter is the more solid, and offers this principal difference. The metatarsal bone of the great toe, by far the strongest of the whole, has feveral motion on the tarsus, and is on the same plane with the others; while that which supports the thumb has a very considerable extent of motion, and is anterior to the rest. This arises from the obliquity in the articulating facet of the tarseum, which is directly transverse in the first cuneiform bone of the tarsus. Further, this bone in the foot is not separated from the other metatarsal bones, by an interosseous space larger than that between all the rest, as is the case with the metacarpal bone of the thumb. These remarkable differences depend wholly on the solidity necessary for station, and the great mobility required for the important offices executed by the thumb in the human subject. In the ape tribe, the great toe on the contrary may be properly regarded as another thumb in its structure and uses. The toes can be inflected further on the back of the foot than the fingers can be on the hand, a disposition which is accommodated to progression, especially to running swiftly; an analogous effect is produced in the hand by the inflection of the carpus backwards on the forearm. At the time of birth the important parts of the hand are already well developed; the metacarpus, and more especially the fingers, are sufficiently formed for the infant to seize objects within its reach, and to distinguish some of their qualities. This early development of the organs of touch would seem to bear a marked relation to the corresponding advancement in the formation of two other organs of sense, the eye and ear, they being all associated closely in forming, or correcting external sensations. The important part of the foot, the tarsus, is far behind in formation, as it is not called into use till some time after birth, till the organs of sense have long been exercised in common, and can now mutually assist each other.

Reflecting this comparison between the upper and lower limbs, see Vicq D'azur sur la comparaison des extrémités en celles dans l'homme, et dans les quadrupèdes, in the Histoire de l'Acad. des Sciences 1774.
