**EPEE**, in Geography, a port of Africa, in the country of Benin.

**EPEDMOLE, Epedemos**, in Rhetoric, the same with parembole.

**EPENCRANIS, a name by which some of the old authors, particularly Erasistratus, have called the cerebellum.**

**EPENDYTES, Epedntes, among the Greeks, a garment worn under the pallium, and above the interula or inner coat, called, in Greek, Epedntes.**

**EPENTHEISIS, formed of épe, in, and -this, q. d. epenthoic, infero, inmutto, in Grammar, the addition, or infliction of a letter or syllable, in the middle of a word; as religio for religis, Moneia for Mare, uttum for ultum. Virg. Æn. lib. vii. ver. 27.**

In the Hebrew language, there are some letters which are called epedntetic, and they occur without any apparent necessity in the middle of words; such are "N. Malefis Heb. Gram. v. i. p. 191.

**EPERIES, in Geography, a town of Hungary, celebrated for its mines of salt; 20 miles N. of Cachau.**

**EPERLANUS, in Ichthyology, a name sometimes given, on account of its pearl colour, to the fround. See Salm. Eperlanus.**

**EPERLEQUE, in Geography, a town of France, in the department of the Straits of Calais; 2 leagues N.W. of St. Omer.**

**EPERNAY, or Esternay, an ancient and handfome town of France, in the department of the Marne, chief place of the district of the same name, with a population of 4452 individuals. It is pleasantly situated on the river Marne, 21 miles N.W. of Chalons for Marne, 18 miles S. of Rheims, and 88 miles E. by N. of Paris. Lat. 49° 21'. The canton has a territorial extent of 110 kilometres, 21 communes, and 13,958 inhabitants. As chief place of a district, Epernay has a sub-prefect, a ranger, a court of justice, and a regifter office. There are several manufactories of wooden flints, horsey, cutlery, leather, and writing-paper; but the most remarkable is that of a fort of glazed earthen-ware, which flands the hottest fire. The district of Epernay has 10 cantons, 215 communes, and 87,413 inhabitants, on a territorial extent of 2592 kilometres. Its soil is uncommonly fertile, and produces corn, but especially that excellent red and white champagne of the very first quality, which is so much sought for all over the world. Epernay is the centre of the best champagne wines; its own vineyards and those of Ay produce the best; and the town has a great trade not only with its...**
EPH

thence, but also with the famous wines of the hills of Hautvilliers, Périgueux, and Comices, which are not far distant. EPERNON, a town of France, in the department of the Eure and Loire; 4 leagues N.E. of Chartres.

EPERON, in Natural History, the spur-hill, so called from its resembling, in some degree, the rowel of a spur. It is a species of small, of the round-mouthed kind, or class of the cochleæ lunares; all its volutes are surrounded with double rows of prickles. See LUNARIS COCHLEA.

EPERONNIER, in Ornithology. See PAVO DICIARATUS.

EPERUA, in Botany. See DIMORPHA.

EPERVER, See Falco.

EPERVIES, in Natural History, a name given by the French authors to a class of butterflies, which make the sixth in Reaumur's method. They have a way of poising themselves on the wing in the manner of kites, and other birds of prey; and always live upon the wing; never settling themselves upon the flowers they feed upon, but keep flying with a humming noise like a humming bee, while they thrust in their trunk and suck the juices of the flower.

EPETIUM, in Ancient Geography, a town of Illyria, on the coast of Dalmatia, between Salone and Pegemoen, near the mouth of a river called Xornovuiria. The town which has been added to Epeticum is named Strokes.

EPHA, a dry measure in use among the Hebrews. The epha was the most common measure they used, and that whereby the reft were regulated. It is commonly supposed that the epha, reduced to the Roman modulus, contained four modii and a half. Now the Roman modulus of grain or flour contained twenty libras or pounds, consequently the epha weighed ninety pounds. Dr. Arbuthnot reduces the epha to three pecks three pints, English measure. See Measure.

EPHALGIA, in Ancient Geography, now Elpisira, a town of Afa, in Melopotamia, upon the banks of the Euphrates, W.N.W. of Cirecium.

EPHEBEUM, Ephesos in Antiquity, the place where the ephèbi or youth exercised; or, as some say, where those who designed to exercise met, and agreed what kind of exercise they should contain in, and what should be the victor's reward.

EPHEBI, Ephesos, among the Athenians, a designation given to their young men, when they arrived at eighteen years of age, at which time they had their names entered in a public register. Pott. Archæol. Grec. bib. 1. cap. 9. tom. i. p. 48.

Gen. Ch. Male. Col. the scales of a catkin, few, fine, flowered, roundish, concave, each the length of the perianth, which is of one leaf, cloven half way down, roundish, inflated, compressed, small and blunt. Cor. none. Stam. Filaments few, united into an awl-shaped column, roundish at the top, and longer than the calyx; anthers roundish, turned outwards, four of them below the reef. Female. Col. Perianth five-fold, one placed upon another so that their segments are alternate, forming an ovate figure; each is nearly oval, at one leaf, cloven, the outer or lower ones smaller. Cor. none. Fil. Germas two, ovate, the size of the innermost perianth on which they stand; styles two, simple, thread-shaped, short; stigmas simple. Peric. none; except the perianths, all become succulent and thickened, constituting a divided berry. See peris. 40, acute, convex, on one side and flat on the other, compressed by the perianth which incloses them on every side.

The species known are but two.

1. E. difjuncta. Linn. Sp. Pl. 1472. Duhamel Arb. t. 92. (Uva marina; Ger. mez. 1116. f. 1, and 1117. f. 2.) "Flower-flakes opposite. Catkins in pairs." Native of various parts of the south of Europe, in a sandy soil about the shores of the sea or of lakes, flowering in June and July. It bears our climate, especially if uplifted against a wall. A fine bush of this kind may be seen in the Oxford garden, ten or twelve feet high. It is a buhly, smooth, leaflets thrify, always green, with the habit of an Ephedra. The catkins are yellowish. Berries scarlet, sweetish, viscid, easy to be broken, but not agreeable.

2. E. monophylla. Linn. Sp. Pl. 1472. (E. polygonoides; Pall. Rolf. v. 1. t. 83.) "Flower-flakes several. Catkins solitary." Native of Siberia. Linnaeus suspected this to be only a variety of the last, and Pallas confirms his opinion.

EPHELEM, in Anatomy, is the place from the hypogastrium, or lower part of the abdomen, to the secret parts.

EPHELICIS, from επελεικός, an ulcer, in Surgery, a sebaf, or crust, upon a fore.—Alfo, a small portion of blood, voided by coughing.

EPHELIS, from επελεικός, επελικός, a name used by the ancient writers on Medicine, for a disorder of the face, brought on by the sun and drying winds, and of the nature of what we call sun-burning. It was a certain roughness, hardness, and bad colour of the skin.

The ephelis, or sun-burning, is removed by an application of rosin, to which a third part of foifie salt, and a little honey are added; but all these disorders, as also the unnatural colour of cicatrices, are remedied by the following preparation, ascribed to Trypho the Elder:

Take equal quantities of myrobolan, erocomaga, cimolar earth of a blue colour, and the meals of barley and bitter vetch, dyer's weed (flour albuminum); all these are to be triturated together, and made up with the most sharp honey. With this preparation the parts affected are to be anointed at night; and the medicine carefully to be washed off the next morning. James Med. Dict. See Freckles.

EPHEMERA, from επεμαφ, a day, in Medicine, the name given by the Greek writers to the mildest form of fever, which runs through its course within the period of one day. By the Romans the same fever was termed diarís, from δια, a day.

A fever which terminates in the course of twelve, eighteen, or twenty-four hours, is not a common occurrence in this climate; unless the slight disturbance of the system, which fatigue, repulsion, a sleepless night, &c. induce, is to be called an ephemerial fever: and in such, indeed, appears to be the disorder to which the term ephemeris has been applied by writers in general, and which constitutes the ephemeris, complex, or peculiar, in their nomenclature. When the febrile condition is more fever, and therefore of longer duration, extending to the third or fourth day, by a felicif in language, it has been denominated ephemera extensa, or ephemera pluvium diurnum. Any slight fever, of three
or four days duration, is occasionally called an ephemera at present; the flight derangement of the habit, from the operation of the causes just mentioned, being scarcely deemed a disease worthy of a distinct appellation.

The ephemera fimplex is a flight febile paroxysm, marked by languor, loss of appetite, thirst, headache, and flight pains in the limbs, with some heat of skin terminating in a gentle perpiration, and with dryness of the tongue and fauces. These symptoms, from their mildness, imply a very flight derangement of any of the functions of the body: they originate from some evident cause of disorder in what have been absurdly termed the non-naturals, and cease spontaneously when the influence of these causes to longer operates. The mildness of the symptoms, and the nature of the evident causes, are mentioned as the principal means of discriminating the ephemera from the various forms of continued fever at their commencement. Among the causes of the ephemera are enumerated the various passions of the mind, when strongly excited, as grief, anger, joy, or care and anxiety, likewise lots of sleep, excessive heat of the weather, fatigue from labour or exercise, a fit of intoxication or of repletion, sudden exposure to cold, failing, too great evacuations, &c. It is admitted, indeed, that many of these causes occasionally give rise to continued fevers of long duration; but, in these cases, the attack is preceded by cold chills and shiverings, by languor and latitude, loathing of food, &c. and is accompanied by more severe disorders of the functions, as by violent headache, pains in the back and limbs, nausea or vomiting, with great anxiety and restlessness. The prevalence or absence of these symptoms, in the commencement, will enable us to anticipate the future progress of the disease, whether it will be a mere ephemera or a more serious continued fever.

Besides the simple ephemera, arising from the causes already enumerated, which Sauvages has included under the four heads of ephemera plethorica, ephemera naefativa, ephemera ñigore, and ephemera ñalose, those flight febile derangements, connected with bruises, dislocations, parturition, congegon of milk in the breasts, dysermenorrhœa, &c. have been also designated by the term ephemera; which, in this case, is a fecondary or synyphomatic ephemera. Asicena, among the ancients, and Forelius, among the modern physicians, have made a still more extensive division of ephemera; namely, into as many species as there are evident causes which induce it. Hence they usefully distinguish ephemera from grief, from joy, from hope, from fear, from thirst, from fasting, &c.

The original signification of the term implied a completion of all the stages of a fever, viz. the beginning, increase, acme, and decline, (in the language of the ancients) within the compass of a natural day. By this definition, Van Swieten observes, the mott acute fevers, which often kill a patient in twenty-four hours, are excluded from the term; for they do not arrive at their declension in that space of time, although they end in death. Yet Cains has described that fatal epidemic, the sweating sickness, or sudor Anglicus, under the term of ephemera; because, on the one hand, it often terminated in the space of twenty-four hours, by destroying the patient; and, on the other, by a sweating, continued for the same space of time, the patients were often cured. But in this case, though immediate danger was removed, yet great debility and other injuries to the functions still remained, for some time afterwards; so that the disease belonged to the class of continued malignant fevers. This disease, under the appellation of ephemera fudatoria, constitutes the seventh species of Sauvages. It has been also denominated ephemera Eri-
E P H

Inhabits watery places throughout Europe.

LUTEA. Wings transparent, reticulated; body yellow.

Fabr. Native of Europe, and is found in Britain.

MARGINATA. Wings white; exterior margin fuscescent; body black. Fabr.

Similar to E. vulgata, but smaller.

FESTIVA. Wings black; posterior ones white.

Linn. Native of Sweden, and other parts of Europe.

HALCERATA. Wings two, white; abdomen whitish, with fuscescent tail. Fabr. Phryganes cauda trista, &c.

Deger. Inhabits flagrant waters in the north of Europe.

INANIS. Wings hyaline; body black; segments of the abdomen from the fourth to the seventh pellucid. Linn. Native of Europe.

MAROCANA. Wings white, immaculate; body yellowish. Fabr.

Found in Morocco.

BEVIACUDA. Wings two, cinereous, with a black rib; abdomen pale; tail brown. Fabr.

A small species, found in the vicinity of Paris.

** Tail with two hairs or bristles.

BICOULATA. Wings white reticulated; head with two yellow tuberules; tail yellow. Fabr. Geoff., &c.

Native of European waters.

RENOA. Wings white reticulated; body brown. Fabr.

Inhabits Denmark.

NIGRA. Body black; wings blackish; posterior pair very small. Linn.

Described by Linnaeus as a native of Sweden; also inhabits other parts of Europe.

CULICIFORMIS. Wings white; body brown. Linn.

Found in Greece by Pada; also in Sweden by Linnaeus, and in France by Geoffroy.

HORARIA. Wings white; thicker-margin blackish.

Linn. Ephemerina minima, Smamerdian.

Very abundant in Europe.

STRIGATA. Wings hyaline, frigated; thorax fuscescent; abdomen white. Fabr. Ephemerina mutasa, Linn. Fr. Suec.

An European species.

DIPTERA. Wings two; costal margin brown, with cinereous spots. Linn.

The abdomen in this insect is marked with red lines.

The species inhabits Sweden.

FUSCATA. Wings hyaline; abdomen brown, with the base whitish; legs pale. Fabr.

ALEIPENNES. Wings white, immaculate; abdomen pale at the base; tail blackish. Fabr.

This and the preceding inhabit France, and other parts of Europe.

NOTATA. Yellow; wings white; abdominal segments with a fuscescent spot each side. Linn.

Ephemerata notata and the three following are inhabitants of watery places in Europe.

TESTACEA. Wings brownish; body brown teataceous; soles of the feet fuscescent. Linn.

FERRUGINEA. Wings yellowish; body ferruginous. Linn.

STIGMA. Wings brownish; body pale yellow; thighs with a black dot in the middle.

Ephemerata is also applied among Botanists, to a kind of flowers which open and expand themselves at sun-rising, and wither or close up again at its setting. Such are the dandelion, vulgarly dandelion, and divers others.

E P H II

EPHEMERIDES, in Almanacs, tables calculated by astronomers, showing the present state of the heavens for every day at noon; that is, the places wherein all the planets are found at that time.

It is from these tables that the eclipses, conjunctions, and aspects of the planets are determined; horoscopes, or celestial schemes, constructed.

We have ephemeres of Regiomontanus from 1475 to 1526, of Engel from 1494 to 1520, of Staelsfer from 1499 to 1531, of Origan from 1595 to 1654, of Kepler from 1617 to 1628, of Argoli from 1620 to 1660, of Hecker from 1666 to 1680, of Wing from 1652 to 1671, of De la Hire from 1701 to 1703, of Manfredi from 1715 to 1750, of Parker, &c. S. Caffini has calculated ephemeres of the sidera medicea, or satellites of Jupiter, which are of good use in determining the longitude.

In England the Nautical Almanac or Astronomical Ephemeris, published annually by anticipation, under the direction of the Commissioners of Longitude, is the most considerable. See Almanac.

In France they have preferred in the national library ephemeres of 1443; and celestial ephemeres have been published by M. Desplaces every ten years, from 1715 to 1745: they were afterwards continued by the abbé Caillé, with many additions, from 1731 to 1774, of which an account may be seen in the History of the Academy of Sciences for 1743, &c.; they were further continued by Lande from 1775 to 1810. The Academy of Sciences have likewise published annually, from the year 1798, a kind of ephemere, under the title of Concorde des Lamps. This has been continued since the revolution under the direction of the "Bureau des Longitudes." The two volumes for the years 8 and 9, edited under the inspection of M. Lalande, contain, besides other important articles, new catalogues of the stars; tables of the moon's horary motion by Delambre; observations of Mercury by Videl, &c. They have also ephemeres at Bologna; those for 23 years from 1787 to 1810, being computed by C. Matteucci, assisted by Isolani, Guglielmimi, Sacchetti, Zanotti, and Cantarani. The ephemeres of Milan contain the result of an important labour of C. Oriani, on the method of correcting the elements of the tables of Mercury by observation, and many interesting observations of C. Reggio and De Cesaris, &c. &c. The ephemeres of Berlin are now conducted by M. Bode, and contain many astronomical observations and memoirs by German, French, and English astronomers. The astronomers of Vienna commenced a similar work in 1757. The geographical ephemeres, undertaken by M. von Zach, of Gottha, at the commencement of the year 1798, contain many curious observations; information respecting new books and charts, new voyages and geographical maps, portraits of eminent philosophers, and, in a word, every thing that can be interesting to astronomers, geographers, and navigators. The meteorological observations of the electoral Academy of Sciences at Mainz, from 1781 to 1792, are comprehended in 12 volumes 4to, under the title of "Ephemerides Societatis Meteorologiae Palatinae;" EPHEMERUM, in Botany, from Ephemera, lasting but a day, in allusion to its transient blossoms; see Lysimachia. The name has also been given in ancient times to the hemlock, on account of the celerity of its destructive action upon animal life.

EPHESIA, in Mythology, a seat instituted at Ephesus, in honour of Diana.

EPHESIANS, Epistle to. See Epistle.

EPHESIORUM PORTUS, in Ancient Geography, a port
port of Asia Minor, upon the Bolphurus of Thrace; the modern name of which is Abydos.

EPHESIUM, the name of a platter, which is described by Celsus.

EPHESIUS, in Biblical History, a manuscript of the gospels written in 1166, and formerly in possession of a bishop of Ephesus, whence it has taken its name. It is noted 71 in the first part of Wetstein's N. T. It is at present in the archbishop's library at Lambeth, to which it was presented by Traherne, together with the extracts which he had made from it. There were infected by Mill, in his collections of readings.

EPHESTIA, in Mythology, a feast celebrated in honour of Vulcan, in which three young lads ran for a prize.

EPHESTRIA, were feasts celebrated at Thebes, in honour of Typhon.

EPHESIUS, in Ancient Geography, a city of Asia Minor, in Ionia, formerly reputed the metropolis of Asia. Stephanius Rylter makes it "Epheanieta," or most illustrious. Philemon represents it as the ornament of Asia; and Strabo describes it as the largest and most frequented emporium of that continent. The ancient city, which was originally a small village, stood about 50 miles S. of Smyrna, near the mouth of the river Cayler, and the shore of the Icarian sea, which is a bay of the Egean; but its precise situation cannot be ascertained, as it was often destroyed and rebuilt. Some modern travellers maintain that the ancient city stood more to the south than the present town, or rather village, which they infer from the ruins that still remain. It was known in ancient times by the names of Alouses, Ortygia, Morges, Smyrna, Trachza, Samomnion, and Peta. Its name Ephesus is derived, according to Heracleides, from the Greek word ἐφεσός, signifying permission; because Hercules, as he says, permitted the Amazons to live and build a city in that place. Others allege, that Ephesus was the name of the Amazon that founded the city: for Pliny, Justin, and Orosius unanimously affirm, that it was built by an Amazon; while others ascribe the honour to Androclus, the son of Codrus, king of Athens, who was the chief of the Ionians that settled in Asia. However this be, it is acknowledged, that the city, which in the Roman times was the metropolis of Asia, was founded by Lydamachus; who, having caused the ancient city to be demolished, rebuilt a new one, at a vast expense, in a place more convenient, and nearer the temple. We learn from Strabo, that when the inhabitants manifested a reluctance to quit their ancient habitations, this prince caused all the drains, that conveyed the water into the neighbourings and the Cayler, to be privately stepped up; so that the city on the first violent rains that fell was in great part laid under water, and many of the inhabitants were drowned; and he thus conformed those who remained to retire into the new city. This new Ephesus was greatly damaged by an earthquake in the reign of Tiberius, but that emperor repaired and adorned it with several stately buildings, of which there are now some few ruins that testify its existence. The aqueduct, of which a part still subsists, is generally believed to have been the work of the Greek emperors; the pillars, that support the arches, are of fine marble, and they are higher or lower as the level of the water required. This aqueduct served to convey water into the city from the spring of Halite, mentioned by Pausanias. The gate, now called for some unknown reason the gate of perdition, is remarkable for three bas-reliefs on the mould, of exquisite taste. The port, of which many medals have been struck, is at present merely an open road, and not much frequented. The Cayler was formerly navigable, and afforded a safe place for ships to ride in, but it is now almost choked with sand. Ephesus is now venerable for nothing but the ruins of palaces, temples, and amphitheatres. It is called by the Turks Afalank (which see), or the temple of the moon, from the magnificent structure formerly dedicated to Diana. The church of St. Paul, said to have been founded by the apostle, is wholly destroyed; but the little which remains of that of St. Mark is looking to ruin. The only church remaining is that dedicated to St. John, who resided here, and this is now converted into a Turkish mosque. The town is merely a miserable village, the habitation of herdsmen and farmers, living in low and mean huts, sheltered from the extremities of weather by mighty maffles of ruinous walls; the pride and ostentation of former days, and the emblem in the inscription of the transient vanity of human glory. All the inhabitants of this once famous city amount not to above 40 or 50 families of Turks, without one Christian family among them; fo strikingly hath the scripture denunciation been fulfilled, that their candlestick should be removed out of its place.

The ancient city, whether it was first built by Androclus, who conducted the Ionians hither and drove out the Carian and Lycians, by whom this situation was occupied before his arrival, or by one Creus or Ephesus, long before the Ionic migration, as others maintain, became soon the metropolis of Ionia. It was at first governed by Androclus and his descendants, who assumed the royal title, and exercised regal authority over the new colony; whence, even in Strabo's time, the polity of Androclus were styled kings, and allowed to wear a scarlet robe, with a sceptre, and all the emblems of royal dignity. In process of time, a senate was established and a new form of government introduced, which continued to the time of Pythagoras, who lived before Cyrus the Great, and was one of the most savage tyrants whose name and character history records; for having expelled the senate and engrossed the whole power, he filled the city with blood and rapine, not sparing even those who fled for shelter to Diana's temple. His successor Pindarius governed the city with a milder sway; and in his time Ephesus was besieged by Creus, king of Lydia, who advised the inhabitants to devote their city to Diana, and in consequence of their following his counsel, treated them with kindness, and restored them to their former liberty. The other tyrants of Ephesus, mentioned in history, are Athenagoras, Comes, Artilarchus, and Hegesias; the last of whom was expelled by Alexander, who, having defeated the Persians on the banks of the Granicus, beftowed upon Diana all the tributes which the Ephesians had paid to the Persians, and established a democracy in the city. After his death, this city became the prey of his successors. Lydamachus took it, and afterwards Antigonus had possession of it and plundered it. Ephesus for a little while was restored to its ancient splendour; but it was always subject to the kings of Syria. In the war between Mithridates and the Romans, the Ephesians took part with the former, and by his order massacred all the Romans that resided in the city; for which barbarity they were severely fined, and reduced almost to beggary by Sylla, but afterwards treated kindly and suffered to live according to their own laws. It was under the reign of the emperor Alexius, father of Anne de Comnen, that the Mahometans made themselves masters of Ephesus. The Greeks retook it in 1266, but they lost it again 1283. At the commencement of the 14th century it became a part of the Turkish dominions; and both the place itself and its vicinity exhibit melancholy traces of in- dolence and inactivity. The Ephesians were much addicted to superstition, forcery, and curious arts, as the Scripture styles them (Acts, xix. 19); whence came the proverb...
proverb "Ephebian letters," signifying all sorts of spells or charms. By these Ephebian letters were meant certain obscure words and incoherent sentences, which superstitious bigots used to write on their girdles, and even imprint on their feet, and other parts of their bodies. They were also noted for their luxury and licentiousness. See Ephes. v. 5.

Ephesus, in its relation to ecclesiastical history, may be considered, first of all, as the abode of many Jews, who obtained the privilege of citizens (Joseph. Cont. Apian. l. 2.), and afterwards, as the place where St. Paul took up his residence for three years (Acts, xx. 31.), where he wrought miracles (Acts, xix. 1 Cor. xvi. 9.), and was resisted by the Jews, (Acts, xx. 19.); and where Timothy was bishop; and where John refuted; and, moreover, as containing one of the seven churches, whose character and doom are recorded in the book of Revelations, ch. ii.

Ephesus, Temple of. See Diana.

EPHETAE, of επέθαι, I send forth, in Antiquity, a sort of magistrates among the Athenians, instituted by king Demophon, to take cognizance of murder, manslaughter, and chance-medley.

Their number was one hundred, whereof fifty were Athenians, and fifty foreigners: they were not admitted to the court till upwards of fifty years of age. Demophon submitted to be tried by this court, for having unfortunately killed one of his subjects by the turn of his horse, as he was coming from Troy. It fulfilled for a considerable time in the same form; but at length Draco new-modelled it, excluded the Argives, and made it to consist of fifty-one Athenians, each above fifty years of age: Ubbo Emnus de Rep. Athen. says, he transferred to them part of the jurisdiction of the Areopagites. See AREOPAGUS.

The occasion of erecting this court and of admitting the Argives to sit as judges, is said to have been as follows. Agamemnon, or, as others say, Diomedes, returning with his forces from Troy, were driven one night into an Athenian port called Phalerus, and thinking themselves in an enemy's country, began their usual practice of ravaging and plundering; upon which the Athenians fell upon and killed a considerable number of them. Next morning they found the palladium, or image of Minerva, which was brought from Troy, lying upon the ground among the slain; by which circumstance they knew that they were their friends the Argives. The oracle having been consulted, ordered them to give the slain an honourable burial in the place where they fell, to build a temple there, dedicated to Minerva, and to set up the palladium in it. Immediately after this transection, it was ordered that this court should be erected to try all cases of personal injury and property. It consisted of fifty members, who were to be above fifty years of age, men of feme and known probity; and who had power of life and death. Upon its first institution Agamemnon insuring that there should be an equal number of Athenians and Argives, the Athenians readily agreed to the proposal.

EPHIALTES, ἐπιαλήτης, in Medicine, from ἐπι upon, and αλήθες, I truly, is synonymous with the Latin incusus, and the English night-mare, which see.

EPHIALTEUM, in Ancient Geography, the most northerly promontory of the isle of Rhodes.

EPHIDRIS, in Medicine, from ἐπι upon, and δρῦς, sweet, a term used by the ancient writers to denote the appearance of a sweat, whether critical or not, and whether general, or on the upper parts of the body only. The modern nosologists have constituted a genus of deliefe under this appellation; under which Sauvages compiles every variety of morbid perspiration that occurs as a symptom of different maladies. He enumerates seventeen species of ephidiros. See his Nofol. Method, Clas IX. Gen. 20. Cullen, Gen. 118.

EPHELEIS, in Botany, from επέλοι, a little cup, or something like it, in a crown or garland, which alludes, happily enough, to the nectary forming a sort of cup, or crown, within the circle of the corolla. Schreb. 253. Willd. Sp. Pl. v. 2. 328. (Mataia; Aubl. Guian. v. 1. t. 128. Juss. 249.) Clas and order, Ottandria Monograph. Nat. Ord. Near the Sapindi, Juss.

Gen. Ch. Cal. Perianth of one leaf, in five deep, spreading, roundish, acute segments. Cor. Petals five, roundish, spreading, notched, with a small point, and having claws as long as the calyx. Nectary of ten roundish hairy scales, smaller than the petals, two of them affixed to the base of each petal. Stam. Filaments eight, bristle-shaped, longer than the corolla, inserted into a gland; another roundish, with four angles. Ptil. German ovate, encompased with the gland which bears the stamens: style none; stigma obtuse. Peric. Capsule oblong, compressed, with a furrow on each side, of one cell and two valves. Seeds two, kidney-shaped, one attached to the middle of each valve, one above the other.

Eff. Ch. Calyx in five deep segments. Petals five, with claws. Nectary of ten scales, two to each petal. Capsule compressed, of one cell and two valves. Seeds two, attached to the valves.

The only known species is E. fraeinea, Willd. a tree 50 or 60 feet high, with copious branches, of which the central ones are erect, the rest widely spreading. Leaves alternate, pinnate, smooth; leaflets four or six, opposite, oval, pointed, entire, bright green, sometimes eight inches long. Flowers on long axillary branching stalks, very small, white. It grows in the forests of Guiana, flowering in October. Jussieu supposes this genus may be more akin to the Leguminosae than to his Sapindi; but he observes that the fruit requires further investigation.

EPHIPPIA, of ἐπι and ὑππο, horse, denoted certain cloths or hounges, which were fastened on a horse by a girth or furcingle, in ancient Greece, before the use of saddles was known. They were composed of different materials, as leather, cloth, and the skins of wild beasts, and sometimes adorned with gold, silver, and precious stones. When these coverings were common, it was reckoned more manly to ride without them. Varro boasts of having rode, when a young man, without a covering to his horse; and Xenophon reproaches the Persians because they placed more clothes on the backs of their horses than on their beds, and gave themselves more trouble to fit easily than to ride skillfully. These coverings were, therefore, for a long time not used in war; and the old Germans, who considered them as disgraceful, defiped the Roman cavalry who employed them. (Caf. de Bell. Gall. l. iv. 2.) Dion Cassius (l. lxxii. 14.) says, that they were first allowed to the Roman cavalry by Nero. But it has been suggested that this author alludes merely to reviews, at which the cavalry were probably obliged to ride without them.

In the time of Alexander Severus, the horses of the whole Roman cavalry had beautiful coverings. (Lamp. Vit. Alex. Severi. c. 50.) Saddles were first denominated ephippa, which originally signified nothing more than a covering for a horse. Beckmann Hill. Inv. vol. ii. Berenger's Art of Horsemanship, vol. i. p. 41. See Saddle.

EPHIPPITIES. See Hippurites.

EPHIPPIMUM, in Anatomy, the excavation in the upper surface of the sphenoid bone, called also fella turca. See Cranium.

EPHOD,
EPIHOD, ἐπίθοδος, from ἐπιθοδίζω, to cloth, a
facerdotal garment, in use among the ancient Jews,
supposed to have been a kind of linen sash, or surplice, wore by
persons of distinction, of various characters; the same with
what the Latins call super-humerale. 2 Sam. vi. 4.
1 Sam. xxii. 18. 1 Sam. ii. 18.
It is very hard to say precisely what the ephod was; and
there is room enough for the interpreters to be divided about
it. The only point they are agreed upon is, that it was an
upper garment worn over all the rest, immediately under the
pectoral or breast-plate. Some held it had sleeves, others deny it.
The generality agree, that it was very short, though some maintain that it hung down to the feet be-
hind.
There were two kinds of ephods; the one, common to
all who attained in the temple, being only made of common
linen, mentioned in the first book of Samuel, ii. 18; the
other, peculiar to the high-priest, mentioned Exod. xxviii.
6. 15. to be made of gold, of blue, and of purple, of scarlet,
and fine twined linen, with cunning work; having two
shoulder-pieces, with a curious girdle of the same manner,
and two onyxes, with the names of the children of Israel
engraved thereon, set upon each shoule. These onyxes were
set in gold, and served as buttions upon each shoule. As
for the shape of the ephod, the LXX call it εἰρηνή, which
signifies that it was worn on the shoulders.
Josephus says (Antiq. i. iii. § 5), that it was a cubit
long. It consisted, as some suppose, of two parts, the one
an oblong rectangular piece, hanging down behind from the
shoulders to the feet; the other a short rectangular piece,
which hung down before, the length of a cubit. There
two pieces were joined together upon the shoulders, with
some proper fastenings, as loops, buttons, or the like.
It is also expressed in the second book of Samuel, vi. 14.
that upon the removal of the ark of the covenant from
the house of Obed-Edom, David danced for joy, girt with a
linen ephod; whence some authors have concluded, that the
ephod was also a regal garment, worn on solemn occa-
sions. It is probable that the peculiarity of the ephod of the
high priest did not consist in its being of a different shape
from that which was worn by other persons; but in the
richness of the materials of which it was made, and the
fine embroidery and jewels with which it was adorned.
EPHORI, ἐφόροι, magistrates established in ancient
Sparta, to balance and check the power and authority of
the kings; as at Rome, there were tribunes created to con-
trol the power of the consuls.
The word is formed of the Greek, ἐφορέω, intune, form-
ed of the preposition ἐπί, and the verb ὄρος, to set; whence ἐφόρος, g. d. infeclor, overseer.
Lycurgus, being envious that a perfect understanding
between the prince and the people was the basis and founda-
tion of both their happiness, to maintain that good un-
derstanding, established ephori, or inspectors, as a kind of
mediators, who should have an eye to the measures and con-
duct on both sides, and preserve for equal a balance between
them, that the regal power should never decline into severity
and tyranny, or the liberty of the people run into licenti-
ous and rebellion. This is the account of their institution given by Herodo-
tus and Xenophon. (Her. lib. i. Xen. de Rep. Laced.)
The authority of the ephori was very great; they presided
in popular assemblies, collected their fullfrages, declared war,
made peace, treated with foreign princes, determined the
number of forces that should be raised, appointed the funds
to maintain them, and distributed rewards and punishments in
the name of the state: they likewise held a court of jus-
tice, enquired into the behaviour of all magistrates, inspected
the education and conduct of youth, had a particular
jurisdiction over the helots, and by degrees drew the whole
administration into their own hands. On certain occasions,
they expelled, and even put to death the kings; and abs-
horised or suspended the power of the other magistrates,
calling them to account at pleasure. Agephius, in the
height of all his conquests, which even struck terror on the
great king of Peria, flapped, and turned back, out of
defence to the ephori, when they recalled him.
Some authors deny that the ephori were established by
Lycurgus, dating their origin 150 years after the time of the
lawgiver.
Lycurgus, in his life of Cleomenes, ascribes their in-
sitution to Theopompos, king of Sparta, which is also
confirmed by the authority of Aristotle. (Polit. lib. v.)
The ephori were five in number, and annually chosen by
the people out of their own body: though some have imag-
ined, that they were at first appointed by the kings at
their pleasure, but that afterwards the people obtained the
power of electing them. The year was divided from the
first election of these magistrates; and the Lacedemo-
nian armies took their names from the principal ephori, as
those of Athens did from their first archon. The
ephori did not rise up at the entrance of the kings, as all the
other magistrates did; and if even the kings offended against the
laws, the ephori took cognizance of their conduct, and
punished them.
EPHORUS, in Biography, a Greek orator and histo-
rion, was a native of Cuma or Cyme in Ionia, and flour-
nified about the year 352 B.C. He was a disciple of
Socrates, at whose judgment he wrote history; which he
commenced after the fabulous periods, with the return of
the Heracleids to Peloponnesus, and brought down to the
20th year of Philip of Macedon. This work, which was
divided into 30 books, was held in estimation by the an-
cients, and is frequently cited by Strabo and other writers;
though the historian is charged with errors and misrepres-
sentations, and plagiarisms. Besides the history, the lofty
of which is regretted, Ephorus wrote several other books on
moral, geographical, and rhetorical subjects, none of which
EPHRAH, in Ancient Geography, a city of Judea, in
the half-tribe of Manasseh, on this side of Jordan. It
was situated on the frontiers of the tribe of Ephraim; suppos-
ed to have been the same with Ephrah. Judg. vi. 11.
EPHRAIM, Tribe of, so described from Ephraim,
the grandson of Joseph by Aseneth, the daughter of Po-
tiphar, who was born in Egypt about A. M. 2394, occu-
pied the south side of Samaria, and extended, like that of
Manasseh, from the Mediterranean on the west, and the river
Jordan on the east; bounded on the north by the territory
of Benjamin and part of Dan, and on the north by the
half-tribe of Manasseh. The extent of this tribe from
north to south was about 7 leagues; and though some parts
were mountainous and rocky, they were covered with trees
and good pasture, and the low lands were rich and fertile, and
even luxuriant. The cities and towns were numerous, large,
and well-peopled. Joshua was of this tribe; and the ark
and tabernacle remained in it at Shiloh for a considerable
time. After the separation of the 10 tribes, the seat of the
kingdom of Israel being in Ephraim, Ephraim is frequent-
lly used to signify the whole kingdom. The district belon-
ging to this tribe is called Ephratath. Pf. e. xxxii. 6. (See
also Judg. xii. 5. 1 Sam. i. 1.) Ephraim was led cap-
tive beyond the Euphrates, with all Israel, by Salmane-
er, king of Assyria, A. M. 3425. B. C. 721.
EPHRAIM, or Ephrem, a city of Ephraim, towards Jordan, whither Jesus is supposed to have retired before his passion. John, xi. 54.—Also, a city of Benjamin, 8 miles from Jerusalem, according to Eusebius, near the wilderness of Judea, in the way from Jerusalem to Jericho, not far from Bethel. Also, a considerable mountain in the tribe of Ephraim, and extending to that of Benjamin, on which several towns were built. Also, an extensive forest situated on the other side of Jordan, not far from Mahanaim, where David abode while the battle was fought, in which Abifalom received the due reward of his unnatural rebellion.

EPHRATA, or DUNED TOWN, in Geography, a village of America, in Lancaster county, Pennsylvania, on the N.W. side of Calico creek, which, joining the Conestoga, falls into the Susquehanna; 12 miles N. of the town of Lancaster, and more than 40 W. of Philadelphia. It is situated in a romantic and sequestered vale, and inhabited by a community of religious people, called "Turners," who are mostly of German descent and believers in the doctrine of general redemption. They are very plain in their dress and language; and will neither swear, nor fight, nor go to law, nor take interest for the money they lend. They have many peculiarities; but their inoffensive manners have occasioned their being called the harmless Turners. This settlement is called "Turners' town," and consists of about 40 buildings, of which three are places of worship. They subsist by cultivating their lands, by attending a printing office, a grist-mill, a paper-mill, an oil-mill, &c. and the spinners by spinning, weaving, &c. Befide this congregation at Ephrata, there were, about 30 years ago, some few others of this sect in various parts of Pennsylvania, and in Maryland. The whole community, exclusively of those in Maryland, comprehended upwards of 2000 persons.

EPHRATAH. See Tribe of Ephraim and Beth-large.

EPHREM, or Ephraim, denominated the Syrian, and honoured with the appellation of Saint, in Biography, was a native of Nisibis in Mesopotamia, and born during the reign of Constantine the Great. Devoting himself at an early period to the monastic life, he sedulously applied to his studies, and to the composition of various theological and moral works. "Towards the close of his life he retired at Edessa, where he began to distinguish himself by his writings about the year 370, and was ordained deacon, determining not to accept of any higher ecclesiastical order. His works were all written in the Syriac language, and several of them were translated into Greek, with which he does not seem to have been acquainted, during his life. He was held in high estimation, on account both of his virtues and his writings. From Dr. Afsmann we learn, that the Syrians gave him the titles of Doctor or Master of the whole world, and of their Prophet; and St. Jerome informs us, that his works were so much esteemed as to be publicly read in some churches after the Scriptures. Sozomen highly commends them both for style and sublimity of sentiment; which excellencies are laid by this father, and also St. Jerome, to have been transferred into the Greek version of them. The subjects of these works were commentaries upon the Old and New Testaments; homilies, or sermons; exhortations to the monks; controversial pieces against Sabellius, Arius, Apollinaris, the Anomians, and the Novatians; treatises of morality; hymns to be sung in the churches; panegyrics, &c. of which we have an account by Cave, Du Pin, and Larder. The most complete edition of the works of this writer was published at Rome, by Dr. Jof. Afsmann, ascribed by father Benedetti, a Jesuit, and Eusebius Afsmann, bishop of Apamea; which was begun in 1732, and finished in 1747, in 6 vols. folio, of which three are Syriac and Latin, and the other three Greek and Latin. St. Ephrem died about the year 378, under the reign of the emperor Valens; ordering his funeral to be conducted in a plain manner, and forbidding any eulogism to be delivered on the occasion, or any monument to be erected to his memory. With the acknowledged and applauded learning of Ephrem, a considerable degree of enthusiasm and fanaticalism was blended; but his charitable disposition, which he manifested on a variety of occasions, endeared his name to survivors; and entitles him to honourable remembrance. Cave. Du Pin. Larder. Jortin. Gen. Biol.

EPHREMENI Codex, in Biblical History, a manuscript of the New Testament, written on vellum, and supposed to be of very high antiquity. It is "Codex Regius 1593," noted in the catalogue of MSS. in the royal library at Paris IX., and in all the four parts of Wetstein's Greek Testament by the letter C. It is particularly described by Griesbach in his "Symbola," p. iii.—liv. The first part of it contains several Greek works of Ephrem the Syrian, written over some more ancient writings, which had been erased, though the traces are still visible, and in mott places legible. These more ancient writings were the whole Greek Bible. The New Testament has many chafms, which are specified by Wetstein. Besides these chafms, it is in many places illegible. Wetstein contends that this MS. was written before the year 542, though his arguments are not wholly decisive. Its readings, like those of all other very ancient MSS., are in favour of the Latin; but no proof can be given that this has been corrupted from the Latin version. It has been altered by a critical collector, who, according to Griesbach, must have lived many years after the time in which the MS. was written, and has probably erased many of the ancient readings. Kuller was the first who procured extracts from it, and he inserted them in his edition of Mill's Greek Testament. Wetstein has repeatedly collated it with very great accuracy; and the numerous readings, which he has quoted from it, greatly enhance the value of his edition. A fac-simile of the characters of this MS., which is written without accents, is given by Montfaucon in his "Palaeographia Graeca." It has many marginal notes, written in uncial letters without accents. In this MS. the disputed, or rather spurious verse, John, v. 4, is written, not in the text, but as a marginal scholiwm. Wetstein supposed, that this was one of the MSS. which were collated at Alexandria in 616 with the new Syriac version; but though this does not appear to have been the case, it is certainly as ancient as the seventh century. Wetstein argues, from a marginal note to Heb. viii. 7, that it was written before the infliction of the seal of the purification of the virgin Mary, that is, before the year 447. Marchis's Michaelis, vol. ii. and iii.

EPHREMEOF, or YPHREMEOF, in Geography, a town and district of Ruffin, in the government of Tulca, situated on the river Metacli, falling into the Don.

EPHRON, in Ancient Geography, a place of Palestine, in the tribe of Judah, about 15 miles from Jerusalem, according to Eusebius and Jerome.—Also, a mountain of Palestine, on the confines of the tribes of Judah and Benjamin, according to the book of Joshua.—Also, a large and strong town of Judea, in the half-tribe of Manasseh, on the other side of Jordan, over-against Scythopolis. It was situated near the torrent of Jabok. This town was taken and sacked by Judas Maccabaeus, and razed to its foundations.

EPHYDOR, Epydie, in Antiquity, an officer in the Athenian courts of justice, who was to provide the plaintiff and
the ancient Greeks. When any person of condition and quality returned home after a long absence or journey, into another country, he called together his friends and fellow-citizens, and made them a speech, or rehearsed them a copy of verses, wherein he returned thanks to the immortal gods for his happy return; and ended with an address by way of compliment to his fellow-citizens.

These verses made what the Greeks call ἡπιστολή, of περίστολος, I go abroad. At going away they had another, called ἡπιστολή, προερύοντος.

Gen. Ch. Male, Col. Perianth double, deciduous; outer minute, flat, of six leaves; inner three as large, as three ovate spreading leaves. Cor. Petals six, smaller than the inner calyx, roundish; three of them external, placed between the calyx-leaves; three internal. Stam. Filaments six, filiform, incurved, the length of the petals; anthers reniform. Female, (on the same plant) Cal. and Cor. as in the male. Pet. German three, superior, nearly globose; styles three, minute, incurved; filaments spreading, compressed. Peric. Drupae three, roundish, pointed with the permanent styles. Nut kidney-shaped, compressed, slightly furrowed.

EPFI, ανδρόν, the only species described, a native of the island of St. Jago. The stem is shrubby, climbing, with long pendulous branches. Leaves alternate, pointing one way, on short foot-stalks, oblong, entire, obtuse with a point, smooth and without ribs, about an inch long. Flowers minute, pale, on solitary, axillary, simple stalks.

EPIBOMEUM, the name of a canticle in the Greek music, which was sung before the altar.

EPIC, an heroic poem, or a poem reciting some great and signal transactions of a hero, called also ἐπιστολή. This kind of poem is universally allowed to be, of all poetical productions, the most dignified, and, at the same time, the most difficult in execution. To contrive a story which shall please and interest all readers, by being at once entertaining, important, and instructive; to fill it with suitable incidents; to enliven it with a variety of characters, and of descriptions; and to maintain, in the course of a long work, that propriety of sentiment, and that elevation of style, which the epic character requires, is unquestionably the highest effort of poetical genius. Hence it is that so few have succeeded in the attempt, and that few critics will hardly allow any other poem to bear the name of epic, except the Illiad and the Iliad.

- An epic poem, according to BoiU, is a discourse invented with art, to form the manner, by instructions disguised under the allegory of an important action related in verse, in a probable, entertaining, and surprising manner. This definition, it has been observed, would suit AEsop's fables, if they were extended, and put into verse. Accordingly the critic draws a parallel between the construction of one of AEsop's fables and the plau of Homer's Illiad. The first thing, he says, which a writer of fables, or of heroic poems, does, is to choose some maxim or point of morality, designed to be inculcated in the work. He next invents a general story, or a series of facts, without any names, such as he conceives most proper for the illustration...
EPIC.

of his intended moral. Lastly, he particularizes his story; that is, if he be a fabulist, he introduces his dog, his sheep, and his wolf; and if he be an epic poet, he draws from ancient history some proper names of heroes to be applied to his actors; and thus his plan is completed. This, says Dr. Blair, is one of the most frigid and absurd ideas that ever entered into the mind of a critic; nor can any person of just reflection and taste ever imagine, that Homer could have proceeded in this manner. No one, indeed, can entertain a doubt that the first objects which strike an epic poet are, the hero whom he is to celebrate, and the action, or story, which is to be the ground-work of his poem. "He does not sit down, like a philosopher, to form the plan of a treatise of morality. His genius is fired by some great enterprize, which to him appears noble and interesting; and which, therefore, he pitches upon as worthy of being celebrated in the highest strain of poetry. There is no subject of this kind, but will always afford some general moral instruction, arising from it naturally. The instruction, which Boffu points out, is certainly suggested by the Iliad; and there is another which arises as naturally, and may just as well be assigned for the moral of that poem; namely, that Providence avenges those who have suffered injustice; but that when they allow their resentment to carry them too far, it brings misfortunes on themselves. The subject of the poem is the wrath of Achilles, caused by the injustice of Agamemnon. Jupiter avenges Achilles, by giving succours to the Trojans against Agamemnon; but by continuing obtrinate in his resentment, Achilles loses his beloved friend Patroclus."

An epic poem is in its nature the recital of some illustrious enterprize in a poetical form. This definition is sufficiently exact; and hence it appears to comprehend several other poems besides the Iliad of Homer, the Æneid of Vergil, and the Jerusalem of Tasso; which are, perhaps, the three most regular and complete epic works that were ever composed. But to exclude all poems from the epic class, which are not formed exactly upon the same model as those, is, says Dr. Blair, the pedantry of criticism. This writer, therefore, does not scruple to class such poems, as Milton's Paradise Lost, Lucan's Pharsalia, Statius' Thebaid, Ossian's Fingal and Temora, Caneon's Lusiad, Voltaire's Henriade, Cambray's Telemachus, Glover's Leonidas, Wilkie's Epipomemium, under the same species of composition with the Iliad and Æneid. They are all, undoubtedly, epic; that is, poetical recitals of great adventures, and consequently belonging to this denomination of poetry.

The epic poem is distinguished from comedy, in that the action of the latter is not important, nor is related by the poet, but acted by the persons introduced for that purpose; which circumstance, likewise, distinguishes it from tragedy. It differs also from tragedy in the event, or conclusion; which, in the latter, is generally unfortunate, but seldom or ever so in the former. See ACTION.

Nor is it a philosophical poem, as that of Lucretius, or the Creation of Sir R. Blackmore; nor a treatise of agriculture, or the like, as the Georgics of Vergil; those poems not being intended to form the manners: before, that the instructions they contain are naked, simple, and direct; without any disguises or allegory. Which second circumstance likewise distinguishes it from a treatise of morality, written in verse; or a simple history in verse; and that its being confined to one important action, distinguishes it from a poem which relates all the actions of a person's life.

M. de la Motte, indeed, in his controversy with madam Ducier, on the subject of Homer, maintains, that the whole life of a hero may justly be made the subject of an epic poem; and even that the Lutrin of M. Boileau might pass for an epic poem; but he seemed afterwards to return to the common sentiment. In effect, the question is not as to the sense which may be annexed to the words epic poem, but the sense which custom has actually annexed to them.

If we had only regard to the etymology of the word epic, of verse, verse, poetry, from verse, dice, I speak (relate), all poems wherein the poet speaks or rehearse things himself, without making the persons of his poems speak, except at second-hand, as he relates what they spoke on this or that occasion, would be properly epic poems; and so there is not an epigram, sonnet, or madrigal, but would come under that denomination: but this was wild.

In effect, the term epic poem is only attributed to a composition whose subject is great, instructive, and serious; that only comprehends one single principal event, to which all the rest refer; which principal action is to be terminated in a certain space of time, ordinarily about a year. It is true, all this is arbitrary; but the sense of all words is too; and in matters of language we must be guided by custom.

If M. de la Motte had only pretended, that one might make a fine instructive poem on the whole life of a hero, or an agreeable and diverting poem on some humorous adventure, all the world would have been on his side. But it is enough that custom has not thought good to apply the term epic either to subjects of too much extent, and that are crowded with too many incidents no-way connected together; or to burlesque poems, as the Batrachomyomachia of Homer, the Secchia Kapita of Tassoni, the Delecta de Dolo, the Lutrin of Boileau, the Hudibras of Butler, the Rape of the Lock of Mr. Pope, or the Dlpenfery of Dr. Garth.

Dr. Blair cannot allow with Boffu and others, that it is the essence of an epic poem to be wholly an allegory, or a fable contrived to illustrate some moral truth; nevertheless, he admits, that no poetry is of a more moral than this. The effect, however, in promoting virtue is not to be estimated by any one maxim or instruction, which results from the whole story, like the moral of one of Æsop's fables; but from the impression which the parts of the poem separately, as well as the whole taken together, make upon the mind of the reader; from the great examples which it sets before us, and the high sentiments with which it warms our hearts. Its proposed end is to extend our ideas of human perfection, and thus to excite admiration; an end, which can be accomplished only by proper representations of heroic deeds and virtuous characters. Epic poems must, according to this statement of their object, be favourable to virtue. Moreover, the general strain and spirit of epic composition sufficiently mark its distinction from the other kinds of poetry. In pastoral writing, the reigning ideas are innocence and tranquillity; composition is the great object of tragedy; and ridicule the province of comedy. But the predominant character of the epic is admiration excited by heroic actions. It is sufficiently distinguished from history, both by its poetical form, and the liberty of fiction which it assumes. It is a more calm composition than tragedy. It admits, nay, requires the pathetic and the violent on particular occasions; but the pathetic is not its general character. It requires more than any other species of poetry, a grave, equal, and supported dignity. It takes in a greater compass of time and action than dramatic writing admits; and thereby allows a more full display of characters. Dramatic writing displays characters chiefly by means of sentiments.
ment and passions; epic poetry chiefly by means of actions. The emotions which it excites are, therefore, not to violent, but they are more prolonged. These, says Dr. Blair, are the general characteristics of this species of composition.

The epic poem may be considered under three heads; first, with respect to the subject, or action; secondly, with respect to the action, or characters; and lastly, with respect to the narration of the poet.

The action must possess the following properties; it must be one, entire, great, and intelligent. (See Action and Episode. See also Aeneid, Iliad, Paradise Lost, &c.) For upon these perfections introduced in an epic poem, it must be discriminated by appropriate and well-supported characters; which is denominated by Aristotle giving manner to the poem. See Character, in Poetry.

If we examine the characters of Milton, we shall find that he has introduced all the variety which his fable was capable of receiving. The whole species of mankind was confined to two persons at the time to which the subject of his poem relates. We have, however, four distinct characters in these two persons. We see man and woman in the highest innocence and perfection, and in the most abject state of guilt and inferiority; the two last characters are, indeed, very common and obvious, but the two first are not only more magnificent, but more novel than any characters either in Virgil or Homer, or indeed in the whole circle of nature. Milton was so fertile that the subject of his poem afforded him but few characters, as to be led to introduce two actors of a fictitious nature, in the persons of Sin and Death, by which means he has wrought into the body of his fable a very beautiful and well-invented allegory. However, it has been thought, that persons of such a chimerical existence are not proper actors in an epic poem, because there is not that measure of probability annexed to them, which is requisite in writings of this kind.

There is one circumstance, relating to the principal actors of the Iliad and Aeneid, that merits particular notice, because it gives a peculiar beauty to these two poems, and was, therefore, contrived with very great judgment. This is the choice for their heroes of persons nearly related to the people for whom they wrote. Achilles was a Greek, and Aeneas the remote founder of Rome. Their countrymen were thus rendered particularly attentive to all the parts of their story, and sympathized with their heroes in all their adventures. Milton's poem is also admirable in this respect; since it is impossible for any of its readers, to whatever nation, country, or people he may belong, not to be related to the persons who are the principal actors in it; but what is still infinitely more to its advantage, the principal actors in this poem are not only our progenitors, but our representatives. We have an actual interest in every thing they do, and no less than our utmost happiness is concerned, and lies, as it were, in the very being of their whole behaviour.

Besides human actors, there are personages of another kind, that usually occupy no small place in epic poetry; such are the gods, or supernatural beings. This constitutes what is called the machinery of the epic poem; and it is the most nice and difficult part of the subject. About the necessity and use of machinery in an epic composition, critics have been divided. The French critics consider it as essential to the constitution of an epic poem; and they allege that a poem, though it should possess every other requisite, has no pretension to be ranked in the epic class, unless the main action be carried on by the intervention of the gods. This decision seems to be principally, if not solely, founded on a superstitious reverence for the practice of Homer and Virgil. But, although these poets very properly embellished their respective story by the traditional tales and popular legends of their own country, according to which, all the great transactions of the heroic times were intermixed with the fables of their deities; does it hence follow, that in other countries, and in other ages, which do not possess a similar advantage of current superition, and popular credulity, epic poetry must be confined to antiquated fictions, and fairy tales? Lucan has composed a very spirited poem, certainly of the epic kind, where neither gods nor supernatural beings are at all employed. The author of Leonidas has also succeeded in an attempt of the same kind; and, without doubt, wherever a poet gives us a regular heroic story, well connected in its parts, adorned with characters, and supported with proper dignity and elevation, though his agents be every one of them human, he has fulfilled the chief requisites of this kind of composition, and has a just title to be classed with epic writers. Dr. Blair, while he cannot admit that machinery is indispensably necessary or essential to the epic plan, differs from those critics of considerable name, who are for wholly excluding it, as inconsistent with that probability and impress of reality, which, as they conceive, should prevail in this kind of writing. (See Elem. of Criticism, ch. 22.) In epic poetry, where admiration and lofty ideas are supposed to reign, the marvellous and supernatural find, if any where, their proper place. They both enable the poet to aggrandize his subject, by means of those august and solemn objects which religion introduces into it; and they allow him to enlarge and diversify his plan, by comprehending within it, heaven, and earth, and hell, and invisible beings, and the whole circle of the universe.

In the use, however, of this supernatural machinery, a poet should be prudent and temperate. The systen of the marvellous, which he introduces, should have some foundation in the popular belief, so that events, which are most contrary to the common course of nature, may derive from it an air of probability; and he should guard against excess in the use of it. As to allegorical personages, fame, discord, love, and the like, they form, says Dr. Blair, the worst machinery of any; and though they may serve for embellishment, they should not be permitted to bear any share in the action of the poem.

With regard to the narration in an epic poem, it is not of any great moment, whether the poet relate the whole story in his own character, or introduce some of his personages to relate any part of the action that had passed before the poem opens. Homer follows one method in his Iliad, and the other in his Odyssey. Virgil has, in this respect, imitated the conduct of the Odyssey;泰山 that of the Iliad. Where the subject is of great extent, and comprehends the transactions of several years, as in the Odyssey and the Aeneid, the latter method seems preferable. When the subject is of smaller compass, and shorter duration, as in the Iliad and the Jerusalem, the poet may, without disadvantage, relate the whole in his own person. It is of very considerable importance in the course of the narration, that it be peripatetic, animated, and enriched with all the beauties of poetry. No sort of composition requires more strength, dignity, and fire, than the epic poem. "It is the region," says Dr. Blair (Lectures on Rhetoric, &c. vol. iii.) "within which we look for every thing that is sublime in description, tender in sentiment, and bold and lively in expression; and, therefore, though an author's plan should be faultless, and his story ever so well conducted, yet, if he be feeble, or flat in style, defective of affecting scenes, and deficient in poetical colouring, he can have no success. The ornaments which epic poetry admits must all
EPI
d
ill be of the grave and chaste kind. Nothing that is loose,
judicious, or affected, finds any place there. All the ob-
jects which it presents ought to be either great, or tender,
or pleasing. Descriptions of disgusting or shocking ob-
jects should as much as possible be avoided; and, there-
fore, the fable of the Harpies, in the third book of the
Aeneid, and the allegory of Sin and Death, in the second
book of Paradise Lost, had been better omitted in those
celebrated poems. Mr. Addison, in his critique on the
Paradise Lost (Spectator, vol. iv.), has introduced several
pertinent remarks on this subject. The sentiments, which
in an epic poem are the thoughts and behaviour ascribed
by the author to the persons whom he introduces, should be
conformable to the respective characters of these persons,
and when this is the case they are said to be jujf. The sen-
timents have likewise a relation to things as well as to persons,
and they are then perfect, when they are adapted to the
subject. If in either of these cases the poet endeavours to
argue or explain, to magnify or diminish, to raise love or
hated, pity or terror, or any other passion, we ought to
consider whether the sentiments he makes use of are proper
to these ends. Homer is confounded by the critics for his
defect as to his particular in several parts of the Iliad and
Odyfley; but candour ascribes this defect to the times in
which he lived. Virgil has excelled all others in the pro-
priety of his sentiments. Milton is likewise commended in
this respect; and he claims peculiar praise from the con-
 sideration, that most of his characters lie out of nature, and
were to be formed purely by his own invention. The loves
of Dido and Aeneas are merely copies of what has paffed be-
tween other persons. Whereas Adam and Eve, before the fall,
are a different species from that of mankind, who are defenced
from them; and no one but a poet of the most unbounded in-
vention, and the most exquisite judgment, could have introduced
into their conversation and behaviour so many apt circum-
stances during their state of innocence. An epic poem
should abound not only with such thoughts as are natural,
but also with such as are sublime. In this respect Virgil is
inferior to Homer. Indeed, Virgil seldom rises into senti-
ments that are astonishing, where he is not lived by the
Iliad. He very few where charms and pleasures are the force
of his own genius; but seldom elevates and transports us
where he does not deduce his hints from Homer. Milton's
chief talent, and distinguishing excellence, lie in the subli-
nity of his thoughts. In the greatness of his sentiments
he triumphs over all the poets both ancient and modern,
Homer only excepted. As sentiments that are natural and
sublime are always to be purfued in an heroic poem, there
are two kinds of thoughts, which should be carefully avoid-
ed; the first are such as are affected and unnatural, and
the second such as are mean and vulgar. In Virgil we meet
with little or nothing that resembles the first kind of
thought: none of those trifling points and peculiarities that
often occur in Ovid, none of the epigrammatic turns of Lu-
can, none of the swelling sentiments that are fo frequent in
Statius and Claudian, and none of the mixed embellish-
ments of Tasso. Every thing is just and natural. Milton
has sometimes erred in this respect; and it is urged as his
apology, that he was infected by the tale and practice of the
age in which he lived. Mean and vulgar thoughts have
rendered Homer obnoxious to cenfure; but his advocates
have imputed sentiments of this kind to the age in which he
wrote, and to that which he describred, rather than to any
imperfection in that divine poet. No blemish of this kind
is observable in Virgil, and Milton is seldom chargeable
with it.

We have already observed, that the language of an
heroic poem should be both perspicuous and sublime. In
proportion as either of these two qualities are wanting, the
language is imperfect. See farther of the nature of the
epic poem under FARRER. For its matter, see ACTION.
For its form, see NARRATION. For its variety, see 
HAGEMETER. See also MANNERS, CHARACTERS, MAC-
chine, &c. See also AENEID, ILIAD, TASSO'S JERUSA-
lem, CAMOEN'S LUSIAD, FENELON'S TELEMACHUS, VAI-
TAIRE'S HENRIADE, and MILTON'S PARADISE LOST.

EPICARIA, a town of Illyria, in Dalmatia. Potl.

EPICAMNA, (from ειηας, and καις, to burn). See En-
cauma.

EPICEDION, Enecion, formed of ειηας, upon, and
καις, funeral, in the Greek and Latin Poetry, was a
funeral eulogy, or a composition in prose or verse, de-
ivered over the corpse of a friend or neighbour, com-
memorative of the virtues of the deceased. In celebrating
the obsequies of distinguished persons three kinds of fu-
neral discourses were used on the occasion. One, delivered
when the friends were assembled to perform the last mourn-
ful offices for the dead, was termed epicedion; another, at
the rogor, hufum, or funeral pile, nenia; and that inscribed
on the tomb or cenothap, epitaphium. In the early ages of so-
icy, the epicedion was generally an extemporaneous effusion
of some near relative or affectionate friend, expressive of the
sentiments he felt at the loss, and calculated to excite the
common sympathy of the surrounding attendants. Beautiful
specimens are given of this species of poetobitary respect by
Virgil in the Aeneid; the one (lib. ix.) on the death of Eu-
ralis, and the other (lib. xi.) on the death of Pallas. But in
infrequent periods, when wealth and luxury had supplanted
the simplicity of nature, and truth of feeling had been obliged
by fashion to yield to the flattery of pomp; the eulogy,
though preferred, materially differed in its character and
form. What once had been the proper expression of undif-
figned efteme, was changed into a degrading fyle of pa-
gentry and vilenity. In most public funerals, but more espe-
cially in the called vindilites, the corpse, previous to interment,
was carried into the forum, attended by a wait train of invited
or hired followers, when one of the relatives, or some orator of
eminence, ascended the rostrum, and harangued the audience
in praise of the departed friend or hero. The origin of this
custom is attributed to Valerius Publicola, after the
expulsion of the regal title. He having honoured the
obsequies of his colleague with a funeral oration, so pleased
the vanity of the Roman people, that it soon became
fashionable to celebrate the fulerals of great or distinguished
characters with panegyrics, or encomiastic orations. The
practice became at length fo popular, that the younger
Pliny, in his epitile, lib. ii. ep. 1. considers it as the laft, but
not the least addition to the happiness of a great and good
man, to have had the enviable honour of being commended
at his funeral by the eloquence of the consul, Tacitus. Nor
was this privilege exclusively confined to men; for Livy
relates that the Roman matrons, having been extremely
liberal and active in raising a collection of gold to enable
the government to deliver the city from the hands of the
Gauls, were allowed, by an act of the senate, to have the
privilege of epicedion being pronounced at the celebration
of their obsequies, equally with the other sex. The abuses to
which this custom was liable, and to which it actually
became in time subfervient, are made the subjects of just
complaint, and pointed animadversion, both by Cicero and
Livy; as tending, by the fullfornens of flattery, to weaken
the motives to virtue, and by the greater attention which

thofe
EPICURUS, among the Athenians. It was ordained by Solon, that once every year the laws should be carefully reviwed and examined; and if any of them were found unsuitable to the present state of affairs, they should be repealed. This was called Διακρίσις τῶν νόμων, from the manner of giving their fulfillments, by holding up their hands. See a farther account of this custom in Pott. Archæol. Græc. lib. i. cap. 26. tom. i. p. 142.

EPICHIORDIS, from χαίρω, an infitute, in Anatomy, a name given by some to the meataly.

EPICHUS, or TAPAE (Gαρ), in Ancient Geography, a town of Africa, on the coast of the Mediterranea sea, S. of Typhara. See GABS.

EPICHIARIASMA, in the Ancient Muses, an air for the cithara, failed to be played at the end of dramatic pieces; which, consequently, must have been to Greek plays what a terminating ballet is now to an opera.

EPICLEROΣ, Εphem period, among the Athenians, a daughter that had no brothers, and therefore inherited her father's whole estate. See EPIDICASIA.

EPICENE, Ἐμφανής, in Grammar, a term applied to nouns, which, under the same gender and termination, mark, indifferently, two kinds of sexes. See Gender.

Such in Latin, are aquila, vesperitia, &c. which signify equally a male or a female eagle, or bat.

Grammarians distinguish between epicene and common. A noun is said to be common of two kinds, when it may be joined either with a masculine or a feminine article; and epicene, when it is always joined to some one of the two articles, and yet signifies both genders.

EPICOLIC REGION, in Anatomy, from χαίρω, upon, and κόλλω, the colon, that part of the abdomen which is above the colon.

EPICRANUS, a thin and broad muscle, covering the superior arched portion of the cranium, and called also fronto-occipitalis, and occipto-frontien; or described as two muscles by the names of frontalis and occipitales.

If we describe this as a single muscle, which we consider as the most natural and correct method, it will belong to the clafs of digastric muscles, or of such as poiffes a middle tenden, with sievey fibres connected to its two ends.

The aponeurosis is a very broad but thin plane, made up of tendinous fibres, variously interwoven, covering the upper part of the cranium, and hence called by Soemmerring galena crani aponeurotica. It is separated, along the middle, by a narrow interval from the opposite muscle, and it extends externally as far as the semicircular line, to which the temporal fascia is affixed. Its outer surface adheres closely to the scalp, while the inner is much more loosely connected, by a yielding cellular substance free from fat, to the pericranium. Its edges are infenibly continued into the neighbouring cellular substance.

The frontal portion is a thin flattened layer of muscular fibres, commencing by a femoral edge from the front of the aponeurosis, and descending in a straight course to the front of the head. Internally it is continuous with the opposite muscle, and detaches a portion of fibres along the line of the nape, to join the compreessor narium, and levator labii superioris and alae naei. It then terminates by joining the obicularis palpaborrum, through the whole of its upper convexity, and it is also connected with the corrugator supercilli. The external surface of this muscle is covered by the integuments of the forehead; and its inner surface lies on the frontal bone and os naei.

The occipital portion is not so broad as the preceding. Arising from the back edge of the aponeurosis, it is inserted into the upper part of the external transverse ridge of the occipital bone. It covers the occipital and a little of the temporal bone, and is covered by the scalp.

It is very obvious that the occipito-frontalis cannot affect the bones of the head; but it moves the integuments in different directions, in consequence of the connection between its...
its tendon and the scalp. When the frontal and occipital portions act alternately, they draw the common tendon backwards and forwards, and thereby impart considerable motion to the whole hairy scalp. If they act together, they will render the aponoeosis tense. When the frontal acts separately, it draws up the eyebrow and skin of the forehead, and throws the latter into transverse wrinkles. Hence it is concerned in the expression of the countenance, and acts more especially in the gay and joyous emotions, directly antagonizing the corrugator supercilii, which throws the forehead, and particularly the eyebrows, into longitudinal wrinkles. It contributes also, by means of its connection with the upper eyelids, to the opening of the eyelids, when we carry that to as great an extent as possible. The separate action of the occipital can only produce a slight effect on the integuments of the back of the head. Its contraction, however, fixes the aponoeosis, and renders it a firm point for the contraction of the frontal in raising the eyebrow and eyelid. This muscle, on the whole, is strongly analogous to the panniculus carnosus of quadrupeds.

**Epicrasis**, in *Medicine*, is a gradual evacuation of all humours in the blood.

**Epicrisis**; Ἐπικρίσις, in *Rhetoric*, a clear and brief declaration of the speaker's judgment concerning the subject in hand. Thus, "ego hic tibatuo, in optimo imperatore quatuor res inefs opertore, &c." Voil. Rhet. lib. vi. p. 495.

**Epiceteth**, in *Ancient Geography*, a people, who, according to Strabo, bounded Bithynia on the east. Hence the western part of Phrygia obtained the appellation of "Phrygia Epicetus." In this territory was the source of the river Hermus, and the town of Anysta was situated in it, on the frontiers of Mypha.

**Epicetetus**, in *Biography*, an eminent Stoic philosopher, no less distinguished for his virtues than his wisdom, was born in a fertile condition at Hierapolis in Phrygia, and flourished in the first century of the Christian era. At an early age he was sold as a slave to Epaphroditus, a celebrated freedman of Nero, to whom Josephus inoffert most of his works, and who was afterwards put to death by Domitian. Epicetetus was lame; and of this infirmity various causes have been assigned by different writers. Celsus relates, that when his master, in order to torture him, squeezed his leg very hard, the philosopher betrayed no symptoms of fear, but laid very calmly to his tormentor: "You will break my leg!" and when it was broken, he only said with a smile, "Did I not tell you that you would break it?" Some say, that he was born lame; and others ascribe his lameness to the heavy chains with which his master loaded him. Epicetetus, having, by some means which are not recorded, obtained his freedom, retired to a small hut within the city of Rome, where, in an indigent condition, he devoted himself to the study of philosophy. Having in his retirement acquired a competent knowledge of the principles of the Stoic sect, and having also received instructions in rhetoric from Rufus; he became, notwithstanding his poverty, a popular preceptor of morals. He was an acute and judicious observer of manners; his eloquence was simple, majestic, nervous, and penetrating: his doctrine inculcated the purest morals; and his life was an admirable pattern of sobriety, magnanimity, and the most rigid virtue. His reprehensions of vice were bold and animated; his instructions and precepts impress and conciliating; and they were communicated without that dogmatism, vanity, and rudeness, which were too generally affected by the philosophers. He was accustomed to observe, that the sum of moral instruction may be comprised in two words, **ἀπάνω καὶ ἀπερημός**, t. c. endure and abstain, or bear and forbear. Aulus Gellius represents him as the greatest man the feast of the Stoics ever produced. The tyranny of Domitian, notwithstanding his extreme poverty and singular merit, included him in the number of those philosophers who were banished from Italy; and to the arbitrary decree of this monarch, he calmly submitted, considering himself as a citizen of the world, and fully apprised, that wherever he went he carried his bel vesture along with him. At Neapolis in Epirus, which he chose as the place of his residence, he pursued his design of correcting vice and folly by the precepts of philosophy. The wisdom and eloquence of his discourses were held in such high estimation, that his hearers were very numerous, and it became a common practice among them to commit his instructions to writing. It is not certain whether he returned to Rome after the death of Domitian; but the respect which Adrian entertained for him renders it probable, that he spent the latter part of his life in that city. Here, however, he obtained no favours, that could induce him to abandon that humble condition of contented and independent poverty, which he had fequested, and in which he determined to remain. Of the time and manner of his death we have no certain account. Themistius and Suidas affirm that he lived till the time of the Antonines; but from the mention that is made of him by Aulus Gellius and Marcus Aurelius, it is probable that he died towards the close of the reign of Adrian. His name and memory were so much respected after his decease, that, according to Lucian, the cartesia lamp, by which he used to light, was sold for 3000 drachmas, or more than 90l. of our money. The testimony of Suidas, who affirms that Epicetetus wrote many books, is not supported by any ancient author; however, his name is the only mention of this philosopher in his beautiful moral manual, entitled "Enchiridion," and his "Differentiations," selected by Arrian, which were drawn up from notes taken by his disciples from his lips. Arrian's account of his life and death is not now extant. Simplicius has left a commentary upon his doctrine, in the eclectic manner. There are also various fragments of his wisdom preferred by Antoninus, Gellius, Stobaeus, and others. Although the doctrine of Epicetetus is less extravagant than that of any other Stoic, his writings every where breathe the true spirit of Stoicism. The tenet of the immortality of the soul was adopted and maintained by him with a degree of constancy suited to a more rational system than that of the Stoics, who inculcated a renovation of being in the circuit of events, according to the inevitable order of fate; and his exhortations to contentment and submission to Providence are enforced on much fuller principles than those of the Stoics. He also strenuously opposed the opinion held by the Stoics in general, concerning the lawfulness of suicide; and his whole system of practical virtues approaches nearer than that of any other instructor, enlightened by revelation, to the purity of Christian morality. We have various editions of the remains of this philosopher, published at Leyden in 1670, in 8vo. cum notis variis; at Utrecht in 1711, in 4to; at Oxford, in 1740, in 8vo. by Joseph Simplic, together with the Table of Cebe's, &c., at London in 1742 by J. Upton, in two volumes 4to, which is the most valuable of all. The Enchiridion was published by C. G. Heyne, in 1776, in 8vo. and, together with Cebe's table, by Schweighauser, in 1797, 8vo. These have been translated into various languages; but the most esteemed version in our country is that by Mrs. Carter, published in 1758, with notes. Fabr. Bib. Græc. v. iii. Aul. Gall. l. i. c. 2. Arrian, l. i. iii. Lucian in Pereg. l. iv.
EPICUREANS.

The doctrines of Epicurus, as they are stated in a just, comprehensive, and elaborate detail by Brucker in his "History of Philosophy," translated and abridged by Dr. Enfield, are arranged under the distinct heads of Philosophy in general, canons or rules of philosophizing, Physics, and Ethics. Philosophy is the exercise of reason in the pursuit and attainment of a happy life; whence it follows, that those studies which conduce neither to the acquisition nor the enjoyment of happiness are to be disdained as of no value. The end of all speculation ought to be, to enable men to judge with certainty what is to be chosen, and what to be avoided, to preserve themselves free from pain, and to secure health of body and tranquillity of mind. Accordingly, the young should apply to the study of it without delay, nor should the old be ever weary in the pursuit of it. As nothing ought to be dearer to a philosopher than truth, he should prosecute it by the most direct means, deviating not from its path, nor suffering himself to be imposed upon by the fictions of others, neither poets, orators, nor logicians; making no other use of the rules of rhetoric or grammar, than to enable him to speak or write with accuracy and perspicuity, and always preferring a plain and simple to an ornamental style. A wise man will embrace such tenets, and only such, as are built upon experience, or upon certain and indubitable axioms. Philosophy consists of two parts:—physics, which respect the contemplation of nature; and ethics, which are employed in the regulation of manners. Of these, the latter is the most important; the knowledge of nature being only necessary as a means of promoting the happiness of life. Philosophers have added a third part, dialectics; which ought to be rejected, as only productive of those disputes, idle quibbles, and fruitless cavillings. In order to facilitate the pursuit of knowledge, a few plain maxims and rules may be useful. Truth is of two kinds; that which respects real existence, and that which consists in a perfect agreement between the conception of the mind and the nature of things. In order to judge rightly concerning truth, it is necessary to use some criterion, or instrument, of judging. This criterion will vary according to the nature of the object which the mind contemplates. In judging of natural and moral objects, the three instruments employed are sense, preconception, and passion. The maxims, or canons, pertaining to sense, are four: First, that the sense of one can never be deceived, and consequently, that every perception of an image, or appearance, is true; that is, that the perception, or simple apprehension, and its efficient cause, the species or image flowing from the object, really agree. Secondly, opinion, or judgment, is consequent upon perception, and admits of truth or falsehood. Perceptions, or infallations, are the effect of real external phenomena; but when the mind judges concerning these appearances, the opinion may be either right or wrong. Thirdly, every opinion is to be admitted as true, which is attested, or not contradicted, by the evidence of the senses, after a careful and deliberate examination of every circumstance which can be supposed to affect the question. Fourthly, an opinion contradicted, or not attested by the evidence of the senses, is false. Thus, the opinion of a Plenum must be false, because it contradicts the evidence of the senses, which attest, that there is such a thing as motion. Concerning the second instrument of judgment, viz. prior, or pre-conception, four canons may be laid down. First, that all pre-conceptions are derived from the senses, either by immediate impression, as of an individual man; by enlargement or diminution, as of a giant or dwarf; by resemblance, as of an unknown city to one which has been seen; or by compulsion, as of a centaur. Secondly, pre-conception is necessary to enable us to reason, inquire, or judge of anything. Thirdly, pre-conceptions, or universal notions, are the principles of all reasoning and discourse; and we safely refer to these in comparing one thing with another. If these notions be agreeable to nature, and distinctly conceived, artificial reasoning will be unnecessary. Fourthly, truths, not self-evident, are to be deduced from manifest preconceptions; or, where the relation of ideas is evident, it is to be made evident by the intermediate use of some acknowledged principle. The third instrument, passion, or affection, which comprehends pleasure and pain, admits of the following four evident maxims. First, all pleasure, to which no pain is annexed, is for its own sake to be pursued. Secondly, all pain, to which no pleasure is annexed, is for its own sake to be avoided. Thirdly, that pleasure, which either prevents the enjoyment of a greater pleasure, or produces a greater pain, is to be shunned. Fourthly, that pain, which either removes a greater pain, or procures a greater pleasure, is to be endured. As to the use of words, two canons are sufficient. First, in speaking, use terms in common use, and in the sense in which they are commonly understood. Secondly, in hearing, or reading, attend carefully to the signification which the speaker or writer affixes to his terms. Attention to these maxims would prevent much obscurity and confusion, and terminate many disputes. By these rules Epicurus undertook to conduct his followers into the secrets of nature, and to lay open to them the origin of things.

The physical doctrine of Epicurus was as follows: Nothing can ever spring from nothing; nor can any thing ever return to nothing. The universe always existed, and will always remain; for there is nothing into which it can be changed. There is nothing in nature, nor can any thing be conceived, besides body and space. Body is that which possesses the properties of bulk, figure, renaissance, and gravity: it is this alone which can touch and be touched. Space, or vacuum, delimit of the properties of body, incapable of action or passion, is the region which is, or may be occupied by body, and which affords it an opportunity of moving freely. The existence of bodies is attested by the senses. Space must also exist, in order to allow bodies place in which to move and exist; and of their existence and motion we have the certain proof of perception. Besides body and space, no third nature can be conceived. But the existence of qualities is not precluded, because these have no subsistence except in the body to which they belong. The universe, consisting of body and space, is infinite. Bodies are infinite in multitude; space is infinite in magnitude. The universe is immovable, because there is no place beyond it into which it can move. It is also eternal and immutable, since it is liable to neither increase nor decrease, to production nor decay. Nevertheless, the parts of the universe are in motion, and are subject to change. All bodies consist of parts, which are either themselves simple principles, or may be resolved into such. These first principles, or simple atoms, are divisible by no force, and therefore must be immutable. The existence of such atoms is indisputable, because it is impossible that any thing which exists should be reduced to nothing. A finite body cannot consist of parts infinite either in magnitude or number; and therefore divisibility of bodies in infinitum is inconceivable. All atoms are of the same nature.
nature, without any difference in essential qualities; and yet it appears, from their different effects upon the senses, that they differ in magnitude, figure, and weight. Atoms exist in every possible variety of figure; and yet, on account of their solidity, they are infrangible, or incapable of actual division. Gravity is an essential principle of atoms; for being perpetually in motion, or making an effort to move, they must be moved by an internal impulse, which may be called gravity. By this internal force, atoms are carried forward in a direction, which is nearly rectilinear; and whilst they pass through free space, their declination from a right line occasions a casual concurrence of corpuscles of different forms. Thus various kinds of curvilinear motion will be produced. Moreover, when one atom is reflected from another, and again repelled by a third, it will acquire a kind of vibratory or tremulous motion. Hence an universal agitation will ensue. The principle of gravity, being essential to the primary corpuscles or atoms, these must have been incessantly, and from eternity, in actual motion; and with a velocity, when no obstacle intervenes, which will cause them to pass through the greatest imaginable space in the smallest imaginable portion of time. All atoms are also supposed, whilst they pass without resistance through the same empty space, to move with equal velocity; and though, by collision, their direction may be changed, their velocity is not diminished. Atoms are the elements from which all things are compounded, and into which they are resolved; and the energy, or principle of motion, which essentially belongs to them, is the sole agent in the operations of nature. Action originates in atoms, and from these proceeds to compound bodies. All the changes which take place in the figure, and other properties of bodies, consist in local motion. Bodies are more or less rare, in proportion to the size of the vacancies which intercept the solid atoms of which they are composed. Transparency depends partly upon the same cause, and partly upon the position of the vacancies between the particles: for rays of light will pass easily through a dense body, as glass, if its vacancies be placed in a straight line. Hardness and softness, flexibility, ductility, and other qualities, may be explained in a similar manner. The weight of a body is the result of the weight of all its atoms; and since gravity is an essential property of all atoms, all bodies must be heavy; and the only reason why some bodies appear to have the contrary principle of levity is, that they are driven upwards by the denser mafs in which they are placed. Heat is the influx of certain small, round, soft corpuscles, which infuse themselves into the pores of bodies in continual increscence, till by their perpetual action, the parts are separated, and at length the body dissolved. The sense of heat is the perception of the separation of parts, which were before contiguous. Cold is the influx of certain irregular atoms, whose motion is slower than that of those which occasion heat, and their effect the reverse of the former. Pleasure and pain, motion and rest, and even time, are actions of bodies. Production and dissolution are nothing more than a change of the position of atoms, or an increase or diminution of the particles of which bodies are composed. The world is finite and terminable, and must have some figure, though this cannot possibly be ascertained. It is not eternal, but began at a certain time to exist; for since every thing in the world is liable to vicissitudes of production and decay, the world itself must partake of them. This may also be inferred from the short date of history, and the late invention of arts.

The formation of the world may be conceived to have happened in the following manner: a finite number of that infinite multitude of atoms, which, with infinite space, constitutes the universe, falling fortuitously into the region of the world, were in conformity of their innate motion collected into one rude and indigested mass. In this chaos, the heaviest and largest atoms, or collections of atoms, first subided, whilst the smaller, and those which from their form would move most freely, were driven upwards. These latter, after many reverberations, rose into the outer region of the world, and formed the heavens. Those atoms, which by their size and figure were suited to form fiery bodies, collected themselves into flares: those which were not capable of rising so high in the sphere of the world, being disturbed by the fiery particles, formed themselves into air. At length from those which subided was produced the earth. By the action of air, agitated by heat from the heavenly bodies upon the mixed mafs of the earth, its smoother and lighter particles were separated from the rest, and water was produced, which naturally flowed into the lowest places. In the first combination of atoms, which formed the chaos, various seeds were, which, being preferred and nourished by moisture and heat, afterwards springing forth in organized bodies of different kinds. Of the animal productions of the earth, some may be conceived to have been produced imperfect, and therefore incapable of life, but others would come forth more perfect. Thence, after the earth was exhausted of its seminal virtues, would respectively continue their species. The world, thus formed, would be preferred by the same mechanical causes which produced it; but by the incessant motion of atoms, which alone are solid and incorruptible, it would gradually tend to diffusion. In process of time nothing will remain but separate atoms and infinite space. As atoms are infinite, the number of worlds may also be infinite. The earth occupies the middle part of the world; but no point within it is properly the centre of gravity; for all heavy bodies fall in nearly parallel lines. The doctrine of Antipodes, according to the Epicurean philosophy, is false. The figure of the earth is a circular plane; and it is preferred from falling towards the lower region by the air, with which it is congenial, and upon which therefore it does not press; their mutual action destroying the effect of gravity. Earthquakes are caused by the agitation of internal winds and water, or by the decay or sudden fall of columns, that support portions of the earth's surface. Or, the internal winds may be converted into fires, which may cause sudden and violent eruptions, as in mount Ætna. Waters passing out of the sea into the crevices of the earth, undergo a filtration, by which the particles of salt received by them from the bed of the sea are separated. Poisils and plants are produced by the motion of atoms, that cause the continual transposition, accretion or diminution of individual bodies. Having no vital principle, they can only be said analogically to live or die. Animals having been once formed, at the beginning of the world, by the casual conjunction of similar atoms, the production of animal bodies is still continued in a constant and determinate order. The parts of animals were not originally formed for the uses to which they are now applied; but, having been accidentally produced, they were afterwards accidentally employed. The eye, for example, was not made for seeing, nor the ear for hearing, but the soul, being formed within the body at the same time with these organs, and connected with them, could not avoid making use of them in their respective functions. The soul is a subtle corporeal substance, composed of the finest atoms; which, by the extreme tenacity of its particles, is able to penetrate the whole body, and to adhere to all its parts. It is composed of
of four distinct parts; fire, which carries animal heat; an
etheral principle, which is moist vapour; air; and a fourth
principle, which is the cause of sensation. These four
parts are so perfectly combined as to form one subtle sub-
stance, which, whilst it remains in the body, is the cause
of all its faculties, motions, and passions, and which cannot
be separated from it, without producing the entire disso-
lution of the animal system. Different sensations are the
casual effects of the different organs, which the soul in its
union with the body is capable of employing, and of the
different properties and qualities of external objects.
These become sensible by means of certain species, or
images, which are perpetually passing by thin films from
bodies, in form similar to the surfaces of the bodies them-
elves, and striking upon organs fitted to receive them.
The mind, or intellect, which is ensnared with the power
of thinking, judging, and determining, is formed of parti-
cles more subtle in their nature, and capable of the most
rapid motion. This intellect is a portion of the soul, form-
ing with it one nature, and yet retaining its distinct char-
acter, which is the power of thinking; the supposed seat of it is
the middle of the brain, or the heart, which we perceive
to be the region of those affections which are excited by
cognition. Thought is produced by subtle images, which
find their way through the body, and, when they arrive at
the intellect, move it to think. The affections and
passions of the soul may be reduced to two, pleasure and
pain. Voluntary motion is the effect of images conveyed
to the mind, by which pleasurable or painful conceptions
are formed, and subsequent desires or aversions are pro-
duced, which become the immediate springs of action.
Sleep is produced, when the parts of the soul, which are
at other times diffused through the body, are expiréd or
separated from each other. Dreams are the effect of images
casually flying about, which from their extreme tenuity penetrate the body and thrive upon
the mind, exciting an imaginary perception of those things,
of which they are images. Death is the privation of sen-
sation, in consequence of the separation of the soul from
the body; in which case, the soul is dispersed into the cor-
puscles or atoms of which it was composed, and therefore
can no longer be capable of thought or perception.
The knowledge of things, which belong to the regions above
the earth, whether aerial or celestial, is to be pursued only
for freeing the mind from imaginary fears, and settling it in
a state of tranquillity. In the heavens, or ethereal regions,
the sun, moon, and stars appear to be fiery bodies; or they
may be smooth mirrors, from which bright fiery particles
flowing through the ethereal regions are reflected to the
earth; or they may be deep vesels, containing fires; or they
may be circular plates heated like mortar, or stones in
a furnace. The apparent motion of the heavenly bodies
may arise from the revolution of the whole heaven in which
they are fixed, like nails in a solid body; or by the revolu-
tion of the bodies themselves through the heaven as a fluid
and permeable medium. The cause of this motion may be,
either an internal necessity in the natures of the bodies themselves, or the external pressure of some ethereal
fluid.

In the universe there are, according to Epicurus, with-
out contradiction, two divine natures; because nature itself
has impressed the idea of divinity upon the minds of men.
The motion is universal, nor is it established by custom,
law, or any human institution; but it is the effect of an
innate principle, producing universal consent, and therefore
must be true. This universal motion has probably arisen
from images of the gods, which have casually made their
way into the minds of men in sleep, and have afterwards
been recollected. But it is inconsistent with our natural
notions of the gods, as happy and immortal beings, to sup-
pose that they encumber themselves with the management
of the world, or are subiect to the cares and passions which
must attend to great a charge. Hence it is inferred, that
the gods have no intercourse with mankind, nor any concern
with the affairs of the world. Nevertheless, on account of
their excellent nature, they are objects of reverence and
worship. In their external shape the gods resemble men;
and though the place of their residence is unknown to
mortals, it is without doubt the mansion of perfect purity,
tranquillity, and happiness.

Upon a review of the preceding summary of the Epicurean
system, furnished chiefly by Lucretius and Lucretius, it must
appear to be a feeble and intellectual effort to explain the
phenomena of nature upon mechanical principles. With this view
Epicurus adopts a variety of wild and fanciful hypotheses,
which evince his incapacity of solving the grand problem
concerning the origin and formation of the world. But the
greatest defect of this system is the attempt of its author to
account for all the appearances of nature, even those which
respect animated and intelligent beings, upon the simple
principles of matter and motion, without introducing the
agency of a Supreme Intelligence, or admitting any other
idea of fate, than that of blind necessity inherent in every
atom, by which it moves in a certain direction. Hence he
leaves unexplained those appearances of design, which are to
manifest in every part of nature, and absurdly supposes,
that the eye was not made for seeing, nor the ear for hear-
ing. Besides the idea which he gives of the nature of the
gods, their existence he admits, as similar to man; and of
their condition, as wholly separate from the world, and en-
joying no other felicity except that which arises from inac-
tive tranquillity, falls infinitely short of the true conception
of Deity, as the intelligent Creator and Governor of the
world.

The doctrine of Epicurus concerning nature differs from
that of the Stoics, (see Stoics,) chiefly in the following
particulars: while the latter held God to be the soul of the
world, diffused through universal nature, the former ad-
mits no primary intelligent nature into his system, but
held atoms and space to be the first principles of all things;
and whilst the Stoics conceived the active and passive princi-
pies of nature to be connected by the chain of fate, Epicu-
rus ascribed every appearance in nature to a fortuitous colli-
sion and combination of atoms. See Atomical and Cor-
puscular Philosophy.

The ethics of Epicurus are much less exceptionable than
his physics; of which we may judge from the following
summary. The end of living, or the ultimate good, which is
to be sought for its own sake, according to the universal
opinion of mankind, is happiness; which men generally fail
of attaining, because they form wrong notions of the nature of
happiness, or do not use proper means for attaining it.
The happiness, which belongs to man, is that state in which
he enjoys as many of the good things, and suffers as few of
the evils incident to human nature as possible, passing his
days in a smooth course of permanent tranquillity. Perfect
happiness cannot possibly be possessed without the pleasure
that attends freedom from pain, and the enjoyment of the
good things of life. Pleasure is in its nature good, and
ought to be pursued; and pain is in its nature evil, and
ought to be avoided. Besides, pleasure or pain is the mea-
asure of what is good or evil in every object of desire or
aversion. However, pleasure ought not in every instance to
be pursued, nor pain to be avoided; but reason is to dilin-
guish and compare the nature and degrees of each, that the result may be a wise choice of that which shall appear to be, upon the whole, good. That pleasure is the first good appears from the inclination which every animal, from its first birth, discovers to pursue pleasure and avoid pain; and is confirmed by the universal experience of mankind, who are incited to action by no other principle, than the desire of avoiding pain, or obtaining pleasure. Of pleasure there are two kinds; one confined in a state of rep, in which both body and mind are free from pain; the other arising from an agreeable agitation of the senses, producing a correspondent emotion in the soul. Upon the former of these, the enjoyment of life chiefly depends. Happiness may, therefore, be said to consist in bodily ease and mental tranquility. It is the office of reason to confine the pursuit of pleasure within the limits of nature, so as to attain this happy state; which neither resembles a rapid torrent, nor a standing pool, but is like a gentle stream, that glides smooth and silently along. This happy state can only be attained by a prudent care of the body, and a steady government of the mind. The diseases of the body are to be prevented by temperance, or cured by medicine, or endured tolerably by patience. Against the diseases of the mind philosophy provides sufficient antidotes; the virtues are its instruments for this purpose; the radical spring of which is prudence, or wisdom, and this instructs men to free their understandings from the clouds of prejudice; to exercise temperance and fortitude in the government of themselves; and to practice justice toward all others. In a happy life, pleasure can never be separated from virtue. A prudent man will confit his natural disposition in the choice of his plan of life. Temperance is that discreet regulation of the desires and passions, by which we are enabled to enjoy pleasures without suffering any consequent inconvenience. They who maintain such a prudent self-command, as never to be enticed by the prospect of present indulgence to do that which will be productive of evil, obtain the truest pleasure by declining pleasure. Sobriety, as opposed to inconstancy and gluttony, teaches men that nature is satisfied with a little, and enables them to be content with simple and frugal fare; thus health is preserved; the offices of life are performed with alertness and activity; and the occasional varieties of a plentiful board acquire an excellent relish, and a person is prepared to meet every reverse of fortune without the fear of want. Continence, which is a branch of temperance, prevents the diseases, insamy, remorse, and punishment to which these are exposed, who indulge themselves in unlawful amours. Music and poetry, which are often employed as incentives to licentious pleasure, are to be cautiously and sparingly used. Gentleness, as opposed to an irascible temper, greatly contributes to the tranquillity and happiness of life, by preferring the mind from perturbation, and arming it against the assaults of calamity and malice. Moderation in the pursuit of honours or riches, is the only security against disappointment and vexation. A wise man will, therefore, prefer the simplicity of rural life to the magnificence of courts. As the events of futurity are uncertain, he neither will be elated with confident expectation, nor deprest by doubt and despair; the one and the other being equally destructive of tranquillity. It will contribute to the enjoyment of life, to consider death as the perfect termination of a happy life, which it becomes us to clothe like satisfied guests, neither regretting the past, nor anxious for the future. Fortitude, by enabling us to endure pain and banish fear, is of great use in producing tranquillity. Philosophy instructs us to pay homage to the gods, not through hope or fear, but from veneration of their superior nature. It enables us also to conquer the fear of death, by teaching us, that it is no proper object of terror; since, whilst we, death is not, and when death arrives, we are not; so that it concerns neither the living nor the dead. The only evils to be apprehended are bodily pain and distress of mind. It becomes a wise man to endure the former with patience and firmness, because, if it be slight it may easily be borne; and if it be intense, it cannot last long. Mental distress commonly arises, not from nature, but from opinion; a wise man, will, therefore, arm himself against this kind of suffering, by reflecting that the gifts of fortune, the loss of which he may be inclined to deplore, were never his own, but depended upon circumstances which he could not command. If, therefore, they happen to leave him, he will endeavour as soon as possible to obviate the remembrance of them, by occupying his mind in pleasant contemplation, and engaging in agreeable avocations. Justice respects man as living in society, and is the common bond without which no society can subsist. This virtue, like the rest, derives its value from its tendency to promote the happiness of life. It is the interest of every individual in a state of society to conform to the laws of justice, for in society, the necessity of the exercise of mutual justice, in order to the common enjoyment of the gifts of nature, is the ground of those laws by which it is prescribed. Nearly allied to justice are the virtues of beneficence, compassion, gratitude, piety, and friendship. He who confers benefits upon others, procures to himself the satisfaction of seeing the stream of plenty spreading around him from the fountain of his own beneficence; at the same time he enjoys the pleasure of being esteemed by others. The exercise of gratitude, filial affection, and reverence for the gods, is necessary, in order to avoid the hatred and contempt of all men. Friendships are contracted for the sake of mutual benefit; but by degrees they ripen into such disinterested attachment, that they are continued without any prospect of advantage. A true friend will partake of the wants and forrows of his friend, as if they were his own; if he be in want, he will relieve him; if he be in prison, he will visit him; if he be sick, he will come to him; nay, situations may occur, in which he would not scruple to die for him. It cannot then be doubted, that friendship is one of the most useful means of procuring a secure, tranquil, and happy life.

From the preceding summary of the ethics of Epicurus, we may be enabled to refute the cenures which many writers have passed upon him, as the preceptor of luxurious and licentious pleasures. These cenures have originated in a misconception of the nature of that pleasure which he recommends and justifies, and which, in his system, is only another name for happiness. Whilft the Stoics taught that virtue itself is happiness, Epicurus maintained, that the motive by which men are induced to practice virtue is the desire of happiness. Both taught, that it is impossible to be happy without virtue, and both supposed virtue to confit in a conformity to nature. Whatever errors and absurdities may be justly charged on the Epicurean system, it must be allowed that, when candidly and fairly interpreted, it afforded no encouragement to immoral conduct. However, it cannot be denied by its most zealous advocates, that by the erroneous representations of the gods, and the disbelieve of providence and the immortality of the soul, which this system propagated, it sired very much to relax the obligations and enfeeble the functions and motives of virtue. This was actually the case both at Athens and at Rome, where those who belonged to the school of Epicurus, partly disseminating his genuine doctrine and partly perverting it, disfigured the system to which they adhered by the laxity and diffoluteness of their manners. Some indeed have expressed
prefled a doubt, whether Epicurus himself disbelieved the
immortality of the soul. (See the notes upon "Cudworth's
Intelectual systen of the Univerfe," subjoined by Dr. Mo-
seim to his Latin translation of that learned work, vol. i.
p. 66. 500. vol. ii. p. 1174.) His followers, however, seem
to have been more explicit on this subject; and Mofheim
affects (Eccl. Hist. v. i. p. 157.) that towards the close
of the second century of the Christian era, of all the
philosophers, the Epicureans enjoyed the greatest reputation, and had
undoubtedly the greatest number of followers, because their
opinions tended to encourage the indolent security of a vo-
luptuous and effeminate life, and to banish the remorse and
terrors that haunt vice, and naturally incommoded the
wicked in their sensual pursuits. Hence it is certain, that
in the common use of the appellation, Epicurean has been
understood to signify an indolent, effeminate, and voluptuous
perfon, who only confines his particular and private pleas-ure
without concerning himself with any thing serious. Ac-
cordingly it has been maintained that there were always
two kinds of Epicureans, the rigid and the refin'd.
The rigid Epicureans were those who were strictly attached to
the sentiments of Epicurus, and who placed their whole
happinefs in the true pleasures of the mind, resulting from
the practice of virtue. The loose or refin'd Epicureans,
taking the words of that philofopher in a more gross fensfe,
placed all their happinefs in corporeal gratifications and
pleasure, in eating, drinking, & c. Thofe of the former clafs, who
were the genuine Epicureans, called the others the f"Softihes
of their felf." In the " Nouveau Dictionnaire Hiftorique"
the reader may find a fhort account of modern Epicurean
fchools in France, the members of which were more diftingui-
hed by their literary refinement, polifhed manners, and
luxurious indulgence, than their culture of the genuine
doctrine of the Greek philofopher.

Before we clofe this article, we fhall briefly trace the
fubfistence and progres of the Epicurean fchool, after the
death of its founder. From Epicurus the charge of it de- 
volved upon his friend Hermachus; and it was continued in
fuccedion by Polyratrus, Bafilius, Protarchus, and others.
The felf bifubfited, in a depraved and degraded state, till
the decline of the Roman empire. It entered Rome, indeed,
in confequence of the opposition excited again it by the
Stoics in Greece, under a heavy load of obloquy. This
was much increased by the vehemence with which Cicero,
(De Fin. l. ii. Tufc. Qu. l. i. 3. Fam. Ep. xiii. 1. Orat.
in Pifton. c. 22.) inveighed again it this felf, and by the easy
credit which he gave to the calumnies indignantly circu-
lated again it its founder. It was, however, patronized by
several perfon of diftinclion in Rome, and particularly by
Atticus, the bosom friend of Cicero. Nevertheless, the true
doctrine of Epicurus was not fully flated by any Roman
perfon, till Lucretius, with much accuracy of conceptions
and clearefs of method, as well as with great strength and
elegance of diction, unfolded the Epicurean fystem in his
poem, "De Rerum Natui;" " On the Nature of Things." The
Epicurean felf, though much degenerated from the
simple manners of its founder, continued to flourish through a
long period of years, under the Roman emperors. This
was owing in part to the freedom of manners which it per-
mitted, and in part to the boldnefs with which it combated
superflition; but principally to the frifcl union which fub-
sifted among the members of this fchool, and the implicit
deferece which they unanimously agreed to pay to the
doctrines of their master. The fucceflion of disciples in this
felf was, as Laertius attests (1. x. s. 9.) uninterrupted, even
when other fchools began to fail. In many places the doc-
trine of Epicurus was publicly taught, and at Athens
the Epicurean fchool was endowed with a fixed fiped:
Among the learned men of this period there were fome,
whofe whole concern was to tranmit the tenets and max-
ings of Epicurus uncorrupted to posterity; and others, who
held the memory of Epicurus in high estimation, and in
many particulars adopted his doctrine, and who, therefore,
may not improperly be ranked in the class of Epicureans.
The principal of fhefe are Piny the elder, Cellus, Lu- 
cian, and Diogenes Laertius. After the revival of letters at a
much later period, there were not wanting several learned
men, who, finding little satisfaction in the obscure and lub-
tle speculations of metaphysics, had recourse to the doctrine
of Epicurus, as the true key to the mysteries of nature. The
firft refurer of the Epicurean fystem among the
moderns was Daniel Sennert, an eminent physician of Wit-
tenburg, who flourifhed at the beginning of the 17th
century. Sennert, however, confounded the caraftries of the
more ancient philofophers with the atoms of Democritus
and Epicurus, and held that each element has primary par-
ticles peculiar to itself. The fame doctrine was taught, with
some Irnconferable variations, by Chryloithon Magnæus,
professor of medicine in the university of Pavia, who, in the
year 1646, published " A treatife on the Life and Philofophy
of Democritus." His fystem is rendered obtufe by an
attempt to unite the incompatible dogmas of Epicurus and
Aristotle. The ableft and moft successul attempt towards
the revival of the physical and moral philofophy of Epicurus
was made by Peter Gaffendi, who, besides a variety of
other learned treatifes, wrote a life of Epicurus, in which
he undertakes to refute that philofopher from the laud of
calumny under which his memory had lain for many ages,
as well as to give a fair and impartial representation of his
doctrine. The moft celebrated followers of Gaffendi were
Francis Bernier, a phyfician of Montpelier, who wrote an
"Abridgement of Gaffendi's Philofophy," Par. 1678, and
Walter Chariton, an Englishman, who wrote a treatife,
titled "Physiologia Epicuro-Gaffendi-Charletoniana,"
London, 1674, in which he undertakes to prove that philo-
sopher from the laud of calumny under which his memory had lain for many ages, as well as to give a fair and impartial representation of his
doctrine. The moft celebrated philofophers of genera
Huygens applies it to explain the caufe of
gravitation, and Newton admits it into his theory of natural
philosopby. (See Anatomical Philofophy.) Diogenes Laer-
tius. 1. x. Lucretius de Rerum Natura. Stanely's Hift.
Phil. part. xiii. Gaffendi de Vita et Moribus Epicuri.

EPICURUS, in Biography, the founder of the fystem
described in the preceding article, was an Athenian, of the
Ægean tribe, the fon of Neocles and Cherefrata, perfon of
honorable defcent but reduced condition, and born at
Gargettus in the vicinity of Athens, at the beginning of
the third year of the 109th olympiad, B. C. 342. Neocles,
being reduced to poverty, was fent with a colony of 2000
Athenian citizens to the island of Samos, where he occupied
a small farm, and took up the profecion of a school-teacher;
and where his wife Cherefrata performed the arts of
incantation and lillation, for the purpose of curving defeased
and driving away evil spirits, which, it is faid, she was uf-
fuly employed in her fon, Epicurus, who furnished her with luftul
fongs for her foeem rites. Epicurus remained at Samos and
in the neighboring island of Teos, till he was 18 years of age,
and then removed, with a view to farther advantage for
improvement, to Athens. Upon the death of Alexander,
he left Athens, and went to his father at Colophon. Soon
afterwards he removed to Mitylene, and after passing one
year in that city, he refided for 4 years at Lampsacus. In
the 36th year of his age, he returned to Athens. From
Epicurus.

his 14th year to this time, he was indubitably employed in the study of philosophy. At Samos he was instructed in the Platonic philosophy by Pamphilus, as Cicero informs us (De Nat. Deor. 1. i. c. 26.), and, as we learn from Clement of Alexandria (Strom. 1. i.), he attended in his early years upon Nauphiæus a Pythagorean, and Pyrrho the sceptic. During his abode at Athens he could not fail to derive considerable benefit from Xenocrates, who taught in the Academy, and from Theophratus, who delivered lectures in the Lyceum. His system of philosophy, however, was the result of his own reflections, after comparing the doctrines of other sects. About the 32d year of his age, he opened a school, first at Mitylene, and afterwards at Lamia; but not satisfied with these obfure retreats, he determined to make his appearance on the more public theatre of Athens; and purchased for his own use, at the expense of 80 mina, a pleasant garden, where he taught his system of philosophy. From this circumstance the Epicureans were denominated "the philosophers of the garden." During the siege of Athens by Demetrius, when Epicurus was 44 years of age, and while the city was distrested with famine, he is said to have supported himself and his friends on a small quantity of beans, which he shared equally with them. The period in which he introduced his philosophy was peculiarly favourable for its purpose: for in the room of the Socratic philosophy nothing remained but the subtlety and affectation of Stoicism, the unnatural severity of the Cynics; or the doctrine of indulgence taught and practised by the followers of Ariippus. The younger citizens were, therefore, disposed to listen to a preceptor who soothed the flen and wrinkled brow of philosophy, and, under the notion of conducting his followers to enjoyment in the bower of tranquillity, led them, unawares, into the paths of moderation and virtue. This circumstance rendered his school popular, so that disciples flocked into the garden, not only from different parts of Greece, but from Egypt and Asia. Seneca, though a Stoic philosopher, bears this testimony to Epicurus (Ep. 21): "I the more freely quote the excellent maxims of Epicurus, in order to convince those who became his followers from the hope of screening their vices, that to whatever sect they attach themselves, they must live virtuously. Even at the entrance of the garden they will find this inscription: 'The hospitable keeper of this manison, where you will find pleasure the highest good, will present you libations with barley cakes, and water from the spring. These gardens will not provoke your appetite by artificial dainties, but satisfy it with natural supplies. Will you not then be well entertained?'" The disciples of Epicurus were so cordially attached to one another, that each individual cheerfully supplied the necessities of his brother. The friendship subsisting in the Epicurean fraternity is described by Cicero (De Fin. 1. i. c. 20.) as unequalled in the history of mankind; and Valerius Maximus (I. i. c. 8.) relates a memorable example of indissoluble friendship between Polycrates and Hippocides, two philosophers of the garden. Epicurus, that he might not be interrupted in the prosecution of his studies, lived in a state of celibacy; and he exhibited an example of that temperance and continence, which he inculcated on his disciples. Towards the close of his life, however, his constitution was enfeebled, and he was afflicted with the stone. When he perceived his end approaching, he wrote a will, in which he bequeathed his garden and its appurtenances to Hermachus, and in succession to the future professors of his philosophy. On the last day of his life, he informs his friend Hermachus, that his pain was extreme: but he adds, "All this is counterbalanced by the satisfaction of mind, which I derive from the recollection of my discourses and discoveries." He concluded with instructing his friend by the affection which he had always manifested to him and to philosophy to take care of the children of Metrodorus. The emperor Marcus Antoninus confirms this account, and further says, that Epicurus, in his letters, relied more upon the recollection of his excellent life, than upon the aid of physicians, and instead of complaining of his pain, conversed with his friends upon those principles of philosophy which he had before maintained. At length, finding nature just exhausted, he ordered himself to be put into a warm bath, where, after refreshing himself with wine, and exhorting his friends not to forget his doctrines, he expired. His death happened in the second year of the 127th Olympiad, or B.C. 274, and in the 72d year of his age. He is said to have written a greater number of original works than any other Grecian philosopher; but none of them are extant, except a compendium of his doctrine preferred by Laertius, and some few fragments dispersed among ancient authors. His memory was held in high estimation, not only by his immediate followers, but by eminent writers, who disapproved his philosophy, but entertained a respect for his personal merit. Nevertheless his character and his philosophy have been severely cenused; and the accusations against the Epicurean school have been stamped and left confirmed by men distinguished for their wisdom and virtue: Zeno, Cicero, Plutarch, Galen, and a long train of Christian fathers. But a candid examination of his doctrine and character will obviate many of those charges that have been alleged against them, and prove, that though in some respects this philosopher is highly censurable, in others he has been unjustly and too severely condemned. The charge of impiety admits of no refutation. The doctrine of Epicurus concerning nature not only militated against the superstitions of the Athenians, but against the agency of a supreme deity in the formation and government of the world, and he divested the Deity of some of his primary attributes. Whilst he professed the utmost contempt for popular superstitions, the gods, whose existence he allowed, were delitute of many essential characters of divinity, and his piety was of a kind very different from that which is inspired by just notions of Deity. Besides, it has been suggested, that his sentiments concerning the gods were adopted and professed for the purpose of throwing the odium and disgrace which would have attended a direct avowal of atheism. Epicurus has also been charged with infidelity and contempt towards other philosophers: but this seems to be scarcely compatible with the general air of gentlemanly and civility, which appears in his character. The charge of intemperance and incontinence is unquestionably an atrocious calumny. That he was eminent for the contrary virtues has been amply attested by Laertius, and also by those who were adverse to his doctrine, particularly Cicero, Plutarch, and Seneca. Epicurus has been with equal injustice represented as un instructed and an enemy to liberal science. "We ought to be thankful to nature," says this philosopher, cited by Stobæus, "for having made those things which are necessary, easy to be discovered, and those things which are difficult to be known, not necessary." The temper and spirit of Epicurus were altogether the reverse of those of Zeno and the Stoics; his mode of instruction was very different; and his school was established in direct opposition to that of the Stoics; and, therefore, we need not wonder, that he should become the object of detraction and calumny. Besides, the design of his philosophy and its general principles were very different, and they endeavoured

to secure their own declining popularity by misrepresenting his principles and character, and holding him up to the public as an advocate for infamous pleasures. For these, and familiar reasons, Euphrus encountered the violent opposition of the Stoics; and yet he had many friends and followers during his life, and his memory was venerated after his death. His three brothers, Nocleus, Chazaradus, and Arisbolus, devoted themselves to the study of philosophy, and were supported by his liberality. Of his intimate friends the most celebrated were Metrodorus, Polyeides, and Hermarchus. After his death his birthday was celebrated by his followers as a festival; and they preferred his image in their rings or cups, or in pictures, which they either carried about their persons, or hung up in their chambers. Their reverence for his authority was such, that they committed his maxims, and some of them the whole body of his instructions, to memory; and for a long period, it was deemed a kind of impiety to innovate upon his doctrine: so that the Epicureans formed a philosophical republic, regulated by one judgment, and animated by one soul. Laertius, l. x. Brucker's Hist. Phil. by Enfield, vol. i.

EPICYCLE, formed of the Greek ἐπίκυκλος, upon, and κύκλος, circle, q. d. a circle on a circle, in the Ancient System of Astronomy, was a suborbital orbit, or circle, which moved on the circumference of a larger one, which latter was called the deferent. If the point C of this ellipse, called the apogee, or perfectly irregular, was resolved into two that were circular and uniform; and when the observed motion was to irregular and complicated as not to be represented by one epicycle, the method was to add others, till a nearer approximation was obtained. This syllem owed its origin to a prejudice that seems to have been extremely ancient, in favour of uniform and circular motion; and the problem that chiefly occupied the astronomers in those times, was to assign the proper proportion of the deferent and epicycle which should approximate nearest to the actual observations.

The representation made by this concentric theory of the solar inequalities in longitude, was as follows:

Let C (Plate XII. Astronomy, fig. 105.) be the centre both of the earth and of the circle F B D, and let H G K be a smaller circle, called an epicycle, whose centre B moves uniformly in the circumference F B D from west to east, or in confecutives, while the sun moves also uniformly, and with the same velocity, in the circumference of the epicycle, in antecedents in the upper part, but in consequentia in the lower part of the earth. The mean of this epicycle, called the ephemeral, as being most distant from the earth, he supposed, at the beginning of the anomalistic revolution, to be placed in the point A of O F produced; and if when it comes to G the arch G H is taken similar to F B, the point H will be the place of the sun when the centre of the epicycle has moved from G to B. If then in O F, to which B H is parallel, we take O E = B H, and on E, as a centre, with the distance E A = C F, describe the circle A H P, the fun would be seen from E to move in this circle equally; for the angle A E H is equal to the angle F C B; but seen from C, the centre of the earth, he will appear to move in it unequally, for the angle A C H in the first semicircle of anomaly, that is, in the passage of the sun from A to P, is always less than A E H or F C B: and his true place H will be left advanced in longitude than his mean B. When, again, the centre of the epicycle, or the mean place of the sun, having described a semicircle of the epicycle, will be found in P, the perigee of the orbit A H P, and his mean and true places B and H, will be seen from C to coincide as they did in A, the apogee; but in the sun's passage from P to A, that is, in the second semicircle of anomaly, his true place H, as seen from C, will be always more advanced in longitude than his mean place B: for in this semicircle the angle A C H is always greater than A E H in D C B. The angle E C H, or C B H, which is the difference between the mean and true place of the sun, is called the equation of the epicycle, as being that quantity which, added to the true motion A C H of the planet in its orbit A H P, in the first semicircle of anomaly, and subtracted from A in the opposite semicircle, will render it equal to the mean motion A E H or F C B; and it is evident that the equation, or difference, will be greatest in N or M, where the centre B of the epicycle is go' distant from either apsides. Any lines drawn from E, the centre of the orbit A H P, to the true place of the sun in H, and from C the centre of the earth, and of the deferent F B D, to the mean place of the sun in B, are equally called the line of the mean motion of the fun, because these lines are always parallel, and mark the same point in the zodiac; and any line drawn from C to the true place of the sun is the line of the sun's true motion.

It was thus that the ancients originally proceeded in their representation of the solar inequalities, and the representation seemed to be sufficiently justified by observation; at least till the days of Tycho Brahe no observations had been made with sufficient accuracy to subject it to suspicion. But when Brahe was alive, the stars were most uniform, and the simple anomalistical one was discovered, was equal in the application of the tain concentric theory to the motions of the moon; and having in two cases thus successfully, by means of one suborbital sphere, or epicycle, reconciled apparent inequality of motion with real uniformity, it was natural to suppose that other inequalities, though more various and complicated, might be explained in a similar manner, and required only the addition of other epicycles. The same method of procedure, therefore, was continued, and every new inequality which observation discovered was accounted for by a new sphere, or epicycle, producing it, till the whole sphere employed in the system amounted to 34.

Aristotle, in narrower examination, found these insufficient, and added to them 22: but if they were deemed insufficient, and the number was at last increased to 72; but though it was not till long after the days of Aristotle that the theory was carried to such a degree of extravagance, the multiplication of epicycles rendered it, even in his time, almost as intricate and complex as the appearances of the heavens. Some examples of this kind occur on the revival of it by Copernicus and Tycho Brahe; and when Hipparchus and Ptolemy introduced eccentric orbits, and by means of them somewhat diminished the multiplicity of the spheres employed by their predecessors, they were thought to do a signal service to astronomy. See Excentric Theory.

What was principally required in these theories was to ascertain in the one the ratio of the eccentricity; in the other, the ratio of the semi-diameter of the epicycle to the semi-diameter of the deferent. If we make the radius of Jupiter's deferent circle to that of the epicycle as 52 to 10, the epicyclical motion arising from this construction will very nearly agree with observation: only we may observe, that the oppositions which succeed each other near the constellation Virgo, are less distant from one another than those observed in the opposite part of the heavens; so that the centre of the epicycle seems to move slower in the first case than in the last. To reconcile this with the turmoil which follows upon the motion of that centre in the circumference of the deferent circle, the ancient astronomers said that the earth was not exactly in the centre of the deferent, but so placed.
placed that the equable motion of the centre of the epicycle appeared slower, because it is then more remote, and after various trials they fixed on a degree of excentricity for the deferent, which accords better than any other with the observations, and really differed very little from them. Copernicus, shows their hypothesis for Jupiter never deviates more than half a degree from observation, if it be properly employed. They found that the epicycle moved round the deferent in 3422 days, with an equation gradually increasing to near 6° degrees; so that if the place of the epicycle be calculated for a quarter of a revolution from the apogee, at the mean rate of 1° a day, it will be found too far advanced by near ten days' motion. See Dr. Small's account of Kepler's discoveries, where this subject is treated at great length.

Epicycloid, in Geometry, denotes a curve generated by the revolution of a point of the periphery of a circle, along the convex or concave part of another circle.

A point of the circumference of a circle, proceeding along a plane in a right line, and at the same time revolving on its centre, describes a cycloid. And if the generating circle, in lieu of moving on a right line, moves along the circumference of another circle, whether equal or unequal, the curve described by any point in its circumference is called an epicycloid. Indeed the common cycloid has been sometimes represented as an epicycloid; formed by the revolution of a finite circle on an infinite circle.

If the generating circle proceeds along the convexity of the periphery, it is called an upper, or exterior epicycloid; if along the concavity, a lower, or interior epicycloid.

In an epicycloid, the part of the circle the generating point moves along, is called the base of the epicycloid; thus in Plate V. Analytic, fig. 9. D C is the base of the epicycloid; V its vertex; V B its axis; D P V half of the exterior epicycloid, made by the revolution of the semicircle V L B (which is called the generator) along the convex side of the base D B; as D P U is the interior epicycloid, formed by the generator revolving along the concave side of the base.

The length of any part of the curve, which any given point in the revolving circle has described from the time it touched the circle wherein it revolved, is to double the vered line of half the arc which all that time touched the quiescent circle, as the sum of the diameters of the circle to the diameter of the quiescent circle; provided the revolving circle moves upon the convex side of the quiescent circle; but upon the concave side, as the difference of the diameters to the semidiameter. Otherwise: the circumference of the epicycloid G E F (fig. 10.) is to four times the diameter of the generating circle B E, as the sum of the diameters of the two circles is to that of the base, in the former of the cases above mentioned; but in the second, e. g. F E G, in the same figure, as the difference, &c. In the first case, if the generating circle be supposed to have its diameter equal to half that of the base, the epicycloid F H E G is equal to 6 B E. In the second case, when F 1 is a quarter of F G, the curve F E G will be found equal to 3 F I. When the generating circle is half the base-circle, as in fig. 11, the epicycloid degenerates into a right line, or the diameter of the base. Hence it appears, that in order to deduce the known property of the common cycloid, or that its circumference is equal to four times the diameter of the generating circle, we need only suppose the base-circle to be infinite; an infinity, augmented or diminished by a finite quantity, being always the same.

Dr. Halley gives us a general proposition for the measuring of all cycloids and epicycloids: thus, the area of a cycloid, or epicycloid, either primary, or contracted, or prolate, is to the area of the generating circle, and also the areas of the parts, generated in those curves, to the areas of analogous segments of the circles, as the sum of double the velocity of the centre, and velocity of the circular motion, to the velocity of the circular motion. The demonstration hereof, see in Phil. Trans. N. 218.

The areas of epicycloids may be determined by the following proportion: as the radius of the circle of the base to three times that radius together with twice that of the generating circle, so is the circular segment B H to the epicycloidal sector B H F, or the whole generating circle to the whole area of the epicycloid F E G B. As to the tangents, it is known from the time of Des Cartes, that the line H b, drawn from any point H, to that of the base which touches the circle, whilst this point is described, is perpendicular to the curve, and consequently to the tangent. Maupertuis in diffusing this subject, conceived a polygon to revolve upon another, the sides of which are respectively equal, one of the angles described a curve, the periphery of which is formed of arcs of circles, and the area is composed of circular sectors and right-lined triangles. He determined the proportion of the area, and of the periphery of this figure to those of the generating polygon. He moreover supposed these polygons to become curves, the figure described to become an epicycloid; and the above-mentioned proportion, modified agreeably to this supposition, gave him the area and the periphery of the epicycloid. Mem. de l'Acad. 1727.

The invention of epicycloids is ascribed to M. Roemer, the celebrated Danish astronomer, during his residence at Paris, about the year 1674. These curves appeared to him to be such as best suited the teeth of wheels, constructed to as to diminish their mutual friction, and to render the action of the power more uniform; hence he was led to consider them, and to this purpose they have been applied. However, M. de la Hire in his "Traité des Epicycloïdes," printed in 1694, makes no mention of Roemer, and seems to claim the merit of this geometrical and mechanical invention. But M. Leibnitz, who resided at Paris in 1674 and the two following years, says, that the invention of epicycloids, and their application to mechanics, were the work of this Danish mathematician, and that he was especially the first to establish the rules for the construction of them. It does not appear, however, that any writer has published an account of epicycloids before the celebrated Newton, who, in his first book of his "Principia" proposed a general and very simple method of rectifying these curves. After him J. Bernoulli, during his residence at Paris, shewed how, by means of the integral and differential calculus, to determine their area, rectification, &c. Many of his "Lecons du calcul integral" are devoted to this subject. In 1694, M. de la Hire published his "Traité des Epicycloïdes," and in the "Memoires de l'Academy for 1706" he communicated to the public an extensive and elegant treatise on these curves.

Spherical epicycloids are formed by a point of the revolving circle, when its plane makes an invariable angle with the plane of the circle on which it revolves. Meiss, Bernoulli, Maupertuis, Nicole, and Clairaut, have demonstrated several properties of these epicycloids, in Hif. Acad. Sc. for 1753.

Epicycloids, Paraboloid, Ellipsoid, &c. If a parabola be made to revolve about another equal to it, its focus will describe a right line perpendicular to the axis of the quiescent parabola; the vertex of the revolving parabola will also describe the cissoid of Diocles; and any other point of it will describe some one of Newton's defective hyperbolas, having a double
a double point in the like point of the quiescent parabola. In like manner, if an ellipse revolve upon another ellipse equal and similar to it, its focus will describe a circle, whose centre is in the other focus, and consequently, the radius is equal to the axis of the ellipse; and any other point in the plane of the ellipse will describe a line of the 4th order. The same may also be said of an hyperbola, revolving upon another, equal and similar to it; for one of the foci will describe a circle, having its centre in the other focus, and the radius will be the principal axis of the hyperbola; and any other point of the hyperbola will describe a line of the 4th order. Concerning these lines, see Newton's Principia, lib. i. De la Hire's Mémoires de Mathematique, &c. where he shows the nature of the epicycloid and its use in mechanics. See also Machamer's Geometria Organica. For the method of forming the epicycloidal teeth of wheels, see Wheel.

EPICYEMA, from κεινόν, i.e. a word used by Hippocrates to signify a fetus, or a false conception, or mole coming on after the conception of a former or regular fetus.

EPIDAMNUS, in Ancient Geography, a town of Illyria, upon a small promontory between Nymphæum and Petra, built by the Corcyreans. Its name, which the Romans confided as inauspicious, was afterwards changed into Dyrhamium, now Durazz, which see.

EPIDAURIA, Epidepia, in Antiquity, a festival celebrated by the Athenians, in honour of Esculapius. See Εσκουλαπις.

EPIDAUROS, in Ancient Geography, a town of Greece, in the ancient kingdom of Argos, mentioned by Homer in the enumeration of its ships, and which he represents as fertile in the production of vines. It was situated on the eastern coast of the peninsula of the Argolid, near the Saronic gulf, and opposite to the island of Ægina. This town was celebrated among the ancients for the temple of Εsculapius, situated about a mile from the river, where the inhabitants of most parts of Europe and Asia resorted for the cure of all diseases. It is pretended that this was the birth-place of Esculapius. (See Εσκουλαπις.) Antoninus Pius, after having been adopted by Adrian, conformed in this place a temple dedicated to the deities called "Epidotes," and another dedicated to the goddess of health, to Esculapius, and to Apollo, a statue of the "Egyptian." He moreover built a house, for the accommodation of persons who inhabited the district consecrated to Esculapius, and also for lying-in women. He also established the portico of Cotys, which had been demolished. The grove of Esculapius near this town was enclosed by two mountains, one called "Tithyon," and the other "Cynortion," upon which was constructed a temple dedicated to Apollo Maleates, and upon its summit another dedicated to Diana Corryphaea. In a rotunda near this town were preserved some curious pieces of painting, the performances of Paunias, a famous painter of Sycony, and contemporary of Apelles. The Epidaurians had a beautiful theatre in the temple of Esculapius, constructed by Polycletus, who also built the rotunda at the entrance of the town. Bacchus and Venus had also temples in this town. Epidaurus was also famous for its temple of Diana the Huntress, and a grove consecrated to her, in which was a statue of Epione, fopposed to be the wife of Esculapius. In this grove was a superb fountain, splendidly ornamented. In the citadel of the town was a very beautiful statue of wood, which represented Minerva, denominated by the Epidaurians "Cilnea." The temple, dedicated to June, was on the side of the port, on a promontory which commanded a view of the sea. The Dorians, having been driven from this town by Deiphon and the Argians, united with the Touians and with them inhabited the islands of Samos and Chios. Epidaurus is now a small place, called "Pidauros."

EPIDAUROS Limera, or Epidaurus Malvesa Vecchia, i.e. the ancient Malvesia, is a port of Laconia, seated on the Gulf of Argos, now "Golfo di Napoli," S. E. of Zarex. It is pretended that this place was founded by a colony of Epidaurians from the Argolid. Having embarked, as it is said, for the island of Cos, they were driven by contrary winds on this coast of Laconia. They were cautioned in a dream from settling here; but a serpent which they brought with them left the ship and conducted them to the land. This false was credited in the country, and the worship of Esculapius was established along this whole coast. The Epidaurians thus contrived to obtain a considerable part of the wealth which supposition had accumulated in the Epidaurus of the Argolid; and hence the new town acquired the appellation annexed to it. It was denominated Limera, i.e. famished, a name which was not improperly applied to a town, the inhabitants of which contrived to exist at the charge of another. It was built upon an eminence, at the bottom of a small gulf; it was well-peopled, and was famous among other things for its excellent wine, called Malvesy or Malmesy, which grew round the vicinity of it, and with which it supplied other parts of Greece. The most remarkable objects of this place in the time of Paunias were two temples; one of Venus, another of Esculapius, with a statue of this god. Its port was honoured with the appellation of the "Port of Jupiter Conventor."

EPIDAUROS, a town of Illyria, in Dalmatia, according to Polemy and Pliny, the latter of whom gives it the title of a colony; in whose time it was joined to the continent, though, as he says, it had formerly been an island. It is now "Ragusa-Vedrach."

EPIDELYCUM, a town of Laconia, on the Argolic gulf, S. E. of Epidaurus.

EPIDELOS, a word used by Hippocrates for a youth in the time of his growth, from the age of seven to that of fourteen. The name author also uses it in a very different sense, expressing by it the observable days in a disease, such as the fourth, eighth, and eleventh, which indicate what sort of crises is to be reasonably expected on the great critical day.

EPIDEMIA, Epidemias, in Antiquity, feasts of Apollo, at Delphi, and Miletus; and of Diana, at Argos. These feasts bore the name epidemis (from εἴδομαι, and ζωή, people) because these gods were imagined to be present on those days among the people. Accordingly, on the last day of the epidemic they sang a hymn called ἅρτος ἄπειτος, to bid them adieu, and let them forwards on their journey.

As those gods could not be everywhere, and yet were honoured in many different places, there were times allowed them to pass from one place to another, to receive the vows of their adorers. See Scaliger, Poet. lib. iii. cap. 114.

EPIDEMIA were also private festivals, and times of rejoicing, when a friend or relation had returned from a journey. Pott. Archæol. Græc. lib. ii. cap. 23. to 1 vol. i. p. 394.

EPIDEMIC DISEASES, from εἴδομαι, and ζωή, the people, are those diseases which prevail extensively, at different times and seasons, among the inhabitants of cities, or countries; when they occasion great mortality among the persons feized; they are termed _influentes_.

Vol. XIII. The
The diseases, which are liable to occur epidemically, or to attack a great number of individuals about the same time, or in rapid succession, are principally those of the acute or febrile class. Thus the plague, the sweating sickness, the yellow fever, contagious fever, or typhus, intermittent and remittent fevers, scarlet fever, small-pox, measles, dysentery, catarrh, (denominated influenza under such circumstances,) ophthalmia, hooping cough, &c. are the diseases which have at different times spread over extensive districts epidemically, some of them occasioning the most destructive mortality. Of these the influenza, or epidemic catarrh, appears to be the most extensive in the range which it takes, and the most independent of local causes: in some instances, as in the years 1781 and 1782, this disease appears to have originated in China, and thence to have spread through Asia, to Europe, and in the year following to have visited America. The other fatal epidemics, such as the plague, yellow fever, and small-pox have been in general the diseases more particularly, though not exclusively, connected with large towns, camps, or other congregations of men. Some of these diseases, as the plague and sweating sickness, are fearfully known except as epidemic; and are altogether unknown, but as diseases of a malignant and fatal tendency: but many of the others, as small-pox, measles, scarlet fever, and typhus, are common and familiar appearances, which seldom cease to exist among us; but which, nevertheless, only occasionally assume those fearful and fatal characters, which belong to them as epidemics.

No circumstance, connected with diseases, has been the subject of more general inquiry, among the physicians of all ages, than this variation in their tendency to spread at one time to multitudes of individuals, to put on a malignant character, and to prove generally destructive; whilst at others they exist in milder forms, affecting few, and destroying scarcely any. Yet the most comprehensive views of the concomitant circumstances, in regard to the obvious conditions of the fevers, and of the moral and political state of the districts where epidemic diseases arise or disappear, continued with the most minute observation during a succession of fevers, have failed to elucidate satisfactorily this interesting topic. Hippocrates, who has noted with accuracy the peculiarities of various years, together with the prevalent species of disease, attributes the variation of the maladies to a divine something, ὁ δὲ ἁλωματικὸς; which some of his commentators consider as signifying merely the atmosphere at large; but others, among whom is Galen, suppose that he intended to express a latent and inferrable cause in the air, which produced these surpising effects. (See Hippoc. lib. i. de Prognost. Galen in Com.—alfo, Sennett. lib. iv. cap. ii. de Caulis Pestilentibus.) Galen obervers, in his commentary upon this point, "non quacunque caulis habent abditas et obfeura, divina vocamus; id ubi admirabilia videantur duntaxat." The modern Hippocrates, Sydenham, states, that he had observed with the utmost diligence the different peculiarities of different years, as to the obvious changes and conditions of the atmosphere, with a view to ascertain the causes of the great varieties of epidemic disorders; but that he had not made the smallest approximation to such a discovery; on the contrary, that he had remarked, that fevers of the most decided similarity, in respect to the manifest qualities of the air, were infected by diseases altogether dissimilar; and vice versâ. "For the constitutions of different years are various;" he says, "yet they do not depend upon the degree of heat or cold, of dryness or humidity, which accompanies them; but probably originate from some occult and inexplicable changes, wrought in the bowels of the earth itself, by which the atmosphere is contaminated with certain effluvia, which predispose the bodies of men to one or other form of disease. This predisposition continues during the prevalence of the same constitution, which, in an uncertain period of time, is superseded by another." (Sydenham, sect. i. cap. 2. De Morbis Epidem. See alfo Van Swieten Comment. ad Aph. 1408.)

From a consideration of the same facts, several writers have attempted to account for these supposed occult changes in the qualities of the atmosphere, which induce epidemic diseases, by tracing them to some of the obvious phenomena of nature, by which such changes may be supposed to be effected. Thus a coincidence has been attempted to be traced between the appearance of comets and of meteors, the occurrence of earthquakes, the eruptions of volcanoes, the conjunction of certain planets, &c.; by all of which it is presumed that some important operations are exemplified. Of the effects of planetary influence, indeed, in inducing or diminishing the morbid qualities of the air, nothing is to be found in the writings of the present times: the hypothesis originated and has gone by with the age of astrology. But a very late writer has filled two volumes with evidence, which he believes goes far to prove the existence and operation of some general agent, or pestilential principle, throughout the physical world. To this agent he ascribes the origin of earthquakes, and volcanoes, and meteors; and he seems to consider it as the medium by which comets exert their influence, producing tempestuous feasons, great heats, and great colds. (See a brief History of Epidemical and Pestilential Disorders, by Noah Webster, 1800. This, as a mere hypothesis, would be scarcely less visionary and futile, than the supposition of planetary influence, just noticed. Mr. Webster, therefore, has collected, with great industry, an historical account of the various epidemic and pestilential visitations on record, which have successively occurred to different countries, and has connected with it a chronological view of the appearance of comets, the eruptions of volcanoes, the commotions of the earth, and of the various atmospheric phenomena, which have been described by authors in order to prove their coincidence. "It is certain," we are told, "that comets have a very sensible effect on the weather;" (loc. cit. vol. ii. p. 122.) and Aristoſtote, Pliny, and Seneca, are quoted to prove that great heat, tides, and winds, are among the general concomitants of comets. "All the comets," Mr. W. affirms, "which have approached this earth, in their passage to and from the sun, especially those which have passed very near us, have been preceded, attended and followed by most extraordinary effects, as great heat and drought in summer, and severe cold in winter; deluging rains, violent tempests, and unusual tides. They occur so uniformly, with the appearance of these bodies, and for some months preceding and following, as to leave no room to question the influence from which they proceed. Ibid. Whatever may occasion extreme variations in the condition of the atmospheric temperature, produce inundations, earthquakes, &c. will thus remotely, no doubt, induce epidemic diseases, as will be shewn in the sequel. A great number of records are quoted by Mr. Webster, to prove the connection of earthquakes with epidemics (an opinion which many writers have adopted); and also to shew that feveral vapours have issued from the earth, contaminating the atmosphere, about these periods, or sometimes without any earthquakes. From these feveral exhalations an inference is readily drawn of the existence of vapours insensible by our senses, according to the conjecture of Sydenham. It appears, however, that great pestilence, even when occurring within
within a short period of earthquakes, has generally appeared before the earthquakes: nor does it occur in the seat of the earthquakes. Thus after the plague in London, in 1665, flocks are said to have been felt on the continent. But Mr. Webster does not conceive this to be any objection to the hypothesis. He believes that pestilence and earthquakes depend on one common cause; which excites into action the internal fires. But he supposes that the action or fermentation may precede, for months, and even years, the explosion in earthquakes and volcanoes; and by means of an insensible vapour or heat, or electrical discharges, the elements of water and air may be essentially affected in such a manner as to impair the principle of animal and vegetable life.

"In ccelo nunquam spectum impune cometam,")

has been adopted by Horstius, Riverius, and echoed by several other writers on the subject of pestilence; but, like many other suppositions upon the same subject, it is altogether gratuitous, and has been received only in the absence of all positive knowledge of the real sources of pestilential diseases. The fame observation applies to the supposed influence of earthquakes, and distant volcanic eruptions; more particularly, as the former are allowed to have followed the effect ascribed to them, and the countries immediately in the vicinities of volcanoes are admitted to have been not more liable to epidemic diseases than other regions.

Two other points have been generally stated as proving the existence of a pestilential principle, which is diffused through the atmosphere at large: one is, that trees and vegetables are affected with mildew, and other diseases; the other, that the animal creation also often suffers, when pestilence is committing ravages among mankind. A rubiga, or mildew, i.e. "a dew impregnated with highly corrosive powers," (see Hird on Pestilence, p. 91.) was anciently deemed one of the causes of epidemic diseases. The Romans, apprised of the pernicious effects of these mildews, instituted what they denominated Feya rubigalis, and worshipped an imaginary god, under the name of Rubigus. The appropriated sacrifice was a sucking whale; whence Coennella,

"Hinc mala rubigo, virides ne torreat herbas,
Sanguiine lactentis catuli placetur et extis.""

Hoffmann mentions such a dew, "ros valde corruivois," as having infested vegetables in 1633-4, whence the cattle died in multitudes. (Tom. i. de Temp. Ann. Infahb.) And Remazzini ascribes an epidemic to similar deews; at which time the vegetables, corn, and fruit became black, being affected with a "lues rubigalis." (Constitut. Epidem.) The same year was remarkable for the scarcity of honey; and most creatures that live upon what they extract from vegetables died, or languished. Probably similar occurrences led many of the ancient writers to mention the influence of the grahsopper, and the drooping inactivity of the bee and the silk-worm, among the prelages of impending pestilence. As to the spots, which are said to have aminated various forms, especially those of crucicule, or little croffes, and to have appeared suddenly on garments, utensils, &c., as they are recorded chiefly on the authority of monks, whose writings are highly tinged with superstition, they are scarcely worthy of serious consideration.

The existence of epidemic disease among cattle is necessarily much connected with the diseased condition of vegetables; and epidemics among cattle seem to have most commonly occurred after excessive humidity. (Webster.) The calamity among brutes has sometimes proved the forerunner of pestilence among mankind; sometimes its follower; and at other times, they have raged concomitantly: but, in general, their appearance has been remote and unalied. (Hird, loc. cit.)

It is curious, again, and not easily explicable on the principle of a pestilential effusion, unfriendly to every form of life, pervading the atmosphere, that, while vegetables droop and are mildewed, the grahsopper is silent, the bee and the silk-worm are idle, and cattle die, from its influence, swarms of insects and creatures of other species are said to be among the precursors and attendants of pestilence. It is surely an absurdity to contend for the existence of a pestilential atmosphere, destructive to the life of both animals and vegetables; and at the same time to describe the myriads of noxious insects, frogs, mice, locusts, frails, serpents, and other animals, which appear during an epidemic pestilence! Is one kind of life preserved by man and the animals useful to him, and another by those which are noxious? This contradiction in the hypothesis appears to be very general among writers. The author, whom we have already often quoted, observes, "one thing is very evident, that what I denominate a pestilential principle does, at certain times, pervade not only the element of air, but the water also. The proofs of this are abundantly numerous and convincing. In all the great plagues which have afflicted the human race, other animals, as horses, cattle, sheep, sometimes cats, dogs, and fowls, together with the fish in rivers and the ocean, and even vegetables, have borne their share in the calamity. The pestilential principle has extended to every species of life. The beasts of the field perish with deadly epidemis; the fish die on the bottom of rivers and the sea, or become sickly; while crops are blighted on the most fertile plains, and the fruits in gardens and orchards wither, or fail to arrive at their usual state of perfection." (Webster, Hist. of Epidemis, vol. ii. p. 153.) And immediately afterwards (p. 166) we are called upon to "attend to the effects of a pestilential" (i.e. universally deleterious) "state of air, and in the production of insects and small animals. This is one of the most remarkable symptoms of a filthy state of the elements, &c."

It is only against such hypotheses that we have any objections. The fact, that myriads of insects have sometimes been produced, about the time when epidemics prevailed, cannot, we apprehend, be questioned; although probably many of the accounts transmitted to us on this point are much exaggerated. In some infestations, such a profusion of insect life may be a result of the same cause with the epidemic, viz., extraordinary heat, or heat and moisture: in others, it may contribute to produce the epidemic, by destroying grain and fruits, the food of man; or grains and herbs, the food of cattle, fowls, and other animals which constitute a part of his subsistence. It proves nothing in respect to any occult quality pervading the atmosphere. Besides, the infestances of the copious generation of insects and small animals have not been universal, but partial: some particular species have been generated in profusion; and, therefore, the origin of them must be ascribed to some partial, and not to a general cause. In the plague of Lanfame, in 1613, according to Diemerbroeck, flies were produced in an incredible abundance; as well as during or preceding that of Holland, in 1635. The approach of the plague at Dantzick, in 1709, is said to have been announced by an immense number of spiders in the preceding year. The year 1633, which produced a pestilential fever among the settlers at Plymouth, in America, was remark-
able for swarms of large flies, which filled the woods with their humming sounds. (Webster.) We cannot but consider, therefore, that the statement above quoted of the universal failure of animal and vegetable life, on the one hand, or the general disposition in the air to generate noxious animals, on the other, as equally erroneous, incompetent, and absurd. How the individual species of infect or animal is generated, in such cases, or what connection the production of them may have with the pestilence, which sometimes occurs in point of time, we cannot easily ascertain. But where the means of observation fail us, gratuitous hypotheses add nothing to our knowledge.

There are, however, several circumstances which are open to our observation, which, if they do not absolutely produce epidemics of the most pestilential kind, certainly contribute to give them birth, and to aggravate them when produced, and are notoriously the sources of epidemics of a less destructive species. Of these obvious causes of the origin or aggravation of epidemic diseases, some contribute directly to excite disease; others to induce, what is fearfully less necessary to their occurrence, a predisposition to them. In fact, the operation of some general agent, inducing a predisposition to be affected by contagion, or other exciting cause of disease, would appear to be the principal source of the predominance of some epidemics. For if the exciting cause never, or fearfully ever, ceases to exist, its occasional activity in infecting disease among multitudes can only be ascribed to the casual operation of some general predisposing cause, which renders them temporarily susceptible of its influence. This is particularly exemplified with respect to contagious diseases. The contagion of small-pox, measles, and scarlet-fever perpetually exists among us; yet it is only at particular times that these diseases attack so many individuals, as to be called epidemic. In crowded towns like this metropolis, the infection of typhous fever is perpetually generated in the close, dirty, and unhospitable habitations of the poor: yet there has been no epidemic typhus in London for seven years past. Nay, even the plague itself existed year after year in this city, without spreading generally. It must not be imagined that the disease was accidentally imported just at the periods when it raged so extensively, and with so much destructiveness. The principal plague-years of the seventeenth century were 1603, 1625, 1636, and 1665; in which the number of deaths from the plague, independent of those from other diseases, are reported in the bills of mortality to have been 36,269, 35,417, 10,406, and 68,596, respectively. But so far was the disease from being extinct in the intermediate periods, that from the year 1603, when the register begins, till 1667, the bills of mortality exhibit only three years entirely free from the plague. It is obvious, therefore, that the presence of infectious matter, or other exciting cause, is not alone sufficient to produce an epidemic disease. Some concurrent circumstances are likewise necessary, to give a predisposition to the human body to be readily acted upon by such cause. Now, some of these circumstances have been well ascertained, namely, particular feaons, marshy and other efluvia, a crowded and filthy population, deficient or depraved aliment, certain passions of the mind, exhaustion of the constitution by fatigue, &c. We shall illustrate the operation of each of these predisposing causes by a few observations.

1. Seasons.—The influence of certain feasons, in favouring the propagation of epidemic diseases, has been observed and confirmed by all the medical writers on the subject, from the days of Hippocrates downwards, and was noticed by the earliest poets, even before the time of that great physician; especially the influence of the heats of summer and autumn, and of the sultry south winds, which blow at those seasons. In many passages of the Iliad, Homer has alluded to these causes of pestilential diseases. Thus, in book v.

"As vapours blown by Atlas' sultry breath,
Pregnant with plagues, and shedding seeds of death,
Beneath the rage of burning Syrian's fire." Pope, 1658.

And again in book xiii. 37.

"Not half so dreadful rites to theight,
Through the thick gloom of some tempestuous night,
Orius' dog (the year when autumn iaways),
And o'er the feebler stars exerts his rays;
Terribile glory! for his burning breath
Taints the red air with fevers, plagues, and death."

In the first book, pestilence is also ascribed to the anger of Apollo, an allegorical expression for the extreme heat of the sun. (See Pope's version, lines 87, and 87.)

These poetic statements accord most accurately with the observations of Hippocrates, who frequently mentions epidemic fevers as common in the summer and autumn, as prevailing most extensively when wet springs with southerly winds were succeeded by hot and close summers. A remarkable constitution of this kind, which continued for two years, is described in his treatise on Epidemics, (De Morbis Vulgaribus, lib. iii.) at which time ardent remitting and intermitting fevers of a bad kind prevailed, attended with fluxes, parotids, and eruptions of a pestilential nature. The autumn and spring were wet, close, and cloudy, without wind, the breezes from the south; and these continued during the hot and sultry summer, when the usual refreshing Eteian winds did not blow.

Excessive heat of the summer, without moisture, has occasionally accompanied an epidemic season. Thus in the year 325 B.C., there was a most grievous famine, occasioned by a feverous drought, in all the Roman territory. "Siccatio eo anno plurimum laboratum est; nec ecelesites modo defuerunt aquae, fed terra quoque, ingentis humores egens, vix ad perennes subfuscit annos;" the cattle throned in multitudes round the arid fountains, and perished with thirst, diseases followed among the cattle, from which they were propagated by contagion among men ("vulgiacetacu in homines morbibus"), the peafantry first suffering, then the lower classes, and at length the whole city was infected. (Tit. Liv. lib. iv. 36.) In more modern times, great droughts have been accompanied by epidemic diseases, especially in cities situated in low and damp countries. In the autumn of 1652, Bartiolone informs us that a malignant fever appeared at Copenhagen, after an unusually hot and dry summer. And a similar fever raged at Leyden in the year 1659, as described by Silvius de la Boe. The spring and beginning of summer were cold, but the remainder of summer, and the autumn, were unusually hot, with little or no rain, and with a constant calm and stagnation of the air. (See Pringle on Dif. of the Army, p. iii. clas 4.)

But epidemic diseases are still more fatal in those seasons, in the damp countries of the south, where the heats are longer and more intense, and much moisture is combined. In some parts of Italy, and in other tracts of the same latitude, epidemic fevers have appeared with such alarming symptoms, as not only to have been called pestilential, but confounded with the plague itself. In this sense we are to understand Cellius, (De Medicina, lib. i. cap. 16. lib. ii. cap. 8.) in the terms pestilenta and febris pestilentialis, which he describes as peculiar to the "grave annis temporibus," and the "graves regiones." His meaning is, that this bad fever is the disease of the latter part of summer, and of autumn, when
Epidemic.

When the air is thicker and most foggy, and that is most frequent in low and marshy countries. Rome was always liable to these fevers. Galen calls the 

herémiríta the epidemic of that city; and speaks of its moist air. (De Temperant. lib. ii.)

In fact the chief malignancy of the worst epidemic diseases, and of the plague itself, has always been felt in the summer and autumn; as the histories of that disease in all the large towns in Europe will testify. Dierensbroek has justly observed, that when the plague has been excited out of its proper season, it has not spread; and Dr. Runnell tells us, that in the winter time, when infected persons have come to places about Aleppo, some of whom have died in the families where they lodged, the distemper by such means was not propagated. In the four great plagues of London, during the seventeenth century, the mortality invariably increased, as the season advanced, reaching its acme in August and September, and thenceforth gradually declining. (See the Bills of Mortality. — See also Dr. Heberden, jun. on the Increase and Decrease of Diseases, 1801.) Thus in the last plague in London, in the year 1665, the mortality of the respective months was as follows; in the spring very few persons had died of the plague, in June 592 persons died of it, in July 1,919 died, in August 2,623, in September 2,430, in October, 1,272, in November 3,349, and in December a few hundreds. (See Plague.) The progress of the pest, in the other three instances, was exactly similar.

Again, the regular decrease of pestilential diseases, with the declining summer, equally demonstrates the necessity of the presence of the hot season for their propagation; which may operate either by rendering the contagion more virulent, by producing certain pernicious effluvia from the earth in moist places, or by inducing a predisposition in the human body to receive the influence of those exciting cauises. At Grand Cairo putrid and pestilential fevers prevailed annually in March, April, and May, which the southerly winds make the hottest months in that country; but they ceased at the overflowing of the Nile, when the cold winds set in. (Profer. Alpin. de Med. Egypt, lib. i. cap. 14. Mead on the Plague, p. 30.) And "as Smyrna the annual plague constantly ceases about the 24th of July, by the dry and cold weather they always have at that time." (Mead, p. 26.) Indeed, when this change of feason takes place, and the weather changes accordingly, it may be presumed, with the contagion, yet it ceases to be detrimental. Prosper Alpinus remarks, that when this change of season comes, in the month of June, even the clothes imbued with the most pestilential contagion then infest no one. "Sed quod velale mirabile creditur, omnia supellexia pestifera contagio infecta tunc nullum contagii effectum in can genem tantum oredit." — And this inertness of the contagion in the most infected places, on the approach of winter, was most remarkable in the last plague of London. "Many who made molt halte in retiring," says Dr. Hodges, "made the molt to return, and came into the city without fear; inimick, that in December they crowded back as thick as they fled: the houfes, which were before full of the dead, were now again inhabited by the living; the shops, which had been molt part of the year shut up, were again opened, and the people again cheerfully went about their wondned affaires of trade and employ: and even what is almoat beyond belief, those citizens, who before were afraid even of their friends and relations, would, without fear, venture into the houses and rooms where infected persons had but a little before breathed their laff: so, such comfortis did inspire the languishing people, and such confidence, that many went into the beds, where persons had died, before they were even cold, or cleansed from the touch of the diseased." (Johnologia, or Hist. Acc. of the Plague in 1665, p. 27.) In the same way we read, that when the plague was in Italy, the Neapolitans used no artifice to purify either their goods or houses; yet the distemper ceased among them as entirely as in the belt regulated towns. (Heberden, loc. cit.)

These facts amply prove the extensive influence of certain seasons, in favouring and interrupting the progress of the most pestilential epidemics; and that not in consequence of any occult, but of certain sensible and obvious conditions of the weather. The same circumstances of the seasons modify the propagation and diminution of the minor epidemics, such as dysenteriy, remittent and intermittent fevers, &c. and even the small-pox. Of the former of these, we shall more properly speak under the second head of cauises; namely,

2. Murmurs and other Effluvias. — Galen affigis two cauises for pestilential fevers; the first of which is great heat of the weather, and the second, which he considers as most frequent, a corrupted state of the air, arising either from a multitude of dead bodies left unburied, as after a battle, or from the evaporation of corrupted lakes and marshes. (De Fibr. in loc.) Other authors of antiquity have noticed the coincidence of epidemic fevers with marshy situations. Thus Diodorus, the historian, has recorded the occurrence of a pestilential distemper among the Carthaginians at the siege of Syracuse, which he attributes to the combination of the following circumstances; the multitude of people confined within a narrow compass, the situation of the camp in a low and wet ground, and the forcihing heats in the middle of the day, succeeded by cold and damp air from the marshes in the night. (Bibl. Hist. lib. xiv. cap. 70.)

In more modern times the origin of epidemic diastes from marsh effluvia had been very generally observed. Fracasto- rius ascribes a malignant epidemic fever, in Italy, in the sixteenth century, to an extraordinary inundation of the Po, which, happening in the spring, left marshes, and those corrupting infected the air through the summer. Forellus remarks, that, from the putrefaction of the water only, the city of Delft, where he practised, was scarcely ten years free from the plague or some pestilential distemper. (Obervat. lib. ii. 70.)

The effects of marsh or putrid effluvia in giving rise to epidemic diates have, indeed, been evinced in most of the large cities, and still more obviously in the camps of modern times. Sir John Pringle, speaking of the hot weather, during one of the campaigns in the Netherlands, in 1748, observes, that though the heats were great, yet they were the cause of little sickness, till the troops were cantonned in the marshes, where a considerable degree of putrefaction and moisture being joined, ardent, remittent, and intermittent fevers, and fluxes became general. It is remarkable that these pernicious exhalations do not rise high, nor spread far from their source, at least without such dilution as diminishes their deleterious qualities. Dr. J. Hunter has affirmed, that in the barracks at Spanish Town, in Jamaica, (which consisted of two floors, the first upon the ground, the second over the first,) the difference in health of the men on the two floors was so great as to engage the attention of the assembly of the island, and upon investigation it appeared that there were taken ill on the ground floor for one on the other. Even at a few hundred feet above the level of the marshes, the situations are extremely healthy. (Oberv. on the Dist. of the Army in Jamaica, note B. p. 268, 3d edit.) The air of a marsh or of a foul camp, the same author observes, may destroy an army almost as soon as the true plague. But the remedies in
in such cares are obvious, and consist in getting at a proper distance from the noxious exhalations, or removing the causes of them. " A very small space frequently includes the limits of healthy and unhealthy ground." It is now necessary to state that agues, or intermitents, originate solely from the effluvia of marshes.

Another species of effluvia, which is the source of epidemic diseases in camps and in towns, when ill constructed and neglected, arises from ground contaminated with human and other excrements, the remains of victims, the water used in cookery, for washing, the foul flraw rotting in tents, &c. Whenever a camp remains long on the same ground, especially in hot and moist weather, fluxes, and intermitting and remitting fevers, seldom fail to become epidemic, unless great precautions are used to bury all excrementitious matter, and proper receptacles and drains under ground are prepared for the urine, water of cookery, &c. (See Dr. Hunter, loc. cit. p. 285.) In this case, however, as in that of marsh effluvia, the diseases produced will disappear, by moving the camp a few hundred yards from the foul ground.

These facts throw great light on the epidemics of large cities, which were formerly so frequent and fatal. A large town may be considered as an extensive camp, but definite of the means of changing its situation, and, consequently, liable to be infected with the same diseases as are endemic and epidemic in camps, unless the precautions just alluded to, for the purpose of removing the sources of the pestilential effluvia, be fully adopted. And we find, accordingly, that during and previous to the 17th century, and even later, in some countries, the large towns were almost constantly infected, in the summer and autumnal months, with the plague, malignant, intermitent, and remittent fevers, and dysentery; the same disorders to which camps are liable. This was the condition of London during the period specified. We have already remarked, that the plague was seldom absent from the beginning of the 17th century to the year 1669, and that four dreadful visitations of that calamity occurred within the same space of time. Of the extent to which intermittent and remittent fevers prevailed, in this metropolis, we have also ample evidence. Dr. Short remarks, that early in the century, viz. between 1629 and 1636, "one of 40 of the whole that died of fevers, died of agues;" whereas, "now (1729) fevcre one of 1100 that died of fevers died of this distemper." (New Obs. Nat. Moral, &c. on Bills of Mortality, 1750, p. 268.) Burnet, in his "History of the Reformation," says, that in the last year of queen Mary's reign "intermitting fevers were so universal and contagious, that they rated like a plague." Both Sydenham and Morton have left us abundant evidence of the frequent epidemic prevalence of agues, as well as of remitting fevers, which last Morton affirms to have been extremely destrutive for several years before the great plague, viz. from the year 1658 to 1664. He states that Oliver Cromwell died of this fever in 1658; and that his own father, himself an experienced physician, also died of it; when his whole family, the writer included, were infected. (Morton, Pyretologia, App. ad Exercit. ii.) Even so late as from 1720 to 1729, according to Dr. Short, "they (intermitents) and remittents afflicted the whole nation grievously." Sometimes together, and sometimes alternating with those autumnal fevers, the dysentery was a frequent epidemic in London, in the times to which we allude, and was often attended with great mortality. For five and twenty years successively, from 1667 to 1692, the bills of mortality shew the sum of deaths under the titles of "bloody flux," and "gripping in the guts," which must both be considered as dysentery, to have amounted every year to above 2000. During the last century, the disease has gradually declined, (Dr. Heberden on Increase and Decrease of Diff. Difeases, p. 34.) and the other fatal epidemics, just mentioned, have quite disappeared. See Annual Medical Register for 1808, vol. i. where the changes of disease in London are discussed at length.

We cannot doubt, that the present comparative healthiness, and especially the great freedom from all epidemics (the contagions of small-pox, scarlet fever, and measles excepted) which this metropolis now enjoys, is to be ascribed altogether to the measures, by which the sources of the effluvia, which excite these, have been removed, and to the general habits of cleanliness and ventilation which are at present observed by the people. These salutary measures are principally the construction of privies, drains, and common fivers; a hard and regular pavement, with a proper level for carrying off the humidity, and well cleaned by scavengers; an abundant supply of water to every part of the town, &c.

In all these points, the condition of London, like that of most other large cities in Europe, during the 17th century, was extremely defective. In the preceding centuries its condition must have been still more insidious, and filthy, so that few years elapsed without the occurrence of a considerable pestilence. We have not so m., in this place, to enter more at large into a description of its circumstances; but must content ourselves with referring to the work of Dr. Heberden, jun. juft quoted, where an abundant collection of evidence, as to the connection of these epidemics with filth and negligence in the economy of this and of other large towns, will be found. (See also the Ann. Med. Reg. for 1808. Maitland's and Northcote's History of London.) See Plague.

It is extremely gratifying, both in a physical and moral point of view, to observe that the same means which contribute to our personal comforts, and to elevate us above the savage, viz. the progress of civilization and refinement, have led to banish the most loathsome and fatal diletremes, to prolong life, and to diminish the prevalence and fatality of other diseases of less fatality. "While the metropolis has extended itself in all directions, and multiplied its inhabitants, to an enormous amount, i.e. while the apparent area of its unhealthy places and habitations has been augmented, it has actually become more favourable to health. In the year 1657, for example, the total mortality of London was 20,970; whereas, the total mortality of 1797 amounted only to 17,014: and when we take into consideration the great increase of the population of the out-parishes at the latter period, the comparative healthiness of London will appear in very strong colours." Ann. Med. Register, p. 321.

Sometimes the air of a particular district seems to have been impregnated with effluvia from putrefying animal and vegetable matter, which has occasioned an epidemic in that neighbourhood. Foretus has mentioned the putrefaction of a large fish, of the whole kind, which was left by the tide, and died, on the coast of Holland, and, during its putrefaction, infected the country with a horrid fench, in consequence of which a fatal epidemic fever broke out in the district of Egmont. (Obs. lib. vi. 9. tom. i.) The same author informs us of a pestilential fever, which raged at Venice in his time, and was produced by the corruption of a small kind of fish in that part of the Adriatic. (Ibid.) Infections are also on record of epidemic fevers occasioned by the effluvia of putrid cabbages, as well as of plants.
phs in marshes. (Rogers on Epidem. p. 41.) These sources of epidemics, however, are rare, and can seldom occur under a well-regulated police.

3. A crowded Population.—From the earliest periods of time, of which we have any record, pestilential diseases were known to be the effect of crowded population. Internal rage peculiarly in cities, forts, and other confined places. In the sacred writings pestilence is everywhere mentioned as the peculiar scourge of cities. "The sword is without," says the prophet Ezekiel, chap. vii., "and the pestilence and famine within; he that is in the field shall die with the sword; and he that is in the city, famine and pestilence shall devour him." And again, chap. xxxii., it is said, "they that be in the forts and the coves shall die of the pestilence." The city of Rome was subject to the most fatal epidemics from a very early period of its history: Athens suffered also extremely; and in modern Europe the great cities have been the common seats of plagues, from Constantinople to Moscow, and from Cadiz and Marfeilles, to Copenhagen and Dantzic. (See an enumeration of the cities infected with the plague, and the dates of its occurrence, by Dr. Heberden, loc. cit. p. 81, et seq.) The same observation applies to the cities of Asia and Africa; to Aleppo, Cairo, &c. &c., as well as to those of America.

We have already stated, that the prevalence of epidemic and pestilential diseases is naturally connected with the existence of filth of every species, and that their gradual disappearance has been coeval with the improvements of the city, and the removal of these nuisances. The same fact is observable in all the cities of Europe: and those which, from natural or political causes, have been backward in adopting the improvements of modern times, have more lately exhibited the same effects of their negligence. The plague appeared at Copenhagen in 1764; and at Moscow so late as the year 1771. It is farther observable, that pestilential diseases generally appear first in the most crowded and uncleanly parts of towns, and rage most fiercely in the most crowded and dirty habitations, &c., among the poor. The plague of 1605, in London, is said to have been by many persons called "the poor's plague." Those of 1626 and 1636 broke out at Whitechapel, a part of the town which abounded with poor, and with slaughter-houses; and that of 1665 is said to have broken out first at St. Giles's, and there, Dr. Heberden remarks, it would probably break out again, if ever we should suffer such an calamity.

For it must be observed, that a crowded and uncleanly population contributes in a double manner, to the origin and propagation of epidemic and pestilential diseases. It not only occasions the accumulation of every species of filth externally, from which effluvia arise to contaminate the atmosphere, in hot and moist seasons, thus producing all the diseases of camps; but it produces another species of effluvia, internally, in the habitations of men; viz., from the bodies of the sick, and even of the healthy, which at once generate malignant fevers, and aggravate those which arise from the other sources. (See Contagion.) So that under the circumstance of the combination of these causes, namely, when the heat and moisture of autumn generate the effluvia from external filth, and contagion is superadded from the accumulation of the corporeal effluvia, from the want of internal cleanliness and ventilation, diseases of an epidemic nature are readily excited, and are propagated extensively and fatally. Hence, before the value of these internal cautions was understood, the crowded population of towns and cities, so frequently occurred in hospitals and gaols, that they obtained the appellation of hospital-fever and gaol-fever. Indeed we are told that, so late as the latter part of the 17th century, in the gait of Newgate, a contagious fever used to break out annually, in hot weather; and that the name was true of most gaols in Europe; ("The City Remembrancer, quoted by Dr. Heberden") and several facts on record, prove, however greatly any state may be in this propagation, under these circumstances of crowded and filthy habitations; although originally, and in cleanly and airy apartments, it was incapable of spreading from one individual to another. Thus Sir John Pringle observed, that, "in autumn 1757, several soldiers were brought into the hospital at Portsmouth, with a disorder compounded of the autumnal and gaol-fever; for these men, upon being feized with the common fever of the season, were confined to the holds of the crowded transports, their distemper assumed that form. (Dif. of the Army.) So Dr. Lind has stated, that, upon admitting into a hospital one person with a flux, several other patients in the same ward have had this symptom added to their other complaints. (Lind on Fever and Infection.) And Dr. Blane has observed generally, that, supposing a ship's company to be predisposed to acute diempeurs, and one man or more ill of a dysterery be brought on board, this will become the prevailing disease. (On the Diseases of Seamen.)

These facts, which evince the facility with which any acute disease, or its leading symptoms, is propagated from place to place, in crowded and crowded apartments, when extreme cleanliness and ventilation are not attended to, will serve to explain several apparent anomalies in the history of several diseases, which have been stated as the result of some mysterious epidemic principle in the atmosphere. We allude to the occasional spreading of particular maladies in hospitals, in a sort of epidemic way; such as the appearance of erysipelas, connected with all flight injuries of the scalp, or other superficial parts, as related by Sir William Blizzard, of the London hospital, and as occurred in the surgical ward of the Royal Infirmary, at Edinburgh, many years ago; the diffusion to inflammation and absides about the perineum and neighbouring parts, mentioned by the same writer, &c. (See a Paper on Some epidemic Effects, Med. Facts and Obs. vol. ii. 1792.) Such occurrences, we believe, are rare in proportion to the degree of cleanliness in these receptacles of the sick. We have been assured that the occurrences of this nature at Edinburgh have ceased, since a more rigid ventilation and purification have been adopted in the Royal Infirmary, and houses of the like kind.

Deficiency and Depraved Aliment.—The obvious cause of epidemic diseases, already mentioned, may operate both as exciting and as predisposing causes; but that to which we now direct our attention, perhaps, chiefly acts in inducing a debilitated and half-morbid condition of the body, which renders it liable to be affected by those exciting causes. Certain it is that famine and pestilence have been observed to go together, since the earliest ages of the world; and are constantly mentioned in combination, in the sacred writings; to which war is frequently added. Death is almost necessarily a part of the delolation of war; which, therefore, contributes to the production of pestilence indirectly by producing death. "O λυγας μετα ραμον, the plague after famine," was an old Greek adage. Where articles of food are extremely scarce, they are often also corrupted, and may thus contribute to reduce the human constitution to a state predisposed to disease. Forelius imputes the plague at Delphi, in the year 1557, to the eating of mouldy grain, which had been long kept up by the merchants in a time of scarcity. (Lac. etc.) And Sir J. Pringle says, he had heard it observed, that in this island the dysterery is frequent among the common people, in those parts where they live.
live mostly on grain, when the preceding crop has been damaged by a rainy season, or kept in damp granaries. (loc. cit. cap. vii. p. iii.) In ancient times the corruption, as well as scarcity of food, was aligned as the cause of pestilence; as by Cæsar himself when besieging Marielles. (De Bellis, and comments which must be omitted, not hex corruptions, names (cell. Malificianos) abominant; quæ ad hujusmodi casus antiquotum paranum, in publicum contumitum."

When we advert to the fact that epidemic diseases have been termed in their description, and called, endemic, and epidemic, and that this has been so called, 1766; p. 702. and Spain. And it may be added, that the only epidemic occurrence of contagious fever in London for several years back, occurred after the excessively violent autumn of 1759, which was exceedingly dammed, and a considerable scarcity ensued.

5. Exhausation by Fatigue, &c. — Defeases the debility of constitution, and consequent predisposition to disease, induced by imperfect nourishment, during a famine, the exhaustion produced by excessive corporeal exertions, loss of sleep, and the depleting passions, probably contributes in no small degree to predispose the body to disease. Thus epidemic fevers have been observed to arise after great battles. Dr. Gottwald traced the origin of the plague at Dantzick to Pinozow, soon after the battle of the Swedes and Saxons, in 1702. (Ingram, Hist. of Plagues, p. 86.) To the same cause, perhaps, we may impute the contagious fever, which raged among the troops of the late sir John Moore, on their return from the harrowing campaign in Spain. (1809.) Van Swieten observes, that "strong passions of the mind, particularly terror, augment the efficacy of infection, as all writers on the plague unanimously allow," and that the same passion contributes to render the disease more fatal. If this be correct, the extensive operation of fear in human beings, which is the seat of war, must produce considerable influence; and it cannot be doubted, that the general panic, which rapidly spreads among the inhabitants of a town, where the plague is discovered to exist, contributes materially to its propagation.

On reviewing the facts above stated, it is obvious that the sources of epidemic and pestilential diseases have been often traced to manifest circumstances, in combination with one or more of which they have generally been observed to occur: and more especially that the heats of summer and autumn appear to be absolutely necessary to the propagation of a general pestilence. The observation of Celsus, in regard to the falsity of the different feasons, has been confirmed by those who have practised in warm climates, (Cleghorn on diseases of Minorca) by the physicians of camps, (Pringle, loc. cit. part ii. chap. i.) and by the condition of this country in the time of Sydenham. "Saluberrimum ver eft; proxime deinde ab hoc, hieus; periculoque et ea, autumnus longa periculofissimus" (Celfi De Med. lib. ii. cap. vi.) But the experience of the last century, during which this order of the seasons, in point of salubrity, has been almost reversed, (for we now find July and August the most healthy months of the year, and February and March the most productive of disease,) has thrown considerable light even on the occult principle, the vis inertiae, of the epidemic atmosphere. It has shown us, what Sydenham could not have anticipated, and what to him indeed must have been incredible, that while the seasons continue to occur, with their former vicissitudes, and while the bowels of the earth (for aught that we know) continue to send forth their vapours as usual, yet those fatal pestilential constellations of the air no longer appear; the plague has not been seen, since the rebuilding of the city (1667); intermittents no longer infet the metropolis, and the autumnal remittents are alike almost unknown; especially since the covering of Fleet ditch, and the other improvements, made in 1766; and the dyestuff, or bloody flux, now scarcely adds twenty to the annual bills of mortality! This occult principle, then, this epidemical somewhat, it must be inferred, neither owes its origin to the atmosphere, nor to the bowels of the earth, nor to the eruptions of Auster, nor to the approach of comets.

For the former of these, are, doubtless, unchanged; and the latter have continued to occur at intervals as usual.

To what, then, are we to attribute the origin of those epidemic constellations, as they have been called, of particular years, in which certain diseases extensively prevail? We have not, perhaps, a sufficiency of facts to enable us to deduce a satisfactory conclusion; but the following inference seems to approximate to the truth, and to spring out of the facts already detailed.

The experience of camps, especially in moist seasons, teaches us how readily epidemic diseases are produced, from the contamination of the lower portion of the atmosphere with the effluvia of foul ground, and also how confined and local that contamination is, since a small elevation, or a removal to the distance of a few hundred yards, from the source of the effluvia, is sufficient to enable us to escape their noxious effects. The experience of galleys and hospitals, and other crowded and uncleanly habitations, has also demonstrated the facility with which human effluvia, accumulated about the sick, become contagious to those in their immediate vicinity; and also how readily, in this predisposed and contagious state, any acute disease, accidentally introduced, is carried from individual to individual, so as to become the prevalent or epidemic disease. Now, London, and all other crowded cities in the 17th century, combined to produce this infection, that the epidemical constitution, belonging as well to camps as to galleys and hospitals. The atmosphere was contaminated with the local effluvia, which rendered it pestilential externally; and, within the dwellings, especially in the poorer parts of the town, infections atmosphere was produced, and thus whatever disease was generated, was propagated readily, and gave a character to the particular constitution of the epidemic season. How variously the epidemics must be modified, according to the various degrees and combination of the exciting and pre-disposing causes, must be obvious on reflection. When the bodies of the people happen to be pre-disposed to disease by want of food, or actually disordered by corrupted food, when the accumulation of filth, or the increase of earthy ground from rains or inundations, tend forth misfortune in a most abundant and concentrated form, in consequence of a peculiar autumnal season, the most extensive epidemic diseases may be expected to arise. And we believe, that under such a combination of obvious circumstances, pestilence never fails to appear.

On the other hand, although a large city cannot, like a camp, be removed from the source of the pestilential effluvia, which it generates, yet industry may remove the source of these effluvia from it. And it appears to be a perfect...
Epidemic.

perfect confirmation of the preceding conclusions, that, as this removal has been accomplished in London, (for example,) as the arts of peace and civilization have advanced, and wealth has introduced the disposition and the power to multiply personal comforts and conveniences; and as habits of cleanliness and ventilation have been generally diffused; in the same proportion, and with equal steps, the improvement of the general health, the absolute disappearance of the plague and other epidemics, and the increase of longevity, are to be remarked. Hence it is only within the last few years, that the deaths have fallen short of the number of births within the bills of mortality of London.

We cannot, from our present knowledge of facts, however, account for all those modifications of diseases, nominally the same, which are observed to prevail at different seasons, and which require different modifications of the treatment. It can only be stated as highly probable, that whether the epidemic diseases originate from contagion, or human effluvia, or from the earth of foul ground, their degrees of violence may depend on the same varied causes of poetic effluvia; and the contagion of a mild or severe disease may tend to propagate more particularly a disease of similar character. We have already seen that peculiar symptoms, superadded to an acute disease, as affections of the lungs or of the bowels with general fever, are readily propagated along with that fever, and have modified both its character and the requisite treatment.

It has been judiciously observed, that in military physic, "the great improvements to be made are not so much in the cure as in the prevention of diseases, which depends altogether upon the knowledge of their causes." (Dr. John Hunter, loc. cit. p. 287.) Now one of the most important circumstances to ascertain, during the prevalence of an epidemic is, whether it arises from contagion, that is, from the influence of effluvia from the bodies of the diseased, or from the contamination of the air by the effluvia of foul ground, &c. For if a disease arise from contagion, as the author just quoted remarks, "there are sure remedies against it, which are so well ascertained, that while the plague, the most contagious and the most fatal of all diseases, commits its greatest ravages in large cities, individuals remain in the midst of them in perfect security, trusting to a careful exclusion under proper regulations. (See Contagion.) Again, if a disease arise from the air contaminated by the foul ground of a camp, or the exhalations of a marsh, it can only be avoided by a change of situation, or by taking care not to come within the sphere of activity of such noxious causes." Or in a large town, it may be added, by a strict enforcement of public and private cleanliness. But it is often extremely difficult to decide upon this point; a generally operating cause affects such a number of individuals about the same time, in the same situation, that they may seem to be infected by each other. So that, in fact, it has been disputed whether the plague itself be a contagious disease; and in regard to the dreadful epidemics of America, medical observers are by no means agreed as to their contagious origin. The contagion of the plague will be discussed hereafter. In the mean time we shall state some observations which may help to guide our decision in such cases.

By a contagious disease, is to be understood a malady in the course of which a poison is generated in the body of the sick, which produces in others a similar disease. The poison in some diseases, as small-pox, measles, and scarlet-fever, is sufficiently apparent; and the other diseases, which also arise from specific contagion, and occur but once during Vol. XIII. life, as measles, scarlet fever, hooping cough, &c. are well known. In others, again, as in typhus and the plague, it almost eludes our senses, and is only active when concentrated or accumulated, or close to the body of the sick. Now these contagious diseases equally affect all ages and descriptions, who suffer exposure to their cause; wherever they prevail, the old inhabitants of a country suffer as much as those that have lately arrived. But this is never the case in the yellow fever, remittent fever, or even intermittent fever, which arise from external miasma; for such as are fated to the country or climate suffer infinitely less than newcomers. Again, diseases proceeding from such a cause, generally diffused, and operating upon all, do most constantly recur in the same persons as long as they remain exposed to the original cause; thus in camps and marly situations, the sick are constantly relapsing in remittents and intermitants, till they change their situation. Dr. Hunter particularly observes, that the mortality among folders in the West-Indies is, in a great measure, owing to these repeated attacks. But the most convincing proof of the existence of contagion, is, that we leave their usual residence, and go to other places which are healthy, without spreading the disease. This constantly happens in the remittent fevers of the West-Indies; for the good effects of changing the air of the towns for that of the mountains is so well known, that it is very generally practiced; but certainly without the slightest suspicion of any mischief arising from any contagion carried by the sick. If we try by this rule the fever epidemic in Philadelphia in 1793, we shall not pronounce it to be contagious. One observation more may be added: when disease arises from a cause generally diffused, separation, which in contagious diseases is commonly effectual, is here of no avail. Thus, ships of war have gone into a harbour in the West-Indies, and have had no intercourse with the people on shore, or with the crews of other ships, and yet in a few days the men have been seized with the prevailing fever in great numbers. (Hunter, ibid.)

With respect to the last argument but one, indeed, the inference is not perfectly conclusive; for malignant typhous fevers, and the plague, which is probably but an extreme degree of the same fever, although they produce a contagion that is active and virulent in a confined and close atmosphere, nevertheless become much less contagious, in a clear and open air; so that we should expect that, on a removal of the sick to the country, the disease would assume a less virulent form. In the plague at Moscow in 1771, we are told by Dr. Mertens, that the patients, who were conveyed to the neighbouring villages, communicated the disease to the inhabitants of those places; which they would not have done if Moscow itself had not been superior to that of Moscow itself.

The specific contagions, as they have been called, as small-pox, measles, and scarlet-fever, which occur but once in the course of life, and chiefly attack children, become epidemic generally at pretty regular periods, in large towns. This may be principally explained, perhaps, by the circumstances of the necessary interval requisite for the production of subjects, who have not undergone these diseases.

On the whole, however, although the progress of refinement in the comforts of human life, during the last century, have thrown much light on the nature and origin of epidemic constitutions, in different years; it must be allowed, nevertheless, that much farther observation of facts will be requisite, in order to illustrate the subject completely.
EPIDENDRAM, from 1747, upon, and calyx, tree, in Natural History, a word used by Sir Hans Sloane, and some other authors, to express those plants which grow upon others, such as the mistletoe, which grows upon the apple-trees, &c. These are more commonly distinguished by the name of parasitical plants. See DONOVA.

Gen. Ch. reformed. Cal. three-leaved. Cor. Petals two, nearly equal to the calyx-leaves, spreading; nectary a lip, turbinated and tubular at the base, connected with the style, distifite of a spur, its termination dilated, ascending, spreading, either undivided or lobed. Stam. Anther an hemispherical, deciduous, terminal lid, of two or four cells; masses of pollen flaked, in pairs. Fil. German inferior, oblong or obovate, erect, furrowed; style semi-cylindrical, often gibbous, concave in front; stigma either concave or convex, in the fore-part of the style near the top. Peric. Capule oblong or obovate, with three or five ribs, with one cell and three valves, opening by clefs between the ribs. Seeds numerous, minute, each clothed with a chaffy tunic, inserted into the downy internal ridges of the valves.

Eff. Ch. reformed. Calyx-leaves spreading. Lip tubular at the base, attached to the fore-part of the style, distifite of a spur. Anther a terminal lid, deciduous.

The original genus of Epipendrum in Linnaeus, whose effential character is "Nectary turbinated, oblique, reflexed," comprehends many species which do not answer to that character, and which have, indeed, in several instances, been referred to this genus without a sufficient knowledge of their flowers. Hence professor Swartz has chiefly derived his genera of Cymbidium, Dendrobium, (see those articles,) Oncidium, Aerides, and Vanda, to that his Epipendrum, whose characters we have given above, is become a much smaller, as well as a more intelligible genus, though perhaps not more natural, it having the closest possible affinity to Cymbidium and Dendrobium. The species in Swartz are 23, in Wildenow 26. Professor Martyn has, with great industry, collected 124 under the original genus. Dr. Swartz mentions 19 new ones as discovered in South America by the authors of the Flora Peruviana and Chiloenes.

Among the genuine species of Epipendrum, as the genus flanks at present, are E. cochleatum, Linn. Sp. Pl. 1531. Curt. Mag. t. 372. Jacq. Ic. Rar. t. 605. Andr. Repof. t. 13. A native of Jamaica, and the first of its tribe that ever flowered in England. It is cultivated in a flower, in rotten bark, contrived so as to imitate, as much as possible, its natural situation in the clefts of aged trees, with occasional supplies of water. The bulb is green and smooth, of a compressed oval figure, each throwing out from its base numerous thick entangled fibres, which naturally adhering to the rugged bark, strongly fix the plant and imbibe nourishment for its support. A pair of oblong, rigid, recurved leaves, entire, as in all this natural order, spring from the summit of each bulb, and between them grows a spike, about a foot high, bearing a spike of several flowers. These are revolved, the long pale-green calyx and petals hanging down, while the broad, concave, somewhat cordate nectary, of a chocolate hue speckled with green, flanks erect. The flower has little or no smell.

E. fragrans. Sw. Prod. 123. (E. coehleatum; Curt. Mag. t. 132.) A native also of Jamaica, flowered in the flower of Chelsea garden, under Mr. Fairbairn's care, in Feb. 1789. This has much resemblance to the foregoing, but the petals are broader, the nectary pale green with red, and tipped with a little point, and the flowers have a sweet smell. The flower is shorter in this species than the leaves.

E. amabile. Linn. Sp. Pl. 1351. (Angraecum album majus; Rumph. Amb. lib. xi. 90. t. 43.) Native of the East Indies. This has beautiful white blooms, twice as large as in Rumphius's plate, on a long slender branched stalk. The lip is five-lobed, and terminates in a pair of very long, taper, almost capillary points. It would be a great acquisition to our flowers.

E. nutans. Sw. Prod. 121. A native of Jamaica, flowered in Kew gardens in March 1791. This has a leafy stem, terminated by a spike bearing a few pale flowers, whose lip is four-lobed. They are about the size of E. fragrans.

E. eichare. Linn. Sp. Pl. 1349. Curt. Mag. t. 453, is a beautiful and magnificent plant, native of the East Indies, which flowered at Mr. Whitley's nursery, Old Brompton, for several years before 1759. (Curtis.) The flowers are numerous, and fragrant; their calyx-leaves and petals each near two inches long, of a yellowish buff-colour; lip white, with two elegantly fringed lobes. This species is now not very rare in the English flowers.

E. fuscatum. Sm. Spicil. t. 23. is rather singular than ornamental. The late Hon. Mrs. Barrington received it from Jamaica, and it bloomed in her garden in 1791. The stem is leafy, and terminates in a very long and slender stalk, bearing a dense corymbus of small flowers, which, like the whole plant, are of a brown purplish hue.

Several species, more or less akin to this last, occur in the works of Jacquin, as well as some more splendid ones with tall branching stalks, none of them yet introduced into our gardens.

EPIDERMIS, in Anatomy, is the thin inelastic membrane which covers the true skin, and which constitutes, therefore, in all parts, the external surface of the body. See Skin.

EPIDERMIS, in Vegetable Anatomy, from 1772, upon, and fibres, the skin, or bide, is the scar tissue, or pellicle, which covers every part of a living plant, as a similar cuticle covers the human skin. In the tender growing parts of vegetables this membrane is of the most delicate texture, pellicul and colourless, extremely thin, yet not deficient of tenacity, being wonderfully extendible on stalks, or other parts, of quick growth. Under a high magnifier it is found to be porous in a regular manner, and differently in different plants, so as to allow of the passage of fluids in a definite degree, in either direction, according to the nature of each plant. Hence some leaves permeate slowly, but imbibe moisture with great rapidity, as those of the succulent tribes; while others transmit their fluids, or imbibe external moisture, with nearly equal facility, as aquatics. Such differences are detected by experience, but scarcely discoverable by microscopic investigation.

The Epidermis is of the most essential importance to the life of the plant, as of the animal, protecting the living parts which it covers from the influences of the air, while it allows of due perspiration and absorption, as well as of the action of light through its nearly colourless sub stance. It differs greatly in thickness according to the part of the plant to which it belongs. Exquisitely delicate on the fine organs of a flower, like the cuticle of the animal eye, it has considerably more sub stance on the leaf, and still more on the branch.
branch of a tree. On old trunks it is generally obliterated or destroyed, being there no longer necessary, the dead layers of bark, (see Bark and Cortex,) answering all the purposes of protection, while the peculiar functions of an organized porous epidermis are not wanted. Yet in the birch, and a few other trees, the membrane in question consists of multiplied permanent layers, like the bark, and clothes the trunk as long as that part exists. The cuticle is easily separable from young flakles in a rapid state of vegetation, and from any part of a plant by means of maceration, boiling or putrefaction, being nearly, if not absolutely, destitute of vitaliy, and very little subject to decomposition.

Besides the essential office of a guard to the living vegetable body against all hurtful stimulants, the epidermis answers many secondary purposes of protection. When naked, as usual, it proves but a feble defence against heat or cold, but it is often covered with hair or wool, in which case it becomes a very powerful one, particularly against the too violent action of a burning sun. Flowers indeed, though peculiarly prepared to all the force of this luminary, have scarcely ever any such woollly or downy defence; for the functions which they have to perform are often urgent with respect to light and heat. Many petals, notwithstanding, are silky or downy on their outide, apparently to protect them from cold, or possibly from too scorching a heat before they are full-grown. examples of which may be seen in Cornusculus, Astraeus, and several other genera; but the infides of such petals are exquisitely smooth.

Examples of a very firm smooth epidermis, of considerable strength and thicknes, may be found in the common currant, Ribes rubrum, the elder, Sambucus nigra, and the laburnum, Clysis laburnum. On the branches of the latter it acquires almost a horny hardness; but it is still more cartilaginous in the hard white tubercles sprinkled over the olaves of Alnus perline, and in the teeth of the foliage of some Saxifrage, as well as the bristly warts of several species of Erinum and others of the afterfifa. On the leaf of the white willow, and the Protea argentea, the cuticle has a fine silky clothing of a silvery hue; while many other plants it is equally white, but destitute of gloe. In the leaf of many kinds of mullein, Verbascum, and the fruit of the peach, we find it densely covered with hairs, more or less branched.

The herbage of the botany, Betonica officinalis, is clothed with rigid bristles, fixed upon the cuticle, which in a dry state excite freezing. Similar hairs on the cuticle of the shining nuttery are curiously perforated, to transmit a venonous fluid lodged in bags at their base, like the poison in a serpent's tooth. Grasses, corn and horsetail, Equisetum, have much flinty earth in their epidermis; while in the cork-tree, the common maple, and the Dutch elm, the same part is of a soft elastic fungous substance. The fruit of the plum, and leaves of the eabbage, have their epidermis covered with a fine bluish powdery refrinous incrustation, which will freely allow rain to come in contact with them, yet such plants readily absorb moisture.

Nothing can be more absurd than the idea which some philosophers have formerly entertained, that the epidermis was defined to give shape to a plant, and that certain lumps or excrescences on the stems of Vines, originally owing to a casual wound or crack in this membrane. This opinion is easily refuted by purposely making such a wound or opening, when it will be found that no tumour can be produced by any such means; spontaneous tumours being in reality the cause, not the effect, of the bulring of the epidermis.

S.

EPIDICASIA, Eteniesis, among the Athenians. Daughters, inheriting their parents' estate, were obliged to marry their nearest relations; which gave occasion to persons of the same family to go to law with one another, each pretending to be more nearly allied to the heirens than the rest. The suit was called eplidicasis, and the virgin, about whom the relation contested, epidesis. Pott. Archzool. Grec. lib. r. cap. 24. tom, i. p. 147.

EPIDIDIUIM, in Ancient Geography, is the name which Ptolemy gave to that peninsula on the western coast of Scotland, which forms part of the country of Argyll, called Cantyre and Knapdale; and including the isles of Islay and Jura, which the Roman geographer considered as being part of it: but whether it then was integral, or not, cannot be ascertained from his account. The peninsula might at an early period have been an island; such changes has the sea made upon our large-beat coasts: for Dr. Smith derives this name from a similar Celtic word, signifying the isle of the Picts, who at that time were the principal inhabitants of that part of Scotland. Sir John Sinclair's Stat. Acc. vol. x. p. 519. But such a conclusion is not justifiable by the rules of Celtic derivation. Yet, in that language, signifies a wedge, and for, land or territory; it is, therefore, obviously derived from those two etymos conjoined, perfectly descriptive of such a tongue of land, i.e. a wedge-shaped territory. Mr. Baxter imagines the Pepidii, synonymous with Epidii, to have derived their name from the Britifh word Papidiane, which signifies any thing shaped like a flute or pipe, as was the peninsula of Cantyro, the country of the Pepidii. From the southern point, called the mail of Cantyre, promontorium Epidium, the coast of Ireland may be plainly seen; it being only 16 miles to the south foreland in Coelaraine.

EPIDIDYMIS, in Anatomy, a part of the testicle, situated behind the body of that organ, and consisting of the excretory duct in a wonderfully convoluted form. It ends in a straight tube, called the vas deferens. See Testis.

EPIDOSIS, from epidosin, to increase, a Surgery, a preternatural enlargement of parts.

EPIDOT. See Strahlstein.

EPIDOTES, from epidotan, to cause to grow, in Mythology, deities which were supposed to preside over the growth of infants.

EPIDROME, from epidotan, upon, and epidotan, to run, in Surgery, an afflux of fluids, or, as they were formerly phrased, humours, especially when it arose from the application of a ligature round any part.

EPIDROMUS, of epidotan, and epidotan, a tree, in the Ancient Shipping, a sail near the stern, which was the largest but one in the ship.

EPIECIA, in Ancient Geography, a town of Greece, towards the sea, and not far from Corinth; N. of Tenea.

EPIEZ, in Geography, a town of France, in the department of the Louet, and district of Beaugency; 12 miles E. of Orleans.

Ch. Cal. Perianthus double, close together, permanent; the outer of three ovato-lanceolate, pointed leaves, of which the external one is larger than the rest; inner in five deep, upright, lanceolate, pointed segments, somewhat longer than the outer. Cor. of one petal, silver-shaped; tube rather longer than the calyx, hairy within; limb spreading, in five deep ovate-oblong lobes. Stam. Filaments ten, thread-shaped, the length of the tube, and inserted into its base; anthers oblong, acute. Pf. Germ.globes,
globose, with five furrows, downy; style cylindrical, as long as the flaments; stigma obtuse, in five lobes. Pericarp nearly globular, depressed, with five angles, five cells, and five valves. Seeds numerous, roundish. Receptacle large, separating into five parts.

Eff. Cl. Outer calyx of three leaves; inner in five deep segments. Corolla salver-shaped. Capule of five cells, with a central five-parted receptacle bearing the seeds.

The species are two.

1. E. repens. Linn. Sp. Pl. 565. Swartz Prod. 74. Andr. Repof. t. 162. Lamarck Illutr. t. 367. f. 1. "Leaves ovate, inclining to heart-shaped, entire. Tube of the corolla cylindrical." Nature of pinnate flowers in Virginia and Canada, but like many plants of a cold or alpine climate, difficult to prefer in our gardens. It flowers in April or May. The root throws out many woody, procumbent, creeping, branched, hairy, leafy stems, which form wide-spreading patches. Leaves alternate, on hairy foot-flakes, ovate, oblong, entire, heart-shaped at the base, veiny, shining, but roughish to the touch. Stipules none. Flowers in terminal, dense, bracted clusters, fragrant, of a pale blush-colour, each about the size of a small cowslip. It is increased by parting the roots, thrives in a light sandy loam, but requires the shelter of a long-continued deep snow, or some equivalent protection, to survive our winters. We saw it in great perfection at Meills. Lee and Kennedy's nursery, Hammermith, in 1797.

2. E. cordifolia. Swartz Prod. 73. Lamarck Illutr. t. 367. f. 2. "Leaves heart-shaped, rounded, serrated, convex, hispid, rigid. Tube of the corolla ovate." Native of boggy places on the highest mountains of Guadaloupe and Cayenne. Smaller than the former, with pointed and more hispid leaves, whose foot-flakes are very short. Flowers in like manner terminal, but with a more inflated tube. The young stalks are very hairy.

Epigaea, in Gardening, comprehends a plant of the low, trailing, shrubby, flowering kind. This is the creeping epigaea, or trailing arbutus (E. repens).

Method of Culture.—This is readily effected in this plant by the trailing flanks, which soon put out roots at the joints, and may then be cut off from the old or parent plants, and be set out in a shady situation, where the soil is moist, in the autumnal season, that the plants may be well established before the spring. In cafes where the winter proves severe, it may be necessary to lay a few dried leaves, or other light covering over them, to protect them from frost; but after they become well rooted, they seldom require more than being kept clean from weeds.

These are ornamental plants in the fronts of the borders of shrubberies.

EPIGASTRIC ARTERY, in Surgery. The proper mode of operating in certain cases of ruptures, so as not to run any risk of wounding this vessel, will be explained in the article Hernia.

Epigastrium, in Anatomy, one of those portions, into which the cavity of the abdomen is divided by anatomists in their descriptions. "The epigastric region," says Winslow, "begins immediately under the appendix ensiformis at a small suprapericulicular depression, called the pit of the stomach, and in adult subjects ends above the navel at a transverse line, supposed to be drawn between the last false ribs on each side.

"This region is subdivided into three parts, one middle, named epigastrium, and two lateral, termed hypochondria. The epigastrium takes in all that space which lies between the false ribs of both sides, and the hypochondria are the spaces covered by the false ribs." Sect. 7. § 79, and 80.

EPIGASTRUM. See Epigastric.

EPIGONOMENA, of 

EPIGNOMENA, a musical instrument among the ancients, with forty strings, so called from its inventor Epigonius, a native of Ambraecia, a city of Epirus. Mem. Acad. Inscript. vol. v. p. 167.

EPIGNONIUS, in Biography, was a mathematician of Sicily, and a native of Ambraecia, who is celebrated by the ancients for the invention of an instrument of forty strings, which was called after his name, Epigonum. When he lived is uncertain, but as it was in times of simplicity, we may suppose that these strings did not form a scale of forty different sounds, but that they were either tuned in unisons and octaves to each other, or accommodated to different modes and genera. The 12 semi-tones of our three-fifths harpischords included thirty-six different strings.

The Greeks were divided into numerous sects of musical speculative, before and after the time of Aristoxenus: as the Epigonians, Damoumi, Eratoclians, Agetonians, and many others enumerated by Porphyrus, in his Commentary on the Harmonics of Ptolemy. Of these, however, all we know is, that they differed; it is, perhaps, little to be lamented, that we no longer know about what.

Music has many obligations to Epigonius. He was the first who played on stringed instruments without a plectron. And, according to Athenaeus, he first united the melody of flutes to that of the citharas; and by this means softened the harshness and inflexibility of the citharas when played alone. He invented the chromatic genus, and was the original author of choruses.

EPIGRAM, in Poetry, a short poem, or composition in verse, treating only of one thing, and ending with some point, or lively ingenious thought.

The word is formed of ἐπιγράμμα, inscription, τοι ἐπιγραμ- 

Epigrams then, originally, signify inscriptions, and they derive their origin from those inscriptions placed by the ancients on their tombs, statues, temples, triumphal arches, &c. See Inscription.

Thefe, at first, were only ample monograms; afterwards increasing their length, they made them in verse, to be the more easily retained; Herodotus, and others, have transmitted to us several of them.

Such little poems retained the name of epigrams, even after the design of their first institution was varied, and people began to use them for the relation of little facts and accidents, the characterising of persons, &c.

The Greeks confine their epigrams to a very narrow compass; for though, in the Anthology, we have there met with a very long one; yet, ordinarily, they do not exceed fix, or, at most, eight verses. The Latins were not always so scrupulous, and the moderns much less, as to these bounds.

M. le Brun, in the preface to his "Epigrams," defines an epigram a little poem, insensible of all kinds of subjects, and ending with a lively, just, and unexpected thought; which are three qualifications essential to the epigram par- 

particularly
EPI

tically the first and laft of them, viz. brevity, and the point or clofe of the epigram.

To attain brevity, only one thing is to be aimed at in the poem, and that to be purfued in the confined terms poifible. Authors are much divided as to the length the epigram is to be confined to; the ordinary limits are from two to twenty verses; though we have inflances, both among the ancients and moderns, where they extend to fifty. But if these epigrams are to carry the thought beyond the letter, and more perfeft, as it partakes more of the nature and character of this kind of poem. The point or turn is a quality much infifted on by the critics, who require the epigram constantly to clofe with something poignant and unexpected, to which all the rest of the composition is only preparatory. Others there are, who exclude the point, and require the thought to be equally diffus'd throughout the whole poem, without laying the whole fires on the clofe: the former is usually Martial's practice, and the latter that of Catullus. Which is the most beautiful and perfeft manner is difputed by a third class of critics.

The Greek epigrams have scarce any thing of the point or brieffnes of the Latin ones: those collected in the Anthology have mult of them a remarkable air of eafe and simplicitie, attended with something jufit and witty: fuch as we find in a fensible peafant, or a child that has wit. They have nothing that bites, but something that tickles. Though they want the falt of Martial, yet, to a good taste, they are not inipid; except a few of them, which are quite flat and frivolous. However, the general faintnes, and delicacy of the pleafantry in them, has given occaftion for a Greek epigram, or "epigram à la Greque," to denote, among the French, an epigram void of falt or sharpenes.

It is principally the point that characters the epigram, and distinguishes it from the madrigal. See Point.

In the modern verification, as observed by F. Mourguès, the epigram and madrigal are diffinguifh'd by the number of verses and the clofe. 1. By the number of verses, which in the modern epigram does not go beyond eight or nine in the modern madrigal comes short of fix; and, 2. In that the clofe, or period, of the epigram, has always something more lively and studied than that of the madrigal.

The epigram is the loweft, and laft conliderable of all the productions of poetry; and it is in general rather an effeft of good fack, than of art, to succeed therein. The fime, and fulbility, of the epigram, M. Boileau observes, fhould turn on the words rather than the thought; which fhews very little to the credit of this kind of compofition, as it reduces it to the nature of the pun, or equivocue. F. Boulhous confirms the hint, in adding that the equivouque is what uflually fhines the moft in the epigram.

One great beauty of the epigram is, to leave fomething for the reader to guess, or supply. Nothing pleafes the mind fo much, as to find fhewing in itself the objects prefented it; nor does any thing difguft it more than to preclude it from flowing and exercising a faculty it values itfelf for. Segrais.

The epigram admits of great variety of subjects: fome are made to praife, and others to faturize, which laft are much the cafieft; ill-nature ferving instead of point and wit. Boileau's epigrams are all fature on one or another. Thefe of Des Reaux are all made in honour of his friends; and thofe of Mad. Scudéry are fo many elogues. The epigram being only a fingle thought, it would be ridiculous to ex- press it in a greater number of verses: it must have its very like the drama. The comedy has an action for its fubjeft, and the epigram a thought.

We might felect a number of excellent epigrams in our own language, if our limits allowed of enlarging this article. We fhall content ourselves with fubjoining the following. The firft is that of Mr. Pope, faid to be written on a glass, with the earl of Chelsea's diamond pencil.

"Accept a miracle, instead of wit,
See two dull lines by Stanhope's pencil writ."

The next is an epigram, expressed concifeely and clofing beautifully, which was written on the leaves of a fan by Dr. Atterbury, late bishop of Rochester:

"Flavia the leaf and flightfeft toy,
Can with refin lefs art employ.
This fan in meaner hands would prove
An engine of small force in love;
Yet with gracefull air and mien,
Not to be told or late in seen,
Directs its wanton motion fo,
That it wounds more than Cupid's bow,
Gives coolnefs to the matchlef dame,
To every other bread a flamme."

Mr. Prior laflhed the impertinence of a bad writer, who had taken the licence of confuming him, in the following epigram:

"While fatter than his coffitue brain indites,
Philo's quick hand in flowing letters writes.
His cafe appears to me like honest Teague's,
When he was run away with by his legs;
Phoebus, give Philo o'er himself command;
Quicken his fteps, or refrain his hand.
Let him be kept from paper, pen, and ink,
So he may eafe to write, and learn to think."

The following epigram was written by Mr. Wesley, on occasion of erecting a monument to Mr. Butler, author of Hudibras, in Westminster Abbey:

"While Butler, needy wretch, was yet alive,
No generous patron, would a dinner give.
See him, when starv'd to death, and turn'd to dust,
Peffented with a monumenta bull!"

"The poet's fate is here in emblem shown,
He ask'd for bread, and he receiv'd a flame,"

See Butler.

EPIGRAPHIE, Enęγραφìα, Superfcription, an inscription on a building, to signify its use, occasion, the time when, and the person by whom it was built.

EPIGRAPHES, Ενενγραφες, among the Athenians, officers that rated all those of whom taxes and contributions were required, according to every man's ability, kept the public accounts, and prosecuted such as were behind-hand with their contributions. Potter. Archzol. Grec. lib. i. cap. 14, tom. i. p. 81.

EPILA, in Geography, a town of Spain, in the province of Arragon, on the Xiloça; 17 miles W. of Saragossa.

EPILEPSY, in Medicine, ἐπιληψις, and ἐπιλήψεις, signifies sudden seizure, is a disease which consists of convulsions of the greater part of the muscles of voluntary motion, attended with a loss of sense and feeling, and ending in a state of insensibility, and seeming sleep.

This disease has received a variety of denominations, especially among the ancient writers. By the early Greeks it was called the sacred disease, from a notion of its origin in supernatural
superficial influence; some of the exorcists and impostors
of those times even pretended to decide, from variations in
the symptoms, whether the fits were occasioned by Cybele,
Neptune, Mars, or some of the heroes. Hippocrates
seems to have been the first who combated these absurd
notions of his countrymen; and severely reprehends the im-
portunities of the exorcists, in pretending to feat aside what
more than human power had inflicted, by incantations,
magic ceremonies, and sometimes by the most contemptible
juggling. (See Hippocr. de Morbo Sacro.) Arcturus,
however, remarks that it might have the denomination of
sacrificed on other accounts; either from its magnitude,
everything great being deemed sacred; or because it could not
be removed by human means, but only by divine power; or
from the opinion that a demon had entered into the patient,
for all these reasons together. (De Caufa. Affect. lib. 1.
See also Cæs. Aureliam. De Morb. Chron. lib. 1. cap. iv.)
In like manner the Romans call every thing remarkable
great "facetum," "facetum anchorum," "auri facer, famas,"
accurately. (Van Swieten. § 1071.) Upon the same ground
epilepsy has been called morbus Herculeus, the Herculean
disease. By the Romans, it was sometimes termed morbus
comitati, "the assembly disease:" either because epileptic
perons were more frequently observed to be seized in a
crowd of people, or because the public meetings, called
comitia, were adjourned if any one happened to be attacked
with an epileptic fit. It has likewise been termed morbus
ekaducus, or "falling sicknes," because the patients, when
they are seized with the paroxysm, fall down.

The leading features and principal circumstances of the
epileptic convulsions are nearly the same in all the different
persons whom the disease affects. The disease consists of
fits, which attack suddenly often those who are seemingly
in perfect health, and, after lasting for some time, pass off,
and leave the persons again in their usual state.
The individual attacked loses suddenly all sense and power
of directing his muscular actions; so that, if standing or
sitting, he falls immediately, or perhaps with convulsions is
thrown to the ground. In that situation he is agitated with
violent convulsive actions, variously moving his limbs and
the trunk of his body, with a force that is altogether
preternatural. Commonly the limbs on one side of the
body are more violently agitated than those upon the other.
In all cases the muscles of the face, eyes, are much affec-
ted, exhibiting various and violent dilatations of the con-
tenance. The tongue is often affected, and thrust out of
the mouth, while the muscles of the lower jaw are also
affected, and, shutting the mouth with violence, often wound
the tongue grievously. While these convulsions continue,
the face becomes red, then livid and swollen, from the in-
terruption to the circulation through the head, and there is
commonly at the same time a frothy moiture issuing from
the mouth; and in the most severe cases the urine and al-
veolar excreta are involuntarily discharged. In some in-
stances a hissing or resonorous noise is emitted. The con-
vulsions have for a few moments some remissions, but are
suddenly again renewed with great violence. Generally,
after no long time, this terrible struggle ceases altogether,
and the patient remains for some time without motion, in a
state of absolute insensibility, and under the appearance of
a profound sleep. After some continuance of this sleep,
he sometimes suddenly, but for the most part by de-
grees only, recovers his senses and power of motion, but
without any memory of what had passed from the first sei-
zure of the fit, and complaining of head-ache, and ex-
cessive pain in all the limbs as if from severe fatigue. During
the convulsions the pulse and respiration are hurried and irre-
gular; but, when the convulsions cease, they return to their
usual regularity and healthy state.

In most cases the attack of epilepsy comes on suddenly,
without any warning symptom; but sometimes it is preceded
by certain sensations for a few moments previous to its actual
commencement. Of these the most remarkable is that,
which has been termed the aura epileptica; which is a sen-
tation of something moving in some part of the limbs
or trunk of the body, and from thence creeping upwards to
the head; and when it arrives there, the person is imme-
diately deprived of sense, and falls into an epileptic fit.
This feeling is described sometimes as resembling that of a
cold vapour, sometimes as like a fluid gliding, and sometimes
like the sensation of a small insect creeping along the body;
and very often the patients can give no other distinct idea
of their sensation, than as in general of something moving
along. It might be supposed that this sensation arose from
some affection of the extremity or other part of a nerve,
acted upon by some irritating cause; and that the sensation,
therefore, followed the course of such a nerve. But it is
not found to follow the course of any nerve distinctly, and
it generally seems to pass along the integuments. There
are occasionally also other sensations immediately preceding
the fit, and generally referred to the head, where no aura
is perceived. In some persons a giddiness comes on; in
others a spark of light, which increased to a bright beam,
usually without in the paroxysm; depending probably on the
sudden turgescence of the vessels in the head, which pro-
duces pressure on the optic nerve, and occasions this de-
praved sensation. Dr. Gregory used to mention in his lec-
tures, at the college of Edinburgh, the case of an officer,
who had a more singular perversion of sight, previous to the
fit of epilepsy; he always fancied that he saw an appar-
tion of an old woman, with a blue cloak, holding a staff
in her hand, with which he knocked him down. He also men-
tioned an instance of visual deprivation which occurred to
Dr. Fothergill; a young lady, whom the Dr. was attending
as an epileptic patient, remarked that he was covered with
spangles, (the more unusual as an ornament to a quaker's
coat,) and immediately she fell down in a fit.

Under the article Convulsions we have entered into a
detail of the circumstances which conduct to their origin
and production; and as the whole of those observations ap-
ply to the epileptic convulsions most particularly, it will
not be here necessary to repeat them. We have there stated
that convulsions occur under two opposite conditions of the
body, viz. of repulsion and insolation; or, in the language
of Dr. Cullen, of excitement and collapse (First Lines,
§ 1286.) and that various irritations in different parts of
the body, but especially in the head, give rise to them in
different influences.

Sauvages has described a great variety of species of epi-
lepsy, which he has distinguished chiefly according to the
causes which produced them. Dr. Cullen has mentioned
only three species, which (as to the utility of division
with a view to the curative indications) might be reduced
to two. His first species is epilepsy cerebralis (from cer-
ebrum, the brain), which attacks suddenly, without any
evident cause, or preceding sensation, except perhaps a giddi-
ness or deprivation of light; and includes the plethoric
epilepsy and eclampsia of Sauvages, as well as his latent
epilepsy. The second species, is E. sympathica, in which
the aura epileptica, before described, precedes the attack;
a circumstance which is scarcely of sufficient importance
to de designate a species. The third, E. occasionalis, includes
those inflections of epilepsy which originate from manifest
and accidental irritation, and which subside when the irri-
tation
EPILEPSY.

The various causes of irritation are, wounds, or blows of the head, from falls, and other external injuries; pain in various degrees, as from parturition, stagnation, worms in the alimentary canal; indigestible food, or other substances in the stomach, as narcotic poisons, spiritsuous liquors, &c.: passions of the mind, especially fear; and a variety of other sources of disturbance to the system, as the creation of small-pox, and other febrile irritations, the venereal orgaism, intense study, the supposition of customary discharges, &c.; and, lastly, the imitative propensity, which is particularly conspicuous in women and children, as illustrated at large under the head of Convulsions.

We have there stated the impossibility of explaining the proximate cause of convulsive diseases, in consequence of our ignorance of the nature of the nervous power, or of the connection between the action of the muscles and the brain, or the faculty of volition, in a state of health. And it was sufficient to mention the attempts to reason upon the subject, which the ablest physicians have made, in order to prove their futility. The learned Boerhaave says, (Abp. 1086.) "Et patet quidem, caufam proximam omnis epileptica exquifite femper effe nimium cerebro in nervis motoredo, nullam in fenticentis, actio cementem." It is obvious that the proximate cause of every perfect epilepsy is always too great an action of the brain upon the nerves of motion, and too little upon those of sense; which is only stating the fact in other words; for it amounts merely to this: "in every true epilepsy the motions of the body are violent, and the sense is lost: the proximate cause is still as obscure as before." Dr. Cullen scarcely pretends to form a theory upon the subject. "I might say," he observes, "that it is an affection of the energy of the brain, which, ordinarily under the direction of the will, is here, without any concurrence of it, impelled by preternatural causes. But I could go no further: for as to what is the mechanical condition of the brain, in the ordinary exertions of the will, I have no distinct knowledge; and therefore must be also ignorant of the preternatural state of the same energy of the brain under the irregular motions here produced." (Fifth Lines, § 128.) The indications of cure therefore cannot be formed from a knowledge of the proximate cause of the disease; but we obtain some useful intimations for the treatment, by diligently attending to the various remote causes; both those which induce a predisposition, and those which occasionally excite the disease. Our principal object, then, will be to avoid the occasioned causes, and to remove or correct the predisposition.

The predisposition to epilepsy, in the majority of instances, seems to consist partly in what may be termed a morbid irritability, or mobility, of constitution, in which the action of slight irritations (which are applied to most persons with impunity) excites great commotion in the nervous system; and partly in a surgescence of the nerves of the head, which accompanies a general phthisia. This appears from the circumstances, that phlegmatic persons are very frequently the subjects of epilepsy; that it is often brought on by causes inducing any unusual surgescence of the blood-vessels; and that it has been frequently cured by diminishing the phthisic state of the body, more frequently, we believe, than by any other system of practice. This principle was inculcated by Dr. Cullen, and is strenuously adopted by the present Dr. Gregory, his successor. It was likewise maintained by the late Dr. Fothergill, who has left us the following excellent remarks on this point of practice.

After stating that many epileptics occurred to him, which eluded all his endeavours to relieve them by means of the medicines ordinarily recommended as specific, and which therefore suggested the necessity of adopting some other mode of procedure, he says, "I had observed that fits were most liable to return in the plentitude of health; that epileptics were often extremely incautious in respect to diet; that children, highly indulged, were liable to the disease; that in every other period of juvenescence, and in middle aged adults, if they were at all subject to the disease, it was when they had either committed some excess, or, by one means or another, were plethoric; and that, in habits subject to epilepsy, the disease seldom recuris, without either an habitual indulgence in eating, or a neglect of necessary exercise. This induced me to recommend, in many cases, a total abstinence from all animal food, and from all spiritsuous liquors. Care was taken to regulate the secretions, and such a course of medicine prescribed, as might seem expedient to induce the patients, or their friends, scrupulously to comply with such a course of diet. It was in vain to restrict the quantity of animal food. There are few who have, at all times, resolution enough to submit to the first intimations of fatiety. It was, therefore, necessary to enjoin such a kind of diet, as was accompanied with but slender provocations to excess, and which, at the same time, would afford the least quantity of nutriment; by which that fulness, which, in many epileptic cases, appears to be a stimulus sufficient to produce the fits, would be avoided, and the parts, which were the immediate seat of irritation, might gradually recover a degree of strength and firmness, that would be proof against all flight impression.

"It often happens in diseases, that a proper plan of diet is of much more importance in the cure than any thing we are acquainted with in the Materia Medica: it is, however, of not less necessity to engage the patients and their friends in a steady perseverance of the method we direct. The generosity of people have very little notion that diet can do more than merely support their strength; that it can be made subservient to the cure of their diseases, they cannot easily be brought to comprehend, &c.

"In young boys, I apprehend, the epilepsy most generally proceeds from their own craving appetites, and the neglect of those who are about them. It may not be improvable, but in such cases woes may also have a share in producing the fits. Be this as it may, at least the less powerful, seldom cure the disease; they may abate occasionally the frequency, or the violence of the attacks, but they too often, at the same time, bring on a greater degree of irritability, and at length, if repeated frequently, and in considerable doses, seldom fail of confirming the disease. Moderate laxatives, with a light chalybeate interposed, and steadily continued, with a course of diet, consisting of milk, vegetables, fruit, and things prepared from them, and in moderate quantities, seldom fail of removing the disease in such habits. Riding and bathing in cold water, and the usual means of establishing good health, may, at the same time, be attended to, and the plan pursued with patience; for it is not to be expected in diseases that affect the nervous system, the most remote and habitual part of the economy, when once they have debilitated, or otherwise disordered, their very feeling parts, and their influence is become habitual, that after-medicines, however active, penetrating, and efficacious, can, in a very short time, restore the ability to perform their functions as they ought to do." (See Medical Obs. and Inquiries, vol. vi. p. 72.)

This plan of light and moderate living, with occasional laxatives, should be adopted in every case of epilepsy, where it does not arise from lots of blood, or other causes of instability, or is not connected with a cachectick or emaciated habit: and even in the last case, the plan is often useful, especially
Epilepsy.

It might be supposed that artificial evacuations, especially blood-letting, would be the most effectual means of diminishing the phlethoric state of the system; and such it certainly proves, when the phlethora has become considerable; and if it threatens immediate disease, this evacuation ought to be made to the quantity the urgency of the case demands to require. It is, however, a matter of old observation, that blood-letting is not the proper mode of preventing the recurrence of the phlethoric state; but, on the contrary, that it is often the means of favouring it, especially when the operation is performed at regular periods. There is, however, a case of epilepsy, as Dr. Cullen remarks, in which there is a periodical or occasional recurrence of the fullness and turgescence of the unguliferous system, giving occasion to a recurrence of the disease. In such cases, when the means of preventing phlethora have been neglected, or may have proved ineffectual, it is absolutely necessary for the practitioner to watch the returns of these turbulences, and to obviate their effects by the only certain means of doing it, that is, by a large blood-letting. When the general phlethora is not great, but the symptoms indicate considerable local turgescence in the head, the application of cupping-glasses, after scarification of the neck, or the use of a lepton, blisters, or flues, near the same part, will afford the means of some relief, by the evacuations which they produce. An open flux, indeed, in distant parts, as in the arm, has been found useful in some instances of epilepsy, by tending to obviate the phlethoric state, or, as Dr. Cullen suggests, by determining occasional turbulences to those parts, and, therefore, diverting them, in some measure, from their action upon the brain.

Epilepsy, however, as we have already stated, is also the result of a state of debility, with which the excessive nervous mobility that is easily excited to convulsions is, in many other instances, observed to be connected; especially in hystria, in the condition of infancy, &c. Where this debility has been the consequence of an intemperance, as from loss of blood, from previous disease, and so forth, a nourishing generous diet will be requisite to re-store the strength; and infirmities are occasionally seen, in which the propensity and success of this practice are manifest. Where there is obviously a feeble state of body, with pale complexion, and without any appearances of local phlethora, the propriety of being much in the open air, of using the cold bath frequently, and of regular exercise, adapted to the strength and habits of the patient, must be equally evident. He may still further contribute to remove debility, and its consequences, especially that great mobility which is a principal part of the predisposition to epilepsy, by the use of tonic and antipathodemic medicines. By a sort of routine, too generally pursued by indiscriminating practitioners, remedies of the last mentioned classes are most commonly given in epileptic cases, more particularly of late the metallic tonics, while the diet and regimen are not sufficiently attended to. However, as the circumstances of the constitution occasionally favour their operation, it cannot be doubted that the disease has, in many infirmities, been removed by these means; and numerous cases are on record, in which particular species of tonic remedies have effected the cure of epilepsy. The preparations of iron have been most commonly employed for this purpose, as the rubigo ferri, or the fulphat of iron, or its combination with ammonia (ferrum ammoniacale); and cures have been said to be accomplished by all these preparations. Dr. Cullen, however, observes, that he never found them effectual; which he attributes partly to their not having been always employed in the proper circumstances of the disease, and partly to the inadequate quantities in which they have been given. (First Lines, § 1355.) A preparation of copper, the cuprum ammoniacum of the Edinburgh Dispenatory, has been one of the most celebrated of the metallic tonics, and Dr. Cullen admits it has often been truly efficacious. It should be given in the dose of one grain at first, twice in the day, and gradually increased to as much as the stomach will bear. Zinc, especially in the form of flowers of zinc, (as the oxide was formerly denominated,) has been much extolled for its virtues in the cure of epilepsy, and other spasmodic diseases, when it was used in small doses. Much larger quantities of it, however, have been administered lately, and its character of efficacy has been considerably diminished. The fulphat of zinc, or white vitriol, appears to be a more efficacious tonic. Arsenic has more recently been introduced as a remedy for epilepsy. The fiery and great powers of this metal, as a medicine, especially in the cure of periodic disorders, such as intermittent fevers, megrim, or intermittent head-ache, &c. have been fully established, and afford an analogy in its favour. A writer on this subject, in the Edin. Med. and Surg. Journal (for July 1829) states, that he has found arsenic useful in the cure of epilepsy, when it occurred in young subjects, principally anterior to the age of puberty, and of which is termed a delicate habit, and feebly fitting on the patient when the disease affinies, or very nearly approaches, a periodic form. The drunken epileptic likeness, when not of a full phlethoric habit, has found a cure from the firm and judicious use of this potent remedy, due attention having been paid to the alvine evacuations. There is still another tonic of the metallic class, which has lately been recommended as an efficacious remedy for epilepsy, the nitrat of silver (or lunar caustic), and is said to have cured the disease, when it had already been of many years standing. (See two cases of this nature, Med. and Physy. Journal, vol. i. p. 184. vol. ii. p. 70.) A quarter of a grain of this active saltpetre, given three times a day, is a sufficient dose for an adult in the beginning; it may be afterwards carefully increased.

The vegetable tonics are admitted to pupils less efficacy in alleviating this dreadful disorder. Among these the bitters have chiefly been employed, and the cichores is the most active. Like the arsenic, it is especially adapted to those epileptics which recur at certain periods, and which are not at the flurrioste accompanied with any phlethoric state, or turbulence of the blood: in such periodic cases, if the bark is employed some time before the expected recurrence, it may be useful; but it must be given in large quantity, and as near to the time of the expected recurrence as possible. The leaves of the orange tree have sometimes proved useful in this disease, probably by the bitter quality which they possess.

But this caution must again be given, with respect to the employment of any of the above-mentioned tonics in this disease, that in all cases where it depends upon constant or occasional phlethoric state of the system, these medicines are likely to be at least ineffectual; and if sufficient evacuations be not made at the same time, they are likely to be very hurtful. The various success with which such remedies have been administered is, doubtless, to be ascribed partly to attention to these circumstances; although it is equally clear, that many epileptics, connected with organic lesion in the head, or a connate disorder of the habit, are beyond the power of any medicine.

With a view of diminishing the tendency to the convulsions of epilepsy, various antipathodemic medicines have been employed,
employed, such as valerian, ephedra, the folid gums, empyreumatic oils, and other substances of strong and offensive odour. But, although these remedies were generally administered at one period, and were much extolled for their antispasmodic powers, they seem to have lost their high character, in a great measure, and are much less employed than heretofore.

Several remedies have also been introduced, as *species*, in the dilmca in question; i.e. as remedies which posseoi a peculiar influence over it, independently of any sensible quality or operation. Such are the viscous quinquecursus, or milletoe, the cardamine pratensis, agarnicus muscarius, &c. Experience has not sanctioned the recommendation of these medicines, which appear to be nearly inert. If the milletoe were ever beneficial, it was probably in those times when it was an object of religious superstitious, and operated through the medium of an impression on the mind. On the same principle, taking remedies that excited horror may have sometimes succeeded in curing the disease; such as the powder of human skulls, *puvris cranii*, &c. A pamphlet has been published lately, however, in which the specific efficacy of the milletoe is again contended for by Dr. H. Frater. But the cafes, there related, are mentioned too briefly and uncircumspectly, that no just inference as to the means of cure can be deduced; and the weight of negative evidence is, on the other hand, so great, that we are disposed to attach little credit to the milletoe. We have employed it, since the publication of the pamphlet alluded to; but without any effect.

Dr. Fothergill, whose experience and sound observation led him to infer, that plethora was the most frequent cause of *curable* epilepsies, and the symptom of diet and evacuation, before mentioned, the most effectual means of cure, was disposed to attribute the reputed efficacy of all the last-named remedies for epilepsy to a very different operation, than was intended by the prescriber: namely, to their impeding digestion, and consequently preventing incurring plethora. "Valerian," he says, "cafeor, the folid gums, empyreumatic oils, and, if there be any thing still more digustful, commonly make a part of the medicines proposed for this disease. There are some others, whose qualities, indeed, are not quite so repugnant to our taste and smell, such as the milletoe, and the *floras cardamine*; but to balance this difference, it is requisite to take those such a length of time, and in such quantities, as make them not less digustful at length. May not, therefore, both these kinds of medicines, and moft of those made use of as specifics from ancient authority, now and then confirmed with instances of benefit, derive the great part of their confequence from their quantity, or their digustful qualities, which, by lefßening the appetite, allow nature to recover herself, and shake off a disease, which indulgence principally produced." (Med. Obst. and Inquir. vol. vi. p. 77.)

The sight of others in a fit of epilepsy is the most common of the mental irritations which produce epilepsy; this, therefore, should be guarded against, especially among children, and more particularly in a family where epilepsy has already appeared. The famous cafes of epilepsy, thus communicated among the orphans at the hospital at Haerlem, are well known; (see Convolvul.) as well as Boerhaave's successful cure, by threatening a severe punishment (burning with a hot iron) to the first who should be seized with a fit. This counter-impression upon the mind, which Dr. Cullen whimsically terms the *tonic* of fear, was sufficient to obviate the effects of the other. (See Kauv Boerhaave impetun faciens, § 4 6.)

Some anti-epileptic powers have been attributed to opium, *Vol. XIII.*

**Epilepsiom**, from *epilepsia*, I cannot forget, a term used by the old writers in *Medicine*, to express a loss of memory.

Gen. Ch. *Cal. Perianth Inferior*, of one leaf, deeply four-cleft; segments oblong, pointed, coloured, deciduous. *Car. Petals four, roundish, broaded upward, cloven, spreading, inserted into the calyx between its segments. Stam. Filaments eight, awl-shaped, alternately shorter; anthers oval, compressed, obtuse. *Pist.* German inferior, cylindrical, very long; style thread-shaped; stigma thick, obtuse, either undivided or four-cleft, the lobes revolute, downy. *Peric.* Capsule very long, cylindrical, with four furrows, *U* n
four cells, and four valves, with a longitudinal linear partion originating from the centre of each. Recept. columnar, square, its angles attached to the partitions, which at length separate from it. Seeds numerous, oblone, crowned with down, and affixed in two rows to each angle of the receptacle.

An elegant genus of plants, with flowers of a paler or deeper rose-colour, natives of watery or boggy situations, chiefly in the cooler or mountainous parts of Europe. The roots in all are perennial, and often creeping. Leaves undivided. Flowers spikes or racemose, terminal. Stamens in some direct, in others declining.

E. angustifolium, Linn. Sp. PI. 403. Curt. Lond. sace. 2. t. 24. Engl. Bot. t. 1947, called the French or Perian Willow, or Rosebay Willow-herb, is one of the most hardy, though most common, of the whole. It rarely with us occurs wild, but thrives and blossoms abundantly in any garden, whether its situation be moist or dry, even in almost any part of London. Linnæus says, Fl. Lapp. n. 146, "it frequently, like a garden, surrounds the hut of the wild Laplander, who vies with Diogenes in the simplicity of his household furniture, but whose habitation seems the palace of a divinity, when this flaxen plant is in bloom." This is an instance, among many, of a truly alpine plant succeeding well in the smoke of a city, while others require the purest air possible.

EPILOGUE, . Epilogus, in Oratory, &c. The perforation, or last part of a discourse, or treatise; containing ordinarily a recapitulation of the principal matters delivered. The word is Greek, ἐπίλογος, formed of the verb ἐπίλάγω, I say after; the epilogue being the end, or conclusion of a discourse.

EpiLOGUS, in Dramatic Poetry, is a speech addressed to the audience, when the play is over, by one of the principal personages or actors in the piece; containing usually some reflections on certain incidents in the play, particularly those of the part of the person who speaks. In the last part of a tragedy, the epilogue has usually something of pleasantrity in it; intended, perhaps, to compose the passions roused in the course of the representation, and send the audience away in good humour; though how far that design is good and laudable will bear some dispute: an ingenious author in the Spectator compares it to a merry jig on the organ, after a good sermon, to obliterare any impressions that might have been made thereby, and send the people away just as they came.

In effect, though the epilogue, in this sense, may seem an abuse, yet it has the countenance of antiquity; the Romans had something of the same nature, though under another name. Their exodum was a kind of farce, brought on the stage when the tragedy was over: "at quicquid lacrymarum ac tritiae cepit extaegit et affictus, hujus spectaculi ritis detergert," says the Scholastra of Juvenal. The epilogue is but of modern date, much later than the prologue. Many, indeed, have taken the exodum of the ancient Greek drama for an epilogue, because Aristotile defines it to be a part rehearsed after the chorus had sung for the last time; but in reality, it was of a quite different nature. The exodum was the last of the four parts of the tragedy; containing the unravelling and catastrophe of the plot, and an account of our last, or fifth act.

EPI MED TINUM, in Botany, as at present understood, is certainly different from the Mepoknus of Dioscorides, which seems to be Offania Lanata, though his description does not exactly agree even with that plant. The derivation of the name has always appeared obscure. Ambrofius deduces it "from μεξων, to close, or shut up, because the leaves conceal the flowers; or from μεξως, because of its growing frequently in Media." Neither of these is a satisfactory, and the word seems rather to have a reference to the plant μεξως, a Campanula, or something very near that genus, which immediately precedes it in Dioscorides. However this may be, the name Epimenium is now universally applied to the Barron-wort. Linn. Gen. 20. Schreb. 79. Wild. Sp. Pl. v. 1. 660. Sm. Fl. Brit. v. 187. Prod. Fl. Ger. 193. Mart. Mill. Dict. v. 2. Julff. 287. Tourr. t. 117. Clafs and order, Tetradria Monaquia. Nat. Ord. Corydalis, Linn. Berberidae, Juss. Gen. Ch. Col. Perianth inferior, of four ovate, obtuse, concave, filiform, spreading, deciduous leaves, placed directly under the petals. Cor. Petals four, ovate, obtuse, concave, equal, spreading. Nectaries four, pouch-shaped, blunt at the base, the stamens and styles being fixed to the receptacle by the edge of their orifice. Stam. Filaments four, awl-shaped, pointed close to the style; anthers oblong, erect, of two cells and two valves, the latter separating from their base upwards, leaving the partition free. Pfl. Stem superior, oblong; style shorter than the germ, as long as the stamina; stigma simple. Petal. Pod oblong, pointed, of one cell and two valves. Seeds numerous, oblong.

Eph. Ch. Petals four. Nectaries four, poutches lying on the petals. Calyx opposite to the petals, caducous. Pod superior, of one cell, with many seeds.

E. alpinum. Linn. Sp. PI. 251. Engl. Bot. t. 438. Fl. Ger. med. t. 150. Ger. em. 480. The only species, a native of shady mountainous places in several parts of Europe, not very difficult of cultivation in our gardens, flowering in May. The root is perennial, creeping, slender, blackish. Stems upright, simple, about a foot high, round, smooth, bearing one large, twice or thrice compound leaf, divided irregularly in a three-fold order, and composed of large, pendent, tremulous, thin, delicate, heart-shaped, pointed, and ciliated smooth leaflets, glaucous beneath; and one upright paniccle, alternately branched, whole stalks arc red, and rough with glandular hair. Flowers singular and elegant, drooping, with dark red petals, and yellow pellucid nectaries. Dr. Smith, in his English Botany, suggests that "perhaps what is called the item ought to be reckoned only the foot-leaf of the leaf, which, as in Taraxa, bears the flower-ark.

EPI MIN ID ES, in Biography, a Cretan philosopher and poet, who was contemporary with Solon, and of whom many fables are related. Among others it is said, that, being bent by his father in search of a straying flock, he slept in a cave, where he repose himself for 30 years, and when he awoke, found to his surprise, that he was become an old man, that every thing about him was become new and strange. It is also recorded of him, that he could diffuse the soul from his body, and recall it at pleasure; and that he had familiar intercourse with the gods, and possesséd the gift of prophecy. Most of these fictions may probably have originated with the Cretans, who were, to a proverb, famous for their powers of invention. (Titus, i. 12.) The more credible account of Epimenides is, that he was a man of superior talents, who pretended to intercourse with the
the gods, and in order to justify his pretensions, lived in retirement upon the spontaneous productions of the earth, and practiced various arts of impiety. At the time of his pretended inspiration he might, possibly, have the art of appearing totally infensible and entranced, which would be considered by ignorant and deluded spectators as a power of dismissing and resembling his spirit. Such was his reputation for sanctity, and for the performance of religious rites, that, during a plague in Attica, which happened in the 46th Olympiad, about 596 years B.C., the Athenians sent for him to perform a sacred incantation; in consequence of which, as it is said, the gods were appeased and the plague ceased. Of this ceremony we have given a particular account under the article Altar. On occasion of this visit to Athens, Epimenides became acquainted with Solon, the Athenian legislator, who is said to have disapproved the conduct of the Athenians in this instance of superstition; and yet, avoiding himself of the advice of the philosopher in compounding his celebrated code. The Athenians, however, were delivered from the peddle, and were disposed liberally to desire Epimenides for his services. The philosopher declined accepting their offered recompense, and contented himself with a branch of the sacred olive, which grew in their citadel, and with this he returned to his native country, after having concluded a league between the Cretans and the Athenians. Soon after his return to Crete he died, as Laertius says, at the age of 157 years; or, as the Cretans pretend, at the age of 299 years. The superstitious Cretans paid him divine honours after his decease; and he has been reckoned by some the 7th wife man of Greece, to the exclusion of Periander from this number. Laertius enumerates a variety of pieces written by Epimenides, both in prose and verse. Among the former was a treatise "On Sacrifices," and "An Account of the Cretan Republic;" and among the latter "The Genealogy and Theogony of the Cretan Gods," "Arch of the Building of the ship Argo, and Jason's Expedition to Colchis;" and "The Life of Minos and Rhadamantus," in 4000 verses; "Of Oracles and Rhetorics," mentioned by St. Jerome, from which St. Paul is said to have taken the quotation in his epistle to Titus, ch. i. 12. Laer. i. c. 10. Brucker's Hist. Phil. by Enfield, vol. i.

EPIMETRON, was and μετέρω, measure, in Antiquity, an allowance given to the tax-gatherers in the Roman provinces, over and above the just quantity of wine or grain they were obliged to furnish. The epimetrus, or over-measurer, in different provinces, was different, being always greater in those that were remote, than in the nearer provinces. The different kinds of things wherein it was given made likewise a difference in the quantity allowed. The reason of allowing an epimetrus, or over-measurer, was to make good the leakage of the wine and waste of grain, that would necessarily happen by transporting it to Rome.

The provinces whose taxes were converted into money, and paid in specie, were free from epimetrus.

EPIMORPHOS, επιμορφελος, superparticular, of μορφή, I divide, an epithet given to Galen to certain differences in the pulse with reference to their inequality as to the time of their beating. All times, rhythms, or modulations of the pulse, according to number, conflict, he observes, of equal or unequal proportions. Of equal, when the time of the division is equal to that of contraction; and of unequal, when the one of these exceeds the other; and this inequality may be from certain or uncertain excesses. The certain excesses may be either in multiple proportion, or as number to number, which is the epimorpha.
the Greek and Latin Poetry, denotes, 1. A feast, ceremony, or rejoicing, on occasion of a victory obtained. 2. A poem or composition, on the same subject. Scaliger treats expressly of the epitaph in the Poetics, lib. i. cap. 44.

EPINOI, in Geography, a small town of France, in the department of the North; 9 miles S. of Lille, and 9 miles N. of Donni.

EPINY CTIS, (from επι, and νυξ, night,) in Surgery, a kind of putrid, of the nature of the furunculus, originating in the night-time; or, according to Cælius and Paulus, attended at this period with the most pain.

EPIDODIUM, in the Ancient Music, a funeral song or dirge with the Greeks; called Memia by the Romans.

EPITACTIS, in Botany; according to Hedericus, from επιτακτιος, or επιτακτις, to conceal, or to grow together at the summit. In this sense the name may very well apply to the Helleborine of some authors, for which Haller and Swartz retain it, and which has always been taken for the επιτακτιος of Dioscorides, whose account of the matter is too short and vague to afford much light. The petals of this plant do indeed approach each other, towards the upper part, more than in many of the Orchides, and such an explanation is more correct than that of Ambroinii, who derives the word from επιτακτιος, ice, or επιτακτος, frozen, “because the herb grows in very cold places, as it were upon or above the ice;” which circumstance by no means applies to it. Haller in Act. Helvet. v. 4. 100. Hill. Stirp. Helvet. v. 2. 147. Swartz. Act. Holm. 1803. p. 231. t. 3. f. N. Traicts on Botany, 159. Schrad. Neus Journ. v. t. 62. Willd. Sp. Pl. v. 4. 83. (Helleborine; Tourn. t. 249. Serpia; Linn. Gen. 402. Schreb. 503. Juss. 65. Gartn. t. 14.) Clafs and order, Gynandria Monandria. Nat. Ord. Orchides.

Gen. Ch. reformed. Cal. three-leaved; leaflets directed, a little spreading; concave, acute. Cor. Petals two, rather smaller than the calyx, slightly spreading. Nectary a lip proceeding from the lower part of the style, tapering, or concave, or rarely a little longer than the calyx, deflexed, entire or cloven, concave or flat-thift, often furrowed above. Stem. Antler an hemispherical, moveable, permanent, terminal lid, of two cells, attached by its posterior edge to the top of the style; masses of pollen oblong, powdery, granulated, sometimes lobed. Pill. Gemen inferior, obovate, erect, furrowed, sometimes twisted; style erect, roundish, notched at the top; stigma in front, oblique, under the anther. Peric. Capsule inferior, oval, with five ribs and one cell, opening by clefts between the ribs. Seeds numerous, minute, tuminate.

Swartz and Willdenow enumerate fourteen species of this genus, eight or nine of which are British. They are divided into two sections, eight of them having an undivided lip, and fix a cloven one. The former are, 1. E. latifolia. (Serpia latifolia; Linn. Syll. Veg. ed. 14. t. 3. Sm. Flor. Brit. 942. Engl. Bot. t. 260.) A native of cold, shady, rather mountainous woods, throughout Europe. The roots are perennial and creeping. Stems simple, about two feet high, leafy, roughish. Leaves ovate, or broad-lanceolate, ribbed and plaited, clasping the stem alternately. Flowers in a long terminal spike, with bracts at least as long as the germs, the lower ones longer than the whole flower. Calyx and petals of a brownish green. Nectary shorter than either, heart-shaped in front, purplish, acute.
399. We fee no advantage in changing the original specific name.

EPIPEDOMETRY, of $\pi\tau\omicron\sigma\tau\omicron\alpha\varsigma\varphi\iota\alpha\varsigma$, foot, and $\mu\nu\tau\omicron\sigma\tau\omicron\alpha\varsigma$, I meaffer, in Mathematics, signifies the measuring of figures that stand on the same base.

EPIPETRON, in Botany, a name given, by Theophratius and Ariotle, to a plant, supphed by many to be the same with the empertrum of Dioscorides. But there is great reason to doubt whether the epipetron of the two older authors be the same plant; and whether, if they mean two different plants by this name, either of them agree with the empertrum of Dioscorides. Theophratius says, that his epipetron never flowers; and Ariotle says, that his epipetron grows on rocky places, and continues to grow after it is taken up, as the orpin and some other plants will do.

EPIPHÆNOMENA, of $\sigma\tau\omicron\alpha\kappa\iota\nu$ and $\varphi\iota\omicron\omega\nu\varsigma$, symptom, in the Writings of the Ancient Physicians, a term used to express such of the symptoms, in certain difeases, as did not usually appear till the time that the disease was actually formed, called also epiphigmena.

EPIPHALLUS, in the Ancient Myth. It appears by a passage in Euflathius, often quoted by Meurinus, that this was also the name of a dance, performed to flates.

EPIPHAN, in Geography, a town and district of Rufsa, in the government of Tula, situated on the Don.

EPIPHANES. See EPIPHANUS. This term in Greek, $\epsilon\pi\rho\iota\phi\iota\nu\varsigma$, denoted eminent or illuftrious, and thus it was applied to Antiochus, which fee.

EPIPHANES, of $\sigma\tau\omicron\alpha\kappa\iota\nu$ and $\varphi\iota\omicron\omega\nu\varsigma$, an epichet given to Jupiter, because he manifested his preference by lightning and thunder, &c.

EPIPHANIA, a word used, by some of the ancient physicians, to express the external habit of the body.

EPIPHANIA, in Ancient Geography, a town of Asia Minor, in Cilicia, near the Mediterranean, between the branches of mount Amanus, on the river Carus; probably denominated Epiphania in honour of Antiochus Epiphanes, king of Syria, who possessed Cilicia. We learn from Tactius, that the part in Cilicia, in which this town was situated, became subject to the dominion of Rome under Lucillus, about the year of the city 685. It was afterwards episcopal under the metropolis of Anazarba.

EPIPHANIA on the Ephratae, a town of Asia, situated on that river.

EPIPHANIA, a town of Syria, on the Orontes; which was subject to the Romans about the year 69, during Pompey's expedition into the territory of Amanus and into Cossocyria. This town was situated between Larissa and Arthusa; and it was reckoned by the Orientals one of the most ancient towns in the world, founded, as they imagined, by Hamath, one of the sons of Canaan; and that its name was changed by the Macedonians in honour of Antiochus Epiphanes. (See Hamath.) It was episcopal under the metropolis of Apamæa.

EPIPHANIA, a town of Asia Minor, in Bithynia, Steph. Byz.—Allo, a town of Asia, on the banks of the Tigris, called by Steph. Byz. Arfecitarta.

EPHUSUS, of EPHIINES, in Biography, the son of Carpoctes, or Carpoctates, an heretarch in the second century, was instructed by his father in the whole circle of the sciences, and particularly in the Platonic philosophy; but his death, when he was 18 years of age, disappointed the hopes which the Carpoctataians entertained concerning him. After his death he was honoured by them as a god, particularly in the island of Cephalonia, where a temple was erected to him, with altars, a grove, and a museum, and where the day of his nativity was celebrated with hymns, libations, fakes, and feastings. These are the reports of Clement of Alexandria and of Epiphanius, unconfirmed by the testimony of other writers. Epiphanius is now called with the Valentinians. Larnder Hist. Heret. c. iii. § 1.

EPHUSUS, bishop of Salamis in the island of Cyprus in the fourth century, and dignified by the Catholics with the title of Saint, was born in the vicinity of Eleutheropolis, in Paleflene, about the year 320. In his youth he went into Egypt, where he inclined to the sect of the Gnostics, but separating from them, he joined himself to the Egyptian Afcetics, imbibing their principles and conforming to their manners. In his 20th year he returned to his own country, and became a disciple of Hilariun, the facher of Paleflene monkery. After some time he founded a monastery at Bezanduco, the village in which he was born, over which he prided for the greatest part of his life. In 367 or 368, he was appointed bishop of Salaminis, afterwards called Conflantia, where his piety and fanctity were held in high estimation, and where he was affidually employed in writing defences of the orthodox doctrines against the attacks of hereticks. His zeal, howevcr, involved him in many troubles, which embittered a considerable portion of his life. One of the principal circumstances which contributed to embarrass and embroil him, and to entail disgrace on his memory, was his inverte-terte opposition to the opinions of Origen. This produced a contest with John bishop of Jerusalem, who favour- ed their opinions, which, after many mutual invectives and recriminations, terminated in a breach between the two bishops, that convailed the eastern churches by the hatred and persecuting spirit manifested in the conduct of their respective partisans. Theophilus, bishop of Alexandria, was an active adherent to the cause of Epiphanius, and held a council in 399, which condemned the writings of Origen, and prohibited all perons from reading them, or having them in their possession. This example was followed by a council of the bishops of Cyprus, summoned by Epiphanius himself in the year 401. Failing of successe by the decrees of these councils and by the persecution against Origen, which they were the means of inflicting, the determined and zealous prelate took a voyage to Confantia, in order to induce the bishops in that city to adopt and sanction the decrees of Alexandria and Cyprus. On his arrival, he declined holding any intercourse with Chrysolom, bishop of that city, unless he joined in the condemnation of Origen, and in withdrawing his protection from the exiled Egyptian monks. Exasperated by the disappointment of his views, he resolved to present himself to the people in the church of the Apostles, and openly to condemn the books of Origen, and all his advocates. But before he could execute his purpose, he was warned of the irregularity of his proceedings, and of the sedition which they might occasion; and he, therefore, thought it most prudent to abandon his design. His next attempt was that of interfetng the court in his favour; and to violent and implacable was his zeal against those who favoured Origen,
that when the empress Eudoxia befought his prayers in behalf of the younger Theodosius, who was dangerously ill, he assured her that he should not die, if she would con- 
form to the heretics, who were sheltered under the 
emperor's patronage. The princess very properly re- 
proved this arrogant and impious message; and his impetuosity was 
also checked by the Egyptian monks, who convinced him of 
the antiquity of the principles of the persians, against 
whom he had been indolently exciting universal indigna- 
tion. Thus foiled and abashed, he set out on his return 
to Cyprus, and died either on his voyage, or soon after his 
return, in the year 402 or 403, at a very advanced age. 
The piety of Epiphanius was unquestionable; but it was 
blended with a gloomy superstition, which led him to pro- 
mote the ascetic discipline of the chiffer, and to employ 
his episcopal influence in multiplying monastic institu- 
tions. In offices of charity for the relief of the indigent, he ex- 
pended not only his own private fortune, but the greatest 
part of the revenues of his church, and large sums entrusted 
to his disposition. His learning was considerable, for, according 
to St. Jerome, who mentions him in terms of high com- 
mendation, and calls him τόῳ ἡγαστῷ ὑμώκος, a man of five lan- 
guages, he understood Greek, Syriac, Hebrew, Egypti- 
yan, and partly Latin. It is allowed, however, that he 
was deficient in judgment, and unskilful in wielding the 
weapons of controversy. Careless in his transcriptions from 
an accomplished author, and credulous in admitting unauthenti- 
cated reports, he has been betrayed into various contradic- 
tions and absurdities, so that his works, with respect to au- 
thority and reference, are depreciated in value. His style 
is mean, harsh, and unpolish'd, without peripeties, and 
without connection. In his remaining works he has given 
several catalogues of the books of the Old and New 
Testament. His canon of the Old Testament was much 
the same with that of the Jews. (See CAXON.) The books of the 
New Testament received by him are the same with 
those generally received by us. For both these classes 
of sacred books he professed the highest regard; nor does he 
ever make use of Christian apocryphal books, written in 
the name of apostles and falsely ascribed to them. With re- 
spect to the books of the New Testament, he says, that 
Matthew preached, and wrote his gospel in Hebrew, and 
that he was the only writer of the New Testament who 
used this language. He had heard, however, that the 
gospel of St. John, and the Acts of the Apostles, had 
been translated from Greek into Hebrew, and were in the 
library of the Jews at Tiberias. Matthew wrote first, and 
soon after Mark, who was Peter's companion at Rome. 
The third gospel, in his enumeration, was that of Luke. 
John wrote his gospel at the age of 90 years, and Epipha- 
niust says, that it was occasioned by the errors of the Ebion- 
ite, the Cérinhitas, the Merinthians, and Nazarites. 
He ascribes the book of the Acts to Luke. He frequently 
quotes the epistle to the Hebrews as Paul's; he also cites 
the epistle of James, the two epistles of Peter, John's first 
and second epistles, and the Catholic epistle of Jude. He 
also received the book of Revelation. Of the baptism of 
Christ, he says, that it took place when he was 29 years 
and 10 months, thus understanding St. Luke's words, 
iii. 23. He says, there are two passovers in our Lord's mi-

nistry, according to St. John's gospel, and that he suffered 
at the third passover, in the 33d year of his life on earth; 
and therefore he did not think the "feast of the Jews," 
mentioned John, v. 1. to be a passover. He says, that 
the apostles did not preach themselves, but Jesus Christ, Lord. 
Therefore there was no festival, or church, called after the 
apostles; for we never heard of Petriasis, or Paulianos, or 
Bartholomew, or Thaddæus, but of Christia via only; as 
they were called at Antioch. The works of Epiphanius 
were first printed in Greek at Batli by Oporinus in 1544; 
and the subsequent impressions have been numerous, of 
which the most valuable is that published at Paris in 1632, 
in two volumes folio, by the learned Petavius, who gave 
a new Latin version, with critical notes and observations. 
This edition was afterwards printed at Cologne in 1682, in 
two volumes folio. Cave's H. L. vol. i. sub fac. Arius, 

Epiphanius, surnamed "The Scholar," a native of 
Italy, and an eminent Greek and Latin scholar, was born 
about the year 510. At the request of Caesidorus he trans- 
lated into the Latin language the ecclesiastical hitherto 
Socrates, Sozomen, and Theodoret, a version more entitled 
to commendation for its fidelity than its elegance. 
Caesidorus was also indebted to Epiphanius for the improved 
version of the "Codex ephesius," or collection of synodal 
letters of the year 458, addressed to the emperor Leo, in 
defence of the council of Chalcedon. Cave H. L. vol. i. 
sub fac. Eutych.

Epiphanus, patriarch of Constantinople in the 6th cen- 
tury, strenuously vindicated the orthodox doctrines against 
the Eutychians, and after elevation to his dignity in the year 
520, procur'd the condemnation of the latter in a synod 
of bishops held at Constantinople. Whilst he was patriarch, 
the decrees of the council of Chalcedon were confirmed, and 
a reconciliation was completed between the churches of 
Constantinople and Rome, after a schism which lasted 35 
years. Five letters of this patriarch to pope Hormidas on 
the subject of the union are extant in the 4th volume of the 
collection of the Latin councils. Cave H. L. vol. i. 
sub fac. Eutych.

EPIPHANY, in Ecclesiastical Antiquity, the feast of 
kings; a double festival, of the first rank, solemnized on the 
5th of January, commonly called "Twelfth day," in honour 
of the manifestation of Jesus Christ to the kings, or 
magi, who came to adore, and bring him presents. 
The feast of Epiphany, now held in honour of the adora- 
tion of the magi, had its first institution among the Greeks, 
from a different object, viz. our Saviour's birth; and was 
called theophany, and epiphany, that is, appearance, and 
manifestation, of God.

Pope Julius, who reigned from the year 337 to 352, 
was the first who taught the church to distinguish the feasts 
of the nativity and epiphany. Papæbroch. Paral. ad Conat. 

The word in the original Greek, ἐπιφάνεια, signifies ap- 
pearance, or apparition; and was applied, as some critics 
will have it, to this festival, on account of the star which 
appeared to the Magi. St. Jerome and St. Chrysostom, take 
the Epiphany for the day of our Saviour's baptism, when he 
was declared to men by the voice, "He is Filius meus 
dilectus, in quo mihi complacui: This is my beloved Son, 
in whom I am well pleased." And accordingly it is still 
observed by the Coptics and Ethiopians in that view. (See 
Ludolph, Hist. Aethiop. lib. xxi. cap. 2.) Others consider 
that the feast of Chrismas, or the nativity of our Saviour, 
was held in diverse churches on this day; which had the 
denomination Epiphany, or appearance, because of our 
Saviour's first appearance on earth, at that time. And 
it must be allowed, that the word is used among the ancient 
Greeks fathers, not for the appearance of the star to the 
magi, but for that of our Saviour to the world. In which 
respect, St. Paul used the word ἐπιφάνεια, epiphania, in his 
second epistle to Timothy, chap. i. ver. 10. Ammianus 
Marcellinus makes mention of this feast, lib. xxi, cap. 2, 
and
and observes, that it was held in January. Upon which paflage Valerius, in his notes, endeavours to show, that the historian meant by Epiphany the feast of the nativity.

The heathen writers used the word epiphania in the like sense, viz. to express the appearance of their gods on earth. And the Christians, after their example, applied it, in the general, to express any appearance, or manifestation of the Deity.

Epiphania, in Botany, the name given by the ancients to the dodder, or cucuta, which grew upon the shrub they called phereus. This was the flabe of the modern Greeks, described by Honorius Bellus. It was a custom, among the old writers, to name the cucuta, or dodder, from the plant it was found growing upon, as they supposéd that it in some degree partook of the virtues of that plant. Thus that which grew upon thyme was called epithymus, and that upon the nettle, epiteura, and that upon flax, epilimum; fo of many others.

The shrub phereus was also called flabe by Dioscorides and Theophrastus; and hence this dodder was sometimes called folliculus.

Epiphaneia, in Botany, a term used, in the Writings of the Old Physicians, to denote such persons as were lean, and of a hot temperament, and whose veins, for that reason, appeared usually very turgid and prominent in the hands, &c.

Epiphnomia, (from εἰς and θεωρεῖν, to examine,) in Surgery, a violent inflammation, accompanied with pain, swelling, and redness. Also, a great internal heat: likewife, the affection usually called erysipelas.

Epiphnomia, (from εἰς and κτός, to inflame,) in Rhetoric, a fententious fort of exclamation, which is frequently added after a narrative, or rehearsal of any thing remarkable; containing usually a lively, close reflection on the subject there spoken of and intended to give it greater force, and render it more affecting to the hearers.

Such is that of St. Paul, when, after discounting of the rejection of the Jews, and the vocation of the Gentiles, cries out,

"O the depth of the wisdom and knowledge of God!"

Such also is that of Lucertius, after relating the story of Agamemnon's sacrificing his daughter Iphigenia:

"Tantum religio potuit suadere malorum."

This figure is frequently expressed in a way of admiration. Such is that of Cicero, when after having observed, that all men are defirous of living to an advanced age, but uneafy under it when attain'd, he makes this just reflection upon their conduct: "So great is their inconstancy, folly, and perverfeness!" (Cic. de Senect. c. 2.)

The epithetam is usually expressive of the milder and more gentle passions, and is not so vehement and impetuous as exclamation.

Epiphora, (from κατακεφαλάζω, to carry with force,) in Surgery. The original import of the word "epiphora" seems to have been a violent determination of fluids to any part of the body. At present, however, all surgeons confine the meaning of the term to an affection, in which the tears, not being able to pass in a proper manner down into the nofe, accumulate in front of the eye, and trickle over the cheek. The disorder is also not unfrequently denominated the "watery eye."

Whoever is in the habit of consulting surgical books, will soon perceive, that writers do not make a clear diftinâtion between the epiphora, and some flates of the fistula lachrymalis. Thus Mr. Ware has particularly considered the species of epiphora, which, he says, "is produced by an obstruction to the free passage of the tears from the eye into the nofe. This obstruction (he adds) may take place either in the ductus leading from the puncta lachrymalis into the lachrymal fac, or in the fac itself. When the ductus are obstruèt, a cafe which rarely occurs, the tears fall over the cheek, and tho fac is constantly empty. Preffure on the fac, therefore, can produce no regurgitation, either of tears, or mucus, into the eye. The method of cure is here evident. A small probe of a suitable size must be introduced through the puncta of the obstruèt ducts into the fac, and this operation be daily repeated until the obstruèt be removed. But, (continues Mr. Ware,) the part in which the obstruèt more commonly lies, is in the fac itself; and in this case, the tears, mixed sometimes with mucus, flow back into the eye through the puncta, when pressure is made on the fac." Now, this latter kind of disease, Pott, Scarpa, and other distinguished surgical authors, consider only as one stage of the fistula lachrymalis.

We do not mean, however, by what has been stated, to make any attempt to defend the manner in which the expression "fistula lachrymalis" is employed; our sole aim is to shew, that, unless a line of distinction is drawn between what should be called "epiphora," and what "fistula lachrymalis," the comprehension of the subject is rather embarrased, than promoted, by having two different terms, which so glaringly encroach upon each other in the extent of their signification. The epiphora, in the meaning of a mere weeping of the eye, may arise from a variety of causes, which must be removed, ere the complaint can be cured. An encanthis, or any other kind of tumour in the inner angle of the eye, or a polypus in the nofe, an eczemat, a trichitis, &c. may obstruèt the ducts flowing of the tears into the nofe, and thus make them fall over the subjacent cheek, so as to occasion epiphora. This latter disorder may also be the consequence of a part of the caruncula lachrymalis having been lost, either by disease, or an unskillful employment of the knife in some previous operation. An epiphora is always attendant on obstructions in the ductus nasales. Mr. Ware observes, with regard to another species of epiphora, originating from a too copious secretion of tears, that, if it does not depend on an affection of the mind, its more remote cause is usually an inflammation of the eye. In this instance, a cure is to be effected by subduing the ophthalmis, and afterwards strengthening the eye by mild astringent applications, such as cold water, either alone, or containing a small quantity of the zincum vitriolatum.

When the membrane, which lines the lachrymal fac, is in a morbid state, the mucus which it secretes is often so thickened, that it becomes incapable of passing through the fac, and lodging in this situation, prevents the natural and regular defecât of the tears from the eye into the cavity of the nofe.

This species of epiphora has occasionally been benefited by the unguentum hydrargyri nitriti, applied to the edges of the eye-lids, and rubbed into the skin over the lachrymal fac. Relief is also alleged to have been derived from the use of stimulât applications to the inflamed of the nofe, which applications are supposèd to have acted by increasing the secretion from the pitsitary membrane.

However, we must confess, that no men of experience, at the present day, place sufficient reliance on the preceding methods, to recommend them to be tried by their patients. At the same time it should be understood, that these plans are sometimes exceedingly proper to be adopted in conjunction with other more efficacious measures.
In the year 1718, Mr. Anel recommended the introduction of a probe, and then the injection of a fluid, through the punctum lachrymale, with a view of clearing away whatever matter might prevent the tears from readily finding their way through the lachrymal sac and nasal duct into the nose. Mr. Anel relates, that he accomplished many striking cures in this manner; and Heister confirms the efficacy of the plan, by appealing to his own practice, in which he had often produced a complete recovery in the short space of three days.

In the year 1780, Sir William Blizard considered, that when water was injected through the punctum lachrymale, it not only had but very little specific weight, but was driven through the lachrymal sac in an unfavourable direction. These reflections led him to make the proposal of introducing quicksilver through a small pipe, which communicated with a long tube full of this metal. Sir William Blizard was of opinion, that the quicksilver, in consequence of its great weight, would have more power when the sac was filled with it, of removing the obstrunction, than the mere injection of water. This gentleman also, in a paper read to the Royal Society, states, that he had produced a cure by the introduction of quicksilver in an example which had lasted seven months; and that the mercury passed readily through the ductus nasalis, at the third and fourth times of repeating the operation.

When the celebrated Mr. Ware was in Paris, in the year 1791, he learnt from Melleurs Grandjean and Mondier Arrachert, eminent oculists in that city, that the plan of injecting water through the puncta lachrymalia, in incontinent cases of fistula lachrymalis, was not given up in France. Mr. Ware even saw some troublesome cases cured on the continent in this way. Hence he was determined, on his return to London, to give Anel's operation a fuller trial than he had previously done. For this purpose he got Mr. Pepys, in the Poultry, to construct a small silver syringe, with pipes of different sizes adapted to it.

The following case, which afforded Mr. Ware the first opportunity of ascertaining more carefully the efficacy of Anel's treatment, is related in his own words, and will serve to inform the reader of several useful practical circumstances.

A lady in Great Russell-street came under my care, who for many months had been subject to an epiphora of the left eye, which prevented her both from reading and working with her needle, without undergoing great inconvenience. Whenever she employed herself in any way that required close attention, her eye became over-spread with tears, and the sight was so much confused, that it obliged her to leave off almost as soon as she began. A great variety of remedies had been applied, under the direction of different medical men, but none of them produced any essential amendment. On examining the eye, I observed that the conjunctiva, near the inner angle of the eye-lids, was slightly inflamed; and on pressing the lachrymal sac with my finger, I perceived that a tear regurgitated through the lower punctum. This appearing to be a proper case for the use of the syringe, I immediately determined to employ it. But I found, that though a tear came through the lower punctum on my pressing the sac, yet this punctum was so small that it would not admit the point of the smallest syringe I then had. I introduced into it, however, a small probe, and by means of this I so far dilated the orifice, that it admitted the point of the syringe on the next day without any difficulty. Upon my first using the injection, the water escaped through the upper punctum almost as fast as it was introduced through the lower; but, notwithstanding this, I preferred in using the liquor on, until the whole contents of the syringe were exhausted. I repeated the injection three times the same day in immediate succession. The lady, however, was not sensible that any part of the water passed through the duct into the nose; and indeed it soon became evident that none had passed; for, having cleared her nose before I began, on her blowing it again immediately afterwards, she could produce no moisture on her handkerchief. I repeated the operation three times, both on the second and on the third day; and every day, during the time that the water was passing, I not only endeavoured to prevent it from coming through the upper punctum, by covering it with the point of my finger, but I occasionally pressed the lachrymal sac in order to give the water an inclination downward. On the fourth day I very plainly perceived, on the patient's clearing her nose after the operation, that a part of the water had passed through the duct; and, the next morning, I had the satisfaction to hear, that the eye, on the preceding day, had watered much less frequently than it had done for a considerable time previous to it. I repeated the process above-mentioned about twenty times, in as many days, and observed that the quantity of water which passed through the duct was augmented every time I used it. The tears, after this, recovering their natural course, the lady recovered the power to read and work without any inconvenience. (See Ware on the Epiphora.)

Mr. Ware, in his practice, uses common water for the injection, sometimes in a cold state, but more frequently warmed. The pipes which this gentleman employs, are also much shorter than the one represented by Mr. Benjamin Bell in his System of Surgery, (vol. iii. pl. 37). They are also a little arched towards their point. Mr. Ware thinks, that when they are made in this manner, they can be more conveniently introduced into the punctum lachrymale than when long and straight. He recommends always having ready several pipes of different sizes, and using the largest one which can be introduced without pain. He finds it also advantageous to fland either behind the patient or on the side opposite to that of the diseased eye; and high enough to have a full command of the patient's head. Thus the operator will gain a complete view of the lower punctum, and will also be in a convenient position to receive the pipe of the syringe. Mr. Ware, moreover, advises us to remove the finger from the lower eye-lid as soon as the pipe is introduced, and to place it over the upper punctum, so as to prevent the fluid from escaping through this aperture. The same finger is likewise to be occasionally used in making pressure on the lachrymal sac, in order to aid in forcing the injection down into the nose.

Mr. Ware has published some additional remarks on the epiphora, and makes some very valuable observations on the treatment of another species of the disorder; we allude to that kind which proceeds from a thickening of the membrane which lines the lachrymal sac and duct, and a spasmodic contraction in any part of the passage, conjoined, perhaps, with a morbid secretion of thickened mucus. Mr. Ware imputes a few occasional failures, in the above simple mode of treatment, to the causses of the disease being sometimes of this nature. The following extract will explain the different methods to which this celebrated oculist has recourse in different cases.

"I in general begin the treatment by injecting some warm water through the inferior punctum lachrymale, and I repeat the operation four or five days in succession. If, in this space of time, none of the water passes through the duct
EPI

Quick into the nose, and if the watering of the eye continue as troublesome as it was before the injection was performed, I usually open the angular vein, or direct a leech to be applied near the lacrimal sac; adding here a caution, that the leech be not suffered to fix on either of the eye-lids, lest it produce an extravasation of blood in the adjacent cells. About the same time that blood is taken away in the neighborhood of the eye, I usually vary the injection, and try the effects either of a weak vitriolic, or aodytone, lotion. In some instances also, when I have found it impossible, after several attempts, to inject any part of the liquid through the duct, I have introduced a golden probe, about the size of a bristle, through the superior punctum lacrymale, and, attending to the direction of the duct, have inflamed its extremity through the obstruction, and conveyed it fully into the nose; immediately after which I have found, that a liquid, injected through the inferior punctum, has passed without any difficulty; and, by repeating these operations, for a few successive days, I have at length established the freedom of the passage, and completed the cure. In other instances, I have recommended a strongly stimulative hermatabol to be sniffed up the nose, about an hour before the time of the patient's going to rest, which, by exciting a large discharge from the Schneiderian membrane, has sometimes also greatly contributed to open the obstruction in the nasal duct.

"Cannot occur very rarely which may not be relieved by some of the means above related." (Ware's Additional Remarks on the Epiphora.)

When the discharge has been fetid, Mr. Ware has sometimes found, that a vitriolic lotion, injected into the sac, has quickly corrected the quality of the matter.

Scarpa, in his "Osservazioni sulle principali Malattie degli Occhi," maintains, that the chief part of the yellow viscid matter, which accumulates in the lacrimal sac, is ferreted by the lining of the eye-lids, and by the little glands of Meibomius; and that the altered quality of this secretion has a principal share in the cause of the disease. He states, that the truth of this fact may at once be ascertained by everting the eye-lids; and especially the lower one of the affected side; and by comparing them with those of the opposite eye. The former will always exhibit an unnatural redness of the internal membrane, which has a villous appearance, all along the extent of the tarsus, while their edges are flaccid; and numerous varicose vessels are distinguishable on its surface. The follicles of Meibomius are also thick and prominent.

Hence, Scarpa advises making such applications to the inside of the eye-lids, as have a tendency to improve the quality of the secretion from them, as the same time, that attempts are made to remove the obstruction in the ductus nasalis. Mr. Ware, indeed, had previously noticed, that such treatment may occasionally be proper.

"When an epiphora is occasioned by an acrimonious discharge from the sebaceous glands on the edges of the eye-lids, itmust be evident, that injections into the sac will be very insufficient to accomplish a cure, because the sac is not the seat of the disorder. The remedies that are employed must be directed, on the contrary, to the ciliary glands themselves, in order to correct the morbid secretion that is made by them; and for this purpose, I do not know any application that is so likely to prove effectual as the unguentum hydrargyri nitriti of the new London Dispensatory, which should be used here in the same manner in which it is applied in common cases of the phlyctenulosis. It will be proper to cleanse the eye-lids every morning, from the gum that collects on the edge during the night, with some soothing application; and I usually advise to apply to them two or three times in the course of the day a lotion composed of three grains of white vitriol, in two ounces of oil, or elder-flower, water."

Mr. Ware very judiciously confines the plan of applying collyria to the eye by means of linen, wet in them; and he recommends eye文中 for the purpose, or infusing the fluid, between the eye and eye lids, with a camel-hair pencil, thoroughly wet in the application. (Additional Remarks on the Epiphora.)

Scarpa also extols washing the eye, three or four times a day, with a vitriolic collyrium; and, besides prattling the ointment recommended by Mr. Ware, he recommends Janin's ophthamalic ointment, to be smeared over the margins and lining of the eye-lids every morning and evening.

EPIPHYLOSPERMOUS PLANTS, of Mus, clove, beef, and cypræa feed, are the same with the capillaries, herbs which bear their seed on the back part of their leaves. See Capillary.

EPIPHYLLUM, in Botany, et, upon, and Clove, a leaf, from the mode in which the flowers grow upon a flat stem resembling a leaf, see Cactus Phyllanthus, ep. 49.

EPIPYSIS, in Anatomy, is a name given to certain parts of bones at a particular period of their formation. See Bone.

EPIPLASMA, from et, and paren, to spread, in Surgery, the name of an application to wounds: it consisted of wheat meal boiled in hydrelum.

EPIPOLOCE, Epiploca, in Ἐὐχοί, the name with cli- max, which fee.

EPIPOLOCELE, from ἔπιπλοσ, the omentum, and κελε, a tumour, in Surgery, an omental hernia, or rupture formed by a protrusion of a piece of omentum from the cavity of the abdomen.

Le Dran informs us, that in an epiplocele there is nothing to be felt, except a doughy softness, which neither absolutely yields to the touch, nor very sensibly refits it. The tumour has a fally unequal feel; and, when there is no firiture, it is perfectly indolent. It is more comprovable than that arising from protruded intestine, and, when the quantity of omentum is large, the epiplocele may, in some measure, be distinguished by its weight.

As the subject of omental ruptures will be particularly considered under the head Hernia, we shall, for the present, content ourselves with referring to the latter article.

EPIPOLOC, in Anatomy, a term applied to parts which belong to the epiploon, or omentum; thus we have epiploic arteries, &c.

EPIPOLOMPLHALON, from ἐπιπλος, the omentum, and μπλόα, the navel, in Surgery, an omental hernia protruding at the navel.

EPIPOLOON, in Anatomy, called also omentum navel, is a membranous expansion contained in the cavity of the abdomen: and continued from the peritoneal covering of some of the viscera. There are two very different productions, of the nature just decribed, distinguished by the appellations of urinm and majus, from their difference in size; and by thee of hepatico-gastricum, and coeco-gastricum from their situation. But when the epiploon, or omentum, is spoken of generally, the greater or coeco-gastric portion is understood. To the peritoneal surface of the large intestines are attached numerous small processes.

Vol. XIII,
which resemble the epiploa in their apparent structure, and are called appendices epiploicae.

Although the omenta are usually represented by anatomists as proceeds of the peritoneum, their organization differs essentially from the structure of that membrane. Their groundwork or basis consists of the most delicate and transparent membrane of the body; which is lacerated on the application of very slight force. This membrane is composed obviously of two layers, connected by cellular tissue, and containing numerous venous and arterial ramifications. A greater or smaller quantity of fat is deposited between these layers, and in the course of the vessels. When this deposition is very considerable, as in very corpulent individuals, or in animals who have been fattened for the slaughter, the peculiarly transparent delicate appearance of the omental membrane is entirely destroyed, and the part is converted into a layer of fat. Ordinarily, however, the adipous substance is confined to the neighbourhood of the blood-vessels, accompanying them in their subdivisions, but leaving intervals in which the membrane exhibits its distinguishing diaphanous appearance. In emaciated subjects, during the period of infancy, and particularly in the foetal state, the quantity of fat is very trifling. Under such circumstances we can observe most distinctly that the deposition of fat is confined to the course of the vessels. As the omenta are entirely unconnected to the parts on which they lie, as well as to those by which they are covered, both their surfaces are smooth and glinting, and moistened like those of other serous membranes, by a serous exhalation, which facilitates their motions over the neighbouring organs. Analogy warrants us in ascribing this secretion to the arteries of the omenta; and we consequently consider these organs as an extension of the general serous surface of the abdominal cavity.

Experiments on living animals, and surgical operations, clearly prove that the membrane of the omenta possesses little, if any, facility in its healthy state.

The lesser epiploa, mesogastrium, omentum minus, or hepaticogastrium, is the portion extended from the small arch of the stomach to the concave or under surface of the liver. It arises, behind, from the posterior half of the transverse surface of the liver; on the right it is continuous with the peritoneum covering the neck of the gall-bladder and the beginning of the duodenum; towards the left it is reflected immediately from the diaphragm. Advancing from these points, in two closely united layers, towards the stomach, it is attached to the end of the oesophagus, to the whole lesser arch of the stomach, to the pylorus, and commencement of the duodenum. At this line its layers divide, and expand over the stomach, one of them forming the superior, and the other the inferior peritoneal covering of this viscus. Between the layers of the lesser omentum are contained the hepatic vessels and biliary ducts, the coronary vessels of the stomach, some branches of the celiac plexus of nerves, and of the par vagum, and a few absorbent glands. Fat is rarely deposited here in so large a quantity as in the large epiploa, so that we can usually test through it that portion of the liver called lobulus fipgellus, which is in contact with its inferior surface.

The biliary ducts, the hepatic vessels with numerous accompanying branches of nerves from the celiac ganglia, and a considerable portion of the hepatic and cystic absorvents, connected end surrounded by adipous and cellular substance, are inclosed in the right edge of the lesser omentum. This part is called capsa Glissonii, from an English anatomist, who described it minutely in a work entitled "De Hepate."

The very margin of the omentum is occupied by the biliary ducts, and the neck of the gall-bladder. At this border the two surfaces of the little omentum are continuous. Behind the unconnected edge, round which the peritoneum turns, is found the foramen of Winslow, or foramen epiploicum, large enough to admit one or two fingers, which can thus be placed in immediate contact with the back part of the liver, and the inferior surface of the little omentum. This opening is situated between the neck of the gall-bladder, and the beginning of the duodenum, with the hepatic vessels in front, and the vena cava behind. It is not unusual to find its edges adhering together. We shall have occasion to mention it again after describing the large omentum.

The great omentum, epiploa majus, vel gastro-colicum, is the loose membrane, more or less loaded with fat, lying in front of the bowels, and generally meeting our eye in laying open the abdomen. It differs extremely in length and situation; in some cases reaching as low as the pelvis, and often defended in ruptures to the very bottom of the pelvis; while in others it extends but a short way below the umbilicus. It is always thicker in children than in adults. We often find it folded, or rolled on itself, and drawn to one part of the abdomen, or tucked up over the flomach, so as to leave the small intestines exposed to our immediate view. Its natural situation between the bowels, and the parietes of the abdomen, explains the frequency of its protrusion, together with the intestines, in hernia. Some anatomists affirm that it hangs lower on the left than on the right side of the abdomen.

The great omentum is a continuation of the peritoneal covering of the stomach. We have already described this as being formed by the separation of the two layers which constitute the little omentum. At the great curvature of the stomach these layers again coalesce into one sheet of membrane, are produced till they meet with the transverse arch of the colon, to incline which they again separate. Meeting at the opposite line they once more unite, and are continued under the name of the transverse mesocolon to the root of the mesentry. The origin of the great epiploa, when minutely examined, commences in the left from the end of the mesocolon, from the notch of Hartmann (where it forms a membranous connection between this organ and the stomach) and includes the whole of the great arch of the stomach nearly as far as the pylorus. The portion of membrane thus formed descends loosely before the transverse arch of the colon, and reaches to different lengths beyond it, constituting the anterior layer, or lamina gastrica of the great epiploa. At the lower or floating border this membranous expansion is doubled on itself, and turning upwards again to meet the transverse arch of the colon, forms the posterior layer, or lamina colica of Haller. On the right side the great omentum is not only attached to the transverse portion of this intestine, but is continued along its hepatic flexure, and for some way down the ascending colon. In some instances it reaches as low as the cecum. It is this lateral extension of the great omentum which constitutes the omentum colicum of Haller. Each of the layers is composed of a duplicature of peritoneum, as we have before stated, containing its proper vessels, and fat, and united closely by cellular tissue. It will be evident, from our description, that the great omentum is formed by the anterior layer alone in the space between the stomach and transverse arch of the colon; below the latter it is composed of the two layers, the lamina gastrica, and the lamina colica lying in contact with each other, but having no further connection in a healthy state of the opposing surfaces.

From this disposition of the great and little epiploa, there
there results, in conjunction with the inferior surface of the stomach, and the superior surface of the transverse mesocolon, a membranous bag, called usually the bag of the omentum. It offers every where on the inside a continuous serous surface, where the sides of the cavity are in close contact, but not adherent. The communication between this pouch, and the general cavity of the peritoneum, is formed by the foramen of Winslow. In order to demonstrate this fact, as well as to display the bag formed by the omentum, we introduce into this opening a pipe, surrounded by some soft substance, to prevent the escape of the air. By blowing gently we are enabled to separate the layers of the great omentum, which were in contact, and give to the whole the form of a large membranous bag, intersected by vessels and bands of fat, between which the membrane lies in pouches of various sizes. The lines formed by the stomach, and transverse arch of the colon, are but faintly seen, owing to the distention of the epiploon, which appears, as it were, suspended between them. To insure the success of this experiment some conditions are necessary, which we are not always happy enough to bring together. There must be no adhesion of surfaces, no large accumulation of fat, the subject young, and the whole conducted with the greatest delicacy, as the slightest rent in the membrane is sufficient to prevent success. In the fetus, and in young children, the lamina of the great omentum are easily separable throughout their whole extent. In adults, and more so in old persons, they are generally more or less united, so that the cavity of the omentum is confined to the space contained between the little omentum, the under surface of the stomach, and the transverse mesocolon.

The arteries of the great omentum are derived from the right and left gastro-epiploic vessels. They are in general small, and descend between the layers of the lamina gastrica, giving off branches on either side, which anastomose freely in every direction. At the lower border of the omentum the trunk is sometimes found to meet the transverse arch of the colon, with the arteries of which it intertwine in the course of the peritoneum, and join the large venous trunks which end in the vena portarum. The few nerves it posses are derived from the hepatic, and splenic plexuses.

The appendices epiploicae, or omentula, are principally observed on the first parts of the great intestine, being in length number on the sigmoid flexure of the colon and the rectum. They are irregularly disposed, hanging in fringes, generally unconnected with each other, sometimes united by intermediate membranous productions. They are usually dependent from the pouches of the intestine, and not from the longitudinal bands. They are obviously formed by the peritoneal covering of the intestines, united by cellular membrane, and containing a deposit of fat in almost every instance.

The use of the omentum is entirely unknown: The lesser epiploon offers a covering, and connecting medium to some nerves belonging to the stomach, and to the hepatic vessels and ducts. To the great epiploon many offices have been ascribed, none of which are satisfactorily ascertained. It varies somewhat in size according to the state of the stomach; since, when the latter is distended, it appears to enter between the layers of peritoneum forming the anterior fold, which lies in this case their form of omentum, and become the temporary covering of this organ. What may be the probable advantages of this construction it is not easy to decide. It has been supposed again to secrete a lubricating fluid from its surface, which preserves the free motion of all the chylous veins existing between each other. That it increases the serous surface of the abdominal cavity is evident; but in what manner this becomes an advantage disposition is more than we have the means of determining. The omentum iliacum, and appendices epiploicae are subject to the same observations, being similar in structure, and consequently in uses. It is certain that a considerable portion of the great omentum may be cut away, without any subsequent inconvenience to the patient, as has been frequently observed in cases of omental hernia.

An epiploon is found in all the mammals, where it is seen under every variety of form and size; so that no inferences can be drawn from its disposition in the particular. In all it contains more or less of fat between its membranes, the accumulation of which would appear to bear some proportion to the active, or sluggish habits of the animal. In the hibernating species during the winter, it is loaded with fat, which exists but in minute quantities during the summer.

The epiploon is not found in the other classes of animals, at least there is nothing analogous to it, but a membranous production between the liver and stomach, answering to the little omentum.

EPISCOLECELE, from πεπόλον, the omentum, ἔπολος, the peritoneum, and κέλεος, a tumour, in Surgery, an omental rupture, situated in the peritoneum.

EPICOMUS, in Botany, πεπόλον upon and πεπόλον, a beard, because the beard, or rather lip, is turned upwards. Gmel. Sib. v. 1. 11. 1. 2. f. 2. is Satyrium Epipogium of Linnaeus; Limodorum Epipogium of Schwartz and Willdenow. See LIMODORUM.

EPIMOLÆ, in Ancient Geography, was originally a piece of high ground without the city of Syracuse, and afterwards so little inhabited that it is not mentioned by Cicero in his description of that city. As it was the most elevated situation, and commanded Tyche and Neapolis, it was judiciously inclosed by Dionythus L., who enclosed it with a wall nearly 4 miles in extent. Its additional defence was the fortresses of Labdalon, at its bottom, on the east; and that of Euryalus, at its top, on the north. See Syracuse.

EPIPOMPEUTICA, in the Ancient Music. Volusius, in his poetic institutes, informs us, that this was a title given to songs composed and sung on occasions of great magnificence.

EPIPOROMA, from πεπόλον, to harden, in Surgery, a hard tumour on a joint: a tophus.

EPIPROSLAMBANOMINOS, Gr. in the Ancient Music, a name given to the string or found below prolabaminos, which word corresponds with gamut in the Guido scale.

EPIRE, in Geography, an ancient kingdom of Greece, now united with Albania, and included in that country, of which it forms the southern part, extending from Valona to Arta.

EPIROTS, in Ancient Geography. See the next article.

EPIRUS, a country of Greece, bounded on the east by Aetolia, on the north by the Adriatic, on the north by the Illyric and Macedon, and in the south by the Ionian sea. This was the ancient kingdom of the Aetolians, and was first called "Epirus Dodonæum," i.e. the country of the Dodonæum, and afterwards Epirus, or "the continent," that being the import of the Greek word Επιρος. It was anciently divided into three districts or provinces: viz. Chaonia, Thessproton, and Molossia; to which some authors add Caphsia, Caphio, or Calphire, and Pindus. This country is said to have been first peopled by Dardanæm, the son of Japhet, and grandson of Japhet, or at least by some of his posterity. We find among the nations which occupied Epirus, before they were united into one people under the common name of Epirots, the Selli, who are thought to have been the
first inhabitants of Epirus, and to have ministered in the temple of Dodona, the Chaones, the Moloffi, the Dolopes, the Dryopes, the Elinantes, the Peliqii, &c. The form of government which prevailed in Epirus was unquestionably monarchical, the whole country being divided into many small independent kingdoms. Homer, and other ancient writers, mention several kings who reigned here at the time of the Trojan war. But while the other Epirotic nations continued to be governed by princes of their own blood, the Moloffi became subject, at an early period, to the power of Pyrrhus, a foreign prince, whose descendants were distinguished AESIDE, from Aeacus, the founder of his family. Some of these petty kingdoms, in process of time, exchanged the monarchical into a republican form of government; for the Epirots informs us, that in his time the Theoprote and Chaones were governed, not by kings, but by annual magistrates. However, the kingdom of the Moloffi soon eclipsed all others; the Molossian princes having subjected the whole country, and united the several small kingdoms of which it consisted into one, known to the ancients under the name of Epirus.

Pyrrhus, the first of theAESIDE, was the sovereign of this country at the period when regular and authentic history commences; and he is said to have distinguished himself at the siege of Troy, when his father was killed. His reign soon terminated by a premature death; for he was murdered by Orelles in the temple of Delphi, on account of his having married Hermione, the daughter of Menelaus, who had been betrothed to Orelles. He was succeeded by his son Molossus, and several other princes, whose names it is needless to record. At length Admetus was the sovereign of Epirus, when Xerxes invaded Greece. This prince, upon the defeat of the Persians, wished to enter into an alliance with the Athenians, about the year 479 or 478 B.C. The successors of Admetus were Thyrymbas, who is said to have introduced the sciences into this country, and to have formed an excellent code of laws; and Alcetas, at whose death the kingdom was divided between his two sons, Neoptolomeus and Arybas, the latter of whom, when his brother died, became sole sovereign of the country, and conducted the government with great prudence, equity, and moderation. He also encouraged literature by extending his patronage to those who excelled in it. His niece Olympias, of whom he had taken great care, was married to Philip, king of Macedon, who had by her Alexander the Great. At his death, he was succeeded by Alexander, one of his nephews; who is said to have been little inferior, in courage and conduct, to his nephew Alexander the Great; but he had the misfortune to engage, on his first setting out, with nations inured to the toils of war, and no less brave than his own Epirots; whence he fled, that the country, which he proposed to conquer, was inhabited by men, whereas the provinces his nephew Alexander went to subdue, were peopled by women only. (Aul. Gell. l. xvii. c. 21.)

The immediate successors of Alexander were AESIDE and Alcetes I.; and the latter was succeeded by Pyrrhus, descended by the father from Achilles, and from Hercules by the mother. (See PYRRHUS.) After two or three short reigns, Deidamia, great grand-daughter to Pyrrhus, succeeded her father Pyrrhus III. and having no issue, she gave the Epirots their liberty, who formed themselves into a republic, which was governed by magistrates annually elected in a general assembly of the whole nation. The Macedonians on one side, and the Illyrians on the other, taking advantage of the intestine divisions, which generally attend a popular government, feized on several provinces belonging to the Epirots, and annexed them to their respective crowns. The Romans, after having conquered Philip of Macedon, restored them to their ancient liberty; but they ungratefully took up arms against their benefactors, and joined Perseus; which induced the Romans to send orders to Paulus Aemilius, after the reduction of Macedon, to plunder their cities and level them with the ground. This order was punctually, though reluctantly, executed throughout the whole country in one day. One hundred and fifty thousand of the inhabitants were made slaves, and sold to the best bidder for the benefit of the republic. All the cities of Epirus, to the number of 70, were dismantled, and the chief men of the country carried to Rome, where they were tried, and most of them condemned to perpetual imprisonment. After this calamity, Epirus never recovered its ancient splendour. Upon the dissolution of the Achaean league, it was made part of the province of Macedon; but when Macedon became a diocese, Epirus was made a province of itself, called the province of Old Epirus, to distinguish it from New Epirus, another province lying to the east of it. On the division of the empire, it fell to the emperors of the east, and continued under them till the capture of Constantinople by the Latins, when Michael Angelus, a prince nearly related to the Greek emperor, feized on Aitolia and Epirus. He was succeeded by his brother Theodorus, who to far enlarged his dominions, that, disdaining the title of despot, he assumed that of emperor, and was crowned by Demetrius archbishop of Bulgaria. Charles, the last prince of this family, dying without lawful issue, bequeathed Epirus and Acaania to his natural sons, who were expelled by Amurath II. Great part of Epirus was afterwards held by the noble family of the Caftriots, who, though they were masters of all Albania, yet styled themselves princes of Epirus. Upon the death of the famous George Caftriot, Epirus fell to the Venetians, who were soon dispossessed of it by the Turks, in whose hands it still continues; being now known by the name of Albania, which comprehends the Albania of the ancients, all Epirus, and that part of Dalmatia which is subject to the Turks. Plutarch tells us, that the Epirots enjoyed the bent of liberty under their kings; for, as he says, a general assembly of the people was annually convened at Paffaron, a city in the province of Molossia, where the king bound himself by a solemn oath to govern agreeably to the laws, and the people to obey and support him as long as he should make the laws the rule of his government.

EPISARCIUM, from ἐπισαρχία, a name given by many of the old authors to an aulace.

EPISCAPHIA, from ἐπισκαφία, boat, feals celebrated by the Rhodians.

EPISCEIA, from ἐπίσκεια, tent, feals celebrated by the Lacedemonians.

EPISCENIUM, ἔπισκενίον, in Antiquity, a place upon the top of the theatre, where all the machines for moving the scenes were kept. Potter. Archzol. Græc. lib. i. cap. 42.

EPISCIPSIS, ἔπισκεψις, an action brought to prove the diamartyria, or profession, that the peron deceased had left an heir, to be false and groundless. Potter. Archzol. Græc. lib. i. cap. 24. i. p. 128.

EPISCESES, from ἐπισκέπτεσ, or ἐπισκέπτης, I refrain, in Medicine, a term used by Dr. Cullen to denote the fifth order of his fourth class of diseases, which includes the re-
tention of accustomed evacuations, viz. contipation of the bowels, suppression of urine, of the catamenies, &c.

EPISCHON, from ἐπίςκοπος, bishop, and κοπάω, ἐπισκαμίνιον, a name given by the old Greek writers to the pulpits.

EPISCOPACY, the quality of episcopal government, or that form of church discipline, wherein diocesan bishops are elected, distant from, and superior to, priests or presbyters. See Bishop, Episcopal, Episcopalian, and Hierarchical.

Episcopacy, and presbytery, have been alternately established and abolished in Scotland.

EPISCOPAL CIVIL, from ἐπίςκοπος, bishop, and κάλπη, i.e., I kill, the crime of murdering a bishop by one of his own clergy. By the ancient laws of England, the same obedience is due from a clergyman to his bishop as from a servant to his master; and therefore the offences of murdering either are made equal, that is, they are both petty treason.

EPISCOPAL, something that belongs to a bishop.

The word is derived from the Greek ἐπίςκοπος, overseer, derived from ἐπίς, upon, and σκοπεῖν, to look.

Episcopal government is the government of a diocese, wherein one single person, legally consecrated, presides over the clergy of a whole district, in quality of head, or superior intendent thereof; conferring orders, and exercising a sort of jurisdiction in the civil as well as ecclesiastical concerns.

The presbyters reject the episcopal establishment, and condemn the episcopal orders as a human institution, the mere refusal of secular policy, or of pride and ambition.

Among the episcopal functions, the principal part is that of holding frequent visitations of the diocese.

EPISCOPALES VALVULAE, called also, by some, valvulae mitrals, two valves in the pulmonary vein, which prevent the reflux of the blood to the heart.

EPISCOPALIA, is sometimes used in the sense feminine of pontificalia.

EPISCOPALIA, is also used to denote synods, or customary payments, due to the bishops from the clergy of their diocese.

These customary payments have been otherwise called onus episcopal; and were remitted, by special privilege, to free churches and chapels of the king's foundation which were exempt from episcopal jurisdiction.

EPISCOPALISTS, or Episcopists, a name given to those who adhere to the church of England, and particularly to the ecclesiastical hierarchy, such as it was in the Roman church before the Reformation; who affect the discipline of bishops, priests, canons, the office, or liturgy, &c. and retain the greatest part of the canon law, with the decrees of the popes, more closely than the Catholics themselves of several countries; though, as to matters of doctrine, or faith, they agree in most points with the Calvinists, or Reformed.

In Scotland, the principal dissenters are the Episcopalian; they are Episcopists enjoy all the same civil privileges with those of the established church. They are under no restrictions; tied to no tests, but are employed in all places of trust, upon taking the oaths to the government. But the episcopal ministers are liable to several penal laws; many of them having been nonjurors.

EPISCOPIS, MoltA. See MolTA.

EPISCOPIS, a word used by writers of the middle ages, to denote a bishop's wife.

EPISCOPUS, simon, in Biography, a Dutch divine of the Arminian persuasion, was born at Amsterdam in the year 1583. Having entered on his academical studies in the university of Leyden in 1602, and graduated M. A. in 1606, he pursued his theological studies with great diligence; but on account of the disputes that subsisted between the Gomarists and Arminians, he found obstacles in the way of his admission to the ministerial office, which the burgomasters of Amsterdam wished him to assume. Disgusted by this liberal treatment, he left Leyden in 1609, and removed to the university of Franeker, where he had to contend with similar difficulties, and in account of his attachment to the Arminian doctrines. In the year 1716, however, he was admitted to the profession of the ministry, and appointed to a church at Ikewyck, in the neighbourhood of Rotterdam. In the following year he appeared as one of the deputies at the conference held at the Hague, before the states of the province, between the anti-remonstrant and remonstrant ministers, where he distinguished himself by his defence of the opinions of his party. In 1712 he was chosen professor of divinity at Leyden, in the room of Gomarus, who surrendered that office. In this situation he conducted himself with ingenuous prudence, as well as ability, so that he lived on terms of amity with Polyander, his colleague, who belonged to the party of Gomarists. The controversy concerning predestination was at this time the occasion of great animosity; and Episcopus, and his friends, were objects of animosity and persecution to the deputed populace. Their condition was rendered more perilous by the partisans of Maurice, prince of Orange, by whom they were condemned, not only as heretics in their theological sentiments, but as enemies to the protestant religion, and to the United Provinces. At length Maurice and the Gomarists, of whom he was the head, succeeded in obtaining a decree of the States for convening a national synod; but the Arminians remonstrated against the meeting of such a synod, because they well knew that it would be composed of their inveterate enemies, who on this occasion would appear both as their accusers and their judges. However, it met at Dort in the year 1618, (See Synod of Dort.) and the business of the synod was conducted as Episcopus and his party apprehended. The ruling members were invincible, and required implicit submission to their decisions. It was in vain that Episcopus and his brethren demurred and remonstrated against their proceedings. They were expelled from the synod, and their cause was tried during their absence. The result was a sentence, which charged them with pietistic errors, and with being corrupters of the true religion. This sentence was followed by their excommunication, a deprivation of their offices, ecclesiastical and civil, a prohibition to exercise their ministry, and besides fines and imprisonment, banishment from the territories of the republic. Accordingly Episcopus, as well as several of his adherents, retired to Antwerp, where he drew up various publications in defence of his oppressed party, some of which are, "A Confession of Faith," expressed for the most part in words and phrases of scripture: a treatise, entitled "Antidotum adversus Synodali Dordraceni Canonum," and two letters, addressed to Wadding, a Jesuit, who wished to seduce him into his church, one on the rule of faith, and the other upon the worship of images. In 1659, Episcopus withdrew into France, and endeavoured to confirm and comfort his brethren, as well as to diffuse the opinions for which he laboured, both by his correspondence and publications. In 1659, after the death of prince Maurice, and the accession of prince Frederick Henry, he returned to his native country, and enjoyed the benefits of toleration and tranquillity. The place of his settlement was Rotterdam, where he exercised his ministry for about 8 years, and composed several pieces of a theological
In honour of the chorus, Amsterdam churches, well rule. Might and glory of them not. The additional difface consequent lies upon a spirit of candour and moderation. His character was highly exemplary. His sentiments coincided with those of Arminius, which he reduced into a syllematic form, and recommended by the graces of composition. His works, confuting of commentaries, theological institutions, controversial treaties, &c. form two volumes in folio; which were edited by Peter Curcellaus, who has prefixed an account of the author. A larger life of him was published by Philip a Limborch, the son of his brother's daughter, written in the Dutch language, of which a Latin version appeared at Amsterdam in 1701. 8vo. Bayle. Motheim. Moreri. Gen. Biog.

Episcopus Puerorum, bishop of the boys, a ludicrous kind of office, formerly exercised in churches, in that called the feast of fools, or the feast of the kalends. See Boy Bishop.

Episemasia, from επισεμασία. I signify, in Medicine, is the very time that a disease feizes a person, and is properly called significatio. Blancard.

Episode, from episódios, upon, and επώδης, entry, is commonly conceived to be a separate incident, story, or action, which an historian, or poet, infers, and connects with his principal action; to furnish out the work with a greater diversity of events; though, in strictness, all the particular incidents wherein the action or narration is composed, are called episodes.

Episode, in Dramatic Poetry, was the second part of the ancient tragedy.

The origin and use of episodes is described by M. Hede- lin, and F. Bosius. Tragedy, in its original, being only a hymn sung in honour of Bacchus, by several persons, who made a kind of chorus, or concert of music, with dancing, and the like; to diversify the representation a little, and divert the audience, they determined at length to divide the finging of the chorus into several parts, and to have something rehearsed in the intervals.

At first, a single person, or actor, was introduced, then two, then more; and what the actors thus rehearsed, or entertained the audience with, being something foreign, or additional to, or before, the song of the chorus, and no necessary part thereof, was called επίσεμασία, episode.

And hence tragedy came to consist of four parts, the prologue, episode, exode, and chorus. The prologue was all that preceded the first entrance of the chorus, and concluded with the first interlude, or choral ode, between the acts. The episode, all that was interposed between the fingsing of the chorus, and extended in general from the first to the last of the interludes. The exode, all that was rehearsed after the chorus had done finging, or comprehended all that was said after the last interlude. And the chorus, was the grec or company, that sung the hymn. See each of these articles.

And as this recitation of the actors was in several parts, and inserted in several places, it might either be considered together as a single episode, consisting of several parts; or each part might be called a distinct episode.

Those several episodes in the same tragedy might either be taken from so many different subjests, or from the same subjeft divided into a proper number of recitations, or incidents.

To consider only the first occasion, and institution of these foreign or additional pieces, it appears no ways necessary, that they should be taken from one and the same subject; three or four recitations of different actions, no wife related, or connected to each other, would ease the actors, and amuse the people, in the intervals of the chorus, as well as if they were all so many parts of the same action. By degrees, what was at first only an addition to the tragedy, became the principal part thereof. Then the several pieces, or episodes, began to be considered as one single body which was not to have parts, or members of different nature, and independent of each other.

The best poets took the thing in this light, and drew all their episodes from the same action; which practice was so fully established in Aristotle’s time, that he lays it down as a rule. Those tragedies wherein this unity and connexion were not observed, he called episodic pieces. See Tragedy.

Episodes, in Epic Poetry. The term episode, by being transplanted from the stage to the epopieis, did not change its nature. All the difference Aristotle makes between the tragic and epic episodes, is, that the latter are more ample than the former.

Aristotle uses the word in three different senses: the first taken from the enumeration already made of the parts of the tragedy, viz. prologue, chorus, episode, and exode; whence it follows, that in tragedy, every thing is episode that is none of the other parts; so that as, among us, there are tragedies without either prologue, chorus, or epilogue, the tragic episode includes the whole tragedy; consequently the epic episode must be the whole poem, in like manner; all there is to retrench from it being the proposition and invocation, which stand in lieu of the prologue. In this sense, the epopieis and tragedy have each only one episode; and if the parts or accidents be ill connected together, the poem will be episodic and defective.

But further, as all that was sung in the tragedy was called the chorus, in the singular number, yet this singularity did not prevent every part or division of the fame from being called a chorus, without making several choruses; so it was with the episode; each incident, and part of the fable and action, is not only a part of the episode, but it is an episode itself.

The term episode, therefore, in this sense, signifies every part of the action expreffed in the plan, or first draught of the fable; as the absence and wanderings of Ulysses, the disorders in his family, and his presence, which retrieved and set all to rights again.

Aristotle furnishes us with a third kind of episode; in shewing that what is contained and expressed in the first plan of the fable is proper, and that all the rest is episode.

By proper he means what is absolutely necessary; and by episode, what in one sense is necessary, and in another not; so that the poet is at liberty to use, or let it alone.

Thus, Homer, having made the first draught of the fable of his Odyssey, was not at liberty either to make Ulysses absent from his country, or not. His absence was essential; and therefore Aristotle ranks it among the things he calls proper. But he does not bestow that appellation on the adventures of Antiphates, Cire, the Sirens, Scylla, Charybdis, etc.
Charybdis, &c. The poet was at liberty to have left these
alone, and to have chosen others in their room; so that
they are episodes distinct from the first action, to which
they are not immediately necessary.

The third scene of the word episode comes to the second;
all the difference between them is, that what we call episo-
des in the second scene, is the ground or plan of the episo-
des in the third; and that the third adds to the second cer-
tain circumstances which are only probable, and not neces-
sary, as the places, princes, and people, among whom
Ulysses was cast by Neptune.

It must be added, that in an episode in the third scene,
the incident, or episode in the first scene, wherein it
is, is fetched and retained, and not such as are
amplified, and attended with particular circumstances;
and lastly, that their union with each other is necessary
in the ground of the episode, and probable in the cir-
cumstances.

Episodes, says Dr. Blair, (Le&ecrnes vol. iii.), as the
term is now understood, are certain actions, or incidents,
introduced into the narration, connected with the principal
action, yet not of such importance as to destroy, if they
had been omitted, the main subject of the poem. Of this
nature are the interview of Hector with Andromache, in
the Iliad; the story of Cacus, and that of Nisus and
Euryalus in the Æneid; the Adventures of Tamer and
Erminia, in the Jerusalem; and the prospect of his descendants exhibited to Adam, in the left books
of Paradise Lost. Such episodes as these, are not only
permitted to the epic poet; but, provided that they be
properly executed, are great ornaments to his work. The
rules that serve to regulate them are such as follow: they
must be naturally introduced, and have a sufficient connection
with the subject of the poem; they must seem to be in-
fierior, or belonging to the poem; and not mere appendages annexed
to it. In the next place, episodes ought to present to us
objects of a different kind, from those which go before, and
those which follow, in the course of the poem. For episo-
des are introduced into an epic composition, principally
for the sake of variety. Lastly, as an episode is a
professed embellishment, it ought to be particularly elegant and well-
finished; and, accordingly, it is, for the most part, in
pieces of this kind, that poets put forth their strength.
The episodes of Taribetus and Arias, in Glover's Leonidas;
and of the death of Hercules, in the Epigoniad, are the
two greatst beauties in these poems. With regard to
episodes in didactic poetry, see Didactic Poetry.

EPISODIC, in Poetry. A fable is laid to be epodic,
when it is veiled with unnecessary incidents; and its episo-
des are not necessarily, nor properly, connected with each
other.

Aristotle lays it down, that those tragedies are most de-
fective, whose episodes have no connection, or dependence
with each other, which he calls epodic, q. d. superabundant
in episodes; because so many little episodes can never
compose one whole one, but necessarily remain in a vicious
plurality.

If an episode be used, the names and circumstances
whereof are unnecessary, and whose ground and subject
make no part of the action, that is, of the matter of
the poem, such an episode renders the fable epodic. This
irregularity is discovered, when one may take away a whole
episode, without sublimating anything in its room; and
yet leave no charm, or defect, in the poem. The history
of Hypsipyle, in Statius's Thebaid, affords an instance of
these faulty episodes. If the whole story of that illustrious
nurse were retrenched, the sequel of the principal action
would be the better for it. Nor would any body imagine
he had forgot anything, or that there was any member of
his action wanting. Doffin, and Arif. Poet. cap. 9.

EPISAPASTIC, from &ddot; and στοιχεῖ, 1 draw, in Medici-
æus, a term denoting the quality of those fultances,
which, when applied to the skin, draw the humours to the
part, and excite inflammation and vesication in it. The
word, therefore, is nearly synonymous with vesicator, or
blistering. See BLISTER.
EPISPHERIA, from εἰς and σφέρα, a sphere, in Anatomy, are windings and turnings in the outer surface of the brain, that the fangunrous vessels may pass more freely.

EPISTÈBE, in Botany, a name given to the cufcuta or dodder, found growing on the plant flabe of the ancient Greeks. See Ephedres.

EPISPhYLINUS, in Anatomy, a name under which the axyges uveal muscle has been described. It will be found, in different writers, under the names of phalylinus, columes musculus teres, musculus uvalis, or muscle de la lutea. It is described in the article DEQUILUTION.

EPISTATES, Epistatès, derived from εἰς, over, and τέταρτος, I send, in Antiquity, a person who has the command and direction of an affair, or of a people.

The term is of considerable use, in speaking of the government of Athens, where the epistates was the senator in command for that day, or whose turn it was to preëd that day. The constitution was this: the ten tribes of Athens formed by Clithenes, elected every year by lot, each of them, fifty senators, which made a senator of five hundred. Every tribe had the precedence in its turn, and succeeded it again successively to another. The fifty senators in office were called prytañes; the particular place where they assemled, prytañum, and the term, or duration of their office, viz. thirty-five days, prytañes. During these thirty-five days, ten of the fifty prytañes professed weekly, under the name of proodri; and of these proodri there was one to preëd each day of the week, under the title of epilates.

No perfon was allowed to hold his office more than once in his whole life, lest he should acquire too much the taste of dominion: the senators of all the other tribes still voted, according to the order the lot had given them; but the prytañes laid the business before them, and the epilates took their votes and opinions.

It must be added, that of the ten prytañes, of each week, there were but seven that would preëd each his day in the quality of epilates; the ten prytañes elected the seven prytañes.

EPISTAXIS, from εἰς and εὔλαβος, injilfe, in Surgery, hemorrhage from the nose.

When bleeding from the nose takes place in such a degree as to be dangerous, or likely to bring on excessive debility, the further effusion of blood may be stopped in the following manner. Roll a confiderable piece of lint round the end of a probe; wet it completely through with a strong solution of the zinicum vitriolum; introduce it into the nostril, and press it as strongly as possible against the part whence the blood issues. As soon as the blood ceases to flow, we may conclude that the preëfure acts on the bleeding point. This plan generally succeeds.

When the blood, however, flows from some point which lies very deeply in the nofril, it might be found impracticable to make preëfure exactly on the bleeding ves[sels]. At all events, we may then pass a piece of catgut through the nostril, and bring it out of the mouth, from the fauces, by means of a pair of common forceps. A tent of lint may next be fastened to the ligature, and drawn backward through the mouth into the nose, so as completely to stop the posterior opening of the nostril. The front aperture may be easily filled with a proper doffil of lint. In this manner, it is clear that no further hemorrhage can happen, as the blood cannot possibly find its way outward.

EPISTEMONARCH, derived from εἰς and τετάρτος, command, a dignitary, in the Ancient Greek Church, appointed to watch over the actions of the church, and to inspect or superintend every thing relating to the faith, in quality of a censor. His office answered pretty much to that of magister faci pulpit at Rome.

EPISTHÔTONOS, from εἰς and τέταρτος, and ὑπό, to extend, in Surgery, a species of tænutus, in which the body is bent forwards. See Tænuus.

EPISTITES, from εἰς and τέταρτος, I keep off, in Natural History, the name of a fome, defribed by the writers of the middle ages, as being of a beautiful red, and finning very elegantly. It was renowned for its many magical virtues, according to the idle tradition of these times; they said it drove away all noxious animals, and kept off storms from the place where any one was who had it about him.

EPISTILE, a letter missive.

The word is formed of εἰς and τέταρτος, I send.

The term epistle is now severely used, but for letters wrote in verse, and letters pedicatory.

In speaking of letters written by moderns, or rather in the modern languages, we never use the word epistle. Thus, we say, the letters, not epistles of the cardinal D'Offio, of Verture of Baltes, of Howell, of Pope, &c., but those wrote by the ancients, or rather in the ancient language, we call epistles; as the epistles, not letters in Cicero, Pliny, Seneca. The epistles of St. Paul, St. Peter, St. John, &c. to the Romans, Corinthians, &c.

Learned writers are not absolutely agreed as to the dates of these several epistles, nor the places whence they were written. It would lead us far too far to examine and produce the various authorities and arguments that have been used for settling these particulars; we shall only mention that Dr. Doddridge dates the 1st Epistle to the Corinthians about.
practice into which the Jewish Christians had fallen, which might otherwise have produced fatal consequences; and then to establish the faith, and animate the hope of sincere believers under their present and approaching sufferings. The Epistles of St. Peter are designed to induce the Christian converts in various parts of the world to maintain a conduct inoffensive and amiable; to support them under their trials, and to encourage their constancy, notwithstanding the arts and wiles of false teachers, and the perfecution of their most inveterate enemies. The leading design of St. John in his first Epistle, is to evince the vanity of faith separate from morality; to inspire the minds of Christians with mutual charity, and to guard them against the snares and efforts of Antichrist, and of all who were engrossed with his spirit. The Epistle of Jude describes the characters of the false teachers, represents the divine judgments which such perfons had reason to expect, and thus cautions Christians against being perverted by them. See Doddridge's Fam. Expositor, vol. iv. v. and vi. in the general introduction prefixed to each Epistle. See also an account of the writers of these epistles, and of the churches to which they were addressed.

EPISTLES, Poetical, a species of didactic poetry, the subjects of which are the manners and characters that occur in ordinary life, and that require to be treated with somewhat of the cause and freedom of conversation. When these epistles are employed on moral and critical subjects, they seldom rise into a higher strain of poetry than fature, which see. Many other subjects may be discussed in the form of an epistle; such as love poetry, or elegiac; specimens of which occur in Ovid's 'Epistles Heroïdium,' and his 'Epistles de Ponto.' As these works are designed to be merely sentimental, and their merit consists in being proper expressions of the passion or sentiment which forms the subject, they may assume any tone of poetry that is suited to it. But didactic epistles seldom admit of much elevation. The poet, commonly restricting himself to observations on authors, or on life and characters, and not intending to compose a formal treatise, or to confine himself strictly to regular method, gives scope to his genius on some particular point of which, at the time, has prompted him to write. Much of the grace of this kind of writing consists in a spirited conciseness, which gives to such composition an edge and liveliness, that strike the fancy and keep attention awake. Much of their merit depends also on judicious representations of characters. Unsupported by those high beauties of descriptive and poetical language, which adorn other compositions, the reader expects them to entertain him with lively paintings of men and manners; and therefore in these certain sprightliness and turn of wit find their proper place, and contribute to the beauty and effect. Of this kind of poetry Mr. Pope's ethical epistles furnish an almost perfect model. In these his wit discovers itself to such a degree as to give a proper seafoning to grave reflections. His paintings of characters are natural and lively; and, never was any writer so happy in that concise spirited style, which gives animation to fatures and epistles. His rhyme likewise adds to the dyle an elevation which otherwise it could not have possessed, while at the same time he manages it so artfully, that it never appears in the least to incumber him, but, on the contrary, serves to increase the liveliness of his manner. In this species of writing, grave and elegance are the distinguishing characters; nothing, therefore, should be forced or unnatural, laboured or affected, but every part of the composition should manifest an easy, polite, and uncontrived freedom.

EPISTOLARIES, among the Romans, under-secretaries.
EPISTOLARY, a term used in the phrase epistolary style. As the matter of an epistle is the same with that of conversation, it should not differ in the manner of expression; and, therefore, all pomp and study of language are not only needless but very improper: the most plain and easy way of conveying our thoughts must certainly be best, as being most natural. "Purity in the choice of words, and justness of construction, joined with perspicuity, are the chief properties of this style: to which purpose Cicero observes, "that in writing letters we make use of common words and expressions." (Ad Fam. lib. ix. cap. 21.) And Seneca says, "I would have my letters be like my discourses, when we either sit or walk together, unaided and easy." (Ep. 75.)

The first and fundamental requisite in epistolary writing is to be natural and simple, for a stiff and laboured manner is as bad in a letter as in conversation. This does not banish sprightlines and wit. These are graceful in letters as well as in conversation; when they flow easily, and without being studied; when employed so as to see, and not to clog. A person, who either in conversation or in letters affects to shine and sparkle always, will not please long. The style of letters should be neat and correct, but not too highly polished. Nicety about words betrays studied on this account musical periods, and appearances of number and harmony in arrangement, should be carefully avoided in letters. Those that are written with the greatest facility are commonly the best. Nevertheless, it should be remembered, that the ease and simplicity of epistolary writing are not to be understood as importing entire carelessnes. In writing to the most intimate friend, a certain degree of attention, both to the subject and the style, is requisite and becoming. The first requisite both in conversation and correspondence, is to regard all the proper decorums, which our own character, and that of others demand. An imprudent expression in conversation may be forgotten and pass away; but with the pen in hand, we should remember the well-known adage, "Littera scripta manet."

As the subjects of epistles are various, they will necessarily acquire some variety in the manner of expression. If the subject be weighty and momentous, the language should be strong and solemn: in things of a lower nature, more free and easy: and upon lighter matters, jocose and pleasant. In exhortations, it ought to be lively and vigorous: in communications, kind and compassionate: and in advising, grave and serious. In narratives, it should be clear and distinct: in requisites, modest: in commendations, friendly, without adulation: in prosperity, cheerful: and mournful, in adversity. In a word, the style ought to be accommodated to the particular nature of the subject about which it is conversant. Although there should be nothing very considerable in the subject; yet, if the spirit and turn of the correspondence be agreeable, if the letter be written in a sprightly manner, and with an agreeable grace and ease, they may still be entertaining, more especially if there be any thing to interest us in the characters of those who write them. As letters from one friend to another make the nearest approach to conversation, we may expect to see more of character displayed in these than in other productions, which are fluided for public view. We are pleased with beholding a writer so situationed as to allow him to be at his ease, and to give occasional vent to the overflowings of his heart. Besides, the different character of the person, to whom the letter is written, requires a like difference in the modes of expression. Superiors should be addressed with respect; inferiors, with courtesy; and equals, with civility. Old men and young, the grave and facetious, courtiers and philosophers, friends and strangers, require some variety in the mode of address. The epistles of Cicero, the style of which is plain and simple, and yet pleafant and engaging, furnish a proper model in this respect. They are the most valuable collection of letters in any language, as they are letters of real business, written to the greatest men of the age, composed with purity and elegance, and without the least affectation; and, what adds greatly to their merit, written without any intention of being published to the world. Pliny's letters are elegant and polite; and exhibit a very pleasing and amiable view of the author; but, according to the vulgar phrase, they smell too much of the lamp. They are too elegant and fine; the writer seems to be shedding an eye towards the public, when he is appearing to write only to his friends. His style abounds so much with turns and quibbles upon the found of words, as to render it more stiff and affected than agrees with conversation, or than a man of sense would choose to use in discourse, if it were in his power. This, indeed, was owing to the age in which he lived, at which time the Roman eloquence was sunk into puns, and an affectation of wit; for Pliny was otherwise a man of fine sense and great learning. We need not here recommend Melmoth's translation of the letters of Cicero and Pliny. The most distinguished collection of letters in the English language is that of Mr. Pope, Dean Swift, and their friends; published partly in Mr. Pope's works, and partly in the collection of Swift. Many letters in this collection are written with ease and a beautiful similitude. Those of Dr. Arbuthnot deliver this commendation. Dean Swift's are unaffected. Several of Lord Bolingbroke's and of Bishop Atterbury's letters are masterly. Mr. Pope's are too artificial. Among the French in the last age, Balzac and Voiture were the two most celebrated epistolary writers. Balzac's periods are swelling, and his style pompous; so that his reputation soon declined. Voiture continued for a long time a favourite author. His composition is extremely sparkling; he manifests much wit, and trifles agreeably. His only fault is, that he is too open and professed a wit, to be thoroughly agreeable as a letter-writer. The letters of Madame de Sevigne are now esteemed the most accomplished model of a familiar correspondence. Trifling as are their subjects, and overloaded as they are with compliments, they shew such perpetual sprightlines, they contain such easy and varied narration, and so many strokes of the most lively and beautiful painting, perfectly free from any affectation, that they are justly entitled to high praise. The letters of lady Mary Wortley Montague polels much of the French ease and vivacity, and retain more the character of agreeable epistolary style, than perhaps any letters which have appeared in the English language. Ward's Orat. vol. ii. p. 213, &c. Blair's Lect. vol. iii. Lect. 37. See Style.

EPISTOLARY is sometimes also applied to authors who have wrote epistles or letters. The principal epistolary authors are Sidonius Apollinaris, Tully, the younger Pliny, Seneca the philosopher, Petrarch, Politian, Erasmus, Linus, Liptius, Muretus, Accham, Milton, Petau, Laonci, Saray, Balzac, Voiture, for W. Temple, Lyttonell, &c. &c. See the preceding Article.

EPISTOMIA, in Anatomy, are the utmost gapings and meetings of vessels. EPISTOMIUM, Epistrophus, from επί, upon, and στόμα, mouth, in Hydraulic, a plug or instrument, by the application whereof
whereof the orifice of a vessel may be opened and shut again at pleasure.

**EPISTROPE** in *Rhetoric*, a figure wherein which that is supposit of one thing is strongly affirmed of another, and the repetition of the same word occurs at the end of each member or sentence.

"Since concord was lost, friendship was lost, fidelity was lost, liberty was lost, all was lost."

Auct. ad Heron. lib. iv. cap. 13. See also 2 Cor. xi. 22.

**EPISTROPEUS**, in *Anatomy*, from επιστροφης, a name given to the second vertebra of the neck, round a particular prosthesis of which the first vertebra turns. See SKELETON.

**EPITYLE,** επιτυλος, from επιστροφης, a name given to the second vertebra of the neck, in the *Ancient Architecture*, a term used by the Greeks for what we call architrave, viz. a massive stone, or a piece of wood, laid immediately over the capital of a column.

The epityle is the first or lowest member of the entablature.

**EPITAPH,** επιτάφιος, from επιστροφης, a monumental inscription, in honour or memory of a person who has defunct; or an inscription engraved or cut on a tomb, to mark the time of a person's decease, his name, family, and usually some eulogy of his virtues or good qualities.

At Sparta, epitaphs were only allowed to people who died in battle. Boxhornius has made a collection of epitaphs, not very ample, but exceedingly well chosen. F. Liebre has likewise given a collection of the like kind in French, intitled, "Tables des Epitaphes." Camden, Weaver, and Toldervy, have done something in the same way with our English epitaphs.

In epitaphs, the dead person is sometimes introduced by way of panegyric, speaking of the living: in which we have a fine instance, worthy the Augustan age, wherein the dead wife thus befeaks her husbanding husband:

"Immatura peri: sed tu, felicior, annos
Vive tuos, conjux optime, vive meos."

The French have a proverb, "M'entoure comme une epistaphe; He lies like an epitaph;" an allusion to the elegies ordinarily contained therein, which are not always over-faulty.

**Epitaph** is also applied to certain elegies, either in prose or in verse, composed without any intent to be engraved on tombs.

The elegance of an epitaph consists in a nervous and expressive brevity, and it is sometimes cloathed with an epigrammatic point. It is observed by Dr. Johnson, in his life of Pope, that the difficulty of writing an epitaph consists, in giving a particular and appropriate praise. This, he says, is not always to be performed, whatever be the diligence or ability of the writer; for the greater part of mankind have no character at all, or little that distinguishes them from others equally good or bad; and, therefore, nothing can be said of them, which may not with equal propriety be applied to a thousand more.

In the *Anthologies*, or collections of epigrams, we have abundance of epitaphs, some of them ludicrous and satirical, others grave. For a specimen, we shall here add a very beautiful one, composed by Mr. Cowley, on himself, to be put in a little country-houfe, whither he retreated from the court and town to spend his last days.

"Hic, O victor, sub lacre parvulo,
Conclusus hic est conditus, hic jacet
Defunctus humani laboris
Sorte, supremaque vita;"

**Non indecora pauperie nitens,
Et non inerti nobilis otio,
Vanoque dilectis popello,
Divitis, animo mutis.
Polliceat illum dicere mortuum,
Et tera jam nunc quantula sufficit
Elseptae fit curis, viator,
Terra sit illa levis, precare.
Hinc spargere flores, spargere breves rosas;
Nam vita gaudeat mortus floribus;
Herculeque odoratis corona
Vatis aduice cieerem calentem."**

The following epitaphs, besides many others, are worth recording. That of Alexander:

"Sufficit haue tumulus, cui non sufficere orbita."

That of Newton:

"Hicaeum Newton
Quem immortalem
Teftamur: Tempus, Natura, Culem,
Mortalem hoc: marmor
Fateur."

That of Dryden:

"Dryden."

Similar to which is that which the Italians have annexed to the tomb of Tasso:

"Les os du Taffe."

The following epitaph on the epitaph of sir Philip Sidney, the countess of Pembroke, and said to be written by the famous Ben Jonson, is distinguished by its admirable conclusion:

"Underneath this noble marble hearth
Lies the subject of all verse,
Sidney's father, Pembroke's mother:
Death, ere thou hast kill'd another
Fair, and learn'd, and good as she,
Time shall throw a dart at thee."

The following also by the same author is well known, and has been much admired:

"Underneath this stone doth lie
As much virtue as could die;
Which, when alive, did vigour give
To as much beauty as could live."

Another epitaph, by Dr. Samuel Johnson, on a celebrated musician, deferves to be recorded, as it is equalled by few, and surpassed by none.

"Philips! whose touch harmonious could remove
The pangs of guilty pow'r and hapless love,
Rest here, distress'd by poverty no more;
Find here that calm thou gav'st so oft before,
Sleep undisturb'd within this peaceful shrine,
Till angels wake thee with a note like thine."

The following epitaphs are specimens of the satirical or ludicrous kind:

Prior on himself, ridiculing the folly of those who value themselves on their pedigree:

"Nobles and heralds, by your leave,
Here lie the bones of Matthew Prior,
The son of Adam, and of Eve;
Let Bourton or Naffau go higher."

On
We shall here subjoin the epitaph of the ingenious and laborious author of the Cyclopaedia, from his tomb in the cloisters of Westminster Abbey, on the north side, written by himself:

"Multis pervulgatis,
Paucis notis;
Qui vitam inter lucem et umbram,
Nec eruditus, nec idiota,
Literis deductis transegit; fec ut homo
Qui humana nihil a fe aleatum putat,
Vita simul et laboribus functus,
Hic requiescite voluit.

Ephraim Chambers,
R. S. S.
Obit 15 Maji, 1740."

In English thus:

"Heard of by many,
Known to few;
Who led a life between fame and obscurity;
Neither abounding nor deficient in learning;
Devoted to study; but as a man
Who thinks himself bound to all offices of humanity;
Having finished his life and labour together,
Here he lies at rest.

Ephraim Chambers."

We shall close this article with some pertinent remarks on epitaphs or, by an anonymous writer in the "Olla Podrida.

The perusal of epitaphs is not to be considered as a light and frivolous amusement. If such only be the object of attention, as have been noticed with our applause, it is unquestionably an introduction to pleasing knowledge, and an incentive to moral improvement. What biography is to history, an epitaph is to biography. It is a sketch which marks the great outlines of character, and excites curiosity to view the portraits as painted in the pages of history. It is likewise an epitome of a sermon, which teaches the most useful truths in the most comprehensible form. Monumental inscriptions remind us, that time is on the wing, that every rank and age must fall a prey to his depredations; that the moments of life are too precious to be squandered away on trifles; that religion is the only support against the horrors of death, and the only guide to the joys of eternity.

Epitasis, formed of versitas, intende, I heighen, in the Ancient Poetry, denoted the second part or division of a dramatic poem, wherein the plot or action proposed and entered upon in the first part or protasis was carried on, heightened, warmed, and worked up, till it arrives at its f als or height called the catastasis,

This portion is laid aside in the modern drama; in lieu whereof our plays are divided into acts. See Act.

The epitasis might properly take up about our second or third act.

Epitasis, in Medicine, denotes the increase or growth, and heightening of a disease; or the beginning of a paroxysm, particularly in a fever.

Epithalamium, formed of epithal, bride; and eptb, chamber, in Poetry, a nuptial-fong, or a composition, usually in verse, on occasion of a marriage between two persons of eminence.

The topics it chiefly insists on are the praises of matrimony, and of the married couple, with the pomp and order of the marriage solemnity: it concludes with prayers to the gods for their prosperity, their happy offspring, &c. This kind of poetry is very ancient: the 44th Psalm, and the book of Canticles, have been considered as specimens of the epithalamium. Stethorus, who flourished in the forty-second Olympiad, has been usually esteemed the inventor of the epithalamium, and Cato, in his Hypnerotomachia,eded that he was anciently compounded of Thetis and Pelus, a work now lost; but a fragment of which is preserved by an ancient scholar. Caletus exceeded all antiquity in his epithalamium, and the cavalier Marino all the moderns.

Among the Greeks, the epithalamium was sung by young men and maid's at the door of the bed-chamber of the married pair in the evening and morning. The former was called epithalameia kymai, and the latter epithalameia.

Epithem, Epitaph, from epithal, upon, and thvim, pen, I put, in Pharmacy, a kind of fomentation or remedy, of a spirituous or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperance thereof.

There are principally three kinds of these external applications, the liquid, the solid, and the soft or poultice kind. See Cataplasm and Fomentation.

Epithem, Volatile, epithema volatile, a form of medicine preferred in the late London Pharmacopoeia, and ordered to be made of certain roots, and spirit of fal arnicae. The turpentine is to be kept continually stiring in a mortar, and the spirit gradually drop in till the whole is reduced to a white mass.

The spirit of sal arnicae used in this mixture must not be that made in the common way, with the addition of quick-lime, but with the alkali salt. Pemberton's Lond. Disp. p. 377.

Epithesis, from epithal, to lay upon, an old term in Surgery, the meaning of which was the straightening of deformed limbs by mechanical contrivances.

Epithet, Epithos, a noun adjective, expressing some quality of a sublative to which it is joined.

The word is formed of epithal, upon, and epithetos, putting. As a fruitful vine, a stately pile, an echoing vault, &c.

Epithets are of great use and convenience among poets and orators, who supply in epithets what they want in other requisites. Card. Ferron even blames Homer on the head of epithets, observing, that he frequently hooks in epithets without any reference or significance at all, to help out his figures; and that he equips every hero with an epithet, not according to the exigence of the case, but the measure of the verse.

Epithet, is also used for a surname, or a person's second appellation.

Epithets were anciently belied very frankly, either on account of excellencies or defects of the body or mind; kings themselves were not exempted from them. Hence
EPI

the epithets so frequent in history, as Edward Longshanks, Richard Cœur de Leun, Edmund Iron-side, Richard Crock-back, John Lack-land, &c.
Nor have the French used their kings any better; witness their Charles the Simple, Louis the Lazy, fainiant (Ludovicus nihil faciens) Pepin the Short, Louis the Stammerer, le beuge.

EPITHRICADIA, in Antiquity, a festival in honour of Apollo.

EPITHYME. See DODDER, and EPITHEOS.

EPITOME, an abridgment, or a reduction of the principal matters of a larger book into a little compass. See ABRIDGMENT.

The word is Greek, ἔπτωμα, formed of ἔπτω, refcore, to trench, abridge, or cut off.

The epitome of Baronius's Annals is done by De Sponde (Spondanus). Bernard has given an epitome of the philosophy of Galenus.

It is a popular objection against the epitomizing of authors, that it frequently occasions the loss of the originals. Thus the loss of the historian Trogo Pompeius is attributed to his epitomizer Julius, and the loss of a great part of Livy to Luc. Florus. See Lilly.

"Epitomes," says the learned Bacon, "are the mists and corruptions of history, that have fettled and corrupted the found bodies of many excellent histories, and brought them into bafe and unprofitable dregs."

EPITRITES, from ἐπίτρις, third, in Profody, a foot consisting of four syllables, three long, and one short.

Grammarians reckon four species of epitrites: the first, consisting of an iambus and spondee, as Χαίρε, Χαίρε; the second, of a trochee and spondee, as οὖς; the third, of a spondee and an iambus, as καλύπτει; and the fourth, of a spondee and trochee, as οὖς. See Fourth.

EPITROPE, See Confession. This is one of the figures of sentences, which grants one thing to obtain another more advantageous. It is either real or feigned; and either the whole of a thing, or only a part is granted. Nothing more confounds an adversary, than to grant him his whole argument, and at the same time either to shew that it is nothing to the purpose, or to offer something else, which may invalidate it. Of the use of this figure we have examples in Cicero's defence of Ligarius, who was accused by Tubero for having joined with Pompey in the civil war between him and Cæsar, (cap. 1.) and in the affair of Rufcius, where the proof depended upon circumstances; and when Cicero, who defended him, inquires what reason could be alleged for his committing so black a crime, as to kill his father, (cap. 27.) Cicero has also given us an example of a feigned or ironical concession in his defence of Flaccus (cap. 38.); when interceding for him on account of his former good services, in the time of Catiline's conspiracy, he says in the way of irony, if such things are to be overlooked, "let us appease the ghosts of Lentulus and Cethegus; let us recall those who are in exile, and let us be punished for our too great affection and love for our country." To these feigned concessions we may refer such modes of reasoning, by which the orator bothjustifies a charge brought against him, upon the supposition of its being true; and also proves that the charge itself, is false. Thus Cicero, in his defence of Milo, represents the taking off of Cledius, with which Milo was accused, as a glorious action; after he has shewn that Milo's servants did it without the knowledge of their master. (Cap. 10. and 27.)

EPITROPUS, a kind of judge, or rather an arbitrator, which the Greek Christians under the dominion of the Turks elect in the several cities, to terminate the differences that arise among them, and avoid carrying them before the Turkish magistrates. See Arbitrator.

There are several epistropi in each city. M. Spon, in his Travels, observes, that at Athens there are eight taken out of the several parishes, and called vecchiarì, i.e. old men. But Athens is not the only place where there are epistropi; they are in all the islands of the Archipelago.

Some Latin authors of the sixth century call epistropi those who more anciently were called villiæ, and fine vidanes.

In times still earlier, the Greeks used the term ἐπιτροπος, in the same sense as the Latins did procurator, viz. for a commissioner or interdictant.

Thus the commissioners of provisions in the Persian army are called by Herodotus and Xenophon epistropi. In the New Testament, ἐπιτροπος denotes the steward of a household, rendered in the vulgar procurator.

EPIZEUXIS, in Rhetorics, a figure where the same word is repeated with vehement in the same sense, without any other intervening, and suited to express anger, surprise, sorrow, and several other passions: thus ages, ages; adole, adole; and of Virgil, nunc, nunc inunctae remis, are instances of it. Thus also, when Cicero would express his indignation against Antony for having been the chief instrument in bringing on the civil war, he says to him: "You, you Antony, you, you Cæsar upon the civil war. (Phil. ii. c. 23.) Thus he tells Cæolin his first invective against him: "You live, and live, not to lay aside, but to pursue your wicked design." (Ibid. cap. 2.) See Matthew xviii. 37. The use of this figure shews the earnestness of the speaker and the great concern of his mind about what he says, and has a natural tendency to excite the attention of the audience.

EPIZOOTIC STRATA, or Mountains, in Geology, are such as contain remains of animals, which a very large portion of all those upon the surface of the earth seem to do, although their reliquiae are by no means equally numerous in all strata, probably owing to their not being preferred in every instance, so that their remains or impressions can be now traced.

EPIZOOTY, a denomination given to an epidemical or contagious distemper among horded cattle. M. de Saive, apothecary to the prince bishop of Liege, has given the following instructions for the prevention and cure of this disorder. As soon as any symptoms of the distemper are perceived, about 1/2 pint of blood should be taken from the beast, unless it has been killed a day or two, in which case it should not be bled; but in both cases the following draught should be given, viz. N. 1. an ounce of the best Venice treacle dissolvd in a pint of vinegar, after which the back-bone and the whole hide must be well rubbed with a dry hair cloth; to heat the hide and promote perspiration. No drink should be given him but a white drink composed of (N. 2.) a handful or two of rye-meal in a pailful of clean water; and if the beast should want food, mix up some crumbs of rye bread with some of this white drink, and give it him. The animal's mouth must be washed twice a day with a cloth dipped in a mixture of (N. 3.) equal quantity of vinegar and water, with a spoon-
ful of honey to a pint of it. If on the second day the beast has not dunged, a cleyer composed of (N. 4.) a pint of water in which bran has been boiled, two spoonfuls of salt, and a small glass of vinegar must be given and repeated every day till the evacuations are natural and regular. Besides the above remedies, the following cordial mixture (N. 5.) viz. a pint of clear water, the same quantity of vinegar, four spoonfuls of honey or syrup, and two glasses of brandy, must be given four times a day to facilitate the evacuation and keep up perspiration; taking particular care to repeat the friction as before directed. If the beast should still continue low and hearty, the draught (N. 1.) must be repeated, unless he should be found to be hot and thirsty, in which case only the drink (N. 2.) should be nced. On the fourth day, if he seems more lively and free from heat, purge him with (N. 6.); two ounces of salts and one ounce of common salt, dissolved in a pint of lukewarm water, with two spoonfuls of honey. If this does not procure four or five evacuations, repeat the cleyer the same day.

This mode of treatment must be continued without intermission till the beast begins to eat; then he must have only the white drink (N. 2) and a little good fodder, or some rye-bread dipped in stale beer, moderately sweetened with honey or syrup. The exterior treatment consists in the application of fetons in the beginning of the distemper, at the bottom of the dewlap, and of cauteries towards the horns, between which some weight, e.g. a stone of a pound weight or more, wrapped up in a cloth, must be fixed in order to keep it steady. This is necessary to keep the head warm. But above all, the friction must be carefully attended to, for determining the critical efforts of nature. It would be proper also to evaporate vinegar in the cow-house, &c. and if it could be done without risk, blowing of a few grains of gunpowder in them twice a day would be a useful fumigation. If, notwithstanding these aids, the beast be not perfectly cured in ten or twelve days, they must be continued without bleeding, unless the inflammation be very considerable; but if, after all, the distemper does not give way, the beast must be killed, buried very deep, and well covered with earth and turf, for the purpose of preventing the exhalation of the putrid vapours and the spread of the infection. The principal preparatives from infection consist in washing the racks, troughs, &c. and the hide of the beast every day, with plenty of water; and instead of expensive aromatic fumigations sometimes recommended, the use of fires made with the branches of green wood, with pitch thrown on it to quicken the flames and perfume the air. Common salt given in small quantities every day to horned cattle, is reckoned an excellent preparative, particularly in a learned dissertation on the contagious distempers among horned cattle, by M. de Limborg, M.D. F.R.S. Letters, &c. on Agriculture of the Bath, &c. Society, vol. I.

EPOCHE; in Heraldry. An eagle eployé is what in English we more usually call an eagle displayed, or a spread eagle. See Displayed.

EPNEUMATOSIS, from ἐνπνευμά, I breathe, in Medicine, the same with expiration.

EPOBOLIA, in Antiquity, a line laid upon those that could not prove the indictment they had brought against their adversaries.

It was so called, because they were obliged to pay the sixth part of the value of the thing they contended for, viz. an obolus out of every drachm. Some of these sums were deposited in all law-suits, a very few excepted, before the trial could proceed. Potter. Archæol. Græc. lib. I. cap. 21. tom. I. p. 117.

EPOCH, in Astronomy, is the mean longitude of a planet for the commencement of a given year. It is one of the principal elements of the elliptic motion. (See Element and Elliptic Motion.) When two observations of a planet are made in the mean distances, that is, at three and nine signs of mean anomaly, it is then practicable to correct, by two such observations, both the epoch and equation of the centre. If the latter be exact, there will be no other difference between the calculation and observation than the epoch of the mean motion, since the place of the apogee does not influence the longitudes taken at the mean distances; the error will, therefore, be equal in the two observations, which for us supposes the mean motion known exactly. Thus, if the errors of the tables are found equal at three and nine signs of anomaly, it is a proof that the equation of the centre is exact, and that the error lies wholly in the epoch being improperly ascribed.

EPOCHA, in Chronology, a term or fixed point of time, whence the succeeding years are numbered or accounted.

The word is 1727, q. d. infulita, reprefato, formed of 1727x, zu fulhunt, λόγος, because the epocha defines or limits a certain space of time. For the difference between epocha and era; see Ε.Λ.Α.

Different epochas obtain in different nations; and no wonder; for there being no astronomical consideration to render one preferable to another, their constitution is purely arbitrary. That principally regarded among Christian is, the epocha of the Nativity or Incarnation of Jesus Christ; that of the Mahometans, the Hegira; that of the Jews, &c. the Creation of the World; that of the ancient Greeks, the Olympiads; that of the Romans, the Building of the City; that of the ancient Persians and Assyrians, the epocha of Nabonassar, &c.

The doctrine and use of epochas are of very great extent in chronology.

To reduce the years of one epocha to those of another, i.e. to find what year of one corresponds to a given year of another; a period of years has been invented, which, commencing before all the known epochas, is, as it were, a common receptacle of them all, called the Julian period. To this period all the epochas are reduced, i.e. the year of this period wherein each epocha commences is determined. All that remains, therefore, is, to add the given year of one epocha to the year of the period corresponding with its rise; and from the same to subtract the year of the same period corresponding to the other epocha; the remainder is the year of that other epocha.

Epocha of Christ, or of our Lord, is the vulgar epocha throughout Europe, commencing from the supposed time of our Saviour's nativity, December 25, or rather according to the usual account, from his circumcision, which is, from the first of January.

Now, the year of the Julian period, wherein Christ was born and circumcised, is usually computed to be the 4713th; consequently, the first year of the era of Christ corresponds to the year 4714 of the Julian period.

Hence, 1. If to any given year of Christ you add 4713, the sum will be the year of the Julian period corresponding thereto, E. gr. If to the year 1809 be added 4713, the sum 6522 is that year of the Julian period. 2 On the contrary, subtracting 4713 from any given year of the Julian period, the remainder is the current year of Christ. E. gr., from the year of the Julian period 6522, subtracting 4713, the remainder is the year of Christ 1809.

In effect, the epocha of our Lord serves not only for the computation
computation of the years elapsed since the epocha commenced, but even of those before it.

Now, to find the year of the Julian period corresponding to a given year before Christ, subtract the given year from 4713, the remainder is the correspondent year required. Thus, e. g. the year before Christ 752, is the year 3961 of the Julian period. On the contrary, subtracting the year of the Julian period from 4713, the remainder is the year before Christ.

The author of the vulgar epocha, or way of computing from Christ, is an abbot of Rome, one Dionysius Exiguus, (which, fee,) by nation a Scythian, who flourished under Julianinian about the year 527, or, according to others, 527, though his Dionysius borrowed the hint from Pandorus, an Egyptian monk. Till his time, the generality of Christians computed their years either from the building of Rome, or according to the order of the emperors and confuls, and by other ways in use with the people among whom they lived.

This variety occasions a great distraction between the churches of the East and West; Dionysius, to compose the same, first proposed a new form of the year, with a new general era, which in a few years time was generally admitted.

Dionysius began his account from the conception or incarnation, by us popularly called Lady-day, or the Annunciation; which method obtained in the dominions of Great Britain till the year 1752, before which time the Dionysian and English epocha was the same; but in that year the Gregorian calendar having been admitted by act of parliament, they now reckon from the first of January, as they do in the other countries of Europe, except in the court of Rome, where the epocha of the incarnation still obtains for the date of their fells.

It must be added, that this epocha of Dionysius is charged with a mistake; the common opinion is, that it places our Saviour's nativity a year too late; or that he was born the winter preceding the time preferred by Dionysius for his conception.

But the truth is, the fault lies on Bede, who misunderstood Dionysius, and whose interpretation we follow, as has been shown from Petavius from Dionysius's own epistles; for Dionysius began his cycle from the year 4712, but his epocha from the year 4713, wherein the vulgar era supposes Christ to have been incarnate.

The year, therefore, which, according to the vulgar epocha, is the first year of Christ, according to Dionysius's era is the second; so that the year which we call 1809, should, in julian, be 1810, though some chronologers, instead of one year, will have the error two.

Others suppose that the Dionysian era is four years too late; which supposition is confirmed by considering that our Saviour was born before the death of Herod the Great; and during the reign of Augustus (Matth. ii. 12. Luke, ii. iv.) and according to the testimony of Josephus, (lib. xvii. cap. 18.) there was an eclipse of the moon in the time of Herod's last illnesses; which eclipse appears to have happened in the year of the Julian period 4710, March 13, at Jerusalem. Now, as our Saviour must have been born some months before Herod's death, since in the interval he was carried into Egypt, the latest time in which we can fix the true era of his birth is about the end of the 4709th year of the Julian period.

In order to ascertain the true year of our Saviour's birth, it is necessary to fix the precise time of Herod's death. The chief opinions concerning the time of this event are three. Some think he died a little before the passover of A. U. 750, Julian year 42; others on Nov. 25 in that year; and others, a short time before the passover A. U. 751.

We learn from Josephus, (De Bell. lib. ii. c. 1. Antiq. l. xvii. c. 9.) whose authority we cannot reject in deciding this question, that Herod died but a short time before one of the Jewish passovers. That Herod died a short time before the passover A. U. 750, Julian year 42, is argued in this manner. His diligence had made great progress before the pulling down of the golden eagle at the temple. The Jewish rabbies excited their scholars to this action, News being brought that Herod was dying (Jos. de Bell. l. i. c. 33. § 31.) or dead (Jos. Ant. l. xvii. c. 6. § 3.) these rabbies were taken up and carried to Joachim, where Herod was, in a very infirm state, and where they were tried and burnt to death. On that very night there was an eclipse of the moon, which, as we have already mentioned, happened March 13th A. U. 750. From this time Herod grew worse and worse; so that he could not live long. The passover of this year happened on the 11th of April; and the interval between the 13th of March and 11th of April would have been sufficient for every thing that Josephus has related concerning Herod's illness: the setting of his affairs, the execution of Antipater, Herod's death and funeral, which are the occurrences between the eclipse and Archelaus's coming to Jerusalem at the passover.

Besides, from circumstances related by Josephus concerning Archelaus, one would be apt to conclude, that he reigned nine years complete, and that the 10th year was current when he was banished. Dio (l. iv. p. 567.) places Archelaus's banishment in the 759th year of Rome. If Herod did not die, as some imagine, till the beginning of A. U. 751, the 9th year of Archelaus's reign could not be completed in the 759th year of Rome. But if Herod be supposed to have died in the beginning of A. U. 760, Josephus and Dio agree. Moreover, Josephus says, that Cyrenius feized Archelaus's elate, and finished the affliction in Judea in the 37th year after the defeat of Antony at Actium by Caesar Augustus. The victory at Actium was obtained Sept. 2, A. U. 723; therefore the 37th year from it begins Sept. 2, A. U. 760, and ends Sept. 2, 760. Supposing then that Herod died in the beginning of A. U. 750, there is in this particular also a very good harmony between Josephus and Dio. Besides, Josephus informs us (Ant. l. xiv. c. 20.) that Herod was appointed king by the Roman senate A. U. 714. i. e. 40 years before the vulgar era. The fame historian observes, that he died in the 37th year of this reign, and 34th after the death of Antigonus, viz. in the 42d Julian year (Antiq. l. xvii. 10.) If to 713 we add 37, the sum will be 750, the year of Rome in which this prince died.

The opinion, adopted by other learned men, that Herod died a short time before the passover A. U. 751, labours under several great difficulties, which are pointed out by Dr. Lardner (ubi infra.) Upon the whole it appears, that Herod did not die before the year 750, nor survive the year 751, and that he died a short time before the Jewish passover of one of these years. It follows, that if Herod died in 750, he died three years and nine months before the vulgar Christian era, which commences January 1, A. U. 754; if at the time above-mentioned, in the year 751, then he died about two years and nine months before the said era. "Which is the truth," says Dr. Lardner, with his usual diffidence and modesty, "I am not able to determine." Accordingly he says, that "if Herod died in March A. U. 750, I should be inclined to place the nativity of Jesus in September or October, A. U. 748; if Herod died in March 751, then the nativity of Jesus might very
every well be placed in September or October 748." The birth of Jesus must be dated about a year and five or six months before the death of Herod, i.e. before the latter end of the year of Rome 748 or 749, i.e. 4708 or 4709 of the Julian period; but for reasons already assigned, the latter date is the most probable.

We shall here add, that an objection has been urged against the 15th year of the reign of Tiberius, compared with the age of Jesus at his baptism. (Luke, iii. 23.) If Jesus, it is said, was born above a year, much more, if above two years before Herod's death, then the age of 30 years, here ascribed to him at his baptism, is absolutely inconsistent with the notes of time mentioned at the commencement of John the Baptist's ministry; even allowing, that the word of God came to John in the very beginning of the 15th year of Tiberius, and that Jesus was baptized a few months after. Dr. Lardner observes, that the true meaning of these words, Jesus himself began to be about 30 years of age, is not that he then entered the 30th year of his age, but that Jesus was about 30 years of age when he began his ministry. This, he says, is now the general opinion of learned men; so the Greek word of this text is used by St. Luke in other places. The objection is thus flatted: Augustus died, and Tiberius succeeded him of the 19th of August, A. U. 767, Julian year 59, A. D. 14. Therefore the 15th of Tiberius began the 19th Aug. A. U. 781, A. D. 28. Herod died before the passover, in A. U. 751, Jul. year 45. If then John the Baptist began to preach in the beginning of the 15th of Tiberius, in the latter end of A. U. 781, and Jesus was supposed to have been baptized by John a few months after, on the 6th of January of the year following, viz. A. U. 782, Jesus must have been in the 32d year of his life, if Herod died in the spring, viz. A. U. 751, and if Jesus was born the 25th of December preceding, viz. A. U. 750. But if Herod died A. U. 750, and Jesus was born the 25th December before, viz. A. U. 749, then he would be at his baptism in the 33d year of his age. But it may be made to appear in several ways, that Jesus was born above a year, probably above two years before Herod died. Dr. Lardner has flatted this objection in its full force; and detailed several circumstances that tend to obviate it. From some of them he infers, that there is no necessity of placing the birth of Jesus above a year and six months before the death of Herod, as we have already flatted. As it is most probable that Herod died A. U. 750, we may be disposed, from other circumstances alleged by this accurate and impartial writer, to place the nativity of Jesus in September or October A. U. 748. The latter part of the summer, or the autumn akath, seems to be the most likely time of the year for the birth of Jesus; nor is there any particular reason that should determine us to the 25th of December. The very depth of winter was not a very proper season for a survey and affinements, if people are to enter themselves according to their tribes or families; the autumn, when harvest and vintage are over, would be a time of general leisure. When Jesus was born in Bethlehem, there were the same country sheep abiding in the fold, keeping watch over their flocks by night. (Luke, ii. 8.) This circumstance is not very favourable to the supposition, that Jesus was born the 25th of December; and we are at liberty to place it in autumn, a more likely season. (See Christmas.) It is not improbable then, that Jesus might be born about the middle of August and the middle of November. Cyrenius, we may suppose, came into Judea at the time, or soon after the time, that Varus became governor of Syria (before Sept. A. U. 748), and published the decree of Augustus, requiring all people to enter themselves, their dependents, and dependents. This affinement could well be made in a country of such small extent as Judea in two or three months; and the short time appointed for this work may be inferred from the peculiar circumstances of Cyrenius, who wished to hasten back to Rome, and also from St. Luke's history of it. Upon the whole, we may conclude, that about a year and five or six months before the death of Herod, soon after the arrival of Varus in the province of Syria, in August or September A. U. 748 or 749, Julian year 40 or 41, Cyrenius (or some other person of eminence) came into Judea, an affinement was made there, and in the time of it, Jesus was born at Bethlehem, in the month of September or October. In order, however, to settle satisfactorily the 15th year of the reign of Tiberius, we should consider that the commencement of his reign may be computed from a different period than that of his sole empire, after the death of Augustus. In fact, it appears, that there were two different dates of the beginning of Tiberius's reign; one from the time of his being made colleague with Augustus, and the other from his sole empire, after the death of Augustus. Many learned writers are of opinion, that St. Luke intends the former of these two computations, referring to a period two years before the death of Augustus, viz. in A. U. 765, when Pilate was prefect of Rome, Tiberius being prince. Archibishop Usher and Prideaux place the beginning of this government of Tiberius in this year. This epoch of Tiberius's empire was followed for some time by some persons, in the provinces at least; but it is not so certain, when this pro-consular empire began, whether about two years, or about three years before Augustus died. If Tiberius's pro-consular empire began about three years before Augustus died, on the 28th of August A. U. 764, A. D. 11, then this 15th of Tiberius's reign (according to this computation and allowing of the time that began August 28th, A. U. 775, A. D. 12). Supposing that John the Baptist began his ministry November following, in the same year, and that Jesus was baptized by him the 6th of Jan. following, in A. U. 779, A. D. 16; then upon the supposition that Jesus was born in Sept. A. U. 748, he would be at his baptism 30 years of age, and some months more. If Tiberius's pro-consular empire commenced about two years before the death of Augustus, in A. U. 765, A. D. 12, then the 15th year of the reign of Tiberius began in A. U. 779, A. D. 26. And supposing that John the Baptist began his ministry in November of that year, and that Jesus was baptized by him the 6th of January following, A. U. 780, A. D. 27, then, upon the supposition that Jesus was born in September, A. U. 749, he would be at the time of his baptism 30 years of age, and some months more; or, if born A. U. 748, he would be from what more than 31 years of age. Again, if John the Baptist began his ministry in the 15th of Tiberius, A. U. 779, A. D. 25, according to the first account, but did not begin August 28th, A. U. 775, A. D. 12, after he had preached somewhat above a year, then Jesus would be at his baptism 30 years of age and odd months, if he was born A. U. 749; 31 years of age and some odd months, if born the latter end of the year 748. Such will be the result, if we take those dates of these events, which appear most favourable to St. Luke; since it is not absolutely certain when Herod died, or when Tiberius's pro-consular empire began. But if we allow on each hand the dates least favourable to St. Luke's numbers, viz. that Jesus was born A. U. 748, and that he was not baptized till January A. U. 785, A. D. 27; yet even then Jesus would be little more than 31 years of age; at which time a person...
EPOCHIA.

Hence, to any given year of the Julian period, adding 787, the sum gives the year of this epocha. E. g., 1809 being the 6722d year of the Julian period, 7509 is that year of this epocha, or the year of the world, according to this computation.

The author of this epocha is Julius Africanus, who collected it from the historians: but when it came to be admitted into civil use, 8 years were added to it, that so every year thereof divided by 15 might exhibit the indication, which the eastern emperors used in their charters and diplomas.

The epocha of the creation used by the latter Greeks and Ruffians is the year 795 before Christ, or the year 5508 before Chrift, commencing from the first day of September. Though the Ruffians, having lately admitted the Julian calendar, begin their year from the first of January.

Hence, adding 795 to the year of the Julian period, the sum gives the year of this epocha. Thus, e. gr. the Julian period of the year 1809 being 6522, that year of this epocha, i.e. the years from the creation on this footing are 7317. Again, from that year 7317 subtracting 3508, the remainder is the year of the common era 1809. This era was used by the emperors of the East in their diplomas &c. and thence also called the "civil era of the Greeks." In reality, it is the same with the epocha of the Constantinopolitan period; whence some call it the "epocha of the period of Constantinople."

The Alexandrian Epocha of the Creation is the year 780 before the Julian period, answering to the year before Christ 5493, and commencing on the 29th day of August.

Hence, adding 5493 to the year of Christ 1809, the sum 3702 gives that year of this epocha, or years elapsed since the creation, according to this computation.

This epocha was first concerted by Pandorus, a monk of Egypt, to facilitate the computation of Easter; whence some call it the "Greek ecclesiastical epocha."

The Euseblian Epocha of the Creation, is the year of the Julian period 486, answering to the year before Christ 4228, and commencing in autumn.

Hence, subtracting 486 from the year 6522 of the Julian period, or adding 4228 to the year of Christ 1809, the result 3706 will be that year of this epocha.

This epocha is used in Eusebius's Chronicon, and the Roman Martyrology.

The Epocha of the Creation, according to Mr. Bedford and Mr. Kennedy, is the year of the Julian period 706, answering to the year before Christ 4007.

The Epocha of the Creation, according to archbishop Uther, adopted in Blair's tables, is the year of the Julian period 710, corresponding to the year before Christ 4004; but it must be allowed, that all the epochs of the creation are uncertain. See Strachusius's Brev. Chron. by Sault, p. 152, &c. See chronological table under the article CHRONOLOGY.

Epocha of the Universal Deluge, in the year of the creation 1656, and according to the different methods of computation; see the table under CHRONOLOGY, and Ante-Diluvian.

Epoch of the Olympiads, is the year of the Julian period 3936, answering to the year 776 before Christ, commencing at the full moon next the summer solstice, and each Olympiad containing 4 years.

This epocha is very famous in ancient history; it was used principally by the Greeks, and had its origin from the Olympic games, which were celebrated at the beginning of
EPOCHA.

Every fifth year. See the table above cited, and Olympic Cycles.

Epocha of the Building of Rome, or Urbis Condita. U. C. is the year of the Julian period 3961, according to Varro; or 3962, according to the Falti Capitolini, answering to the years before Christ 753 or 752, and beginning on the 20th of April. Hence, if the years of this epoch be fewer than 754, subtracting them from 753 or 752, you have the year before Christ; and, on the contrary, if they be more than 754, you must subtract 754 to have the year of Christ, and add the year of Christ to 753 to have the year of this epoch, or the time since the building of Rome. Thus, e. g. the year 1809, according to Varro, is the year of Rome 2503.

The sentiments of the earliest Roman writers, with respect to this epoch, are various; Polibius refers it to the year B. C. 751. Cato, whose opinion is adopted by Solinius, Eutichius, Dionysius Haly. &c. places it one year earlier. Fabius Pictor, who flourished in the time of the first Punic war, and who is styled by Dion. Hal. an accurate writer, brings it down to the 29th year of the olympiads, i. e. 747 B. C. Diodorus Siculus adopts this opinion. Sir Isaac Newton, on the testimony of some later Roman writers, observes that Rome was built in the 13th age after the destruction of Troy, that is, after the 14 kings who reigned in Alba. Allowing 21 years to the reign of every king, and computing from the year B. C. 904, when he supposes Troy to have been taken, he brings forward this epoch to the 38th olympiad, i. e. 627 B. C. The date of Varro has been adopted by the Roman emperors in their proclamations, by Plutarch, Tacitus, Dion, Gellius, Centorius, Onophrius, Baroanius, and by most modern chronologers.

Epocha of Nabonassar, is the year of the Julian period 3567, answering to the year before Christ 7471, commencing the 26th day of February of the Julian year at mid-day. The solar cycle was 19, the lunar 15, and the cycle of indiction 7.

This era takes its denomination from its instillator Nabonassar king of Babylon, and is that used by Hipparchus, by Ptolemy in his Astronomical Observations, by Cenforius, and others.

This epoch is of singular service in chronology, as it serves to connect and adjut all other epochs. The form of this era, which included a period of 424 Egyptian years from the commencement of Nabonassar's reign to the death of Alexander the Great, and which was thence carried down to the reign of Antoninus Pius, is singular. Every year consists of 365 days, and is divided into 12 months. Every month contains 30 days; five intercalary days are added to these months, and the form comprises the quantity of the Nabonassarean year. In every four Julian years, the corresponding four years of this era were evidently deficient by one day; therefore the beginning of the Nabonassarean years must have moved retrogradely; and in the space of 1460 Julian years, must have gone through every day of the year. Wherein it appears, that 1460 Julian are equal to 1461 Nabonassarean years. If the first year of the era of Nabonassar began on Wednesday, Feb. 26th, the second and third years must have begun on the same day; because these two years contain 365 days each in the Julian, as well as in the Egyptian calendars. The following year, i. e. 744 B. C. being a bissextile, one day was added to the Julian year, consequently the Nabonassarean year began on Feb. 25th in this and the three succeeding years. In the year 740 B. C. it began on February 24th; in 736 B. C. on February the 23rd, &c. The first day of any year of the Nabonassarean era may be found by the following general rule.

Divide the given year by 4 (because in 4 years the Nabonassarean year anticipates the Julian by one day), and the quotient will be the number of days of anticipation, or of the omitted leap-days. If the quotient be less than 57 (the number of days from January 11th to February 26th), let it be substracted. If the quotient exceeds 57, subtruct it from 422, i. e. from 57 + the number of days in one Julian year, and the remainder will be the day of the Julian year, reckoned from January 11th, which is the Thoth, or first day of the year following the given one; (Thoth being the name of the month, which in the first year of this era corresponded to Feb. 4th of the Julian year.) From the day found, subtruct 1, and the remainder will be the number of the day required.

E. G. On what day of the Julian year did the Thoth of the Nab. era 250 fall? Divide 250 by 4, and the quotient 57, substracted from 422, leaves a remainder of 365. This shows that the Thoth of N. E. 251 falls on December 31st, or on the 365th day of the Julian year; subtruct 1, and the remainder 364, or December 30th, will be the day required.

Epocha, or Era of Constantinople, is supposed to have commenced before the creation of the world; for the 550th year of it answers to the 1st of the vulgar Christian era. It was adopted by the Greek church and empire, all the public acts of which are still dated by it; and the Meuxvitae computed by it until the reign of Peter the Great. Those who reckon by it make use of civil and ecclesiastical years. The former begin with the month of September, and the latter, sometimes with the 21st of March, and sometimes with the 1st of April.

Epoch of New Rome, or Constantinople, is usually computed from the time of the confecration of the city. Accordingly the first year of this era was the 225th of the reign of Constantine, A. M. 3838, as the modern Greeks estimate the era of the creation, Julian period 5043. Thus directed, the consecration of the city is fixed in the 333rd year of the vulgar era, on the 11th of May.

Epocha, Diocletian, or Epocha of Martyrs, is the year of the Julian period 4997, answering to the year of Christ 284, called the "era of martyrs," from the great number of Christians who suffered martyrdom under the reign of that emperor.

The Abyssinians, among whom it is still used in all ecclesiastical computations, call it the "era of grace," though they do not reckon their years in a continued series from this epocho. But when the Dionysian period of 534 years is expired, they begin their computation afresh from 1, 2, &c.

Epoch of the Hegira, or Mahometan Epocha, is the year of the Julian period 5335, answering to the year of Christ 622. It commences on Friday the 16th of July, the day of Mahomet's flight from Mecca to Medina.

This epoch is used by the Turks and Arabs, and even all who profess the Mahometan faith. It was first introduced by Omar, the third emperor of the Turks. The ak blonds Alfraganus, Albagugnus, Alphonus, and Ulugh Beigh, refer Mahomet's flight to the 15th of July; but all the people who use the epoch agree to fix it on the 16th. See Hegira.

Epocha of the Seleucida, which is used by the Macedonians, is the year of the Julian period 4402, answering to the year before Christ 312. This is reckoned from the time when Seleucus, one of the generals of Alexander's army, took Babylon and ascended the Asiatic throne.

This
This era is sometimes called the Grecian era, and the era of the Roman provinces among the Triumvirs, and is reckoned from the 11th of January in the year 38 B.C., so that the first year of the Christian coincides with the 59th year of the Spanish era. The most famous synods of Spain and Africa have been distinguished and described according to the computation of this era; but by a decree of the council of Tarracon, A.D. 1180, the Christian era was substituted in its room, though it continued in use till the year 1383. The Portuguese were the last people who computed by this era, and they gave it up A.D. 1415 or 1422. See "ERA.

**EPOCHA,** A.D., or **Adiant,** is the year of the Julian period 4684, answering to the year before Christ 30, commencing in Egypt on the 29th day of August, and on the 11th of September among the Greeks of Antioch; but among the Romans on the 11th of January in the year of Rome 724.

**EPOCA of the Reformation.** See Reformation.

For other epochs or eras, and the dates of remarkable events, see the table under Chronology.

**EPOCHETEUSIS,** from *εποχή, canal, of επόχα, canal,* a word used by Hippocrates, and others of the old writers in *Medicine,* to express the derivation of the blood, or juices, from one part to another.

**EPODE,** **Επόδης,** in Lyric Poetry, the third or last part of the ode; the ancient ode, or song being divided into *irophe,* anti*Irophe,* and epode.

According to its most common acceptation, it signifies a number of Lyric verses of different construction, comprised in a single stanza; and it was sung by the priests, standing still before the altar, after all the turns and returns of the *irophe* and anti*Irophe.* The invention of epodes is ascribed to Archilochus.

The epode was not confined to any precise number, or kind of verses, as the *irophe* and anti*Irophe* were: but when the ode contained several epodes, *irophes,* &c. they were all alike.

As the word *epode,* then, properly signifies the end of the *irophe,* and as in odes, what they called the epode finished the singing, it became customary, as M. Dicker shows, for any little verse which, being put after another, closed the period, and finished the sense which had been suspended in the first verse, to be called *epode,* *εποδής.

And hence it is, that the sixth book of Horace's *Odes* is entitled "Liber Epoden, Book of epodes," because the verses thereof are all alternately long and short; and the short one, generally, though not always, closes the sense of the long one. The name of epode was likewise given to a small Lyric poem, composed of trimeters or iambics, of six feet, and dimeters of four feet alternately. Of this kind were the epodes of Archilochus, mentioned by Pindar. But the signification of the word is extended still further; epode being become a general name for all kinds of short verses, that follow one or more long ones; and in this sense, a pentameter is an epode, after an anapest, which in respect thereof is a procla.

**EPODOS,** from *επόνοια, song,* in *Medicine,* a word used to express the curing of diseases by incantation.

**EPOIKODOMESIS,** from *εποίησις, I build upon,* in *Rhetoric,* is sometimes used for what is otherwise called *chimaera.*

**EPOISSES,** in *Geography,* a small town of France, in the department of the Côte d'Or, 9 miles W. of Semur.

**EPOMIS,** in *Anatomy,* the upper part of the shoulder, reaching up to the neck.

The word is Greek, *ἐπόμος,* which primarily signifies a short cloak or mantle made to cover the shoulders.

Some authors apply the word *epomis* to the upper part of the
the on humeri; but the ancient Greek physicians only use it for the muscular, or fleshy part, placed as above mentioned. See DELTONEA.

EPOPHALION, from επόφαλιον, and ποϕαλον, novel, any medicine which purges on being applied to the navel. EPOPOEIA, ἐποπεία, in Poetry, the history, action, or fable, that makes the subject of an epic poem. The word is derived from the Greek ἐπο., carmen, verfe, and εφα, facio, I make.

In the common use of the word, however, epopeia is the same with epos, or epic poem itself: in which sense it is defined a discourse invented with art, or a fable agreeably imitated from some important action, and related in verse, in a probable and surprising manner; with a view to form the manners, &c. See Epic Poem.

EPOPS, in Ornithology, a name by which some of the ancient writers have called the bird we call the upupa, or hoopoe. See UPURA, of which it is a species.

EPORA, in Ancient Geography, a town of Spain, 28 miles from Cartaluma, according to the Itinerary of Antonine. Phyll calls it Ropora. It is thought to be Mentoro in the table of Cordova. M. D'Anville places it on the river Bectis, in Bética, N. E. of Corduba.

EPOREDIA, ἐπορέδια, a town of Gallia Transpadana, situated towards the west, on the Doria Major.

EPOTIDES, in the Ancient Ship-Building, two large thick pieces of wood on each side of the prow of a galley, which resembled two ears, whence they had their name. The epotides were chiefly designed to ward off the blows of the rostra of the enemies' vessels.

EPPHA, or EPHA, in Ancient Geography, a country of Arabia, in the vicinity of the Midianites.

EPPING, in Geography, a market town in the hundred of Waltham, in the county of Essex, England, is irregularly built, and consists of two parts or expansions of houses; one round the church, called Epping Upland; the other, nearly a mile and a half south-east from the church, called Epping Street. The latter is by far the largest, and consists of one wide street, nearly a mile in length, situated on the high road from London to Newmarket, on a ridge of hills extending as a considerable distance north and south. Here a market is held on Fridays: the chief commodities exposed for sale, are butter and poultry, which are chiefly purchased for the use of the metropolis. At the west end of the street is a small new chapel: and near the middle are the fishmarkets. The inns and public houses are numerous. Epping is 17 miles from London; contains, in both divisions, 315 houses, inhabited by 1726 persons; it has two annual fairs.

Epping Forest, is an extensive tract of good woodland, deriving its present name from the town, but was formerly called Waltham Forest, and in very remote ages the Forest of Epping. Since it obtained the latter appellation, it has, however, been greatly curtailed, many thousand acres having been grubbed up, and the land cultivated. This forest is under the jurisdiction of a lord warden and four verderers: the wardenship is hereditary in the family of Sir James Tilney Long, bart.; the verderers are elected by the freeholders of the county, and retain their offices during life. The forest rights are as various as the tenures of the different manors that surround it. In this forest, though so near to London, wild flags are yet found; and a flag is annually turned out on Easter Monday, under an establishment patronized by the principal merchants of the city. The hunt is well supported: the kennel for the hounds, and the building belonging to the hunt, have been lately erected at the expense of several thousand pounds.

EPING, a town of Germany, in the archduchy of Austria; 4 miles S. of Aigen.

EPING, a post town of America, in Rockingham county, New Hampshire, taken from the N. W. part of Exeter, and incorporated in 1741. It contains 1121 inhabitants, and lies 6 miles N. W. of Exeter and 23 W. of Portsmouth.

EPINGEN, a small town of the kingdom of Bavaria, in the palatinate on the river Elsatz, 21 miles N. E. of Philippsburg, and 18 miles N.W. of Heilbrun. N. lat. 49° 12′.

EPROUVETTE, a machine, of which there are several varieties, used for proving the strength of gun-powder. The principle of this invention, in whatever form it may be applied, is to ascertain how far a certain measure or weight of gun-powder is capable of overcoming the resistance either of a certain weight, or of a spring, whose pressure against the explosion is computed. The former is evidently the most regular, and, consequently, the best adapted to military purposes, wherein the strength of the powder is often of the greatest moment, not only on account of the advantages gained by the greatest concentration of force, but because in the mortar and howitzer practice it is necessary to have a very accurate knowledge of the powers of expansion in the powder when ignited; by which means shells may be thrown, with the greatest precision, to any intended distance; whereas the explosion takes the greatest possible effect.

In our artillery, an eight inch mortar is ordinarily employed as an eprouvette: being charged with two ounces of powder, and an iron ball of sixty-four pounds, the latter should be projected at least 150 feet; the elevation of the piece being 45°, and the ball being placed perfectly horizontal, we consider this to be a fair standard: though some powder made from the best materials, and fresh from the mill will sometimes exceed even 180 feet; while, on the other hand, weak powder, that is, such as has not been kept very dry, or that has been re-stored, will rarely make a range equal to 120, and generally not exceeding even 110 feet.

The above mode of proof relates to cannon-powder; that intended for the use of musketry is ascertained by an eprouvette of a different description; namely, a musket barrel, of which the interior is highly polished. This should, with a charge of only four drachms, impel a steel ball through fifteen wet elm boards, each a quarter of an inch in thickness, and placed at 2 of an inch asunder; the first being 30 feet and 10 inches distant from the muzzle of the barrel. We must confess this exact number of inches in the distance, appears to be more falshous than necessary, for we are apt to believe, that, in experiments of this nature, the odd two inches, necessary to complete the fourth foot, would by no means alter the process.

The French eprouvette for cannon powder comes very close to ours, they using a brass ball of 60 lbs. (French weight) whose diameter is 7 inches and 9 points, or 2 of a line, (French measure) with one line of windage, (or space between the shot and the sides of the bore.) The chamber holds precisely three ounces; which quantity of their best powder will throw the ball full 180 yards; their re-stored powder throwing it about 160 yards. But Monf. Lombard's
bards experiments give a result of 250 yards, with the powder now manufactured at the French mills; the eprouvette being always elevated to 45°.

Fine powder is sometimes tried by means of a small machine resembling a pistol, of which the barrel is very substantial, and the bore not more than the eighth of an inch in diameter. Over the barrel is a circular plate, acted upon strongly by a spring, which offers considerable resistance to the revolution caused therein, by the action of the powder on a projection which shuts down close upon the muzzle. The bore being filled with powder, and the wheel, or plate, turned so that its projection closes the muzzle, the explosion will, in proportion to its force, throw up the projection, and cause the wheel to revolve; the power of the powder is supposed to be ascertained by means of figures on the circumference, which indicate how much the wheel has been thrown round.

But such a machine cannot possibly give a correct standard; it being a subject to variation; as is also that contrivance which causes the powder to act underneath the hammer of a pistol lock. The pan being filled, the powder should have force enough to throw the hammer back. We need not comment on the uncertainty of such an ellimative.

EPSOM, or EBSHEIM, in Geography, a parish and formerly a market town in the hundred of Capthorpe, Surrey, England, is fifteen miles S.E. from London. In the year 1869 it contained 414 houses, and 2454 inhabitants. The houses are disposed chiefly on two sides of a long wide street, or public road, and are situated on the west side of Banstead Downs. These are distinguished for their fine sweet verdure, which is mostly grazed by sheep; and the Banstead water is much esteemed for its flavour. Of these downs are annual horse-races, which are much frequented by gamblers and sharers, from the metropolis. The church, above a mile from the centre of the village, was served for many years by the late Rev. Jonathan Boucher, who died here in the year 1804. A large old seat near the church, called Durand's, was originally built by George, the first earl of Berkeley, with the materials brought from the palace of Nonfuch, when that celebrated royal mansion was taken down. The first house being destroyed by fire, another was erected, and subsequently pulled down by the Earl of Guildford. Several other spacious seats, and pleasant villas, are found in the vicinity of Epsom, among which are Woodcote Park, the late lord Baltimore's; and Pit's Place, which receives its name from being situated within the excavation of a chalk pit. It is a singular and curious place.

Epsom, a town of America, in Rockingham County, New Hampshire, E. of Pembroke, adjoining, 10 miles E. of Concord, and 45 N. W. of Portsmouth. It was incorporated in 1727, and in 1800 contained 1034 inhabitants.

Epsom Salt and Water. This so much celebrated salt was first extracted from the purgative mineral spring at Epsom in Surrey, which had long been celebrated for its medicinal qualities, by Dr. Napham. It was, in 1675, who published a treatise concerning it (De Natura Salis Cathartici Amari). Dr. Grew gave it the appropriate name of salt catharticam amaris, or bitter purging salt; which is still retained, together with the names of Epsom salt, magnesia vitriolata, or sulphate of magnesia of modern chemical nomenclature; which see for the chemical properties of this salt.

The original Epsom salt, or that which was procured by the evaporation of the Epsom water, was sold in London at a very high price. Afterwards it was prepared, very extensively, by chemists of the name of Moul, about the year 1700, by evaporating the water of some springs at the foot of Shooter's-hill; which were found to resemble that at Epsom. Soon after it was discovered, as appears by Haukowitz, a celebrated trading chemist in London, that the same salt could be procured from the bottom of sea-water; and in a few years the secret transpired, and the same was prepared from sea-water at Portmouth, Lymington, and at Newcastle; by which the salt from the Shooter's-hill springs was underlaid, and the works were abandoned.

Epsom salt was for a long time only prepared in this country, and the continent was supplied from hence; on which account it became known in Europe under the name of Epsom, or English salt; but Bergman afterwards discovered the same in the Sedlitz or Seydheitz waters in Bohemia, whence the name Sedlitz salt was added to its other appellation.

A considerable confusion prevailed for a long time between this salt and Glauber's Sal Mirabile (fulphat of soda), the acid of both being the same, and the medicinal uses of each, and comparative doze, not materially differing. In fact it appears, that sometimes the true Glauber's salt was made small grained, by diluting it as it began to crystallize, and sometimes the true Epsom salt was made large grained to imitate Glauber's; and each was occasionally passed off for the other as either happened to be in most request. This kind of fraud indeed is still practiced pretty extensively on parts of the continent where the Epsom salt is not easily procured. Some chemical difference between the two salts was very soon ascertained. Dr. Grew gives it as characteristic of the Epsom salt, that it coagulates with an alkali; but the nature of the earth that forms this coagulum, was not fully understood till the researches of Black and Bergman proved it to be the earth magnetia.

Epsom salt is a highly and justly esteemed purgative medicine, and is in very constant use. The table is salt and bitter, attended, however, with a peculiar flavour approaching to sweetness. Notwithstanding its nauseous taste, it is often found to remain on the stomach when rhubarb and most other medicines are rejected, and in general it operates speedily, effectually, and without griping or debilitating. The usual dose for an adult is from half an ounce to an ounce; but it should be pretty largely diluted in gruel, broth, or any mucilaginous liquor.

EPSTEIN, in Geography, a small town of Germany, formerly in the Landgraviate of Hesse Darmstadt, but since the peace of Lunenburg, in the territory of the princes of Nassau Dietz; it is situated at no great distance from the confluence of the Rhine and Mayn, 18 miles N.W. of Frankfort on the Mayn; and is chiefly remarkable for some good iron mines in its neighbourhood.

EPTACTIS, in Natural History, a name given by Linnaeus, and some other authors, to a species of Ilar-fish, of the Calliophyside kind, whose naked, or, branched, at their first going out from the body, are only seven in number, but which very soon spread into more. See Stom-fish.

EPTAMERIDES, in Medicina, a name given by M. Sauvageau, to one of the subdivisions of the ylum, in the Mem. de l'Acad. des. Sc. for 1701.

This author begins by dividing the octave into 43 parts or merides, then each of these 7 eptamides, to that the octave entire comprehends 301 eptamides, that it shall subdivide. (See Decameridae.) The word is formed of ept, seven, and of merides, a part. In Sauvageau's subdivision the octave is 23 $\frac{1}{2}$ $\sum$ + 7 $\frac{1}{2}$ $m$: and its common logarithm is $= .9959999 .0035$. or $9999000000$ according to the assumption of M. Sauvageau, wherein the octave is $6699000000$ and its reciprocal $3010, &c.$

Epte, in Geography, a small river of France in the 6 department...
department of the Eure, which has its source near Bernay, and falls into the Seine below Vernon.

EPULÆ. See Entertainments.

EPULARES, in Antiquity, an epithet given to those who were admitted to the sacred epulæ or entertainments, it being unlawful for any to be present at them who were not of the ephesian colleges.

EPULIS, (from επυλος, upon, and επομαι, the gums,) in Surgery, a tubercle on the gums. There are two kinds; one of a benign nature, and free from pain; the other more malignant, being very troublesome, and occasionally becoming, according to the description of surgical writers, of a cancerous quality. Some of the excrements are represented as having a narrow particle, while others are connected with the gum by means of a broad base.

The best plan of treatment consists in extirpating an epulis, as soon as the nature of the case permits itself. The object may be accomplished either with cauticum, or the knife. The latter mode is that, to which we should generally give the preference, because attended with the greatest degree of certainty, and not more pain.

Some writers advise us to tie the excrements, when its neck is narrow. However, in such a cafe, the knife, or a pair of scissors, might also be very conveniently employed.

EPULO, in Antiquity, the name of a minifler of sacrifice among the Romans.

The pontifices, not being able to attend all the sacrifices performed at Rome, to so many gods as were adored by that people, appointed three minifters, whom they called epulones, because they conferred on them the care and management of the epula, feasts in the solemn games and festivals.

To them belonged the ordering and serving the sacred banquet offered on such occasions to Jupiter, &c. They wore a gown bordered with purple, like the pontifices, their number was at length augmented from three to seven, and afterwards by Caesar to ten.

Their first establishment was in the year of Rome 578, under the confulate of L. Furius Purpureo, and M. Claudius Marcellus.

EPULOTICS, (from ετυλων to cicatrice), in Surgery, topical applications, which difpose wounds and ulcers to heal.

EPULUM, in Antiquity, banquet, a holy feast prepared for the gods.

The statues of the gods were commonly laid upon a bed, and livered in the epula, as if they had been very hungry; to perform which was the function of the minifters of sacrifice, hence called epulones.

EPWORTH, in Geography, a market town in Lindsey division of Lincolnshire, Englad, is situated 158 miles from London: it is built in a fragging irregular manner; and contains, according to the late population return, 275 houses, and 1434 inhabitants, who are chiefly employed in spinning hemp and flax, of which great quantities are grown here, and in the manufacture of lacing and bagging, which is the chief trade of the town. A weekly market is held on Thursdays, and two fairs annually. Quantities of large oaks, firr and other trees, some of which appear to have been burnt, and others cut down, are frequently found here three feet beneath the surface of the earth. The reproof of Epworth was held by the Rev.

Samuel Wesley, the father of the distinguished leaders of the Arminian Methodists, John and Charles Wesley.

EQUABLE. See Equale.

EQUABLE Motion, is that whereby the movable body proceeds with the same continued velocity; neither accelerated nor retarded.

EQUABLE Pulse. See Pulse.

EQUABLE Style. See Style.

EQUABONA, in Ancient Geography, a town of Spain, in Lusitania, according to the Itinerary of Antonine, situated on the left side, and at the mouth of the Tagus, not far from the sea.

EQUA, a term of relation between two or more things of the same magnitude, quantity, or quality.

Wolius defines equal to be those things which may be substituted for each other, without any alteration of their quantity. It is an axiom in geometry, that two things which are equal to the same third, are also equal to each other. And again, if to or from equals you add or subtract equals, the sum or remainder will be equal.

EQUA, in Practical Astronomy. One of the most practicable and certain methods of determining the time, and thus ascertaining the error of a clock or chronometer, is by observing equal altitudes of the sun, or of a fixed star. For this purpose all that is necessary is to observe the instant the sun or star is at any altitude towards the east, before the meridian passage; and the instant must likewise be marked when the same object attains exactly the same altitude towards the west, after the meridian passage: the mean between the above quantities will be the instant marked by the clock at the moment the sun or star was on the meridian. The preceding operation, however, suppose that the declination of the object has not varied during the elapsed interval, but this with the sun seldom happens. The observation, therefore, must be corrected by a table, or by a direct calculation.

Let P (Plate XII. Astronomy, fig. 166.) be the elevated pole, Z the zenith, S the sun, S B an arc parallel to the horizon H O, so that the points B and S have the same altitude; P S the polar distance of the sun in the morning, P B its polar distance in the evening (supposed to have become less). When the sun in the afternoon arrives at the point B, whose altitude is supposed 29°, the same as the morning, the hour angle Z P B, or the distance of the sun, and its hour angle from the meridian P Z, will be greater than the morning hour angle Z P S. We have, therefore, two triangles, Z P S, Z P B, which have each the side P Z common, and the sides Z S, Z B, each equal to 70°, since they are the complements of the altitudes, 20° in each case. The sides P S, P B, differ by a quantity which is equal to the change of the sun’s declination in the interval between the two observations. If the two triangles be resolved separately, the two hour angles will be found different: half of this difference is the correction, which must be applied to the middle point of time to obtain the exact instant of the sun’s passage over the meridian. This correction is given in the annexed table, which is taken from the last edition of La Lande’s Astronomy. It is calculated from the following differential analogy.

\[ \frac{2 \times \text{tang. latitude}}{30 \left( \text{ho. hour-angle} + \text{tang. dec.} \right)} \]

Multiply the Tangent by the Latitude, and if it is South, change the Signs.
EQUA-L Altitude Instruments, an instrument used in ASTRONOMY for ascertaining the exact time at any place, by means of equal altitudes of any heavenly body, as observed successively at the opposite sides of the meridian. Formerly, the instrument used exclusively for this purpose was a refracting telescope of considerable length, attached to a vertical axis of motion, placed truly perpendicular to the horizon by means of a plumb-line or Spirit-level, so that when the telescope had a given elevation, it might be fixed at that elevation, and describe a parallel of altitude as the vertical axis turned round; which method was equally simple and accurate, as it required no graduated circles for reading either horizontal or vertical angles, but then its utility was limited to the single operation of determining the instant when any celestial body, on the western side of the meridian had the same altitude that it had at a given instant on the eastern side, and hence the intermediate instant when the said body was on the meridian, provided its declination had not sensibly altered during the interval. But in the present improved state of astronomical and nautical instruments, almost any of them will measure equal altitudes with great precision, and at the same time indicate the quantity of the altitudes observed, so that an instrument to take equal altitudes only is no longer a desideratum, and its origin and construction may now be considered as matter of curiosity, or as a link in the historical chain of astronomical instruments, but yet at the time was a link of great importance.

When Sir Isaac Newton presented to the observatory at Trinity college, Cambridge, an excellent pendulum clock for the use of the professor, it became a matter of great importance to have the ready means of ascertaining the rate of the clock to exact time; professor COATES, therefore, contrived an equal-altitude instrument, which was made at very little expense, and which yet fully answered its purpose.

This instrument is described in Dr. Robert Smith's Optics, and also another, which is an improvement on it, as being at that time in the possession of the Earl of Ilay. As we presume it will not be unacceptable to our readers to see how an instrument, that does not indicate any measure, will yet determine equal altitudes with accuracy, we shall give in succession brief descriptions of the two instruments we have already named, accompanied by corresponding figures.

Professor COATES's Equal-altitude Instrument.—Fig. 3. of Plate XVII. of Astronomical Instruments, is a representation of Mr. COATES's equal-altitude instrument, as applied in taking an observation. A B is a strong wooden axis in a vertical position about six feet long, and having the extreme ends of well-tempered steel; the superior end A has a cylindrical pivot, and the lower end a conical one, both refting in adjustable pieces of metal, that are not necessary to be described; two strong bars, C D and D E, are firmly attached to the axis, so as to form a right angle where they are united at D; the like manner two other bars are fixed together and to the axis, namely, G F and E F, making a right angle at F; and below these a thick pin Y passes quite through the axis. Near the top at T is a piece of tappet wire ferewing into the axis, and supporting a plumb-line TV, which falls at the point of a fine needle inserted a little out of the centre of the thick pin Y; so that by turning this wooden pin round, the needle point may be brought into contact with the line whenever it does not touch it; the bar C D has half a dozen tapering pins or pegs turned round, inserted into holes at equal distances, or nearly so, and the bar E F has one such pin. The pin at F supports the lower end of the telescope P Q, and the upper or object end hangs by one of the six pins on the arm C D, as the elevation in any observation may require; the piece L K M, that carries the peg N, by which the telescope hangs, being made fast to its tube. The telescope, not being an achromatic at that time, was five feet long, and therefore required the axis of motion to be at least fix feet. When the pivots of the axis were nicely adjusted with respect to call and well, and also to north and south, which was known by the plumb-line hanging in apparent contact with the needle point, during the whole of an entire rotation, then the object-end of the telescope described an exact parallel to the horizon, or parallel of altitude, and whatever bodies appeared in the centre of the eye-glass, which we suppose to have been a single one, had all equal apparent altitude, and at the same time time was ascertained.

The Earl of Ilay's Equal-altitude Instrument.—The instrument said to have been in the possession of the Earl of Ilay, is represented by fig. 4. of Plate XVII. We know not who was the maker, otherwise we should have given his name in preference. The axis ab is of steel squared, thirty inches long; the upper end of it, a, bears a sextant arch c d, fixed at a immovable; the telescope N is thirty inches long also, and is moveable together with its graduated semi-circle round the same point a as a centre of motion: this semi-circle may be fixed to the sextantal arch at any elevation of the telescope, by the finger-nuts c and d, passing through the circular aperture of the semi-circle, and screwing into the sextantal arch. Immediately under the semi-circle is a spirit-level l m, with screws of adjustment, and at c under it, the axis, for a short way down, is cylindrical, about an inch in diameter, and well-polished. The lower end of the axis is conical, and the eye-piece of the telescope has in its focus five vertical wires representing altitudes parallel to each other, and two parallel cross wires, as represented in fig. 5. When the instrument here described is used, its axis is let down into a stand of the shape of a long hollow parallelopiped, wanting two sides. Its other sides f g, h are a couple of brafs plates, equal in length to the part b e of the axis, and are screwed together edgewayes, but the centre of the upper square end piece b, four inches square, is a round hole, just large enough to receive without touching it, and over this hole is fixed another plate with a triangular hole, concentric, one of the sides of which triangle is moveable by an adjustment screw, to make the cylinder bear aline on all sides: on the lower square, or base i, lies another adjustable piece, with a fine conical hole to bear the point b of the axis, and to adjust the axis vertically by means of its screws, as pointed out by the level. The frame, thus furnished with the instrument, is then firmly fastened to a solid pillar K, by means of a niche made in it to receive the brafs plates. The axis is known to be truly perpendicular when the bubble of the level will remain in the middle of the tube during every part of an entire revolution of the axis. If the axis of this instrument were to be placed parallel to the earth's axis, and in the true meridian, its construction is equally adapted for an equatorial telescope, in which case the semi-circle would in every situation be a secondary to the equator, or would measure declinations. The cross wires in the telescope are very useful for taking five pairs of observations, from which a mean may be taken with greater accuracy than one pair of observations alone would give, and in cloudy weather will afford five chances of seeing the body at the proper instants of required altitude. For the methods of applying the corrections for equal altitudes, and of ascertaining the exact time as deduced from the observations, the reader is requested to consult our article CHRONOMETER, where the requisite problems are exemplified. It is scarcely necessary to add, that a common Hadley's sextant or octant is a good instrument.
In the directions given by earl Stanhope, pages 13 and 14, of his stereotype "Principles of the Science of Tuning," for adjusting his two successive biaural 3ds, and three successive triple notes, his lordship directs that these shall be made to beat equally quick respectively; and falls into the mistake of supposing that this would produce the equal temperament of those 11ths and the 8ths respectively, that he had previously calculated for them, by mean proportions, for his monochord fylem, contrary to the demonstrations of Dr. Smith above; and in a printed "Letter to the Duke of Cumberland respecting the Stanhope Temperament," this error being perferted in, after it had been pointed out by Mr. Farey in the Philosophical Magazine, vol. xxvii. p. 203, it becomes necessary for us to point out (as could not be done under Biaural Thirds, in our work), that the ratios \( \frac{4}{5} \) and \( \frac{3}{2} \) exactly represent the notes \( E, \ bA \) and \( e \) respectively, when the two successive 3ds (which his lordship calls biaural) \( E, bA \) and \( bA \), whose ratios are \( \frac{4}{5} \) and \( \frac{3}{2} \), make an equal number of beats in a second of time; and this number of beats, when \( C \) makes 240 complete vibrations in \( 1 \), is exactly ten times in a second. Thus we see, that there are three different intervals, called by his lordship biaural thirds, whose ratios are \( \frac{4}{5}, \frac{3}{2}, \) and \( \frac{3}{4} \) and their common logarithms are \( 0.895423, 0.5924, 0.895400 \), &c., 1873776.5811 respectively, or in the new notation \( 206.228, 18 m, 207.5, 4 \), and 208.772 nearly respectively; and there are, indeed, others which arise from the new instructions which his lordship gives in the letter to the duke of Cumberland above referred to, for tuning equally-tempered concords by means of the abfence of "beating between the two beatings," which new species of equal beating is considered in the Philosophical Magazine, vol. xxxiii. p. 297, and is shown to produce other intervals than the above, and which yet come under the appellation of biaural thirds, as defined by earl Stanhope.

**Equal Harmony,** has been applied by Dr. Robert Smith to the different concords V, VI, and III, (or their complements 4th, 3rd, and 6th,) when they are so tempered, as to be equally harmonious or pleasanter to the ear, as tempered concords, and the result of his laborious calculations for forming a fylem, wherein every concord within the compass of three octaves shall be equally and the most harmonious, (Harmonics, p. 140,) is, that each \( V, VI, \) and \( III \), are to be tempered \( \frac{5}{18}, \frac{5}{18}, \frac{5}{18} \) and \( \frac{2}{1} \), &c.

In the text, vol. xii. to prop. xx., the doctor gives a table of beats to be made in fifteen seconds of time, by four successive 3ds above \( C \) respectively, in order to form a fylem for the common instruments with twelve notes in an octave, whereon every 11th shall beat sharp, as fast as the \( V \) in the same fylem beats flat: let it be observed, however, that this will not be the case in the 11ths or \( V \)s affected by the beating notes, or resulting 5ths, after this method has been pursued through the first twelve notes.

In the fylem table we have the number of beats for the above succession of 3ds, so calculated, that the \( V \)s and \( V \)s to the same base notes, may equally, the former flat, and the latter sharp; which will give the notes of the doctor’s fylem of equal harmony in three octaves, as far as the fylem can be applied on a defective or dozzevace instrument. At page 220, mention is made of another equal-beating fylem, wherein the 11ths and the \( V \)s to the same base notes, beat equally, and which is said to approach so near to the fylem of equal harmony, as not to need a particular table.

**Vol. XIII.**
EQU.

EQU.

Equal, in Optics. We say, that things seen under equal angles are equal. Equal parts of the same interval, or magnitude, if unequally distant from the eye, appear unequal. Equal objects, and at equal distances, only the one placed directly, and the other obliquely, seem unequal; and that placed directly, the bigger.

Mahony's Equal Courses. See Masonry.

EQUALITY, in Algebra, is a comparison of two quantities, that are equal both really and representatively, i.e. which are so both in effect and letters.

A comparison of two quantities equal in effect, but unequal in letters, to render them equal, is called an equation, which fec.

Equality is usually denoted by two parallel lines, as =: thus \( z + 2 = 4 \), i.e. \( 2 + 2 \) is equal to \( 4 \). This character was first introduced by Robert Recorde. Des Cartes, and some after him, in lieu thereof, use \( \mathcal{R} \) thus: \( z + 2 \mathcal{R} 4 \); for \( z - y \mathcal{R} b + c \), signifies that \( z \) minus \( y \) is equal to \( b + c \).

From an equation we arrive at an equality, by changing an unknown letter into another, whereby the two members of the equation, i.e. the two quantities compared together, and connected by the sign of equality, are rendered equal.

Thus, in the equation \( a x = b c d \); supposing \( x = \frac{\text{bed}}{\text{aa}} \), we change \( x \) into \( \frac{\text{bed}}{\text{aa}} \), and by this substitution arrive at the equality \( \text{bed} = \text{bed} \).

In the solution of a numerical problem, which is to be rendered rational, if there be only one power to be equalled to a square, or other higher power, it is called simple equality.

Where there are two powers to be equalled, each to a square, it is called double equality, &c.

Diophantus hath given us a method for double equalities, and F. de Billy, another for triple equalities, in his Diophantus Redivius.

EQUALITY, in Astronomy. Circles of Equality, or the equant. See Circle and Equal.

Equality denotes the exact agreement of two or more things in respect of quantity. Thus, figures are equal which may occupy the same space, by the fluxion or transformation of their parts. See on this subject an elaborate dissertation by Dr. Barrow, in the 11th and 12th of his Mathematical Lectures.

Equality, ratio, or proportion of, in Geometry, is that between two equal numbers, or quantities.

Proportion of Equality evenly ranged, or \( \text{e} \text{e} \text{q} \text{w} \text{o} \text{n} \text{i} \text{d} \text{a} \text{r} \text{a} \text{t} \text{a} \text{s} \), is that in which two terms in a rank, or series, are proportional to as many terms in another series, compared to each other in the same order, i.e. the first of one rank to the first of another; the second to the second, &c.

Proportion of Equality evenly disturbed, called also \( \text{e} \text{e} \text{q} \text{u} \text{a} \text{n} \text{i} \text{m} \text{i} \text{t} \), is that in which more than two terms of one rank are proportional to as many terms of another compared to each other, in a different and interrupted order; \( \text{v} \text{a} \text{s} \), the first of one rank to the second of another; the second to the third, &c.

Equality, Union of. See Union.

Equality, in Law, the law delights in equality; so that when a charge is laid upon one, and divers ought to bear it, he shall have relief against the rest. 2 Rep. 25.

EQUANIMITY, in Ethics, denotes an even, uniform temper of mind, amidst all the varieties and revolutions of time and chance. This virtue, together with prudence, forms the character which Homer gives of Aresippus:

"Omnis..."
A **quadratic equation**, is that in which the unknown quantity is to two dimensions, or that contains both the unknown quantity and its square; as \(x^2 + 10x = 32\), or \(a x^2 + 6 x = c\).

A **cubic equation**, is that in which the unknown quantity is of three dimensions, or that rises to the cube or third power; as \(x^3 - 3 x = 1\), or \(x^3 + 2 x^2 = 4\), or \(a x^3 + b x^2 + c x + d = 0\).

A **biquadratic equation**, is that in which the unknown quantity is of four dimensions, or that rises to the fourth power; as \(x^4 + 3 x = 5\), or \(x^4 + 3 x^3 = 10\), or \(x^4 + 4 x^3 + 7 x = 50\), or \(a x^4 + b x^3 + c x^2 + d x = e\). And if \(x = 0\), for the fifth, sixth and other higher orders of equations; which are all denominated according to the highest power of the unknown quantity contained in any one of their terms.

The **root of an equation**, is that quantity, whether positive, negative, or even imaginary, that, when substituted for the unknown quantity, will make both sides of the equation vanish, or become equal to \(0\).

Thus, in the equation \(x^2 - 6 x = 72\), either \(x = 12\) or \(x = -6\) is a root, or value, of the unknown quantity; for if each of these numbers be separately substituted for \(x\), they will be found to satisfy the conditions of the equation.

In the resolution of an equation, containing only one unknown quantity, several previous operations are often required to be performed, in order to adapt it to the rule to which it belongs; the greater part of which may be performed by means of a few self-evident and obvious principles; namely, that if equal quantities be added to, or subtracted from, equal quantities, the sums or remainders will be equal; if equal quantities be multiplied or divided by the same quantity the products or quotients will be equal; or if equal quantities be raised to the same power, or have the same root extracted, the results will still be equal.

From these simple considerations are derived the following rules, which will equally apply to equations of all orders, and are alone sufficient for the resolution of simple equations.

**Rule 1.** Any quantity may be transposed from one side of the equation to the other by changing its sign.

Thus, if \(x = 5\) = \(8 + 3\)

Then \(x = 5 - 3\)

And if \(4 x - 8 = 3 x + 7\)

Then \(4 x - 3 x = 7 + 8\)

Or \(x = 15\)

From this rule it also follows that if any quantity be found on each side of the equation, with the same sign, it may be left out of both. And that the signs of all the terms of an equation may be changed into the contrary ones, without affecting the truth of the equation.

Thus, if \(x + 2 = 7 + 2\)

Then \(x = 7\)

And if \(a - x = b - c\)

Then \(x = a + c - b\)

**Rule 2.** If the unknown quantity, in an equation, be multiplied by any quantity, that quantity may be taken away, by dividing all the rest of the terms by it.

Thus, if \(5 x = 49\)

Then \(x = \frac{49}{5}\)

And if \(ax = b - c\)

Then \(x = \frac{b - c}{a}\)

**Rule 3.** If any term of an equation be a fraction, its denominator
EQUATION.

The principal methods, made use of for this purpose, as far as regards the resolution of two simple equations, are the three following:

1. Observe which of the unknown quantities is the least involved, and find its value in each of the two equations by the methods already explained.

This being done, let the values, thus found, be put equal to each other; and there will arise a new equation, with only one unknown quantity in it, the value of which may be found as before.

As an example in this case, let it be required to determine \( x \) and \( y \) from the following equations,

\[
\begin{align*}
2x + 3y &= 23 \\
5x - 2y &= 10
\end{align*}
\]

Then, from the 1st equation \( x = \frac{23 - 3y}{2} \)

And from the 2d, \( x = \frac{10 + 2y}{5} \)

Hence, if these two values be put equal to each other,

\[
\begin{align*}
2x + 3y &= 23 \\
5x - 2y &= 10
\end{align*}
\]

Then, \( 10 + 2y = 23 - 3y \)

\[
\begin{align*}
5 &\quad 23 - 3y = 23 - 3y \\
10 &\quad 23 - 3y = 23 - 3y
\end{align*}
\]

And consequently \( y = \frac{5}{2} \)

And \( x = \frac{10 + 2y}{5} = \frac{10 + 10}{5} = \frac{20}{5} = 4 \)

2. Consider which of the unknown quantities you would first exterminate, and find its value in that equation where it is the least involved.

Then substitute this value for its equal in the other equation, and there will arise a new equation, with only one unknown quantity in it, the value of which may be found as before.

Thus, taking the same example as in the former rule,

\[
\begin{align*}
2x + 3y &= 23 \\
5x - 2y &= 10
\end{align*}
\]

Then, from the 1st equation \( x = \frac{23 - 3y}{2} \)

And, if this value be substituted for \( x \) in the 2d equation, we shall have

\[
\begin{align*}
5 \left( \frac{23 - 3y}{2} \right) - 2y &= 10 \\
115 - 15y - 4y &= 20
\end{align*}
\]

Therefore \( 115 - 15y - 4y = 20 \)

Or \( 19y = 95 \)

And consequently \( y = \frac{95}{19} = 5 \)

And \( x = \frac{10 + 2y}{5} = \frac{10 + 10}{5} = \frac{20}{5} = 4 \)

3. Let the given equations be multiplied or divided by such numbers or quantities as will make the term which contains one of the unknown quantities the same in both equations.

Then, by adding or subtracting the two equations, as occasion may require, there will arise a new equation with only one unknown quantity in it, which may be resolved as before.

Thus, taking the same example as in the two former methods,

\[
\begin{align*}
2x + 3y &= 23 \\
5x - 2y &= 10
\end{align*}
\]

Then, to exterminate \( x \), let the first equation be multiplied by \( 5 \), and the 2d by \( 2 \), and we shall have

\[
\begin{align*}
10x + 15y &= 115 \\
10x - 4y &= 20
\end{align*}
\]

Having thus shewn the manner in which a simple equation, containing only one unknown quantity, may be solved, it will be proper, in the next place, to explain the methods by which two or more equations of this kind may be resolved: and this the reader will find by some of the following rules: observing, in this case, that there must always be the same number of equations as there are unknown quantities, otherwife the question will admit of a variety of answers.

nominator may be taken away, by multiplying all the rest of the terms by it.

Thus, if \( \begin{align*}
\frac{x}{2} &= 3 \\
\therefore x &= 6
\end{align*} \)

And if \( \begin{align*}
\frac{x}{a} - b &= c \\
\therefore x &= ac + bc
\end{align*} \)

Or the denominators may be taken away from several terms of an equation, by one operation, if all the terms be multiplied by any number which is a multiple of each of the denominators.

Thus, if \( \begin{align*}
\frac{x}{2} + \frac{x}{3} + \frac{x}{4} &= 6
\end{align*} \)

Then, if all the terms be multiplied by 12, which is a multiple of 2, 3 and 4,

We shall have \( \begin{align*}
6x + 4x + 3x &= 72 \\
\therefore 13x &= 72
\end{align*} \)

Or \( x = \frac{72}{13} = 5 \frac{7}{13} \)

It also appears, from this rule, that if each of the terms of an equation be either multiplied or divided by the same quantity, that quantity may be left out of them all.

Thus, if \( ax = ab + ac \)

Then \( x = b + c \)

And if \( \frac{x}{a} + \frac{b}{a} = \frac{c}{a} \)

Then \( x + b = c \)

Or \( x = c - b \)

4. If the unknown quantity, in any equation, be in the form of a furd, let it be made to stand alone on one side of the equation, and the remaining terms on the other; then involve each side to a power denoted by the index of the furd, and the quantity will thus be rendered free from any furd expression.

If, for example, \( \sqrt{x} + 2 = 5 \)

Then, by transposition, \( \sqrt{x} = 5 - 2 = 3 \)

And, by squaring both sides, \( x = 9 \)

In like manner, if \( \sqrt[3]{x^2} + a - x = b \)

Then, by transposition, \( \sqrt[3]{x^2} + a = b + x \)

And by squaring \( x^2 + a = b^2 + 2bx + x^2 \)

And by leaving out \( x \) on each side \( a = b^2 + 2bx \)

Or \( a - b^2 = 2bx \)

Or \( x = a - b^2 \)

\[
\frac{2b}{2b}
\]

5. Any analogy, or proportion, may be converted into an equation, by making the product of the two extremes equal to that of the two means.

Thus, if \( \frac{3x}{16} : 5 : 7 \)

Then \( \frac{3x}{16} - 3.5 = 10 \times 5 \)

Or \( 21x = 80 \)

Or \( x = \frac{80}{21} = \frac{17}{21} \)

Having thus shewn the manner in which a simple equation, containing only one unknown quantity, may be solved, it will be proper, in the next place, to explain the methods by which two or more equations of this kind may be reduced to a single one, and thence resolved by some of the foregoing rules; observing, in this case, that there must always be the same number of equations as there are unknown quantities, otherwise the question will admit of a variety of answers.
**EQUATION.**

10x + 15y = 115
10x - 4y = 20

And subtracting the latter of these two equations from the former, the result will be

19y = 95

And consequently y = \frac{95}{19} = 5

And if this be substituted for y in the last of the two given equations, we shall have

5x - 2 \times 5 = 10
Or 5x = 10 + 10 = 20
Or \(x = \frac{20}{5} = 4\)

As another example of this third method, which is commonly more easy and expeditious in practice than either of the other two,

Let there be given \(\{ax + by = c\} \) to find x and y

Then, in order to exterminate y, let the first equation be multiplied by \(f\), and the second by \(b\), and we shall have

\(afx + bf y = cf\)
\(b dx + bfy = bg\)

And by taking the difference of these two equations, there will arise

\(af x - b dx = cf - bg\)
Or \((af - b d) x = cf - bg\)
And consequently \(x = \frac{cf - bg}{af - bd}\)

In like manner, if the first of the two given equations be multiplied by \(d\), and the second by \(a\), we shall have

\(adx + bdy = cd\)
\(a dx + afy = ag\)

And the, difference of these equations being taken as before, will give

\(bdy - af y = cd - ag\)
Or \((bd - af) y = cd - ag\)
And consequently \(y = \frac{cd - ag}{bd - af}\)

In which case, \(x\) and \(y\) are here found in general terms; and consequently the solution will hold true, whatever numbers may be substituted for \(a, b, c, d, e, f, g\).

If it be required to exterminate three unknown quantities, or to reduce the three simple equations containing them to a single one, it may be done as follows:

Find the value of one of the three unknown quantities in each of the three simple equations containing it; then compare the first of these values with the second, and the second with the third, and there will arise two new equations, containing only two unknown quantities, the values of which may be found by either of the former rules.

Let there be given, for example, the three following equations, to find \(x, y, \) and \(z\):

\(x + y + z = 53\)
\(x + 2y + 3z = 105\)
\(x + 3y + 4z = 134\)

Then, if \(x\) be exterminated in each of these equations, we shall have,

\(x = 53 - y - z\)
\(x = 105 - 2y - 3z\)
\(x = 134 - 3y - 4z\)

And by comparing the first of these with each of the other two, there will arise the two following equations:

\(53 - y - z = 105 - 2y - 3z\)
\(53 - y - z = 134 - 3y - 4z\)

From which, by transposition, and the rules of addition and subtraction, we shall readily find,

\(y = \frac{52 - 2z}{2}\)
\(y = \frac{81 - 3z}{2}\)

And consequently, by equating these two values of \(y\), we shall obtain,

\(\frac{81 - 3z}{2} = \frac{52 - 2z}{2}\)
Or \(81 - 3z = 104 - 4z\)
Or \(4z - 5z = 104 - 81 = 23\)
Hence \(z = 23\)
\(y = \frac{52 - 2z}{2} = \frac{52 - 4 \cdot 23}{2} = 6\)
\(x = 53 - y - z = 53 - 6 - 23 = 24\)

And if the three following equations be proposed, in general terms,

\(ax + by + cz = d\)
\(a'x + b'y + c'z = d'\)
\(a''x + b''y + c''z = d''\)

Then the values of \(x, y, \) and \(z,\) found in a similar manner, will be as below:

\(x = \frac{ab'd' - ad'b' + bd'y - ab'd'' + ad'b'' - bd'y}{ab'c' - ac'b' + bc'a' - ab'c'' + ac'b'' - bc'a''}\)
\(y = \frac{ad'c' - ac'd' + cd'a' - ad'c'' + ac'd'' - cd'a''}{ab'c' - ac'b' + bc'a' - ab'c'' + ac'b'' - bc'a''}\)
\(z = \frac{abc'' - acb'' + bca'' - abc' + acb' - bca'}{ab'c' - ac'b' + bc'a' - ab'c'' + ac'b'' - bc'a''}\)

Where, if any numbers whatever be substituted in the place of the literal coefficients, the equation will hold; and in a manner analogous to this, we may exterminate four or more unknown quantities in general terms; and thence, by substitution, determine their values in any numeral equations that may be proposed.

Having thus sufficiently shown the method of solving simple equations, it will next be proper to proceed to the resolution of quadratic equations, or those of the second power, which, omitting the simple case \(x^2 = a,\) and confining ourselves only to such as are compound, may always be reduced to one of the three following forms:

1. \(x^2 + ax = b\)
2. \(x^2 - ax = b\)
3. \(x^2 - ax = -b\)

Where the value of the unknown quantity \(x,\) in each of the equations, taken according to the order in which they stand, may be exhibited as below:

1. \(x = -\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}\)
2. \(x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b}\)
3. \(x = +\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}\)

Or the general equation \(ax^2 + bx = \pm c,\) which comprehends all the three cases above-mentioned, may be resolved by means of the following rule:

Transpose all the terms that involve the unknown quantity to one side of the equation, and the known quantities to the other; observing to arrange them so, that the term which contains the square of the unknown quantity may be positive, and stand first in the equation.

Then, if the square of the unknown quantity have any coefficient prefixed to it, let all the rest of the terms be divided by it, so that the coefficient of the square of the unknown quantity may be 1.

This
EQUATION.

This being done, add the square of half the coefficient of the unknown quantity itself to both sides of the equation, and the side which involves the unknown quantity will now be a complete square.

Lastly, extract the square root of both sides of the equation, by which means it will be reduced to a simple one; and if the unknown quantity be made to stand alone, on one side of the equation, and the known terms on the other, its value will be determined as was required.

Note. The square root of the first side of the equation is always equal to the sum or difference of the unknown quantity, and half the coefficient of the second term, according as that term is + or -.

It may also be observed, that all equations, in which there are two terms involving the unknown quantity, and which have the index of the one just double that of the other, are solved like quadricities, by completing the square.

Thus, \( x^2 - ax^2 = b \), or \( x^2 - a x = b \), are the same as quadratics; their roots being as below.

\[
x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} + b},
\]

As an illustration of the rule for quadratics given above, the following simple examples in numbers will be found sufficient.

1. Given \( x^2 + 4 x = 140 \), to find \( x \).

Here \( x^2 + 4 x + 4 = 140 + 4 = 144 \), by completing the square.

And \( \sqrt{x^2 + 4 x + 4} = \sqrt{144} \), by extracting the root.

Or, which is the same thing, \( x + 2 = 12 \).

And consequently, \( x = 10 \).

2. Given \( x^2 - 6 x + 8 = 80 \), to find \( x \).

Here \( x^2 - 6 x = 80 - 8 = 72 \), by transposition.

Then \( x^2 - 6 x + 9 = 72 + 9 = 81 \), by completing the square.

And \( x - 3 = \sqrt{81} = 9 \), by extracting the root.

Whence \( x = 9 + 3 = 12 \).

3. Given \( 2 x^2 + 8 x - 20 = 70 \), to find \( x \).

Here \( 2 x^2 + 8 x = 70 + 20 = 90 \), by transposition.

Then \( x^2 + 4 x = 45 \), by dividing by 2.

And \( x^2 + 4 x + 4 = 45 + 4 = 49 \), by completing the square.

Whence \( x + 2 = \sqrt{49} = 7 \), by extracting the root.

And consequently, \( x = 7 - 2 = 5 \).

4. Given \( \frac{x^2}{2} - \frac{x}{3} + \frac{20}{3} = 4 \frac{2}{3} \).

Here \( x^2 = 42 \frac{5}{6} - 20 \frac{1}{2} = 22 \frac{1}{2} \), by transposition.

And \( x^2 = \frac{3}{2} x = 44 \frac{1}{2} \), by dividing by \( \frac{3}{2} \), or multiplying by 2.

Whence \( x^2 - \frac{3}{2} x + \frac{2}{3} = 44 \frac{1}{2} + \frac{3}{2} = 44 \frac{1}{2} = \frac{4}{3} \frac{1}{6} \), by completing the square.

And \( x = \frac{1}{2} \sqrt{\frac{4}{3} \frac{1}{6}} = \frac{4}{3} \).

Therefore \( x = \frac{4}{3} + \frac{1}{2} = \frac{11}{6} = 7 \).

It must here, however, be observed, that since the square root of any quantity may be either positive (+) or negative (-), it follows that all quadric equations will admit of two solutions. Thus, the square root of \( a^2 \) (or \( \sqrt{a^2} \)) is either + or -; for (+a) \times (+a) or (-a \times -a) are each equal to \( a^2 \), by the rules for the signs in multiplication. So, in like manner, if there be given \( x^2 + ax = b \), where \( x + \frac{a}{2} \) is found \( = \sqrt{b + \frac{a^2}{4}} \), the root may be + or - \( \sqrt{b + \frac{a^2}{4}} \) or \( - \sqrt{b + \frac{a^2}{4}} \), since either of them being multiplied by itself will produce \( b + \frac{a^2}{4} \). And this ambiguity is usually expressed by writing the uncertain sign + or - before \( \sqrt{b + \frac{a^2}{4}} \), by which means we have \( x = \pm \sqrt{b + \frac{a^2}{4}} - \frac{a}{2} \); and the same mode of reasoning is equally applicable to any literal or numerical quadratic equation whatever.

Thus, in the first numerical example above, \( x^2 + 4 x = 140 \), it has been found that \( x + 2 = \sqrt{144} \), but if the uncertain sign + or - be put before \( \sqrt{144} \), it will become \( x + 2 = \pm \sqrt{144} + 12 \) or \( x + 2 = -12 \), and consequently \( x = 10 \) or \( x = -14 \), which are the two roots of the equation \( x^2 + 4 x = 140 \), as will be found by substituting either of them for \( x \); the result in both cases being 142.

In addition to this, it may be still further remarked, that a quadratic equation may be propounded of such a form, or have its coefficients so related to each other, that the value of the unknown quantity can only be exhibited by means of the square root of a negative quantity, which, it is plain, cannot be determined; as there is no quantity, either positive or negative, which being multiplied by itself produces such a form of expression. If, for example, the value of \( x \) were required from the equation \( x^2 + 15 \) = 4x, or \( x^2 - 4x = -13 \), we should find \( x = \pm \sqrt{-13} \); and as it is here necessary to extract the square root of \( -13 \), which cannot be determined, the question is shown to be impossible, or to involve a contradiction.

But although imaginary expressions of this kind are of no other use in the resolution of quadratic equations, than to shew that a particular problem cannot be solved, they must not, on this account, be altogether rejected; as they are well known to be of the greatest use in many mathematical investigations, particularly in some of the higher branches of the science, where no other mode of reasoning could be so successfully or advantageously employed.

Thus, if \( e \) be made to represent the number of which the hyperbolic logarithm is 1, it is well known, as a theorem in trigonometry, that

\[
\text{Cof. } x = \frac{e^{x/e} + e^{-x/e}}{2}
\]

\[
\text{Sin. } x = \frac{e^{x/e} - e^{-x/e}}{2} \cdot \frac{1}{e}
\]

Where the sine and cosine of any arc \( x \) is exhibited in a very commodious manner, by means of imaginary exponential expressions; which formulae, though objected to, and ridiculed by certain writers, are confided by the celebrated Lagrange (Lecons, fur des Fonct. Analytiques) as one of the finest analytical discoveries of the eighteenth century.

Having thus sufficiently explained the nature of quadratic equations, it will be necessary, before we proceed to the resolution of cubics and those of higher dimensions, to shew how the second term of any equation may be taken away, in order to fit it for a solution; which is done as follows:

Divide the coefficient of the second term of the propounded equation by the exponent of the first term, and add the quotient, with its sign changed, to some new unknown quantity; then if this sum be substituted for the unknown quantity in the propounded equation, a new equation will arise, which will want the second term, as required.

For example, let the quadratic equation \( x^2 = 8 x + 15 \) = 0, be that of which it is required to take away its second term.

Then since \( \frac{1}{2} = 4 \), if \( x \) be put = \( y + 4 \), we shall have, \( x^2 = \).
EQUATION.

\[ x^3 = y^3 + 8y + 16 \]
\[-8x = -8y - 28\]
\[ + 15 = + 15.\]

Whence \( y^3 - 1 = 0 \), the equation required.

From which it appears, that any quadratic equation may be solved without completing the square, by only taking away the second term; for since in the above reduced equation \( y = \sqrt[3]{1} = 1 \), we shall have \( x = y + 4 = 1 + 4 = 5 \).

Again, let the equation \( x^3 - 9x^2 + 26x - 34 = 0 \) be given, to exterminate the second term.

Then since \( \frac{b}{a} = 3 \), if \( x \) be put \( = y + 3 \), we shall have:
\[ x^3 = y^3 + 9y^2 + 27y + 27 \]
\[ -9x^2 = -9y^2 - 54y - 81 \]
\[ + 26x = + 26y + 78 \]
\[ -34 = -34.\]

Whence \( y^3 - y - 10 = 0 \), or \( y^3 - y = 10 \), the equation required.

In like manner, let the following literal equations of the fourth power \( x^4 + px^3 + qx^2 + rx + s = 0 \) be given, to exterminate the second term.

Then, by putting \( x = y - \frac{p}{4} \), we shall have,
\[ x^4 = y^4 - py^3 + \frac{3p^2}{8} y^2 - \frac{p^3}{16} y + \frac{p^4}{256} \]
\[ px^3 = px^3 - \frac{3p^2}{2} y^2 + \frac{3p^3}{16} y - \frac{p^4}{64} \]
\[ qx^2 = qy^2 - \frac{p^2}{2} y + \frac{p^3}{16} \]
\[ rx = r y - \frac{p^3}{8} \]
\[ s = s.\]

Hence \( y^4 + \frac{8q - 3p}{8} y^2 + \frac{8r - 4pq + p^2}{256} y + \frac{256s - 64pq + 16q^2 + 4p^3 + p^4}{256} = 0 \), the reduced equation required. And the same method of solution may be applied to the taking away of the second term of any equation whatever.

Another species of transformation, of use in reducing equations to their simplest form, is that of converting each of the terms as has fractional coefficients into others that shall be integral; which is done by substituting a new unknown quantity, divided by the product of all the denominators, instead of the unknown quantity in the equation; and then, by proper reductions, the equation will be found to have the form required.

Thus, let \( x + \frac{p}{a} = \frac{y}{b} \), \( x + \frac{q}{c} = \frac{r}{d} \), be the given equation.

Then, if \( x \) be assumed \( = \frac{y}{a} \), \( \frac{b}{c} \), \( \frac{d}{e} \), we shall have, by substitution,
\[ y^4 = \frac{a^4b^4c^4d^4}{a^4b^4c^4d^4} + \frac{p^4y^4}{a^4b^4c^4d^4} + \frac{q^4y^4}{a^4b^4c^4d^4} + \frac{r^4}{a^4b^4c^4d^4} + \frac{s}{a^4b^4c^4d^4} = 0.\]

And by multiplying the whole equation by \( a^4b^4c^4d^4 \) it will become
\[ y^4 + \frac{p^4y^4}{a^4b^4c^4d^4} + \frac{q^4y^4}{a^4b^4c^4d^4} + \frac{r^4}{a^4b^4c^4d^4} + \frac{s}{a^4b^4c^4d^4} = 0,\]
which is of the form required.

This preparation being made, it will now be proper to proceed to the solution of cubic equations, or those of which the highest power is of three dimensions; all of which, when expressed in general terms, are of the form
\[ x^3 \pm px^2 \pm qx \pm r = 0.\]

Or, if the second term be taken away, by means of the above-mentioned rule, any equation of this kind may be exhibited under the form
\[ x^3 \pm px^2 = \pm q.\]

And, in this case, the value of the unknown quantity \( x \) according to the rule usually ascribed to Cardan, is as follows:
\[ x = \sqrt[3]{\frac{1}{2} q + \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}} + \sqrt[3]{\frac{1}{2} q - \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}}\]
\[ Or \quad x = \sqrt[3]{\frac{1}{2} q + \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}} - \sqrt[3]{\frac{1}{2} q - \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}}\]
the values of \( p \) and \( q \) being always supposed to be taken with the sign \( + \) or \( - \) according as they are found in the given equation.

The rule may be demonstrated thus:

Let the equation, whose root is to be determined, be
\[ x^3 + px^2 = q.\]

Then if \( x \) be assumed \( = y + z \), we shall have, by substitution,
\[ x = \sqrt[3]{\frac{1}{2} q + \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}} + \sqrt[3]{\frac{1}{2} q - \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}}\]
\[ Or \quad x^3 + px^2 = y^3 + \frac{3xy}{x + z} + \frac{x^2}{x + z}\]
\[ 3xy = -p \]
\[ y^3 + z^3 = q.\]

Where, since in the first of them, \( z = -\frac{p}{3y} \), if this value be substituted in the second, it will become
\[ y^3 - \frac{p^3}{27y^3} = q.\]

Or by multiplying by \( y^3 \), and then transposing the terms,
\[ y^6 - qy^3 = \left(\frac{p}{3y}\right)^3.\]

And as this equation is now in the form of a quadratic, on account of the index of the highest term being double that of the second, we shall have, by the rule already given for that purpose, and by simple equations,
\[ y = \sqrt[3]{\frac{1}{2} q \pm \sqrt{\left(\frac{1}{2} q\right)^2 + \left(\frac{1}{2} p\right)^3}}\]
\[ z = \frac{1}{3p} \pm \sqrt{\left(\frac{1}{2} q\right)^3 + \left(\frac{1}{2} p\right)^3}\]
\[ \text{Whence} \quad x = y + z = \sqrt[3]{\frac{1}{2} q \pm \sqrt{\left(\frac{1}{2} q\right)^3 + \left(\frac{1}{2} p\right)^3}} \pm \frac{1}{3p} \]

as was to be shown.

As a practical application of the rule, let there be given, the equation \( x^3 + 6x = 20 \), to find the value of \( x \).

Thus, if \( p \) be put \( = 6 \), and \( q = 20 \), the analytical expression will become
\[ \sqrt[3]{10 + \sqrt[3]{100 + 8}} - \sqrt[3]{10 + \sqrt[3]{100 + 8}} = \sqrt[3]{10 + \sqrt[3]{100 + 8}} - \sqrt[3]{10 + \sqrt[3]{100 + 8}}.\]
\[ = \sqrt[3]{10 + 10.3923} - \sqrt[3]{10 + 10.3923} = \sqrt[3]{20.3923} - \sqrt[3]{20.3923}.\]
\[ = 2.732.\]
EQUATION.

\[ 2.732 - \frac{2}{2.732} = 2.732 - 0.722 = 2, \] which is the re-
quired value of \( x \).

It happens, however, that the value of the unknown quantity is here only found by approximation; but this, \( \sqrt{10} + \sqrt{10} = 1 + \sqrt{3} \), as may be proved by raising it to the third power, if this be substituted in its proper place, in the above expressions,

we shall have

\[ \frac{2}{1 + \sqrt{3} + \sqrt{10}} = 1 + \sqrt{3} \]

\[ \frac{2 + 2 \sqrt{3}}{1 + \sqrt{3}} = 2, \] as before.

Again, as a second example, let there be given \( x^2 - 6x = 0 \);

Thus, finding the value of \( x \),

Here \( p = -6 \) and \( q = -q \).

Then, by substituting these values in the above formula, we have

\[ x = \sqrt[3]{-\frac{4}{2} + \sqrt{20} \frac{1}{2} - 8} = \sqrt[3]{-\frac{4}{2} + \sqrt{20} \frac{1}{2} - 8} \]

\[ = -1 + \frac{2}{3} = -1 - 2 = -3, \] the required value of \( x \).

But as a quadratic equation has been shown to have two roots, or values, of the unknown quantity, so, in like manner, it may be proved that the unknown quantity, in a cubic equation, has three values or roots, each of which will be found to answer the conditions of the question.

Thus, in the first equation \( x^3 + 6x - 20 = 0 \), given above, where \( x \) has been found to be 2, or \( x = 0 \), if \( x^3 + 6x - 20 = 0 \) be divided by \( x - 2 \), we shall have \( x^3 + 2x + 10 = 0 \), or \( x^3 + 2x = 10 \), the roots of which equation, found according to the rule for quadratics, are \(-1 + \sqrt{3}, 1 + 3, -1 - 3\). Each of which, as well as the former root 2, are values of the unknown quantity, as will be found by substituting them for \( x \) in the given equation.

It must be observed, however, that neither the formula of Cardan, nor any other that has yet been discovered, will be found sufficient to determine the numerical value of the unknown quantity in every cubic equation that can be proposed; for when the coefficient of the second term of the equation is negative, and the cube of \( \frac{1}{3} \) of it is greater than the square of half the absolute term, the expression for the root becomes imaginary, and therefore no intelligible result can be derived from it.

Thus, if the equation proposed, were \( x^3 - 3x = 1 \), the analytical expression, when converted into numbers, will become

\[ x = \sqrt[3]{\frac{4}{2} + \sqrt{20} \frac{1}{2} - 8} = \sqrt[3]{\frac{4}{2} + \sqrt{20} \frac{1}{2} - 8} \]

\[ = \frac{2}{3} + \frac{1}{2} \sqrt{3} - 5 - \frac{1}{2} \sqrt{3} - 5, \] the value of which cannot be determined either in integers, fractions, or rational surds; although, by substituting it for \( x \) in the given equation, the terms will all vanish as they ought; and consequently, in a certain sense, it may be said to be a root of the equation.

This defective state of Cardan's formula, or that in which it fails as a general rule, has commonly been called the irreducible case of cubic equations; and notwithstanding the reiterated efforts of the most celebrated analysts in Europe, from the time when the want of generality in the rule was first observed, to the present day, no remedy has been found for this defect, except by a method of solution which is derived from the trisection of an angle, or by converting the expression into an infinite series; in which latter case that part of the quantity which is imaginary disappears, and by that means enables us to compute the root to any degree of exactness. For it is to be remarked, that although the unknown quantity cannot be determined from the formula itself, yet all the three roots are, in this case, real, and can be found, at least approximately, by either of the two methods last-mentioned.

Leaving this part of the subject, for the present, we shall next proceed to biquadratic equations, or those of the fourth power; any one of which, when the second term is taken away, may be represented, in general terms, by \( x^4 + a x^2 + b x + c = 0 \); and the rule for the resolution of any equation of this form, is as follows:

Find the value of \( y \) in the cubic equation \( y^3 - \frac{a^3 + 12 c}{3} y = b^3 + \frac{2a}{27} (a^3 - 36 c) \), by the rule before given for this purpose; and let the root, thus determined, be denoted by \( v \).

Then find each of the values of \( x \) in the following two quadratic equations,

\[ x^2 + (\sqrt{v - \frac{3}{2} a}) x = - \left[ \frac{1}{2} a + \frac{1}{2} (v - \frac{3}{2} a) \right] + \frac{b}{2} \sqrt{v - \frac{3}{2} a} \]

\[ x^2 - (\sqrt{v - \frac{3}{2} a}) x = - \left[ \frac{1}{2} a + \frac{1}{2} (v - \frac{3}{2} a) \right] - \frac{b}{2} \sqrt{v - \frac{3}{2} a} \]

And the values of \( x \), thus found, will be the four roots of the biquadratic equation \( x^4 + a x^2 + b x + c = 0 \), as was required.

The rule, which is here given in a more commodious form than that of Des Cartes, may be readily demonstrated, by making the given equation \( x^4 + a x^2 + b x + c = 0 \), equal to the product of two quadratic equations, and then equating the coefficients of the homologous terms. Thus, if \( x^4 + p x + q \) be multiplied by \( x^3 + r x^2 + s x + t \), and the product hence arising put \( = 0 \), we shall have \( x^4 + (r + p) x^3 + (s + r q - p t) x^2 + (r q - p t) x + r q t = 0 \).

Hence \( r + q - p = a, p (r - q) = b, \) and \( r q = c; \) and consequently \( 2 r = a + p^2 + \frac{1}{2}, \) and \( 2 q = a + p^2 - \frac{1}{2} \).

\[ b \]

\[ - \]

And if these values be substituted in the equation \( r q = c \), or its equal \( 4 r q = 4 c, \) we shall obtain, after proper reduction, the equation \( p^2 + 2 a p + (a^2 - 4 c) p + b = 0 \).

Or, by putting \( p' = r - \frac{3}{2} a, \) and substituting it in the latter equation, we shall have for the result the cubic equation

\[ y^3 - \frac{a^3 + 12 c}{3} y = b^3 + \frac{2a}{27} (a^3 - 36 c) \], which is that given in the rule.

Hence, if the value, or root of \( y \), in this equation, be put \( = v \), we shall have, from the equations given above,

\[ \frac{v}{2} = \sqrt{v - \frac{3}{2} a}, q = \frac{1}{2} a + \frac{1}{2} (v - \frac{3}{2} a) \]

\[ \frac{1}{2} a + \frac{1}{2} (v - \frac{3}{2} a) + 2 \sqrt{v - \frac{3}{2} a} \]. And by substituting
EQUATION.

Substituting these values in the two quadratic equations

\[ x^2 + px + q = 0, \]  
\[ x^2 - px + r = 0, \]

they will become

\[ x^2 + \left( \sqrt{v - \frac{1}{3} a} \right) x = -\frac{1}{2} a - \frac{1}{2} (v - \frac{1}{3} a) \]

and

\[ x^2 - \left( \sqrt{v - \frac{1}{3} a} \right) x = -\frac{1}{2} a + \frac{1}{2} (v - \frac{1}{3} a). \]

The roots of which equations will be the 4 roots of the proposed biquadratic equation \( x^4 + ax^2 + bx + c = 0. \) As a practical example for the exercise of this rule, let there be given \( x^4 - 6x^2 + 16x + 21 = 0, \) to find the 4 values of \( x. \)

Then, if the numbers = 6, = 16, and = 21 be substituted in the place of \( a, b, c, \) in the cubic equation \( y^3 = \frac{3}{3} x^2 + 12xy \)

\[ y^3 = \frac{2a}{27} \left( a^2 - 36c \right), \]

it will become \( y^3 = \frac{3}{3} \left( 36x + 2 \right) \)

\[ y = \frac{256 - 12}{27} \left( 36 - 36 \right), \]

or \( y = \frac{96y}{576}, \) where the value of \( y, \) as determined by the preceding rule for cubic equations, will be found = 12.

Hence, if 12 be put for \( v, = 6 \) for \( a, \) and = 16 for \( b, \) in the two quadratic equations,

\[ x^2 + \left( \sqrt{v - \frac{1}{3} a} \right) x = -\frac{1}{2} a - \frac{1}{2} (v - \frac{1}{3} a) + \frac{b}{2 \sqrt{v - \frac{1}{3} a}} \]

and

\[ x^2 - \left( \sqrt{v - \frac{1}{3} a} \right) x = -\frac{1}{2} a - \frac{1}{2} (v - \frac{1}{3} a) - \frac{b}{2 \sqrt{v - \frac{1}{3} a}} \]

they will become,

\[ x^2 + \left( \frac{12}{3} + 4 \right) x = \frac{3}{3} - 8 - 2 = -7 \]

\[ x^2 - \left( \frac{12}{3} + 4 \right) x = \frac{3}{3} - 8 + 2 = -4 \]

Or,

\[ x^2 + 4x + 7 = 0 \]
\[ x^2 - 4x + 3 = 0. \]

In the first of which \( x = -2 + \sqrt{3}, \) or \( x = -2 - \sqrt{3}. \)

And in the second, \( x = 3 \) or \( 1, \) which are the roots of the given equation \( x^2 - 6x - 16x + 21 = 0; \) there being always as many values of the unknown quantity, in any equation, as there are units in the index of its highest power; as will be shown in a succeeding part of this article.

But before we proceed to any enquiries of this kind it will be proper to observe, that no general rule has hitherto been found for resolving equations of the 5th, 6th, or other higher orders, notwithstanding the numerous attempts that have been made for this purpose; so that in this respect we have not been able to advance a single step beyond what had been done by Louis Ferreri, Bombelli, and others in the early part of the 17th century, who were all acquainted with the method of resolving biquadratic equations; which is still the boundary that the most skilful analysts, assiduous by all the advantages of a more comprehensive and commodious calculus, have not been able to pass.

But although no general resolution has hitherto been given of equations higher than those of the 4th power, there are, notwithstanding, many particular equations, of all orders, which, on account of certain relations subsisting between the coefficients of their different terms, may be resolved by the rules which have been given for those of the first four orders.

This is particularly the case with what have been usually called reciprocal equations, which are such that the coefficients of the terms form the same numerical series, whether taken in a direct or an inverted order; or that remain the same when the reciprocal of the unknown quantity, or \( \frac{1}{x} \) is substituted for \( x. \)

Thus, for example, the equations \( x^4 + px^2 + qx^2 + px + 1 = o, \) \( x^4 + px + qx + px^2 + px + 1 = o, \) and such of this kind, may always be transformed into others of a degree denoted by half the exponent of the highest power of the unknown quantity, if be an even number, or by half the exponent diminished by 1, if it be an odd number.

Thus, let the last of the two equations given above, \( x^4 + px^2 + qx^2 + px + 1 = o, \) be taken in the form

\[ x^4 + \frac{1}{x^2} + p \left( x + \frac{1}{x} \right) + q = o, \]

which it can be readily reduced; then if \( x + \frac{1}{x} \) be put = \( z, \) we shall have \( x^2 + 2 \cdot \frac{1}{x} + \frac{1}{x^2} = z \); and if this be substituted in the original equation \( x^4 + px^2 + qx^2 + px + 1 = o, \) it will become \( z^2 + p = 2 - q. \) And since \( x + \frac{1}{x} = \), we shall have \( x^2 - \frac{2}{2}x + 1 = o. \)

Hence, if the two roots of the equation \( x^4 + px^2 + qx^2 + px + 1 = o, \) be denoted by \( r \) and \( r', \) we shall have the following equations \( x^2 - r + 1 = o, \) and \( x^2 - r + 1 = o; \) the roots of which will be the four roots of the given biquadratic equation \( x^2 + px + qx^2 + px + 1 = o, \) which is another reciprocal equation, a degree lower than the former; and having the index of its highest power an even number, it is consequently resoluble in the manner above explained.

Also, if two or more roots of any equation are equal to each other, the equation may always be reduced to another of an inferior degree, and the roots, by that means, determined. Thus, if the cubic equation \( x^4 - px^3 + qx^2 - rx = o, \) has two equal roots, each of them will be \( x = \frac{p^3 - 2q^2}{p^3 - 6q}. \)

For, let the three roots be denoted by \( a, b, \) and \( c; \) then by the composition of equations we shall have \( x^3 - (2 + b) \)

\[ x + (a + 2ab) x - a' b = o; \]

where \( 2a + b = p, a^2 + 2ab = q, \) and \( c = b; \) and if these values be substituted in the above form, it will become \( x = \frac{p^3 - 2q^2}{p^3 - 6q} \)

\[ x = \frac{2a + 4ab + 2ab - a^2 + a + b + 2ab - a^2 + 2ab + 2b^2 - 6a^2 - 12ab}{2a + 4ab + 2b^2} \]

as was to be shewn.

Thus, let the equation \( x^4 + 5x^2 + 32x + 56 = o, \) which has two equal roots, be the one proposed to be solved.

Then since \( p = -5, q = -32, \) and \( r = -56, \) if these values be substituted in the formula \( x = \frac{p^3 - 2q^2}{p^3 - 6q}, \) it will become \( x = \frac{-5 	imes -32 - 9 	imes -36}{-5 	imes -32 - 50 - 192} = \frac{-150 + 324}{242} = \frac{48}{242} = \frac{1}{2}, \) which is one of the equal roots of the equation.

Vol. XIII.
And in a similar manner may the equal roots of equations of the higher orders be determined; but though the subject considered as a branch of Analysis is highly curious, and on that account has been more completely and scientifically investigated than in the case here given, its practical importance is too trifling to render any farther elucidation of it necessary, in an article so confined as the present. The same may also be said of the method usually given for determining the roots of an equation by means of the divisors of its left term, and other similar processes, which are mostly tentative, and only adapted to the finding such roots of the equation as are rational, and for that reason readily discovered by a few trials.

It remains, therefore, only to shew how the roots of any numeral equation whatever may be determined by approximation; for which purpose, it will be sufficient to give the rule first employed by Newton and Raphson, which, though attended with some defects, is as commodious, when considered as a general method of ready and easy application, as any one that has yet been proposed. The rule is as follows.

Find, by trial, a number nearly equal to the root required, which call $r$; and let $z$ be put equal to the difference between $r$ and the true root $x$.

Then, instead of $x$ in the given equation, substitute its equal $r + z$, and there will arise a new equation, affected only with $z$, and known quantities.

This done, reject all those terms in which there are two or more dimensions of $z$, and the value of $z$ will then be found by means of a simple equation.

And if the value of $z$, thus found, be added to, or subtracted from, that of $r$, according as $z$ was assumed too great or too little, it will give the root required nearly.

And if this root should not be thought sufficiently near the truth, the operation must be repeated, by substituting the last result instead of $r$, in the equation exhibiting the value of $z$; by which a second correction of the root will be obtained more accurate than the former, and so on to any degree of exactness required.

As a practical example, for the illustration of the rule, let there be given the equation $x^4 + x^3 + x = 90$, to find the value of $x$ by approximation.

Here it is found, by a few trials, that the root is something greater than 4.

Let, therefore, $4 = r$, and $r + z = x$, then,

$$x^4 = r^4 + 3rz^3 + 3r^2z^2 + z^4$$
$$x^3 = r^3 + 2rz^2 + z^3$$
$$x = r + z$$

And consequently by rejecting the terms $z^4 + 3rz^3 + z^2$, we shall have $r^4 + 3rz^3 + 2rz^2 + r + z = 90$;

or, $z = \frac{90 - r^4 + r^3 - 2rz^2 + r + z}{3r^3 + 2rz^2 + 48z + 4} = \frac{90 - 64 - 16 - 4}{57} = \frac{6}{57}$,
and $z = \frac{6}{57} = 0.10$, nearly.

And again, if 4.1 be substituted in the place of $r$, in the last equation, we shall have,

$$z = \frac{90 - r^4 + r^3 - r^2 - r}{3r^3 + 2rz^2 + 48z + 4} = \frac{90 - 64 - 16 - 4}{57} = \frac{6}{57}$$

And by proceeding in this manner, the root may be obtained to any degree of accuracy required.

The chief defect in this rule is, that it does not shew the progress made in the approximation at each operation, and that when the roots are small and some of them nearly equal to each other, they may be passed over, by this method of operating, without their being perceived; both of which circumstances have been particularly noticed by Lagrange, who has given an improved method of approximation in his excellent work on the "Réolution des Équations Numériques," to which we must refer the reader, as being but little susceptible of that kind of concise elucidation which necessarily belongs to an article like the present.

It, therefore, only remains to give some account of the general theory of equations; in which it will be first necessary to shew, that every equation, of any order whatever, has as many roots as there are units in the index of the highest power of the unknown quantity in that equation.

For this purpose, let us take the general equation $x^n + P x^{n-1} + Q x^{n-2} + \ldots + T x + U = 0$; to which all others may be readily reduced: then if a root of this equation be denoted by $a$, the first side of it will be divisible by $x - a$.

For, since $x^n + P x^{n-1} + Q x^{n-2} + \ldots + T x + U = 0$.

And $a^n + P a^{n-1} + Q a^{n-2} + \ldots + T a + U = 0$.

Therefore, by subtraction, $(x - a) (x^{n-1} + P x^{n-2} + Q x^{n-3} + \ldots + T) (x - a) = 0$.

But any expression of the form $(x - a)^n$, where $n$ denotes any whole positive number, is $= (x - a) \times (x^{n-1} + P x^{n-2} + Q x^{n-3} + \ldots + T) (x - a) = 0$.

Or, if the same expression be arranged according to the powers of $x$, they will become

$$x^n + a x^{n-1} + a^2 x^{n-2} + \ldots + a^{n-1} + a^n + P x^{n-1} + P a x^{n-2} + \ldots + P a^{n-2} + Q x^{n-2} + Q a x^{n-3} + \ldots + Q a^{n-3} + \ldots + T$$

Where, by putting $P' = a + P$, $Q' = a^2 + a P + Q$, &c, we shall have $x^n + P' x^{n-1} + Q' x^{n-2} + \ldots + T' x + U' = (x - a) \times (x^{n-1} + P' x^{n-2} + Q' x^{n-3} + \ldots + T') (x - a) = 0$.

And if $b$ be supposed to be a root of the equation $x^n + P x^{n-1} + Q x^{n-2} + \ldots + T x + U = 0$, the former of these will become $x^n + P x^{n-1} + Q x^{n-2} + \ldots + T x + U = 0$, &c; which latter equation may be shown to have a similar factor, $x - b$; and by proceeding in the same manner, the original equation may be decomposed into as many factors, $x - a$, $x - b$, $x - c$, &c., as there are units in the exponent $n$ of its highest term.

Hence, by considering equations as formed by the product of certain factors, $x - a$, $x - b$, $x - c$, &c, we are enabled to discover a number of relations which subsist between its roots and coefficients.

Thus supposing $a$, $b$, $c$, &c, to be the roots of the biquadratic equation $x^4 + P x^3 + Q x^2 + R x + S = 0$, if this be represented by its factors $(x - a) (x - b) (x - c) (x - d) = 0$, we shall have, by multiplying them together,

$$x^4 - (a + b + c + d) x^3 + (ab + ac + ad + bc + bd) x^2 - (abc + abd + acd + bcd) x + abcd = 0$$
and by proceeding in the same manner, a similar result may be obtained for any equation whatever.

Hence, from the bare inspection of this equation, the following consequences are readily derived.

1. The coefficient of the second term of any equation, taken with a contrary sign, is equal to the sum of all the roots of that equation.
2. The coefficient of the third term is equal to the sum
EQUATION.

The sum of the products of all the roots, multiplied together, two by two.

3. The coefficient of the fourth term, taken with a contrary sign, is equal to the sum of the products, of all the roots, multiplied together, three by three; and so on to the last term, which is equal to the product of all the roots with contrary signs.

From this it also follows, that in an equation wanting its second term, there must be both positive and negative roots, and that the sum of the former is equal to that of the latter.

And in the same way, a number of other properties of the various orders of equations may be derived, which will be found of great use, not only with respect to their resolution, but as furnishing the materials for a complete investigation of this curious and interesting branch of analysis.

We shall only farther add, that besides the simple factors into which any equation may be decomposed, it may likewise be produced by multiplying together factors of any degree, provided the sum of their dimensions be equal to that of the proposed equation.

For the application of the principles and rules, illustrated in the preceding article, to the solution of arithmetical, geometrical, and other questions and problems, we refer to Reduction of Equations, Application of Algebra, &c.

Equation, in Algebra, is a term used to express the correction, or quantity, to be added to or subtracted from the mean position of a heavenly body, to obtain the true; it also, in a more general sense, includes the correction arising from any erroneous supposition whatever. E.g. The time of noon, determined by taking equal altitudes of the sun, is first obtained by supposing the sun's declination constant during the whole interval, which false supposition is corrected by an appropriate equation. Most of the principal equations will be found under their different articles, in the various tables to which they belong.

EQUATIONS. Conversion of. See Construction of Equations.

EQUATIONS. Absolute, adjusted or affected, differential, eminental, exponential, fluential, fluxional, literal, numeral, and transcendental. See the adjectives.

EQUATION of a Curve, is an equation having the nature of a curve, by expressing the relation between any abscissa and its corresponding ordinate, or else the relation of their fixations, &c. Thus, the equation for the circle is \( a x - x^2 = y^2 \), where \( a \) is its diameter, \( x \) any absciss or part of that diameter, and \( y \) the ordinate at that part of the diameter; and the equation denotes, that whatever be the absciss expressed by \( x \), the square of its corresponding ordinate will be \( a x - x^2 \). Thus also the equation for the ellipse is \( \frac{x}{a} + \frac{y}{a} = x^2 \); for the hyperbola \( \frac{x}{a} - \frac{y}{a} = x^2 \); and for the parabola \( p x = y^2 \); in all which \( a \) is an axis, and \( p \) the parameter. This method of expressing the nature of curves by algebraical equations was first introduced by Des Cartes, who, by thus connecting together the two sciences of algebra and geometry, made them naturally subservient and auxiliary to each other, and thus laid the foundation of the most considerable improvements that have been made in every branch of them since that time. See Application of Algebra, &c. See also Curve.

EQUATION of Payments, in Arithmetic, is the method of reducing several debts payable at different times, and bearing no interest till after the term of payment of a single debt or payment, to be discharged at once, without loss either to debtor or creditor, allowing simple interest; or, it is the method of finding the equated term at which these several debts should be paid in one sum. Cocker, Hatton, Kersey, Sir Samuel Moreland, and Ward, have given rules for this purpose, which Mr. Malcolm has examined and found to be erroneous; and though the error resulting from any of the rules which they have proposed is not very considerable, the following process furnishes one more accurate.

Let the debt first payable be called \( D \), the last payable \( T \), and the difference \( D - T \).

The distance of the term of payment \( d \); the distance of the term \( t \); the distance of the term \( x \).

The rate of interest, or 1 year's interest of \( 1 \).

The distance of the time \( x \) is \( x - t \) for \( x \) lies before \( t \).

The distance of the time \( T \) and \( x \) is \( T - x \) between them.

Then the interest of \( d \) for the time \( x - t \) is \( d r \times x - t \), or \( d r \times d x - d t \), the interest of \( d \) being one year's interest of \( d \); and \( D T - D r x \) is the discount of \( D \) for the time \( T - x \), because \( T - r x \) is the interest of \( 1 \) for that time, which is consequently the discount of \( 1 + T - r x \) for the same time; consequently, from the nature of the question, we shall have \( d r x - d t = \frac{D + d}{d r} x \times x - x^2 = \frac{D + d}{d r} x + T t \). Then make \( T + t + \frac{D + d}{d r} = a \), and \( D T + d t + T t = z \), and \( a x - x^2 = z \); and resolving this quadratic equation, \( x = \frac{a}{2} \pm \sqrt{\frac{a^2}{4} - z} \).

E. g. Suppose 1000. payable one year hence, and 100\( \frac{1}{2} \) payable three years hence; what is the equated time, allowing simple interest at 5 per cent. per annum?

Here \( D = 105 \), \( T = 3 \), \( r = .05 \).

Then \( D + d = 205 \), \( d r = 5 \); and \( D + \frac{d}{d r} = 205 \times 5 = 41 \).

And \( T + t + \frac{D + d}{d r} = 41 \), or \( a = 4 + 41 = 45 \).

And \( x \) or \( \frac{D T + d t}{d r} = 315 + 100 \times 3 = 83 + 3 \times 5 = 86 \). Consequentially, \( x = 45 \pm \sqrt{\frac{2025}{4} - 86 = 45 \pm \sqrt{625 - 86 - 22.5} \neq 2 \times 45 \), but 43 cannot be the true answer by the conditions of the question, since it is greater than the distance of the last term in the question; and therefore 2 is the answer required.

If there are more debts than two you must first find an equated time for the two that are first payable; then consider their sum as a debt payable at that equated time, and find another equated time for that debt and the next of the given debts, &c. See Malcolm's Arith. book vi. § 5. or p. 616-621.

EQUATION of the Centre. This is the first and most considerable of all the equations that are applied to the mean motion of a planet. It arises immediately from the nature of the ellipse. If the orbit of a planet was perfectly circular
circular it would have no equation of the centre; and a spherical body, revolving round a centre of force in an elliptical orbit, undisturbed by the motion of other bodies, would require no other equation to correct its mean motion than the equation of the centre.

The necessity of applying this equation to the motion of the sun, in its apparent orbit, was known to the early astronomers; for, in fact, no very accurate observations were necessary to show that the sun did not perform equal parts of its annual motion in equal portions of time. When, by means of gnomons, the length of the year and the obliquity of the ecliptic were pretty well established, it must have been easy, with the same instrument, to have observed the declination of the sun every day, and from thence to have computed its longitude. The first astronomers who undertook this examination must naturally have expected to find a regular increase in the sun's longitude for every day in the year; but when they found that in the course of three months the observed longitude differed near two degrees from that which they had computed, it became then evident, that if the sun's orbit was circular, and its motion uniform, at least the earth was not placed in the centre of it.

This difference, which we now call the equation of the centre, was named by the ancient astronomers \( \varepsilon \alpha \beta \eta \gamma \sigma \iota \nu \iota \iota \sigma \), from \( \varepsilon \alpha \beta \eta \gamma \sigma \iota \iota \sigma \iota \), addition, and \( \sigma \alpha \iota \iota \iota \sigma \), subtraction, because this equation is sometimes additive and sometimes subtractive, a name almost applicable to all equations, but applied to the equation of the orbit as the most considerable of all. Hipparchus was acquainted with this inequality in the motion of the sun, which had not long been discovered before his time. He observed, that from the equinox of spring to the summer solstice, there was an interval of 944 days, and from the solstice to the next equinox 923 days; that is, two days less, notwithstanding these periods were equally 96° from each other. The motion of the sun in two days is 1° 58', which is nearly the quantity of the greatest equation. To explain this difference, and to assign the exact proportion to every day in the year, the ancient astronomers either placed the earth out of the centre, at a sufficient distance to produce the greatest equation, or imagined an epicycle to revolve upon the circular orbit, on whose circumference the sun was supposed to move. These suppositions would give the sun's longitude near enough the truth to satisfy the imperfect observations of those days, and when similar inequalities were observed in the moon and planets, new cycles and epicycles were invented to explain them. But these contrivances, however ingenious, had very little pretension to be classed as theories or hypotheses, capable of giving a satisfactory explanation of the causes of these phenomena. An ingenious mechanic may make a clock, that shall represent all the inequalities of solar time, and by a proper application of some very simple principles in practical mechanics, we may represent the most complicated system of motions; yet these machines would give us no instructions as to the original motions which they imitated; and in proportion as they became complicated, should we be the less inclined to suppose any resemblance between their mechanism, and that of the motions they represent.

Nevertheless, in the simple case that we are now considering, had observation accurately agreed with the supposition, there would have been no reason for not admitting it; it would have reflected on the fame ground as Kepler's elliptic hypothesis, before Newton had demonstrated how obviously it is derived from one general law of nature.

For the method of calculating the greatest equation of eccentric orbits, we refer the reader to De la Lande's Astronomy, vol. ii.

We shall here only explain the nature of this equation in an orbit perfectly elliptic. The equation of the orbit of a planet is evidently nothing at the apsides: beginning to reckon from the apsides it augments rapidly; as the true or mean motion being there the flower, differs more from the mean motion, it continues to increase, but less and less rapidly, till the planet has arrived at some point about three signs, and something more from the apsides, at which point the true and mean motions are equal. At this time the equation is the greatest, it begins then slowly to diminish, and the diminution becomes more and more rapid, as it approaches the perihelion, at which time the true motion exceeds the mean motion by the greatest quantity. When it arrives at the apsides the equation is again nothing. In the same manner it increases again to a maximum, and then diminishes till its return to the apsides, where it is again nothing. The equation is subtractive in the first six signs from the mean motion, and additive in the others.

The greatest equation may be derived directly from observation; or if the eccentricity be known it may be computed, and at the same time the degree of anomaly in which it happens. For this purpose it is sufficient to find the point M (Plate XII. Astronomy, fig. 107.) where the plant is at its mean distance. For it is evident, that the moment the planet arrives at the point where its angular velocity \( D, M \) is equal to its mean velocity, the mean longitude will cease to gain upon the true longitude, but their difference will be a maximum; because till that moment the real velocity, which was less, had continually caused the mean velocity to accelerate upon the true, but from the moment they are equal, the real velocity begins to accelerate upon the mean, and to regain the quantity which it had before lost: from this time the true and mean place approach each other, and the equation begins to diminish. Thus the problem consists in finding the point \( M \), and the true anomaly \( A, M \) of the planet, at the moment that its true velocity is equal to the mean angular velocity.

Take \( F, M \) a mean proportional between the two semi-axes of the orbit. With the focus \( F \) as a centre, and distance \( F, M \), describe a circle \( M, N \), which circle will have a surface equal to the ellipse. Suppose a body to describe uniformly this circle in the same time in which the planet describes its ellipse, its angular velocity will always be equal to the mean angular velocity of the planet in the ellipse; and the area described in the circle will be always equal to the area described in the ellipse, because the planet always describes equal areas in equal times. For example, if the planet describes in one day an area \( A, D, F, \) as the part of the elliptic surface, the area \( E, F, O \), described in the circle, will likewise be the \( \frac{1}{2} \)th part of the area of the ellipse; and the real velocity of the planet, or the angle \( D, F, R \), will be equal to the mean velocity in \( M \), that is, to the angle \( E, F, O \); for there are two equal factors having the same length \( E, M \), the same surface, and consequently the same angle. Befides the equal triangles \( E, M, D \), \( M, R, O \), which are the one without, and the other within the circle, shew that the elliptic factor is necessarily equal to the circular factor, that has the same angle in \( F \). Therefore to find the point of the mean velocity, we must find at what degree the intersection of the ellipse corresponds with the circle equal to it in surface. From the point \( M \) let the straight line \( M, B \) be drawn to the other focus of the ellipse, then in the triangle \( B, E, M \) three sides will be known; namely, \( B, F \), which is the double of the eccentricity, \( F, M \), which is the mean proportional between the two semi-axes, and \( B, M \), which is the difference between \( F, M \).
EQUATION.

From the planet A to the time it arrives at the point M of its greatest equation, its true anomaly is less than its mean velocity; therefore, the true anomaly is less than the mean anomaly, and differs from it more and more. When the planet has passed the point P, or its perihelion, and arrives at the point G, having about nine signs of anomaly, its true distance AFG from the aphelion is, in the same manner less than its mean distance, by a quantity equal to the greater equation. If we observe two true longitudes of the planet in G and M, they will differ from each other by the angle GFM, which is the sum of two true anomalies: but the sum of two mean anomalies will be greater by the double distance, since each true distance is less than the mean distance by the whole of the equation. It is easy to calculate the sum of two mean anomalies without knowing the place of the planet A, because the sum of two mean anomalies is equal to the mean motion of the planet for this interval of time, which is found by taking its proportion of the whole revolution; thus, the excess of the mean motion, calculated over the true distance observed, will be double the greater equation, and the two observations are made in M and G, the times that the mean velocities equal the true. It will, on the contrary, be the true or observed motion that will exceed the mean, if the observations are taken on each side the perihelion. To determine the time and the observations made suitable to this investigation, an observer, who should be supposed to have no previous knowledge of the situation of the orbit, must begin by collecting a great number of observed positions, and compare them two and two together, and observe how much the observed motion differs from the mean for each interval; in this manner the greatest of the observed distances will be found double the greater equation; but if this comparison is made with a single observation, then the greatest difference additive and the greatest subtractive, added together, will give double the equation. But since at present we know very nearly the place of the aphelion, and of the mean distances of all the planets, we can immediately select the observations that are made about the time of the greatest equation.

Example.—The 7th October, 1751, the place of the sun observed by La Caille, was, after three successive observations:

<table>
<thead>
<tr>
<th>Date</th>
<th>Longitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>23rd March, 1752</td>
<td>0° 15' 47&quot; 13'.7</td>
</tr>
<tr>
<td>28th March, 1752</td>
<td>0° 8' 25.5</td>
</tr>
</tbody>
</table>

The difference is 5° 24' 22" 11.8

The mean motion calculated for this interval is 5° 20' 31" 43.2

The difference, or double the equation is 0° 3° 50' 28.6

The half of the equation required is 0° 1° 55' 14.5

This would be exactly the greatest equation, if the observations had been made exactly at the moment of the greatest equation; but having calculated by the tables these equations, it was found that 18°.6 must be added to have the greatest equation, which will make the above quantity 18° 57' 33'.

With respect to this 18°.6 it may be remarked, that an error of several minutes in the equation of the tables would have produced no sensible alteration in this correction, as the error would be the same for the given day as for the greatest of all which happened extremely near it.

As it is extremely rare to meet with two observations which are precisely situated in the two points M and G of the mean time, so it is not easy to find by the first calculation the exact value of the equation; but after having found it very nearly, and likewise the place of the aphelion, the equation may be calculated for the times of observation, and likewise the greatest equation; by the method explained above, it may be then seen how much the equation derived from the observations should differ from the greatest. It was by this means that La Caille, in the preceding example, found the above correction 18°.6. The greatest equation of the sun is that which may be observed the most frequently, and with the greatest ease. A person studying astronomy, and desirous of making himself conversant with the methods by which all these elements of the planetary motions have been obtained, may deduce them himself from the Nautical Almanac, or other similar publications; he must regard the longitudes and latitudes of the planets there found as so many observations, and by computing from them, the original elements should be found, from which the tables themselves were calculated. If the minutes and seconds can be omitted, or the nearest half or quarter of a degree only taken, they will represent the observations of the early astronomers, and it will then be seen what very imperfect theories were sufficient to explain such inaccurate observations.

These methods of finding the greatest equation cannot be applied to Mercury, as we never can observe its heliocentric longitude but when on the sun's disc. Its elongation, and that of Venus, is found by observing the greatest diurnal motion when the planet is in the aphelion. For a farther account of this method consult De la Lande's Astronomy.

Cassini employed the transits of Mercury observed in 1661, 1660, and 1667, and found the greatest equation 24° 3'. De la Lande, from the transits of 1740, 1743, and 1753, found 23° 27' 51'. But these observations are not well fitted, as the three points of the orbit are not dispersed at distances sufficiently great. The equation of the centre does not remain for ever the same; by comparison with ancient observations the equation of the earth's orbit appears to have undergone a diminution, and the theory of attraction explains the cause, and affirms the quantity more correctly than can be obtained by observation. La Place makes the diminution for the earth's orbit 0°.0058 decimals in a century.
EQUATION.

The motion of the moon, and its elements, do not remain constant, but undergo progressive alterations, which would soon render the tables inaccurate, if we were obliged to improve merely by comparison with recent observations. The only method of avoiding this inconvenience is to calculate the elements of the lunar motion for different periods very remote from each other, to deduce the variations they have undergone, and then to investigate the laws proper to represent them.

We may apply these considerations to the mean and secular motion of the moon. The mean motion, and its elements, may be obtained with great exactness by modern observations, and which serves as a basis for all the other results, and compare it with ancient observations, to see if it is the same, or if it has materially changed. The method of making this comparison consists in considering the ancient observations of the moon as so many observed longitudes; the place of the moon is then calculated by the tables for this distant epoch, and the result compared with the observation.

The most ancient eclipse upon record may be taken as an example. It was observed by the Chaldeans 721 years before the Christian era, and recorded by Ptolemy. The observation was made at Babylon the 19th March: the moon began to be eclipsed about an hour after its rising. At the middle of the eclipse the longitude of the moon was equal to that of the sun; this latter is easy to calculate by the solar tables; thus the longitude of the moon is given at the period of the eclipse. Now, if the place of the moon be calculated by the tables for this epoch, it will be found less advanced in its orbit, than it must have been by the observation: the difference is about one degree and a half; and this is too great an error to be attributed to the inaccuracy of the tables, we must conclude that the motion of the moon is now accelerated; so that in referring it to a distant period, we throw it too far back in its orbit, which diminishes its longitude.

And this result acquires additional confirmation, by making similar comparisons with observations made at intermediate periods; for if the motion of the moon is really accelerated, we should find the longitude calculated by the tables too small, though the error should be less as the interval is smaller; and this appears to be the case by a similar comparison with an eclipse observed at Cairo by Ibn-uniq, an Arabic astronomer of the 10th century.

This coincidence leaves no doubt as to the reality of the phenomenon; and it appears certain, that the motion of the moon has accelerated from the time of the Chaldeans to the Arabsians, and from that time to the present. To represent this acceleration, a third term, proportional to the time, must be added to the secular motion of the moon, and another secular term proportional to the cube; this, together, is what is called the secular equation of the moon. According to LA PLACE, (Mecanique Celeste, vol. iii. p. 273.) if $e$ be the number of centuries elapsed since 1750, the formula for the correction will be $34^1.424757\,\pi^2 + 0.05721742\,\pi^4$. These seconds are according to the decimal division.

But we are not to infer that this acceleration will always be increasing, or that the preceding formula will always represent it; the theory of attraction, in making known the cause, has shewn that it is periodic, and connected with the variations of the eccentricity of the terrestrial orbit. See Eccentricity, and Equation of the Centre.

This acceleration, after increasing to a certain limit, will be changed into a retardation, but the extent of this period is very considerable; and the interval, which separates us from the most ancient observations, has yet only developed an extremely small part of this revolution. The inequalities which will result in the motion of the moon will amount at least to a 40th part of the circumference of her orbit. Pottery, who will observe these great phenomena, may remark, and not without gratitude, that the geometricalians of the present age have foreseen, calculated, and prepared for the succecors the means of judging of the past and future state of the system of the world, with the fame certainty as in the age in which they lived.

It was the celebrated Dr. Halley who first discovered the effects of this acceleration; and LA PLACE, by a most profound
found analysis, has explained both the cause and the law. The
observer and the geometer are each entitled to admiration.
If the result of the latter is more satisfactory and
useful to science, it must be confessed, that it was a proof
of no small facility in the former to be the first to doubt of
the uniformity of the mean motions which had been admitted
as an established principle for above two thousand years.

Equations, Secular, which affect the Elements of the
Orbit of the Moon. The motion of the lunar perigee is not
uniform, but subject to secular equation analogous to that
of the mean motion, and depending on the same cause. The
comparision of ancient observations with the modern leaves
no doubt of this fact; but it is to the theory of attraction
that we are indebted for the discovery. This equation is
equal to that of the mean motion, multiplied by the co-
efficient \(-3.00052\); that is to say, that if \(k\) represent
the secular equation of the mean motion, the term \(-3.00052k\)
must be added to the mean longitude of the perigee, calcu-
lated from the duration of a tropical revolution.

The motion of the nodes is likewise subject to a similar
inequality, and the equation has the same sign as that of
the perigee; it is equal to the equation of the mean motion
multiplied by \(-0.73542\); that is, to the mean longitude of
the nodes added \(-0.73542k\). These results are confirmed
by observation.

It appears from this, that the secular equation diminishes
the longitude of the perigee and of the nodes when it aug-
ments the mean motion of the node, and reciprocally; hence
the motion of the perigee and of the nodes becomes
flatter, when that of the moon is accelerated, and on the
contrary is accelerated when that of the moon is retarded.
Moreover, these inequalities are connected together by very
simple analogies, since they are represented by the numbers
1; 3.00052; \(-0.73542\).

The anomalistic revolution, depending at the same time on
the motion of the moon and of the perigee, is likewise
modified by the secular variation. It is the same with all
the quantities which depend on the apogee, and on the
nodes.

The theory of attraction indicates, that the distance of
the moon from the earth, the eccentricity, and the incli-
nation to the orbit, are equally subject to secular equations,
which are connected with that of the mean motion. But
hitherto their effect is scarcely perceptible; nevertheless,
in the course of ages, it will become necessary to attend to
them, and they have been calculated in advance. The ex-
pression for the greater axis of the orbit contains no in-
equality of this kind. This likewise is the refult of theory.
The cause of all these extremely curious facts has been ex-
plained by La Place, who was led to them by the discovery
of the original cause which produced the secular equation
of the moon. For the secular equations of the other cele-
tial bodies, see their respective names, and Secular.

Equation-Clock, in Horology, is a clock contrived so
as to indicate both mean and equated solar time, and con-
sequently their difference, which at any instant is the equation
of time. Various contrivances have been invented to anwfer
this purpose by ingenious men, who at one time were feazed
with a rage for inventing such useless appendages of the
clock, but the dictatorial power of fashion has nearly
baffled such superfluities, that are now considered as mere
matters of curiosity. For a description of a clock of this
fort by Enderlin, see our article Clock, and Plate XXIV.

Of Horology.

Equation-Mechanism, in a planetarium or orrery, is a
mechanical contrivance for representing the alternate acce-
lerations and retardations of motion in the requisite parts
of the respective orbits of the different planets, which contrivance
has been variously effected by different ingenious men. If
the motions of the heavenly bodies had been in concentric
circles, and perfectly equal in every part of their orbits,
the construction of a common planetarium would have been
well calculated to exhibit all the phenomena in a natural
and exact manner, provided the trains of wheelwork were ac-
curately calculated for the respective periods, and the length
of the arms proportional to the respective distances; but as
all the planets that have considerable eccentricity, and con-
fsequently considerable equations of the centre alternately
plus and minus, have their motions constantly varying in
angular velocity, a common planetarium, without equation-
mechanism, is a very imperfect machine, and by no means
competent to solve any of the phenomena, in a particular
way, that depend on the relative velocities; for when the
heliocentric motions are improperly represented, the geo-
centric appearances depending on them are deranged, and
no dependence can be placed in the times pointed out of the
apparent conjunctions, oppositions, eclipses, retrogradations,
longitudes, or latitudes of any of the heavenly bodies. For
instance Mercury, which planet performs its period through
the ecliptic in somewhat less than 88 days, instead of con-
triving 44 days in each half of its orbit, at opposite fides
of the conjugate axis, as it does respectively in those at
each side of the transverse axis, continues about 55\(\frac{1}{2}\) days
in the aphelion portion and only 32\(\frac{1}{2}\) in the perihelion
portion, so that the times of conjunction with the earth or other
planet, even allowing the motion of that planet to be equa-
table, would from this cause alone become very irregular,
exceeding or falling short of the mean synodic period by
many days, according to circumstances. It is evident,
therefore, that the variations of velocity depending on the
equation of the centre of both orbits of two planets, one
received from the other, require to be taken into considera-
tion, and allowed for in the construction of any mechanism
that professes to be accurate in the representation of pla-
etary motion.

Contrivances by Mr. Huygens.—The earliest attempt
that we have met with, to produce the requisite inequalities
of planetary motion by mechanism, is that of Mr. Huygens,
the Dutch mathematician and philosopher, who has de-
scribed in his Latin treatise on the construction of his
Automaton, or self-moving planetarium; he has availed him-
sfelf of two different applications of the same principle,
that are respectively applicable to different degrees of in-
equality of motion, that the eccentricity of an orbit may require;
his account and demonstration of both which methods we
shall give in a free translation from his own words, which
will probably be interesting to those who cannot read the
original, particularly as there has been no notice taken
of them by any writer, or instrument-maker, except per-
haps Rowley, during the last century.

"It remains now," says our very ingenious author, "that
we explain how the true anomalies may be represented by
wheelwork; for this purpose let A N P, fig. 1. of Plate
III., of Planetary Machines, be the orbit of a planet, the
centre of which is C with the fun at S, and let the point E
be taken any where in the line S C, so that the eccentricity
S C may be to the radius C A, as C E is to E D; with
which radius and centre E let the circle D M be describ-
ed. Now let it be understood, that upon the centre of the circle
A L there be fixed immovable the contrate wheel D M
with equal teeth, which therefore will necessarily revolve
round the point C as a centre; let it be also supposed that
the arbor of the long pinion K H be directed to C, and
turned equally with its teeth adapted to those of the wheel
D M, which will agree sufficiently, although on account of the
eccentricity of this wheel it will not always have the
pinion at right angles; by this motion, I say, a planet will be
be carried unequally in its orbit, and in such a manner that its motion will very nearly correspond to Kepler's hypothesis. For having taken in the circle DM, described from the point E, any arc DO, let the teeth of that arc pass over to the line CD by turning the pinion KH, and the line CO will coincide with the line CAD, but not so that the point O may fall on the point D, but within at R, because CD, which is equal to both CE and EO, is greater than CO: now whatever may be the angle OCD, such will be that over which the line CAD has moved round the centre C; therefore if we make the angle DCT equal to the angle DC O, CT will be the right line into which CAD will have proceeded from A to the point N, where the right line CT cuts the circumference of the circle AN described from the centre N. But the circle DM, having its centre E advanced to F by making FT equal to ED, will have the same situation as the circle TR: and it appears that on account of the equality of the angles OCD and DCT, the arc DM, which is the right line CT cuts in the circumference of ODM, is equal to the arc DO; so that M and E being joined, the angle MED will be equal to DEO. If, therefore, the arc AL be made to contain as many degrees as the arc DM, and CF be joined, this line will be parallel to EM.

"In the triangles CEM and SEL, therefore, the angles LSC and MEC will be equal, and the subtending sides proportional; for by construction SC is to CL, as CE is to EM, and being equal, to CA, and EM to EC. Also the angles MEC and LSC are equal, and consequently the lines CM and SL are parallel.

"Now by this rotation of the circles DM and AL, the planet placed in A will be moved through the circle AL, very nearly according to Kepler's hypothesis, as may be thus shewn. Let the planet be supposed to have moved from A to N, the space or area ANS will be equal to its mean anomaly; but seeing the lines SL and CN are parallel, the triangles NSC and CLN will be equal, at least their difference will be inexpressible; the space or area, therefore, CLA, and consequently the arc AL, will answer to the mean anomaly when the planet has advanced from A to N. If, however, we make AQP the elliptic orbit of Kepler, the planet will be in Q, where the perpendicular NQ falling on AQP cuts the ellipse AQP, and not in N; but the ellipses are so like circles, that the variation in a machine is imperceptible, N will, therefore, be the true place of the planet corresponding to the mean motion AL, which arc is equal to DO or DM.

"Again, if the pinion be placed in any other point, as at G, equally distant from the centre C, to which the arrow is directed, and the point D, which is the most distant from the centre C, in the wheel ODM, he placed under the pinion, the planet being again at its aphelion A, it appears that the same angles are formed round the centre C by an equable motion of the pinion placed in G as in D. Wherefore in whatever situation the pinion be placed, the motion of the wheel will be unequable, notwithstanding the teeth of the wheel DM are made equal among themselves, provided the pinion is placed in contact with the centre C; it has its teeth made long enough to set with all the teeth of the wheel which come successively to it at different distances from the centre C, and provided that the planet be put to its aphelion point of its orbit, when the longest line, or radius, drawn from C to DM, is in contact with the pinion.

"But since in our machine (automaton) all the pinions are placed on one common arbor, it cannot be placed properly towards the centres of more than two planets; we must, therefore, consider how the same effect can be produced by unequal teeth: for this end let us suppose the circle DM divided into the equal parts Da, b, M, and M, and right lines be drawn to them from the point C, these lines Ga, Ch, CM, Cg, will divide ANL, the orbit of the planet, into the unequal parts Ad, df, dN, Nf. By this method as many unequal teeth may be determined in the circle ANL, as there are equal ones in the circle DM. If now the pinion be applied to these teeth, cut into the fame number as in the former case, they will work together pretty well, though some are too large and others too small for the pinion, and the wheel AN will move unequally as the wheel DM did before, which has been proved to be according to the hypothesis of Kepler."

This is a faithful translation of Mr. Huygens' account and demonstration of his two methods of representing the irregularities of a planet's motion in its orbit, concerning which we have to observe, that, though both of them manifest great ingenuity as to the originality of the project, yet they fall short of producing separately that full effect which he attributes to them, and which he seems to have credited; whereas the truth is, that instead of effecting the whole equation of the centre, the methods just described effect each only one half thereof; for agreeably to Kepler's theory, which supposes equal areas in equal times, bishop Ward has proved that double the eccentricity of a planet's orbit subtends very nearly its greatest equation, and that, according to his elliptic hypothesis, which is an excellent approximation to the truth, if the angular velocity of a planet round one focus of the ellipse be uniformly equal, its angular velocity, as seen from the other focus, will be so unequal, that one will represent the mean and the other the true or equated anomaly very nearly; but the distance between the two foci of any ellipse is its eccentricity laid off both ways from the centre, or doubled; whereas the method of Mr. Huygens' posposes the eccentricity to be taken only once, so that he has demonstrated rightly enough, but from wrong data; for if he had made the distance CE equal to double the eccentricity, then the whole of the equation would have been very nearly represented. The demonstration which Mr. Olinthus Gregory of Woolwich, then of Cambridge, has given in the 2d vol. of Mr. Nicholton's Philosophical Journal of the 8vo. series, to which we beg leave to refer, has proved with great peripetia what the Rev. W. Pearson of Parson's Green had before asserted, that "the eccentricity of any planet's orbit is very nearly equal to the sine of one half only of its greatest equation."

It may be considered as a singular circumstance that a man of Mr. Huygens' genius and mathematical skill, whose whole life was devoted to the sciences, should not discover that the methods which he so ingeniously devised to exhibit a planet's equated motion, produced but one half of the grand equation; and equally singular, perhaps, may it be considered, that no one before the writer of this article has detected the deficiency. When both these methods of constructing a planetary wheel are united, the full effect will be produced: or either of them may be united with any other contrivance that produces only one half the equation.

Mr. Roemer's Contrivance. The next contrivance that we have met with, for representing planetary motion, is that of Roemer, who was mathematician to the king of France in the time of Mr. Huygens; this contrivance is detailed in Mr. Nicholton's Journal, vol. 4. of the 4to. series, by a correspondent, who translated his account from the French of "Machines and Inventions approved by the Royal Academy of Sciences for 1699," and who, in our opinion, speaks better of it than it deserves. The plan proposed might answer for one planet only, but is not applicable to a number of planets at the same time, for the planetary wheel proposed
is intended to be so thick as to constitute the frustum of a cone, on the surface of which a diagonal elliptical line is to be drawn round it, from the smaller to the larger diameter and back again, in which line the teeth are to be formed, after they have been laid down by a pair of dividers from a diagram previously made; so that, setting aside the tediousness of making such a wheel by the mechanical manipulation described; there could not be a number of these wheels brought into action by any of the usual arrangements of wheelwork, seeing the pinions that are to act with them must necessarily be conical also, and be the drivers in every case, which the requisite calculations of the trains in planetary machines will not always admit, where the extreme ratios of relative velocity are so widely different from each other. This plan, therefore, of exhibiting unequable motion in a planetarium, or orrery, must be considered among those projects of ingenuity which are more plausible in theory than serviceable in practice, and no doubt was abandoned for the reasons that have been here stated; which are our reasons for passing over it without further notice.

Dr. Defaguliers's Contrivance.—The next mechanism in the order of time, as far as we know, was Dr. Defaguliers's elliptic pulleys, or oval wheels with grooves at the circumference, and an endless cut-gut surrounding them, as described under our article Cometarium. This was certainly a scientific contrivance, and admits of application where the excentricity of the orbit is great; for the excentricity and shape of the pulleys may be made exactly similar to the excentricity and shape of the orbit to be represented. The principal objection to the adoption of this invention in a planetarium, is the liability of the cut-gut to contract and clagolate with the variations of moiture in a room, and consequently to be sometimes too tight for the pulleys, and sometmes too loose, so as not to perform their office of giving motion to the elliptic plates. We have seen the elliptic plates with their edges cut into teeth, which is a great improvement in the contrivance; and where the excentricity is not very great, a pair of excentric circular wheels will act together very well, to answer the same purpose, as we shall have occasion to shew presently.

Mr. Adam Walker's Contrivance.—Another method of exhibiting planetary motion we have witnessed in the philosophical lectures of Mr. Walker, junior, which, if we recollect perfectly, was this: A wooden board was shaped nearly into the form of a epicycloid, and had equal teeth cut on its circumference by hand, with an arm fixed fast to one of its extremities, that carried the stem of a planet, or of a ball to represent a planet; then a pinion was fixed on the surface of an inclined plane, down which the epicycloidal wheel was suffered to slide by its own weight, in a detached flat, till its teeth came in action with the teeth of the pinion; and a motion given to the pinion by a handle, made the wheel, thus circumstanced, to revolve with unequal velocities, accordingly as its central point was near to, or removed from, the pinion, during its revolution in this sliding flat; thus were not only the accelerations and retardations of motion alternately exhibited, but also the variations of distance, as they regarded the sun's ball fixed in the focus of a elliptical board, placed over this mechanism, and divided into twelve triangular areas, so that the planetary body was seen to move through the twelve sectors, coloured alternately white and black, in a manner corresponding to the same number of revolutions of the pinion; and to perform apparently equal areas in equal times. It is hardly necessary to observe on this contrivance, that, however convenient it might be to illustrate in a general way the nature of planetary motion to an audience, it is obvious that detached wheels acting thus at liberty cannot be introduced into any machine that gives motion to a cylinder of bodies, where their apses cross one another in various directions, and would require as many inclosed spaces as there are planets to be represented; likewise the planetary arms would require to be attached to wheels in every instance, though the calculations of the ratio of velocity might, and, according to the general contrivances, would require in some instances pinions to be the last movers; all which difficulties in practice are insurmountable. The shape of the planetary wheel, we have understood, was not determined geometrically, nor yet by calculation, but by a repetition of manual rectifications of the figure till it was found to correspond with the areas previously delineated.

Mr. Joseph Prieikey's Contrivance.—When Dr. Birbeck was appointed professor to succeed the late Dr. Garnet, at Anderson's University in Glasgow, his friend, Mr. Joseph Prieikey of Bradford, contrived an orrery, which was made for him by a watch-maker at Halifax, of the name of Thomas Litter, which orrery the doctor has lately brought with him to London, on quitting the said professorship. It was finished in the year 1801, and will be described in its proper place with the other planetary machines. The inequalities of motion in this machine are produced by two separate methods; the two superior planets Saturn and Jupiter have their equations effected by inequalities made in the teeth of the last moving wheels; but the others have their equations, with the exception of the earth, produced by a contrivance which is at the same time novel, simple, and accurate enough for mechanical representation. The inventor has been kind enough to comply with our request of his giving us an account of his mode of producing unequal motion by mechanism, which account we shall present to our readers in his own words. The figure to which he refers, is fig. 2, of Plate III. of Planetary Machines.

Let A P B, says Mr. Prieikey, be the orbit of the planet, O its centre, and S and F the two foci; in the former of which the sun is supposed to be placed. On the other focus F, as a centre, describe a circle D E P. Let P be any given place of the planet in its orbit; draw F P, cutting the circle D E P in p. Now, agreeably to the hypothesis of Ward, it will be,

As the periodical time of the planet, is to the time of its pasling from A to P;

So is 360 degrees, to the angle E F P.

Hence, if a point p be made to revolve equably in the circle D E p, described on the lower focus F of the orbit, performing one revolution in the periodical time of the planet; and if, at any given time, the point be found at p, then a line drawn from the focus F through p, will cut the orbit of the planet in P, its place at the same time.

There are different ways of adopting this hypothesis in machinery. The first I shall mention, will immediately occur to any one viewing the figure. Let a wire, something longer than F P, be made to revolve equably round F, in the time representing one revolution of the planet. On this wire let a fluid P be made to slide freely, and confine to move in the orbit A P B; then the motion of the fluid will, very nearly, represent that of the planet.

In the construction of an orrery, where each planet will require a separate arm F p, movible on its particular centre, with the filder F confined to its own orbit, it may not be easy to construct the whole so as to prevent one part of the machinery from interfering with another; nor can this method be conveniently used, where the wheels carrying the
arms are rims. The following construction has been found to answer the intention, and the motion to be very free and regular.

Let \( E \rho D \) be the toothed rim moving equably, the time of a revolution representing that of the planet. This rim may have any convenient diameter, not differing greatly from the orbit. Upon this rim, or on any projection attached to it, is fixed a pin \( C \), round which one end of a bar \( C P \) moves; on the other end of the bar is fixed a perpendicular wire, or item \( P \), which carries the planet. This item is confined to move in the orbit \( A \rho B \); and, during its revolution, is made to rise and fall, so as to show the inclination of the orbit to the ecliptic. The bar \( C P \) may be any convenient length, and the pin \( C \) should be so situated, that when \( P \) is at \( f \), the bar becomes a tangent to the circle \( E \rho B \). This is necessary, that the end \( P \), in its vibrations on \( C \), may be always found, as nearly as possible, in the line \( E \rho P \); and on this account, the length of the bar should be as great as circumstances will conveniently admit.

Contrivances by the Rev. William Pearcy.—Some time previously to the year 1756, the Rev. William Pearcy, who lived at that time in the city of Lincoln, had read the accounts of Mr. Benjamin Martin's and Mr. James Ferguson's planetary mechanism with such attention, as enabled him to discover many imperfections in them, which it appeared to him might be avoided, and among the rest that defect which arises from equable motion and unvarying distance. On entering into a correspondence with one of the instrument-makers in London, he found that the modern machines owed their origin chiefly to one or the other of the above-named authors, and that little or no improvement had been made in the accuracy of their representations since their time. In consequence of this information, he undertook, with the contrivances we have just described, except that of Dr. Defaguliers, described by Mr. Ferguson, he turned his mind towards the subject with a view of devising some improvements in this kind of machinery, which required an union of mechanical skill, with a knowledge of the science of astronomy, to enable him to strike out original plans for the accomplishment of his purpose. His first object was to render the trains of wheel-work as nearly as possible such as would produce the true periods of the different planets in their orbits, in doing which he found no difficulty after he had adopted a direct and unerring system of calculation, which became easy and familiar by practice; but this part of his pursuit is not the object of our present article; the next object of his attention was to deviate the mechanical means of exhibiting planetary motion, both with regard to variable velocity and variable distance; different methods presented themselves in succession at different times, some of which he afterwards found had been tried before by others, but the first project that promised to be really serviceable to his purpose was that which was represented in fig. 2, of Plate III. of Planetary Machines, and which was made for the arm of Mercury, in an orrery constructed under his direction, by a clock-maker at Lincoln. The contrivance had three objects in view, the variable distances, the variable velocities, and the latitudes of the planets, or deviation from the ecliptic, two of which purposes it answered most completely, and the third in a certain degree, besides preferring, fourthly, the parallelism of the planet's axis in every part of its orbit. It occurred to the contriver of the mechanism in question, before he had ever seen Mr. Adams's "Geometrical and Graphical Essays," and before he had heard of "Sevrié's Geometric Pen," that if a small arm were by any means made to rotate in a retrograde direction, when placed at the distant end of the long arm, or radius vector of any planet, during the time that the radius vector itself revolved just once by a direct motion round the fun in the centre, the curve traced by a pencil placed at the remote end of the small arm would be an eccentric circle; and also that there would be an alternate acceleration and retardation of angular velocity in the pencil with respect to the fun, or central point round which the radius vector might be carried; which velocity would be the quickest when the pencil was in its nearest situation, and slowest when most remote; because in the former case, the compound motion would be the sum of two motions, both in the same direction, and in the latter the difference of two motions in contrary directions. This idea, having at the back of it such considerations as are mentioned on the mind of the inventor, excited in him much impatience to have it brought to the practical test of an experiment; the small frame, shown in fig. 3, was roughly put together, and the equal wheels \( A, B, \) and \( C \), were included, so that \( A \) was fast to the arbor \( S \), but \( B \) and \( C \) revolved on their arbors in the frame; the arbor of the latter, however, was left long enough for its pivot to protrude downwards, and to receive a crank-piece \( P \), bearing a short pencil: the item or arbor \( S \), having its conical point at \( S \) fixed on a sheet of paper, was then held fast by a милликуt above it, to prevent its revolving, and the frame was carried round while the three small wheels, with equal numbers of teeth, were connected together; the consequence was, as had been expected, that the pencil traced a circle of a diameter equal to twice the distance of the arbors \( A \) and \( C \) from each other, but the centre of the circle was found to be at \( G \) instead of \( S \), just the length of the short arm or crank-piece \( P \), from the point \( S \), from which the eccentric circle was described. This fact determined at once that the frame and the arm ought to be to each other in length as the distance is to the eccentricity of the orbit of any planet thus to be described, and, as orbits with but little eccentricity are very nearly eccentric circles, a circle thus described cannot be differentiated in a machine from an ellipse of the same eccentricity.

Before we proceed to describe the mechanism resulting from the principle of a little arm revolving backwards on the end of the radius vector of any planet just once in each revolution of the planet, let us illustrate the principle itself more clearly. Suppose the line \( A C \), in fig. 4, of Plate III., to represent the length of the frame or radius vector \( S C \), and also the short arm \( C A \), representing the eccentricity or distance from the centre to the focus of the orbit, to be both directed into one right line \( S A \), before any motion be communicated to the frame; then as the teeth of the three wheels \( A, B, \) and \( C \), of equal numbers of teeth, are connected together, and the wheel \( A \) is at rest, the wheel \( B \) will have a motion in the same direction as the frame, and the wheel \( C \) will have its motion in a contrary direction, but of the same velocity; conceive the centre of the wheel \( C \) to be carried along the circumference of the concentric circle \( C O F \), the space of the quadrant \( C O \), this wheel \( C \) by means of its connection with the wheel \( A \), through the medium of wheel \( B \), will in the same time have made a quarter of a revolution, and the remote end of the small arm attached to this wheel will be at \( N \), in eight angles to the radius vector, after having passed along the quadrant \( A N \), of the eccentric circle \( A N P E, \) of which the point \( G \) is the invisible centre, and during the whole continuance of these two equal but contrary motions of the radius vector and short arm, through these quadrants respectively, the latter will have preferred itself parallel to its original situation \( A C \), again, while the radius vector is moving through the three remaining quadrants of the concentric circle.
circle from O to I E and C, successively, the remote end of the small arm will describe the three corresponding quadrants of the eccentric circle from N to P, M, and A, in equal portions of time, and its parallelogram will still be preferred throughout the whole circle, as seen in the figure. Thus, while the centre of the wheel C describes the concentric circle COIE round the point S with an equal motion, the remote end of the small arm, supposing to carry a planetary body, will describe the eccentric circle ANPM, during the whole of which time the motion of the planet will be equal as it respects the point G or centre, but unequal as it respects the point S out of the centre, where the fun is supposed to be placed: for conceive lines like SN to be drawn from S to the planet in different parts of the circle ANPM, or orbit, and they will intersect the circle COIE behind the remote end of the radius vector in one half of a revolution, and before it in the other, and the angle at S, subtended by the short arm in any situation, will express the equation of the centre in that point of the orbit, which equation, therefore, is additive to the mean motion of the radius vector in one six figure of anomaly, and subtractive from it in the other six. The nature of the alternate retardation and acceleration of motion produced by this mechanism round the point S, and also the variation of distance, may be easily apprehended by attending to the successive retrograde and the direct motion of the arm in each revolution of the radius vector; from A to N these move in opposite directions, and the difference of their velocities, as viewed from S, is equal to the quantity of retardation in any particular point of this quadrant; at N the difference is nothing, in which situation of the arm the equations would be a maximum if the arm were perpendicular to the line SN, i.e. if SN were a tangent, to the circle of which the arm ON is radius; but this will not happen till the radius vector has advanced beyond the space of an exact quadrant, and the arm has come to S, where the angle subtended at S by the arm will be the greatest possible.

The distance of this point, where the equation is a maximum from 90° of mean anomaly, will evidently depend on the relative proportions in length of the radius vector and short arm, or which is the same thing, of the mean distance and eccentricity of the planet to be represented. From n to P, through the remainder of the first semi-circle, the radius vector and arm will both move in the same direction, and will cause an acceleration which will be greatest at P, the perihelion point, where they will both be again in a straight line, shortened by double the whole length of the short arm, as compared with the original situation at the aphelion point. From the perihelion to the point of greatest equation at the opposite side of the orbit, the motions of the radius vector and arm continue to be in the same direction, but through the half quadrant and a small portion of the third, the directions are again opposite till the planet arrives at the aphelion point A, where it has undergone all its changes of velocity and distance, and where it commences the familiar alternation of slow and quick motions that were before exhibited.

Thus, if S be considered as the fun, A the place of the aphelion of any planet, P its perihelion, n and n, in the small circle of the arm, the places of mean motion, the concentric circle COIE the ecliptic, and the eccentric one ANPM the planet's orbit, it is evident that both the eccentricity, and also a certain equation of the centre of a planet's orbit, may be very conveniently represented by the figure apparatus that has long been used for no other purpose but that of preserving the parallelism of its axis.

But still the main question is not disposed of; viz. what portion of the equation, considered as an arc of the orbit, will a line equal to the eccentricity subtend? The analogy for resolving this query is as follows:

As the mean distance, or radius vector, of the planet, Is to radius, So is the eccentricity, or short arm, To the line of the greatest angle at S subtended by the short arm.

This angle, taken in degrees and minutes, we find is invariably, as nearly as may be, one-half of the greatest equation, as has been already mentioned.

It will now have occurred to the reader, probably, that, if a line equal to the eccentricity subtends one-half the equation of the centre of a planet, double the eccentricity will be the measure of a short arm that will subtend the whole equation; this is nearly true as to the question of the equation alone, but then the distances and eccentricity of the orbit, on which the geocentric appearances depend, would be greatly out of proportion; and what is gained in the heliocentric apparent places would be lost in the geocentric appearance in the syllum. To keep all the deferentia within their due bounds, and to make the elements of the orbit accord with both heliocentric and geocentric appearances in the mechanical representation, an additional contrivance was superadded, which supplied the defect of the revolving short arm without deranging materially the effect of its operation; the last wheel of the train, which carries the radius vector round in the due period, had its teeth so unevenly cut as to represent the second half of the equation, by causing an alternate acceleration and retardation in the revolution of the radius vector itself, so that the total effect produced by these two contrivances acting together was very nearly agreeable to the real motion of the planet itself in its own orbit. But we have said, that the latitude of the planet was represented by the same contrivance that shews the distances and one-half of the equation. This was done by placing the stem of the planet in a square socket, at the remote end of the small arm, in so detached a way, that it was at liberty to roll on the plane of an inclined plate, carried by the radius vector, to represent the inclination of the orbit, and to receive the circular scale of latitudes pointed to by the end of the stem as it travelled up and down the said plane in its retrograde revolution.

The little frame we have had occasion to mention might do very well as a piece of mechanism for a radius vector, where the length is small, but where the planet is represented as moving at a considerable distance from the sun, the mechanism contained in fig. 3 of Plate IV, is better adapted, where A B is the radius vector proportional to the mean distance, and embracing half the upper extremity of the tube of the wheel with unequal teeth; C is a contrate wheel of any number of teeth made fast to a surrounding tube that has no motion; the horizontal arbor D has two pinions of equal numbers, no matter what, one of which, E, is connected with the fixed wheel G, and the other, F, is connected with a second contrate wheel G, which is every way like the wheel C, except that its position is inverted for the sake of making its direction of motion retrograde; the lower pivot of wheel G rests in a cock H, attached to the end of the radius vector, and its upper pivot ascending above the same carries the short arm that supports the stem of the planet; half, I is the inclined plate with a scale of latitudes, on which the end of the stem rests, and by which it is made to ascend through one portion of its orbit, after which its own weight brings it gradually down again. The inclined plate is so placed that the nodes may fall at their respective
respective distances from the aphelion point; and all the changes of place arising from the combined causes of varying distance, varying velocity, and inclination of the orbit, are duly represented.

A similar combination of mechanical contrivances was afterwards, in the year 1802, adopted by Mr. Pearson, when he contrived and superintended the construction of the large planetarium at the house of the Royal Institution in Albemarle Street, London; though the means are somewhat different. The plane of the instrument was defined by Dr. Thomas Young, at that time the lecturer, to be vertical instead of horizontal, as before, and he contrived two wheels to which the short arms, representing the respective excentricities, revolved backwards by a weight suspended to each, instead of the wheel-work which we have described: the inequalities among the teeth of the tubed wheels in this instrument effect one half of the equation, and the retrograde revolutions of the little arms produce the other, and make all the planets revolve according to equated motion, while the levers round which the said short arms revolve are, agreeably to Dr. Young's suggestion, so bent, as to represent also the inclination of the orbits, and consequent heliocentric latitudes, for estimating which the ecliptic plate is put exactly in the plane passing through the centre of the sun, or coincident with the plane of the earth's orbit. The small divided plates carried by the ends of the radii vectors indicate both the equations and heliocentric latitudes; which observations we make here, because the construction of the instrument has never yet been publicly explained, except perhaps partially in the lectures, and because the uses of the different parts, not being obvious by mere inspection, are not yet fully understood. For a more particular description of this instrument, see our article PLANETARIUM.

But we are not to take for granted, because one half of the greatest equation will be thus represented at the point of mean distance by a radius vector and short arm, that are to each other as the mean distance to the excentricity, that therefore half the equation will be equally well represented in every other part of the orbit of a planet. Let us examine this matter more particularly, and bring it to the test of actual calculation. Let the line S H, fig. 5, of Plate III, be the radius vector of Mercury, and H A the short arm representing the excentricity, which are to each other very nearly as 5 to 1; then when the planet is at A, its greatest distance from S, the Sun, it is obvious from what has been said, that its angular velocity, as it respects S, must be slower than if it were at P, or any other part of the line S A; conceive now the point H, round which the little arm revolves, to move forwards so far that the planet may fall back by means of the arm to the point a; then if the line were drawn from S to a, the equation or angle at S would be subtended by a b, the line of the angle A H a to radius A H, which line consequentlly is perpendicular to the radius vector at the point b; the distance b H is the cosine of the same angle, and we have S H + H b for the base of a right-angled triangle, and a b for the perpendicular of the same, to determine the angle at S or semi-equation, which is one of the simple cases in plane trigonometry, where the base is used as radius, and the perpendicular as tangent of the required angle. For example, the mean distance of Mercury, as given by La Lande, is 38710, and its excentricity 7955.4; the mean distance of the earth being 100000; then if, agreeably to this ratio, we take the small arm representing the excentricity at unity, the radius vector must be 4.86587; for as 7955.4: 38710:: 1: 4.86587; let the point a now be taken equal to 30° from A, and from the tables of natural

</table>
EQUATION.

In examining the preceding table it may be seen that the place of mean motion, or point where the equation is a maximum, falls, according to the mechanism, somewhere between 100° and 110°, which, in L. Landes' tables, is at 105°; let us try where it will fall exactly by the mechanical representation.

The point B, where the line SB is a tangent to the small circle, is the place of the planet's greatest equation, and this point will be found beyond the first quadrant, a quantity equal to the angle QH, or, which is the same thing, HS, or greatest semi-equation; for as SH and SB are both right-angled, and have the angle at S common to both, the third angle, HQS, is equal to the third angle BHS, and, consequently, the supplemental angle QH is equal to the supplemental angle HST, or greatest semi-equation. Q.E.D.

But the greatest semi-equation by the mechanism when computed is 1° 51' 34'', therefore the place of mean motion falls at 90° + 1° 51' 34'', or at 101° 51' 34'', which point is short of 105° by a quantity upwards of 3''.

This want of exact coincidence is, however, of little or no moment in the mechanical representation of the orbit, because the quantity of the greatest equation is nearly stationary for many degrees both before and after the exact point of mean motion. The representation will be still more accurate where the orbits have less excentricity, than that of Mercury, which is the case with all the other planets, except two out of the four newly discovered ones, viz. Pallas and Juno.

As we have had frequent occasion in this article to speak of a wheel with unequal teeth, made for the purpose of effecting alternate accelerations and retardations of angular motion, and have also seen the theory explained by Mr. Huygens, it may be proper to say a few words here about the practical method of cutting such a wheel. This operation may be done by three different methods; first, the divided circle of the plate, to be used with the engine, may have the divisions laid down unequally by Huygens' mode of transferring equal divisions from an eccentric circle to a concentric one, as already explained; and then the teeth may be cut in the ordinary way from these unequal spaces, when punched or drilled into dividing holes; or, secondly, an equally divided circle of the engine plate may be used, and the increments and decrements, previously calculated, may be given at each tooth by the micrometer screw of such an engine as either Hindley's or Rebe's; or, thirdly, which is the readiest method, the wheel to be cut may have a hole drilled in the eccentric point, and be placed thereby on the arbor of the engine, till all the teeth are marked with slight notches by the cutter, adjusted for distance at each cutting, and then the hole in the centre must be used for completing the teeth in their proper direction; for when the cutter is put into the notches face to face, it will cut the teeth towards the centre without any guidance of the index or alidade; and this method is practicable with any common engine without a micrometer screw for taking and giving small portions, as deductions from or additions to the mean tooth. For the wheels with unequal teeth in the large planetarium of the Royal Institution, in Albemarle street, London, the first method was used by the maker, Mr. McCulloch, under the direction of the contriver both of the machine itself, and of the method used of rendering the teeth of certain wheels gradually unequal round each separate semicircle, accordingly to the planetary motions to be produced thereby in the planets themselves; but in an accurate and elegant machine since made (by Fidler) for himself, the last method was used with success for the large wheel that produces the sun's, or rather earth's annual equation.

Another, and that a very recently contrived method of exhibiting the equations of all the planetary orbits at the same time, together with their variable distances, by very simple mechanism, has been adopted by Mr. Pearson in the machine we have just mentioned, as made by Fidler, under his own direction; this method has the advantage of showing also the mean motions, and is well calculated for illustrating the irregularities of motion on which the various phenomena of the heavenly bodies depend, as well as for showing the exact times at which they occur, and the countries to which they will be visible. For a description of the machine itself we refer the reader to the articles PLANE
erium and ORB ity, and satisfy ourselves in this place with an account of the principle by means of which the equations of the centre are effected. Fig. 1. of Plate IV., of Planetary Machines, which is illustrative of the principle in question, is derived from fig. 4. of Plate III., which has been explained, but has the addition of a third diminutive arm at the end of the longer arm placed at the extremity of the radius vector; we have seen that one arm, equal in length to the excentricity of the orbit to be represented, will, by its retrograde revolution, give the distances and one half of the equation, very nearly, in every part of the orbit, and we have seen that if the said arm were made equal to twice the excentricity, it would give the whole equation near enough, but would not give the distances truly; now the introduction of the additional arm is to make the apparent place of the planet fulfill both these conditions, which it does in a furrowing manner. Let S, in fig. 2., be a radius vector, revolving equally round the point S, in fig. 1., in which case the extreme end J will describe the concentric circle J K O L Q R T; let J be a short arm equal in length to the excentricity once and a half taken, which arm is made to revolve in a backward direction by means of the fast grooved circle d, of the catgut e f, and of the pulley g of the fame diameter as d, which mechanism answers as well as that in fig. 3., before described, and is simpler: over the pulley g is fixed half to a limb, borne by the radius vector, round which the pulley turns, another grooved circular piece J, round which the gut h i goes, and embraces also a diminutive pulley a of half the size of J, so that when the radius vector and arm J a go each once round in contrary directions, the third or little arm a A, which is equal in length to only one half the excentricity, goes twice round in the fame direction, in which the radius vector moves, and thus carries a planet at its extremity round the point S, in which the sun is placed, very nearly agreeable to the laws of planetary motion, with regard both to angular velocity and distance in every part of the orbit. To render the effect this produced more intelligible, conceive two pins made half in the line J A, fig. 1., considered as one line equal to twice the excentricity of the orbit to the radius S J, and let one of them be at C, the middle of the line, and the other at A, the extremity; then if this line prefer itself parallel to all round the orbit, by a retrograde motion given to it by the catgut e f and pulley g, fig. 2., the pin C being at the distance of the excentricity S G from the end J of the radius vector, will describe the excentric orbit 1, 2, 3. L 4 5 6., of the planet, while the pin at A will have the proper velocity as from S, but will move in the circle A B D E P F M H, which is too excentric to become the true orbit; but if the point A of the additional small arm be put to C when the motion begins, and has the planetary body placed on its extremity, then it will move in the same eccentric circle.
circle as the first pin C, but with the apparent angular velocity of the second pin A as seen from the other focus W, and very nearly so as seen from the sun at S; for conceive the radius SJ to have moved to K, the pin A will be found at B, on a count of the angle BK, which is here 45°, but the planet has moved a quadrant to r, and is found in the circle described by the pin C, or middle circle; but, viewed from W, according to the elliptic hypothesis, is seen in the line WB, as though it had been actually at B in the outermost circle; again, when the radius vector has completed a quadrant and is in the situation SO, the full pin is in the line W, and the planet at D, in the circle in which WB was before, and the additional arm has now described a semicircle: here the equation DSO is subtended by double the eccentricity very nearly; when J is advanced 135° to L, the additional arm has moved 2 of a circle, and is found at 3, still in the middle circle, and also in the line WE, extended; and when S Q is the situation of the radius vector the planet is at I, the perihelion point of the middle circle, and also in the line WP, extended as before. In like manner in the other semicircle of mean anomaly, when the extreme end of the radius vector is successively at the points R, T, and V, the planet will be found at the points 4, 5, and 6, and also in the lines WF, WM, and WH, respectively, still moving in the middle circle, till it arrives at the aphelion point C, from which it originally set out. When the pulleys are made to produce this effect very nicely, the hand or gut, that embraces two pulleys of different diameters, will take the ratio of 1: 2 in practice, and will require the larger pulley to be somewhat less in diameter than what the exact proportion requires in theory. The radius vector will fit in its remote end, with a thumb-finger under it, to fix the pulley at a greater or lesser distance, as the tension of the gut may require, and the whole contrivance being simple, ready in its motion, and light in its construction, as well as having a tendency to prevent the radius vector from bending downwards, is far preferable, in every point of view, to any contrivance we have before seen for answering the same purpose. The mechanical representation of the orbit bears the same analogy to the elliptic hypothesis, that an eccentric circle does to an ellipse of the same eccentricity, and in the orbits of the planets these figures are so nearly alike, that they may be substituted for each other, without sensible error; and we may add, that the equation produced by only one arm, equal to twice the eccentricity, is by no means so accurate as the equation doubled, that is, produced from an arm equal to the exact eccentricity, because the tangents of different angles do not increase by equal quantities.

Besides the preceding methods of producing the equation of a planet's orbit, our authors have contrived to indicate the quantity thereof in any point of the orbit, as well as the latitude also, as seen from the sun; this is done by means of a hand fixed under the revolving pulley L, travelling over a divided and silvered plate, fixed half in the situation of the dotted circle, on the end of the radius vector, concentric with the pulley, which plate not only fixes the equation and latitude at any time, but is of use in placing the arms in their proper situations by the latitudes taken from the Ephemeris or Nautical Almanac.

These are all the methods that have fallen within our notice, of effecting the grand equation of a planet's orbit, as applied to an orrery, or planetarium; but there remain yet two pieces of mechanism, contrived by our present inventor, that are well calculated to explain in a lecture-room the equation of an individual planet, as detached from the sytem, which we shall briefly describe, as being contrivances equally novel and competent to their purpose. The first is represented by figs. 4 and 5 of our last plate, the former being a section of the wheel-work, and the latter a sketch of a part of the visible part of the instrument. AB is a little frame, containing four wheels, a, b, c, and d; a and b are equal in diameter, and of similar numbers of teeth, a fixed on the arbor of the handle e, and b on a tubed arbor f, that carries the index g, seen in fig. 5 of the shape of a T, with a point touching the circle K, which is an elliptic circle; so that whatever velocity is given by the handle to the wheel a in an equable manner, the fame is communicated, by the medium of the wheel b, to the index g, which therefore moves according to mean motion in the elliptic circle EK. The wheels c, d, and d are eccentric, and have also similar diameters and numbers of teeth, but are placed to act so, that the longest radius of one always acts with the shortest of the other, and thus produce the same effect as Dr. Desaguliers's elliptic grooved plates with the endless caylet. The eccentricity of the wheels bears the same proportion to their common radius, that the eccentricity of the planet's orbit does to its mean distance: wheel c is fixed fast to the fame arbor of the handle as wheel a is, but wheel d has a separate arbor, which goes with the tube of wheel e, and carries the handle f, and on its upper end a ball to represent the sun. The sectoral arc of the index g is graduated, for Mercury for instance, into 24° each way from the middle, to which the hand i must be put when the index points to that part of the elliptic circle in which the apsis of the planet is; then as the handle is turned the index shows the mean motion in the elliptic, which may have a second circle divided into signs of mean anomaly, beginning at the apsis point, and as the motion proceeds the hand f falls back, till at the end of three signs and half, a dotted line is found near the extremity of the sectoral arc, at g; at that point the hand is again in the middle; and at eight and a half signs of mean anomaly it will be in its present situation again, at its greatest equation, at the opposite end of the sectoral piece; and lastly, at the apsis point the hand will be again found in the middle, which is the zero of both the positive and negative equations, which are respectively marked + and - on the opposite ends of the graduated sectoral arc. Thus, the index g shows the mean motion, the hand f the equated motion, and the graduated portion of the index has the quantity of the equation plus or minus, shown by the hand i in every part of the orbit, while a line drawn from s, the sun, over the point of the hand f to the elliptic K, shows the equated or true heliocentric place of the planet. The other instrument for explaining the nature of the mean and equated anomaly of a detached planet, and of its equation, which is their difference, is simply a mechanical construction of the elliptic hypothesis of bishop Ward, and is represented by fig. 6 of the same plate. S GW is an elliptic plate of wood or metal, described from the focus S and W, the small circle at S is fixed into an elliptic circle with a plunger fixed in the centre bearing a ball to represent the sun, and the other and familiar circle at W is divided into as many spaces as there are days or weeks in the period of the planet; of which 884 are proper for Mercury; the bar a G is concealed under the dotted line, and turns on the vertical stem of the disk that supports the elliptic plate at G, by means of a piece of brass tube fixed at its end; on the bar a a sliding piece b is inserted, that bears a small pulley c, and a planet in the angular point behind it, on a line as high as that of the sun; this sliding piece has two rollers, bearing against the edge of the elliptic plate, to facilitate the motion of the bar round the plate, which is produced by
hand, an endless gut or silk cord $S\ W$ draws the sliding piece close to the said plate, and causes the pulley and planet to describe the proper ellipse for the orbit. According to the elliptic hypothesis, if the angle $e\ W\ A$ be the mean of the mean anomaly, the angle at the fun in the other focus, $\text{i.e.} S\ A$, will always be the equated anomaly, and the small angle $S\ W$ will, in every situation, be the equation of the centre, as being the supplement of the fun of the other two angles, that is, the external angle $e\ W\ A$, that represents the mean anomaly, is equal to the sum of both the internal angles of the triangle at $S$ and $e$, as being respectively the supplement of the other internal angle at $W$; but the internal angle at $S$ is the equated anomaly; therefore the angle $e\ W\ A - c\ W\ S$ is the angle $e\ W$, or equation during the first six signs of mean anomaly; in the other six signs the angle representing the mean anomaly at $W$ will be smaller than the angle at $S$, representing equated anomaly, therefore the equation, or difference between them, which has been subtractive, becomes now additive; and the hypothesis, thus mechanically constructed, affords the ready means of explaining the particulars of planetary motion, for which purpose equal sectorsial areas are laid down on the plate alternately black and white, which the thread $S$ moves over in equal arcs of the circle $W$, moved over by the thread $e\ W$; which are equal portions of time; and when the circle $W$ is divided into days or weeks, and the circle $S$ into signs of longitude, and also into signs of anomaly, the same refuits will follow as from the preceding mechanism, as nearly as may be, while, at the same time, all the variations of distance, as well as of the equation, will be faithfully exhibited. Both these conivancies may be constructed fo as to be used either horizontally or vertically, and on any scale of magnitude that the audience of a lecture room may require.

Equation of Time. Having, under the article Day, explained the origin of the difference between solar and mean time, we have now only to explain the method by which this difference is calculated.

To effect this, it is necessary to know precisely the motion of the fun, and the dimensions of its orbit; we may then calculate the arc which it describes every day in the year parallel to the equator. If this real and variable motion be compared with its mean motion, the difference will be the equation of time.

If we imagine two meridians, drawn through two extremities of the arc of the ecliptic, which the fun describes in one day, the arc of the equator, which they intercept, is the difference between the solar and a sidereal day; for when the rotation of the celestial sphere is terminated, this small arc of the equator must traverse the meridian before the centre of the fun can arrive there. Now as this arc is not always of the same length, the solar days are not all equal.

Nor would they be so, even if the fun described every day an equal arc of the ecliptic, for these arcs take successively different inclinations relatively to the equator. At the moment of the equinoxes, they cut this plane at an angle equal to the obliquity of the ecliptic, and at the period of the solstices they are parallel to it. The meridians drawn through the extremities of these diurnal arcs are more separated at the solstices than if they contained the same arc at the time of the equinoxes; and, as it is this separation of the two meridians which causes the successive retardations of the fun, these are unequal, and less at the equinoxes than at the solstices. The daily variation of the motion of the fun in its orbit is another source of inequality, as it augments and diminishes the diurnal arc of the ecliptic, and this produces a corresponding variation in the arcs of

of the equator contained between the above-mentioned meridians.

Thus the inequality in the solar days arises from two different causes, the obliquity of the ecliptic, and the unequal motion of the fun in its orbit. As these two causes each produce their separate effect, they must be both destroyed, to render the solar days equal, that is, the motion of the fun must become uniform, and the ecliptic must coincide with the equator.

To calculate the value of the equation of time, we must calculate the arc which the fun describes each day on the ecliptic, and project it on the equator, and from this deduction the mean diurnal motion: the difference will give the equation of time for that day.

To represent these results geometrically, we may suppose an artificial fun to move in the manner described under the article Day, the mean day is the interval between two successive returns of this fictitious fun, and the mean noon the instant of its passage over the meridian; and the mean equinox is the instant of its passage through the equinoctial point.

It is obtained by a simple proportion, when the longitude of the perigee is known, and the epoch when the true fun is in the apsides, the time which elapses between two consecutive returns to the mean equinox, forms the mean tropical year, and which is equal to $365\frac{1}{4}$ days.

To calculate the place of the mean fun on the equator for a given instant, it is sufficient to calculate the mean longitude, and this, reduced to the equator, is the mean right ascension of the fun.

The projection of the true fun on the equator may either be determined from observation, or from calculating its right ascension. The difference between their right ascensions, reduced into time, in the proportion of $24\:\text{to}\:365\frac{1}{4}$, indicates the interval between the passage of the true and mean fun, and is the required equation of time; it is sometimes additive, and sometimes subtractive, and has the remarkable property of becoming zero four times in a year.

To understand the reason of this phenomenon, let us imagine (fig. 108.) two funs, $S'$ and $S'$, to set out at the same time from the equinox, both moving with a uniform motion; the one, $S'$, in the ecliptic, the other, $S'$, in the equator, and let the motion of each be referred to the latter plane. $S'$ will at first advance upon the meridian of $S'$, but afterwards this latter will approach it, and they will arrive together at the solstice; after this the meridian of $S'$ will advance upon that of $S'$, till the second equinox, where they will arrive together. The same circumstances will occur in the other half of the orbit, and thus the two funs will coincide together four times in the year, namely, at the equinoxes and solstices.

But, in reality, the mean fun does not set out at the same time as the true fun; they will not therefore, meet at the same points; the unequal motion of the fun changes this difference, but these two causes united only change the epoch of the coincidences; their number remains the same.

Let us consider the motion of the two funs, $S'$ and $S'$, supposed to set out together from the antumnal equinox, and proceeding towards the perigee. The true fun, $S'$, which describes the ecliptic, being referred by its meridian to the plane of the equator, will then be found behind the others, for it is preceded by $S$ till the perigee; let us now consider the motion of the other two. Till the moment of the solstice, $S'$ precedes $S'$, and $S'$ precedes $S'$, their order is therefore $S'$, $S'$, $S'$. At the solstice $S'$ joins $S'$, and afterwards they pass; their order is then $S'$, $S'$, $S'$, but at the perigee $S'$ coincides with $S'$, and afterwards precedes it; to do this $S'$ and $S'$ must meet in the interval. The order then becomes $S'$, $S'$, $S'$. 
EQUATION.

Thus between the winter solstice and the perigee the true sun $S'$, referred to the equator, meets the mean fun $S$; and the equation becomes zero. From the perigee to the vernal equinox $S'$ precedes $S'$, and $S'$ precedes $S'$; but $S'$ cannot 7 remain long between the two others, for at every quadrant the separation of $S'$ and $S'$ increases to $3^\circ 24'.24''4$, as appears by calculation; but the distance of $S'$, $S'$ is never exceeds $3^\circ 55'.27''$, which is the greatest equation of the \textit{centre}, and as, in the present situation of the polar orbit, this takes place near the equinoxes, the arc which corresponds to it on the equator is still less than it. It is evident, therefore, after the vernal equinox, and before the summer solstice, there must be some moment when the mean fun $S'$ arrives upon the meridian of $S'$, when the equation is again zero. From that point to the summer solstice the order is as follows, $S'$, $S'$, $S'$; at the solstice $S'$ joins $S'$, and afterwards passes it. But $S'$ precedes $S'$ so far as the apogee, consequently the meridian of $S'$ joins the mean fun $S'$, before the solstice, and the equation becomes zero for the third time.

From the solstice to the apogee, the order of the three funs is as follows, $S'$, $S'$, $S'$; at the apogee $S'$ joins $S'$, and afterwards precedes it till the perigee, the order thus becoming $S'$, $S'$, $S'$; but at the autumnal equinox $S'$ joins $S'$, and consequently meets in this interval the meridian of $S'$, and the equation becomes zero for the fourth time.

The order of the three funs then becomes $S'$, $S'$, $S'$, and the same appearances are re-produced in the same order as before.

Hence it appears, that in consequence of the obliquity of the ecliptic, combined with the unequal motion of the fun, the equation of time becomes zero four times a year, \textit{viz.}, once between the winter solstice and the perigee, twice between the vernal equinox and the summer solstice, and for the last time between the apogee and the autumnal equinox. The epochs of these phenomena evidently vary with the position of the greater axis of the polar orbit; at present they happen about the 24th December, 15th April, 15th June, and the 31st of August. If the equation coincided with the ecliptic, that part of the equation of time depending on their inclination would disappear, and the mean motion would only differ from the true by the equation of the centre, and mean and true time would agree twice a year when the fun is in the apides.

Dr. M. C. Motte has invented a rule for computing the equation of time, in which all the three causes are considered; it was investigated in the following manner.

Let $A P L Q$ (Plate XLI. fig. 129) be the ecliptic, $A L Q$ the equator, $A$ the first point of Aries, $P$ the point where the fun's apparent motion is flowed, $S$ any place on the fun; draw $S'$ perpendicular to the equator, and take $A n = A P$. When the fun begins to move from $P$, suppose a star to begin to move from $n$, with the fun's mean motion in right ascension or longitude, \textit{viz.}, at the rate of $0^\circ 59'.8$ in a day; and when $s$ passes the meridian, let the clock be adjusted to $1$, take $m s = P s$, and when the star comes to $n$, if the fun moved uniformly with his mean motion he would be found at $s$, but at that time let $S$ be the place of the fun. Let the fun $S$, and consequently $A n$, be on the meridian; and then as $m$ is the place of the imaginary star at that instant, $m A n$ must be the equation of time. The fun's mean place is at $S$, and as $A n = A P$, and $m = P s$, we have $A m = A P s$; consequently $m v A n = A v A P s$. Let $A$ be the mean equation, or the point where it would have been if it had moved with its mean velocity, and draw $A z$ perpendicular to $A Q$; then $A m = A z + x m = A d A x$, cosine $A a z = z m e$; or because the cosine of the obliquity of the ecliptic $23^\circ 5\, 8' = 44.09''$, we have $A = 44.09 x + x m e$; hence $m v = A v = z m e - 44.09 A x$. Here $A v$ is the fun's true right ascension, $z m e$ the mean right ascension, or mean longitude; and $44.09 A x$ (\textit{viz.}, $A x$) is the equation of the equinoxes in right ascension; therefore the equation of time is equal to "the difference of the fun's true right ascension, and his mean longitude corrected by the equation of the equinoxes in right ascension." When $A m$ is less than $A$, mean or true time precedes apparent; when it is greater, apparent time precedes mean; that is, when the fun's true right ascension is greater than his mean longitude, corrected as above shewn, we must add the equation of time to the apparent to obtain the mean time; and when it is less we must subtract. To convert mean time into apparent, we must subtract in the former table, and add in the latter.

Tables of the equation of time are computed by this rule for the use of astronomers; they are either calculated for the noon of each day, as given in the Nautical Almanac, or for every degree of the fun's place in the ecliptic, as is done in the annexed tables.

EQUATION.
EQUATION, lunar and solar, in Chronology. See METEOROLOGY.

EQUATOR, or Equator, in Astronomy and Geography, a great circle of the sphere, equally distant from the two poles of the world, or having the same poles with those of the world.

Such is the circle DA (Plate XII. Afron, fig. 169.) its poles being P and Q. It is called the equator, because when the sun is in it the days and nights are equal; whence also it is called the equinoctial; and when drawn on maps and planispheres, the equinoctial line, or simply the line. Every point of the equator is a quadrant's distance from the poles of the world; whence it follows, that every node divides the sphere into two hemispheres, in one of which is the northern, and in the other the southern pole.

By the palliages or tranits of arcs of the equator over the meridian, equal or mean time is estimated; hence we have frequent occasion for the conversion of degrees of the equator into time; and again, for the re-conversion of parts of time into degrees or parts of the equator.

For the performance whereof, we subjoin the following table, wherein are exhibited the arcs of the equator, which pass the meridian in the several hours, minutes, &c. of equated or mean time.

</table>

The construction of this table is very easy; for the equator being divided into 360 degrees, and revolving always in 24 hours, any point of it moves through 15' in one hour, and in one minute through the 60th part of 15', or 15" of a degree, and in one second through 15" of a degree, &c.

The use of the table is obvious; suppose, e.g. it were required to turn 20° 15' 30" of the equator into time; against 15 deg. in the first column we have 1° 30' 00"; against 4 deg. we have 16° 00' 00"; against 10 minutes, 45°; against 5 minutes, 12° 00' 00"; against 2 seconds, 8"; which, added together, give 1° 16' 52" 28".

Again, suppose it were required to find how many degrees, minutes, &c. of the equator answer to 25 hours 25 min. 17 sec. and 9 thirds. Against 21° in the fourth column of the table, you have 315' and against 2 hours, 30'; against 20°, 5'; against 5°, 1' 15"; against 10°, 3' 30"; against 5°, 1' 15" 00"; against 2 sec., 30° 00'; against 6 thirds, 1" 30"; and against 3 thirds, 45°; which, added together, give 35° 19' 17" 15". See EQUINOCTIAL.

EQUATOR, elevation or altitude of the. See Elevation of the equator.

EQUATOR of the Sun, or Solar Equator. The sun revolves from east to west on an axis inclined to the ecliptic, and the plane, passing through the centre of the sun perpendicular to this axis, is called the plane of the sun's equator. It cuts the plane of the ecliptic in a straight line, called the line of the nodes of this equator; and the nodes themselves are the points where this line, produced each way, meets the celestial sphere.

To determine the position of the axis of rotation in space, it is necessary to determine the inclination of the solar equator to the ecliptic, and the angle which the line of nodes makes with some fixed line in the plane of the ecliptic, for example, with the line of the equinoxes. This angle is called the longitude of the nodes of the solar equator, and is thus determined: when the position of a spot on the disc of the sun has been observed, and its latitude and longitude determined, the direction of the visual rays drawn to the spot at the moment of observation is known. The longitude of the sun at the first instant is likewise known, its distance from the earth, and its apparent diameter.

The intersection, therefore, of its surface with this ray, is found by a simple geometrical process. Three similar observations of the same spot determine three points upon the surface of the sun, and these three points are situated on the same circumference of some circle parallel to the solar equator, and the position of a plane is known when it passes through three given points. The plane of this circle described by the spot will, therefore, be known by these observations, by which the position of the solar equator may be determined.

To determine the successive positions of the spots on the surface of the sun, suppose spherical, we may imagine the three rectangular co-ordinates or axes passing through the centre of the sun, and continuing parallel to each other during the whole annual revolution. The first of these axes is perpendicular to the ecliptic, the two others are situated in this plane, one parallel to the line of the equinoxes, and the other perpendicular to it. Latitudes and longitudes, reckoned relative to these axes from the centre of the sun, are called heliocentric, and they may evidently be found by trigonometric methods, if we can determine their analogous longitudes and latitudes measured in the same manner from the centre of the earth, and which are called geocentric.

By methods of this kind it has been found that the solar equator is inclined to the ecliptic about 7°. It continues constantly parallel to itself, the points of this equator, as they are raised by the rotation motion of the sun above the plane of the ecliptic, traverse this plane in a point which, being from the centre of the sun, was, in 1750, 8'. This was then the heliocentric longitude of the solar equator. Since that time it has undergone no variation except what arises from the motion of the equinoxial points.

EQUATORIAL INSTRUMENT, is an instrument made use of in Practical Astronomy. When a simple telescope, mounted on a stand, is elevated to view any heavenly body at the moment of its meridian passage, the observed body appears to pass horizontally across the field of view, but in
any other situation to the east or west of the meridian, the apparent passage of any heavenly body through the field of view, is in an oblique direction, and the more so, the greater the declination towards the visible pole, and also the greater the distance from the meridian line. Hence the motion of the simple telescope, which moves in a parallel of altitude, or circle parallel to the horizon, when turned round in a state of elevation on its vertical axis, will never coincide with the motion of a heavenly body, that moves either in the equator, or in a circle parallel to it; unless indeed the observer could stand at one of the poles, in which case the equator would become the horizon, and circles of altitude would be also circles of declination. But no observer can be so circumstanced. He may, however, incline the axis of motion of his telescope, so as to be placed in the meridian, and exactly parallel to the earth's axis, and then, when the field of view is directed to take in any heavenly body, the motion of such inclined axis, or the motion of the telescope round such axis, supposing the axis to be fixed, will attend the said body during the remainder of its path above the horizon. Accordingly we find Christopher Scheiner using a telescope mounted on a polar axis in the year 1620, which time was soon after Galileo had invented the simple dioptric telescope, and though John Müller, or Regiomontanus, had contrived and described his torquet, a kind of portable equatorial, in the year 1544, and also Tycho Brahe had given the name of equatores to some of his instruments about thirty years afterwards, yet the idea of Scheiner's polar axis no doubt fugged to the modern instrument-makers the chief principle on which an equatorial instrument, as well as an equatorial sector, and equatorial stands, ought to be constructed. Scheiner's contrivance was competitive to the following of a star or other heavenly body through its diurnal arc, but had no appendages by which to ascertain the place of the observed body, as to right ascension, declination, distance from the meridian, &c. neither would the telescope be directed to a body invisible to the naked eye for want of such appendages.

Mr. Henry Hindley, an eminent clock-maker at York, was probably the first man who contrived and attached the different adjustable circles as companions to the telescope. Mr. Smeaton, in his paper on the "Graduation of Astronomical Instruments," read before the Royal Society of London, on November 17, 1785, has informed us, that Hindley contrived an instrument of the equatorial kind so early as the year 1741, which was sent up to London to be fold in the year 1748. This instrument had the equatorial plate, quadrant of latitude, and declination semi-circle indented at the circumference, and moved by worm-screws, containing fifteen threads each, all in action together, which screws at the same time measured as micrometer screw, the angular motions, and, as it seems, without other graduations. The telescope was of the reflecting kind, and inverted the object viewed. "It flowed with ease," says Mr. Smeaton, "two years, in which time I showed it to all my mechanical and philosophical friends, amongst whom was Mr. Short, who afterwards published, in the Philosophical Transactions, an account of a portable observatory, but without claiming any particular merit from the contrivance. However, the model of it differs from Hindley's equatorial instrument as well as in the following articles: he added an azimuth circle and compass at the bottom; he omitted the endless screws, placing verniers in their stead, and at the top a reflecting telescope instead of a refractor. This instrument of Hindley's being afterwards returned to him unfolded, I pointed out the principal deficiencies that I found therein; viz. that in putting the instrument into different positions, the spring

ing of the materials was such, as in some positions to amount to considerable errors. This remained with him in the same state till the year of the first transit of Venus in 1761, when it was sold to --- Contable, efq. of Burton Constable in Holderness. Mr. Hindley, to remedy the evil above-mentioned, applied balances to the different movements. He soon after completed one, de novo, upon this improved plan, for his Grace the late duke of Norfolk." The next, in point of time, to Mr. Hindley, was Mr. Short, who placed his reflecting telescope over a system of graduated circles, and who has generally been considered as the first contriver of the equatorial instrument, though it appears evident from Mr. Smeaton's account, that Hindley's instrument may be ascribed to his. Mr. Short published his account in the Transactions of the Royal Society, not in the year 1789, as stated by a typographical error in our article CIRCLES, but in 1749, in vol. xlv. N° 493.

About the year 1770 a rage for making equatorial instruments generally prevailed, and numberless were the modifications that makers of every description produced, but the chief improvers of the instrument at that period were Nairne, Ramsden, and Dollond, who married Ramsden's sister, all of whom, soon after the year just specified, improved on the original portable instrument, chiefly by introducing the improved dioptric in place of the heavy catoptric telescopes, and by using the belt divided circles, together with the most accurate adjustments, balancing of the parts, and nicely divided verniers. Mr. Ramden, to secure the advantages of his share of the improvements, took out a patent for his instrument, including the refraction apparatus, and hanging level in the year 1775.

Still, however, the equatorial instrument had its scale of magnitude adapted only for portability, and its circles connected were not deemed sufficient for the accuracy of celestial observations, demand, to be of real use in the present improved state of astronomy; and it remained for Mr. Edward Troughton to contrive an equatorial instrument sufficiently large to be placed in an observatory, for the purpose of making useful observations. This ingenious artist contrived many commodious modifications of the instrument under our present consideration, but we mean to confine our notice to one of the principal of them, both worthy of future imitation; one as a moveable, though not very portable instrument, and the other as a fixed one. The first was made to go to Coimbra, in Portugal, where it has had the ill fate to be shot up in the dark, though it was finished so long ago as the year 1788; the latter is now in use under the direction of Dr. Hamilton, at Armagh, in Ireland, and is that with which the Armagh observations were made; of these Mr. Pond, the lecturer on astronomy at the Royal Institution, availed himself when he composed his famous catalogue of declinations of some of the principal stars, which we noticed under our article Circles, and which is inserted in the article Description. This instrument was made in the year 1796; about three years after Sir George Shuckburgh's large equatorial instrument was described in the Philosophical Transactions of London, as an instrument on a large scale, carefully made under Mr. Ramsden's direction by Mr. Barge, who has since become his successor. The principal modern authors who have described the different equatorial instruments, are Mr. Short, Mr. Benjamin Martin, Mr. Nairne, Mr. Dollond, the Hon. Stuart McKenzie, professor Vince, and Sir George Shuckburgh; at one time it was our intention to describe one or two only of the different constructions of this instrument, and to have noticed the differences of the others; but to do justice to the subject, and to show more clearly the progressive

...
progressive improvements in the art of constructing astronomical instruments of this description, we have determined to give drawings and corresponding definitions, in succedence, of each instrument that appears to possess any claim to originality. Of course we must avoid, as far as the space will allow, repetitions of the descriptive matter that has been published of the various instruments that have been before described; but our detail will be a condensed one, and interspersed with original remarks, tending to affix the reader in forming his opinion of their respective merits; and where no description has been previously given, as is the case with Mr. Troughton's instruments, and a neat portable one by his nephew, Mr. Farer, we shall supply the accounts from original and authentic sources, preferring, as we proceed, that order of time in which the several instruments were contrived, except in the instance of Mr. Farer's, which being portable, we have thought it better to place immediately after the portable ones of older date, by way of contrast, than to give it a place after the larger and more complete instruments.

**Portable Equatorial Instrument by Mr. James Short.**

We have already said that Mr. Short's equatorial instrument, called by him the equatorial telescope, or portable observatory, was the first instrument probably made in England that could be considered as a well arranged assemblage of graduated circles for ascertaining the various data of a heavenly body's place, out of the meridian, by a single observation. Mr. Ben. Martin has given a brief description of this instrument, together with its uses, in appendix II. of his *Philosophia Britannica*, the substance of which, not being in every one's hands, we think may be acceptable to our readers, particularly as its perusal will afford the best means of contriving the more improved instruments with the original model, and, consequently, of tracing the progress that the art of making instruments of this kind has made within the period of our own recollection. *Fig. 1.* of Plate XI. of *Astronomical Instruments*, exhibits a perspective view of all the essential parts of Mr. Short's instrument, which is composed of four graduated circles, two of them entire, and two of them about three-fourths of a circle, together with a four-footed stand, a variety of supporting pillars, levels, wheels, and endless screws, axes of motion, and reflecting telescope surmounted over the whole. A, A, are two horizontal plates one over the other, and representing the horizon of the place of observation; these plates rest on four pillars of the pedestal, that contains a magnetic box and needle, and that is supported by the four adjustment screws B, B, B, B, the lower plate being fast to the pillars, and the upper one, that carries two spirit levels on its plane at right angles to each other, being moveable by a rod or handle C, the screw on which takes into the teeth cut on the edge of this upper horizontal plate. This moveable plate is divided into 360°, and a vernier borne by the under plate reads to the accuracy of every three minutes. Another set of four pillars, inserted into the moveable horizontal plate, supports the vertical circle D D, or rather portion of a circle, which is divided into twice 90°, and somewhat more at each side, and is called the meridian circle; its vernier, placed on the upper horizontal circle, reads also every three minutes of space. The handle or rod E moves this circle in like manner as the rod C moves the horizontal circle described. On the upper or moveable part of the meridian circle D D, are placed two other plates, the upper one moveable on the under one, like the horizontal plates, and the vernier carried by the under one. It does not appear from the drawing or account whether the axis of motion rotates or is fixed. The upper or moveable plate, marked F Y, is divided into hours and ten-minute spaces, and these again are subdivided by the vernier into single minutes of time. This plate, which is called the equatorial plate, has a third set of pillars inserted into it, and is moveable by the rod G, like the other moveable plates; the pillars support a fourth circle, or rather a multiplied circle H H, on the upper part of which the telescope L L is mounted, as seen in the drawing. This uppermost circle is called the circle of declination or horary circle, and is divided into twice 90°; it is also moveable by the rod or handle K, like the rest of the moveable circles; and has every three minutes of space, by its vernier, placed on the plane of the equatorial circle. The telescope is of the Gregorian construction, with a great speculum of 18 inches focal length. In making the adjustments of this instrument for observation, the horizontal plates A, A, are first levelled by the joint aid of the two levels and screws of adjustment that bear the whole fabric; this adjustment is not perfect till the bubbles of the levels will remain stationary, in the middle of their tube, while the upper plate is carried quite round the subjacent one. In the next place the meridian circle D D is turned by its handle E, till the equatorial plates are parallel to the equator; that is, till they are raised equal to the complement of the latitude of the place of observation, and the instrument is said to be fit for making observations; of course the placing of the circles relatively to each other, in regard to perpendicularity, and of the line of collimation of the telescope in regard to the points zero in the declination circle, are supposed to be immovably adjusted by the maker, so as to require no future rectification. As it will be of some importance to the development of the progressive improvements of the different equatorial instruments, to confine ourselves to the uses that this instrument by Mr. Short was applied to, we cannot do better than confine ourselves to the words of one of the early descriptions of its practical application.

"To find the Hour of the Day, and Meridian of the Place;"

First, find, from astronomical tables, the sun's declination for the day, and for that particular time of the day; then set the declination-semicircle to the declination of the sun, taking particular notice whether it is north or south, and set the declination-semicircle accordingly.

You then turn about the horizontal handle, and the equatorial handle, both at the same time, till you find the instrument perfectly concentrical with the field of the telescope. If you have a clock or watch at hand, mark the instant of time; and by looking upon the equatorial plate and vernier, you will find the hour and minute of the day, which comparing with the time flown by the clock or watch, shews how much either of them differs from the sun. In this manner you find the hour of the day.

"Now, in order to find the meridian of the place, and, consequently, to have a mark by which you may always know your meridian again, you first move the equatorial plate, by means of the equatorial handle, till the meridian of the plate or hour-line of 12 is in the middle of the vernier; and then, by turning about the declination-handle till the telescope comes down to the horizon, you observe the place or point which is then in the middle of the field of the telescope; and a supped line, drawn from the centre of this field to that point in the horizon, is your meridian line. The best time of the day for making this observation for finding your meridian is about three hours before noon, or as much after noon. The meridian of the place may be found by this method so exactly, that it will not differ at any time from the true meridian above 10° of time; and if a proper allowance be made for the refraction at the time of observation, it may be found much more exact."
EQUATORIAL.

line thus found will be of use to save trouble afterwards; and is, indeed, the foundation of all astronomical observations.

"To find a Star or Planet in the Day-Time, even at Noon-Day.—The instrument remaining as rectified in the last experiment, you set the declination-femicircle to the declination of the star or planet you want to see; and then you set the equatorial plate to the right ascension of the star or planet at that time, and, looking through the telescope, you will see the star or planet; and after you have once got it into the field, you cannot lose it: for, as the diurnal motion of a star is parallel to the equator, by your moving the equatorial handle for as to follow it, you will at any time, while it is above the horizon, recover it, if it be gone out of the field.

"The easiest method for fixing a star or planet in the day-time is this: your instrument being adjusted as before directed, you bring the telescope down low to look directly at your meridian mark; and then you set it to the declination, and right ascension, as before-mentioned.

"By this instrument most of the stars of the first and second magnitude have been seen even at mid-day, and the sun shining bright: as also Mercury, Venus, and Jupiter: Saturn, and Mars are not so easy to be seen, upon account of the faintness of their light, except indeed when the sun is but a few hours above the horizon.

"And in the same manner in the right-time, when you can see a star, planet, or any new phenomenon, such as a comet, you may find its declination and right ascension immediately, by turning about the equatorial handle, and declination handle, till you see the star, planet, or phenomenon; and then looking upon the equatorial plate, you find its right ascension in time; and you find upon the declination-femicircle its declination in degrees and minutes.

"In order to have the other uses of this instrument, you must make the equatorial plates become parallel to the horizontal plates; and then this instrument becomes an equal altitude instrument, a transit instrument, a theodolite, a quadrant, an azimuth instrument, and a level. The manner of applying it to these different purposes is too obvious to need any explanation.

"As there is also a box with a magnetic needle fastened in the lower plate of this instrument, by it you may adjust the instrument nearly in the meridian; and by it likewise you may find the variation of the needle; if you set the horizontal meridian, and the equatorial meridian, in the middle of their verniers, and direct your telescope to your meridian mark, you observe how many degrees from the meridian of the box the needle points at; and this distance or difference is the variation of the needle."

These are the uses to which Mr. Short's instrument, before us, was principally applied, and had the circles been divided with verniers subdividing the divisions more minutely, it would have been something more than an astronomical play-things, to which it cannot be considered as any thing superior, when it comes to be contrasted with one of the most improved kinds, even of those that are equally portable. We cannot dismiss our notice, however, of the present instrument, without remarking further, that the manner in which the two pairs of plates A A, and F F, move over each other respectively, is by no means calculated to preserve a steady undeviating motion, for want of a sufficient length in the axis of motion. This is the principal objection we expressed to Dr. Wollaston's circle made by Mr. Cary, and if the doctor borrowed his notion of such a position of his circles from Mr. Short, he copied one of the worst properties that this artist's instrument posses.

This equatorial instrument has obtained the name of universal, from the circumstance of its being applicable to use in any latitude; which name is equally due to its usefulness.

Portable Equatorial Instrument by Mr. Ed. Nairne.—The imperfections of the preceding instrument were attempted to be removed by Mr. Nairne, whose construction introduced a long axis of motion for the horizontal circle, thereby effecting a neatness in its performance, and placed the telescope on the axis of the declination femicircle to obtain a slightly encumbered elevation of the telescope; but still the circles were not graduated so minutely as to render them of real use in practical astronomy. A brief account of this instrument is contained in vol. xii. part i. of the Philosophical Transactions of London, and was read before the Society on Feb. 7, 1771. Its substance is this:—

The instrument consists of the following parts, Plate XII. fig. 1. of Astronomical Instruments, a mahogany triangular stand A A A, and three adjusting screws B B, B, a movable azimuth circle C, which is divided into degrees, and by a vernier index into every six minutes; above this azimuth circle is the horizontal plate D, to the under part of which is fixed the vertical conical axis E; on the middle of the upper surface of the horizontal plate is placed a ground glass level F, by which the plate D is set parallel, and the pillar E perpendicular to the horizon; from this plate rise perpendicularly two quadrants G, G, one of which is divided for the latitude into half degrees, and has a vernier index to three minutes; the equatorial plate H, with its hour circle, is supported by the two quadrants G, G, its axis of motion, which is placed near the hours XII, XII, passes through the centres of the quadrants, and carries the index I, pointing to the divided quadrant; the equatorial plate is divided into half degrees, and has a vernier index fgiving every three minutes of right ascension, or 12 seconds of time; it is figured to show both degrees and time. To prevent misapprehension it may be right to remark that the hours XII, XII, ought properly to have been placed according to the meridian line; but they are here placed otherwise for the convenience of better seeing the meridian distance shown by the vernier. On the upper part of the equatorial plate is the plate K; upon this plate K are fixed the two supports M, M, which support the axis N, under which is fixed the semicircle of declination O, divided into half degrees with a vernier subdividing it into every three minutes. On the upper part of this axis is fixed an achromatic telescope P, which magnifies about 50 times; to the eye-end of this telescope is applied a small reflecting speculum, making an angle of 45° with the axis of the telescope, whereby objects that are in the zenith or in any other altitude may be observed without putting the body in an inconvenient position. To the under part of the axis N is fastened a brass arm carrying the weight Q, which counterbalances the telescope, and brass-work annexed to it; whilst the weights R, R, counterbalance in like manner the whole of the instrument that is movable on the equatorial axis, so that whatever position the instrument is put in it will remain, being perfectly balanced. The four motions of this instrument may, when required, be moved extremely slowly, by means of the indented edges of the circles and femicircles, and the screws or worms of the handles S, T, V, and W, for the horizontal circle, the motion for latitude, the equatorial and declination motions respectively. The adjustments and uses of this instrument are so similar to those of its predecessor, both in kind and extent, that it would be superfluous to particularize them again. In this account it is not stated whether the axis of motion of the equatorial circle is prolonged,
longed, but as the height to which it is elevated above the horizon circle seems to admit of it, and as the axis of this is elongated, we are disposed to believe that a similar advantage belonged to the former; otherwise it would not have that liability that is necessary in this part of the instrument for making the most effective motion slowly enough to be depended on. How far the mahogany legs were firm and steady enough for the purpose of affording a motionless pedestal it is not said; but the want of accuracy, or rather the want of uniformity in the divisions and sub-divisions of the graduated circles, quadrant, and semicircle, made this consideration of less importance than it would have been in an instrument possessing greater powers. We have been informed, from credible authority, that Mr. W. Ludlam, of St. John's college, Cambridge, was the principal contriver of Mr. Naimé's construction.

Rumford's portable equatorial instrument.—The principal parts of this instrument, says Professor Vince, (Traité ou Prac. Afnr.) are, the azimuth circle G H, the equatorial, or hour circle E F, and the declination circle C D; (see Plate XL. fig. 2. of Astronomical Instrumets,) to this latter there is fixed a telescope A B, having under it a rod m u, passing through two pieces x, y, in one of which, as x, are two screws acting on the rod against each other, in order to adjust the rod perpendicular to the axis on which the declination circle turns. The azimuth circle G H lies on a brass plate t u, supported by three feet, resting on the fevers X, Y, Z, and on this plate it turns about an axis T, by means of a screw S 1, upon this circle are placed two spirit levels e d, a b, at right angles to each other, supported at each end by a screw, by which they may be adjusted; the circle is divided into twice 180°, and has a vernier V fixed on the plate t u, by which the degrees are subdivided into minutes or half minutes, according to the size of the instrument; and by means of the screw I the circle may be fixed to the plate t u. K K is a polar axis moveable about a centre L, sustained by two supports g, h, resting on two pieces W, V, firmly connected to the plane of the circle G H; the lower end of this axis has an arc fixed to it, which runs against an arc x, y, attached to G H, and to which may be fixed by a key at r; and in this situation, if you apply the key to Q, it gives a motion to the axis, by which you may very accurately adjust the telescope to an object. To the centre L, and perpendicular to the polar axis, are fixed two strong pieces of brass, one of which is here represented by x, and the other is on the other side of the axis; these support a circle a β; γ; δ, on the top of the polar axis, and perpendicular to it, is placed a brass plate, moveable about a pivot on the top of the axis; to this are fixed four pieces, two of which are represented by f g; these are connected to the hour circle E F, lying on a β; γ, and carry it about; upon a β; γ, at W, is fixed a vernier to the circle E F, which circle is divided into twelve hours. The declination circle C D is supported by its centre, on an axis resting on two supports b, k, on one side, and two others of the like kind on the other; these rest upon the brass piece on the top of the polar axis, and may be adjusted by two pair of screws at the feet of the two supports, to let the plane of the declination circle perpendicular to the hour circle, which, by the maker, is placed perpendicular to the polar axis. This circle is divided from zero both ways to a little more than 90°, and a vernier is placed at R to subdivide, as at V. A small quadrant is fixed to the eye-piece of the telescope, which turns round upon the piece, carrying two wires perpendicular to each other, for the parallel of declination and hour circle. The eye-piece carries two crofs wires to represent the circle of altitude and a parallel to the horizon. The quadrant has two radii r, perpendicular to each other, and move together; the former has a round or circular spirit level upon it, so that by turning about the eye-glass and the quadrant till the bubble rests in the middle, the plane of the quadrant becomes perpendicular to the horizon; and the vernier on the latter shows the altitude to which the telescope is directed, and the corresponding refraction; and in this position the circle of altitude is perpendicular to the horizon. At P is a small micrometer circle, called the refraction circle, (with a fixed index,) moveable by a finer screw; this circle is divided into half minutes, and one revolution is equal to 3° 18' when moved it raises or depresses the centre of the crofs wires in a circle of altitude.

After this general description of the parts of the instrument, let us consider what motions it is capable of, and what the circles may be made to represent, before we proceed to its adjustments. And first, the azimuth circle G H, being set parallel to the horizon, will represent the horizon; secondly, if the polar axis K K is inclined to the horizon at an angle equal to the latitude of the place, the equatorial circle E F will be inclined to the horizon in an angle equal to the inclination of the equator to the horizon; therefore, if we turn about the azimuth circle, and consequently the equatorial circle, the latter may be made to coincide with the equator; thirdly, if the declination circle be set perpendicular to the equator, then the consequencies must be, that if the line of collimation be adjusted parallel to the plane of the declination circle, or perpendicular to its axis, and also parallel to the equatorial circle E F, when zero on the declination circle coincides with zero on the vernier R, then the telescope is directed to the equator in the heavens, and by turning about the declination circle the line of collimation will describe a secondary to the equator; and by setting the declination circle to the declination of any body in the heavens, if we turn about the circle E F, and consequently the circle C D with the telescope, on the brass plate, on the top of the polar axis (which is kept fixed,) the equatorial circle, moving in its own plane perpendicular to the polar axis, must continue to coincide with the equator, and consequently the telescope will describe a parallel to the equator, and therefore must bring the body into the field of view. Thence being the motions of the parts of the instrument, we may now proceed to describe the necessary adjustments for them.

Adjustments.—1. To adjust the azimuth circle parallel to the horizon. Turn it till one of its levels becomes parallel to a line joining two of the screws at the feet, as X, Z, and then adjust that level with one of them; turn the circle half round, and if the bubble be not in the middle, adjust it half way, by one of the above-mentioned screws, and half way by the screws at one end of the level; repeat this operation till the bubble stands right in both these positions; then turn the circle at right angles to these positions, and, if necessary, let the bubble right by the other screw Y at the foot, and the adjustment is made. If you previously adjust the other level by one of the screws at the end, then the circle may be adjusted horizontal by them, without turning it.

2. To adjust the level r s parallel to the rod m n. — Set the polar axis, as nearly as you can, perpendicular to the horizon, and turn about the declination circle C D by a pinion for that purpose, until the bubble of the level r s stands in the middle; reverse the level, and if the bubble do not stand in the middle, adjust it half way by the screw at S, under 5 E.
one end of the level, and half way by turning the declination circle; and repeat the operation till the bubble stands in the middle in both positions.

3. To adjust the rod \( mn \) perpendicular to the axis on which the declination circle turns.—Set the polar axis as near as you can parallel, and consequently the equatorial circle perpendicular to the horizon; set the declination circle to zero, and turn the hour circle till the bubble stands right; then set the declination circle to \( 90^\circ \), and adjust the bubble by the polar axis; then turn the declination circle to the opposite \( 90^\circ \), and if the level be not right, correct half the error by the polar axis, and the other half by the two screws in the piece \( r \), releasing one and screwing up the other; repeat this operation till the bubble stands right in both positions, and the adjustment is made. For these two adjustments tend, the former to set the axis of the declination circle, on the axis about which the rod revolves, perpendicular to the horizon: and the other to set the rod \( mn \) parallel to the horizon, and consequently perpendicular to that axis; when, therefore, the bubble thus continues right, both circumstances must have taken place.

4. To set the axis of the declination circle perpendicular to the polar axis.—The instrument remaining as in the last adjustment, that is, the declination circle at \( 90^\circ \) and the bubble right, turn the equatorial circle half round, and if the bubble be not right, correct half the error by the polar axis, and the other half by the two pair of screws at the feet of the two supports \( b, k \); and repeat this operation till the bubble is right in both positions, and the adjustment is completed.

For the former adjustment tends to set the axis of the declination circle perpendicular to the horizon, and the latter to set it parallel to the equatorial circle, or perpendicular to the polar axis; consequently, when the bubble is right in both the above positions both circumstances must take place, that is, the polar axis must be parallel to the horizon, and the axis of the declination circle perpendicular to it. And as this adjustment is made by the level, which is horizontal when the axis of the declination circle is thus adjusted perpendicular to the horizon, and which is previously adjusted parallel to the rod, they must both be perpendicular to the axis, about which they turn; and, consequently, they move in a plane passing through the polar axis, or perpendicular to the equatorial circle. Hence, also, the declination circle, being perpendicular to its own axis, becomes perpendicular to the equatorial circle.

5. To make the centre of the cross wires cut the same object whilst you turn round the eye-glasses by the motion of the refraction apparatus.—Set the index on the refraction circle to the beginning of the divisions, and turn round the eye-glasses, and if the centre of the wires do not continue to cut the same object, correct it by four small screws (which you will find by unscrewing the nearest end of the eye-tube which contains the first eye-glasses), the two opposite at a time, and repeat the correction till the centre continues to cut the same object.

6. To make the line of collimation describe a great circle perpendicular to the equatorial circle.—Set the declination circle to \( 90^\circ \), and the equatorial circle to \( VI \), and bring the bubble to the middle by the polar axis. Then note some object covered by the centre of the cross wires, representing the parallel of declination and hour circle, and turn the equatorial circle half round, and if the same object be not now covered by the centre of the wires, move, if necessary, the declination circle in its own plane, until it is in the same vertical circle with the object, and then bring the centre half way to it by the upper and lower of the four small screws which move these wires, and turn the declination circle back through half the space it was moved, and you get a new object, now covered by the centre of the wires; repeat this operation till the same object be covered in both these positions; then set the hour circle to \( XII \), and bring the bubble to the middle by the declination circle, and if the centre do not now cover the same object, bring it to the object by the other two screws, and the line of collimation is then adjusted parallel to the level, or to the rod \( mn \), and, consequently, it must be perpendicular to the axis of the declination circle. Hence as that circle is turned about in its own place, the line of collimation must describe a secondary to the equator. The line of collimation for the centre of the cross wires being thus adjusted, it is, at the same time, in the centre of motion, on which the wires parallel and perpendicular to the horizon turn; hence, when the index of the refraction circle is set to the beginning of the divisions, the interections of the two sets of wires coincide. The adjustment of the wire parallel to the equatorial circle may be examined by the passage of a star through the telecscope, (all the other adjustments being previously made), and the equatorial circle adjusted to coincide with the equator in the heavens, and the declination circle set to the star's declination;) for if the star do not run upon the wire, it must be adjusted till it does; or it may be done thus. Set the equatorial circle to \( XII \), and having directed the line of collimation to some small well defined object, turn the declination circle in its own plane, and observe whether the perpendicular wire continue to cut the same object as it passes through the field of view; if not, adjust till it does.

7. To adjust the verniers of the equatorial and declination circles.—Elevate the equatorial circle to an angle of about \( 45^\circ \), as most proper for this purpose, and set the declination circle to zero, and turn the equatorial circle in its own plane till the bubble stands right; then turn the equatorial circle half round, and if the bubble do not stand right, adjust half by moving the equatorial, and half by moving the declination circle; and repeat this operation till the bubble stands right in both positions, then, by moving the verniers, set zero on the vernier belonging to the equatorial circle to \( VI \), and zero on the vernier belonging to the declination circle to zero, and the verniers are adjusted. Thus the instrument is ready for observation, except that the azimuth circle is not adjusted to shew azimuths, which will be done when we come to shew the methods of making observations.

The method here used arises out of the two distinguishing features of the instrument under our consideration, namely, the position of the level near the telecscope, and the want of graduations on the latitude arch, or arch for giving the polar axis its due inclination.

But the Hon. Mr. McKenzie's method appears to us more simple, as well as more intelligible, for elevating the equatorial circle to the co-latitude of the place, thus; "lower the telescepe as many degrees, minutes, and seconds below zero, on the declination-emicircle, as the complement of your latitude is; then elevate the polar axis till the bubble be horizontal, and the equatorial circle will be elevated to the co-latitude of the place, as required; after which the level may be made to stand true in opposite positions, and the verniers be placed to zero, as above directed.

Mr. Atwood, in his Syllabus, has given another method of making this adjustment, which professor Vince acknowledges to have the advantage over his in point of both ease and accuracy, the substance of which is as follows:

Having
Having set the declination circle to 90° in either quadrant, direct the point of intersecion of the cross-wires to coincide with some distant object as a mark, turn the equatorial circle in its own plane 180°, and if the intersection does not now coincide with the distant mark, correct half the error in declination by moving the declination circle in its own plane, and half the error in right ascension by the feet screws of the supporters that adjust the axis of the declination circle: now if these adjustments be accurately made, the intersection will coincide with any distant mark, chosen anew, when the equatorial circle has been turned 180°; but if the coincidence is not perfect, the same adjustments must be repeated till the condition is fulfilled. The line of collimation being now directed to coincide with the distant mark, let the vernier of the declination circle to 90°, and turn this circle 180° in its own plane, and the axis, perpendicular to the plane of the declination circle: therefore correct 3rd of the error by the screws of the declination axis, and 4th by moving the line of collimation perpendicular to the plane of the declination circle; if the first trial of these adjustments be not attended with complete success, when the distant mark is again examined in reversed positions they must be repeated till they are correct. Hence it is manifest, when the above adjustments are properly made, that the line of collimation is parallel to the plane of the declination circle; also, that the plane of the declination circle is perpendicular to the plane of the equatorial; also, that the errors of division are at the opposite points 90°, if any are discovered in the declination circle, and, 4thly, that when the declination circle is set to 90°, the line of collimation is perpendicular to the plane of the equatorial circle, or, when it is set to 0°, is parallel to it.

The azimuth circle being adjusted horizontal, and the declination circle to 90°, make the vertical wire parallel to it, turning the equatorial and azimuth circles in their respective planes; direct the point of intersection to a distant mark near the horizon, and move the azimuth and declination circles each in their own planes to 180°, so that the mark may appear somewhere in the vertical wire, and if there is an error in altitude, let the line of collimation bisect it, by moving the polar axis, and it will then be horizontal. Let this new bisected point or mark in the horizon be noted; then the declination circle being put to zero, turn the azimuth circle 90°, so as to bring the new mark upon the cross-wires, and direct the intersection to it by turning the equatorial circle in its own plane, and the declination is then in that situation parallel to the horizon. Let this circle change its axis, turn the equatorial and azimuth circles in their respective planes 180°, and if each circle be accurately divided, the telescope must evidently be brought into a position exactly parallel to its former one, and therefore the intersection of the wires will again coincide with the new mark in the horizon. If the quantity each of these circles must be moved further or back, will shew their respective errors of eccentricity and alo of division. Lastly, the declination circle being at zero, and the line of collimation or intersection made to coincide with the horizontal mark, by moving the equatorial and azimuth circles, let the equatorial vernier to V, and the adjustment is finished; for the line of collimation being parallel to the horizon, and to the plane of the declination circle when the vernier stands at V, that plane, by revolving about the polar axis, must be perpendicular to the horizon when the vernier stands at XII, which is the thing required.

**Methods of making Observations.**

1. To take the altitude of a body above the horizon.—Set XII on the equatorial circle to zero on its vernier, and the plane of the declination circle is then perpendicular to the horizon, to make, therefore, the line of collimation horizontal, by bringing the bubble to the middle of the level in the telescope, and observe what point of the declination circle stands against zero in its vernier, and then by moving the declination and azimuth circles in their own planes, bring the body to the centre of the cross-wires, and observe again what point of the declination circle stands against zero, and the arc intercepted between these two points gives the apparent altitude. If the declination circle had been set to zero, and the line of collimation been adjusted horizontal by moving the polar axis, then, when the body had been brought to the centre of the cross-wires, the declination circle would have shown its altitude at once. For Mr. Atwood's indirect methods of taking an altitude, see pages 163, 164, and 165 of Vince's "Treatise on Practical Astronomy."

2. To measure very small vertical angles.—Let the elevation of the equatorial circle be \(a\), the polar distance of the telescope (either more or less than 90°) be \(b\), and set XII (corresponding to noon) on the equatorial circle to zero; then if that circle describes an angle whose verified line is \(\alpha\), and the line of collimation be brought (by moving the azimuth circle) back to the same vertical, it will have been depressed through a vertical arc equal to \(\alpha \times s \cdot s \times a \times b\), radius being unity. Or, if \(b = 90°\),

\[
\sin b = a \sin \alpha
\]

the depression is \(\alpha \times \tan a\). Hence, if, for example, it should be required to find the angle which the horizontal wire of the telescope subtends, select some well-defined distant object, set the declination circle to zero, and XII on the equatorial to zero, and elevate the equatorial so as to bring the object into the field of view, and make the upper edge of the wire coincide with it, then move the equatorial and azimuth circles in their own planes till the lower edge coincides with it, and read off the equatorial arc. *Ex.* If the elevation of the equatorial be 41° 3' and the arc denoted by the equatorial vernier be 57°, the angle required = \(\tan 57° \times \tan 41° 3' = 24° 6'\). Hence also the diameter of a planet may be measured. When the planet comes to the meridian (the two circles being fixed as before) alter the elevation of the equatorial circle, and bring the upper edge of the horizontal wire to be a tangent to the upper limb of the planet (or the apparent upper limit), and then by turning the azimuth and equatorial circles in their own planes, bring the lower edge of the wire to be a tangent to the lower limb of the planet (or the apparent lower limit), and the rule gives the sum of the diameters of the planet and wire, from which subtract the diameter of the wire, and you get the diameter of the planet.

3. To find the latitude of a place.—Take the altitude of the sun's upper or lower limb a little before noon, and continue your observation till it rises no longer, and you get
EQUATORIAL.

his apparent meridian altitude; with which and his declination you may find the latitude by the commutative rule.

4. To incline the equatorial circle so as to make any angle with the horizon. Set the declination-circle (in the southern quadrant) to the given angle, and XII on the equatorial circle to zero on its vernier; then bring the line of collimation horizontal by moving the polar axis till the bubble in the level on the telescope stands in the middle, and the equatorial circle stands at the proper angle.

5. To determine the position of the meridian.—Elevate by the half article the equatorial circles, to make an angle with the horizon equal to the co-latitude of the place, and let the declination-circle to the declination of any known star, then turn the equatorial and azimuth-circles in their own planes till the star is brought to the centre of the cross wires, and correct the position of these circles on account of refraction, by the small quadrant and apparatus at the eye-piece of the telescope, and the equatorial circle will then coincide with the equator in the heavens, and the vernier will show how far, in time, the star is from the meridian; and hence, if we turn the equatorial circle till XII stands at zero on the vernier, the plane of the declination-circle will have the same altitude as the meridian plane. Hence, if we direct the telescope to the horizon, the point which the centre of the wires will cut is the fourth point of the horizon, and may serve for a meridian mark. If the point of the arc of the azimuth-circle lying against zero on its vernier be noted, the error in its position will be known; and if this be very small, so that by moving the vernier till zero on it may be brought to zero on the arc, it may be adjusted to new azimuths. The position of the vernier of the azimuth-circle may also be verified thus. The equatorial-circle being set parallel to the horizon, and XII set to zero on its vernier, turn the azimuth-circle, and by moving the declination-circle, bring a star on the call side of the meridian to the centre of the cross wires, and note the azimuth, then turn the azimuth-circle (the telescope remaining fixed) and do the same when the body comes to the well side; and if the azimuths at both observations be the same, the vernier is adjusted right; if not, half their difference is the error. The instrument being set upon a moveable plane, if the points on which the three screws at the feet revolve are marked, it will always be easy to set the azimuth-circle very nearly in its proper position.

6. To determine the apparent time of the day.—Proceed as in the last article, only take the sun instead of a star, and bring its centre to the centre of the cross wires, and correct for refraction, and the arc intercepted between XII and zero on the vernier shows the distance of the sun, in time, from the meridian, or from apparent noon.

7. To find a star or planet in the day-time. —Elevate the equatorial-circle to make an angle equal to the co-latitude, and adjust it to coincide with the equator in the heavens, and set the declination-circle to the declination of the body. Find by the usual way the distance of the star from the meridian at the time required, and reduce it to sidereal time; then turn the equatorial-circle in its own plane, east or west, as the star lies, till the arc between XII and zero on the vernier be equal to that time, and the star will be in the field of view. By this means Jupiter, Venus, and fixed stars of the first magnitude, may be observed in the day-time.

8. To find the right ascension and declination of a star. —Elevate the equatorial-circle to the co-latitude of the place, and previously set it to coincide with the equator in the heavens, and set XII on the equatorial-circle to zero on its vernier. After this set the declination-circle to the sun’s declination, and take the time of its transit; then set the declination-circle to the star’s declination and take the time of its transit, and the difference of the times will give the difference of the right ascensions; and the star’s transit being taken at the intersection of the wires, the declination-circle (corrected for refraction) will give its declination. Thus also you may compare two stars, or the moon and a star. Or it may be done at any time, if you move the declination and equatorial-circles in their own planes till the star is brought to the centre of the cross wires, and correct the position of these circles on account of refraction, and the declination-circle will give you the declination required; and the vernier of the equatorial-circle will give you the star’s distance, in time, from the meridian, or your clock will give you the star’s distance, the difference of which times gives the difference of their right ascensions, and, therefore, knowing the sun’s right ascension, you have the right ascension of the star.

9. To find the longitude. —The equatorial-circle being set to coincide with the equator in the heavens, and XII to zero on its vernier, take the time of the transit of the moon’s limb, and also of a proper star as near as possible to the moon’s path, the difference of these times will determine therefrom by the lunar method, in the usual way.

10. To measure horizontal angles.—Adjust the equatorial-circle parallel to the azimuth-circle; and having directed the line of collimation to one of the objects, move the equatorial-circle in its own place, and also the declination-circle, if necessary, and bring the line of collimation to the other, and the arc through which the equatorial-circle has moved gives the angle required.

As an appendix to this account, by professor Vince, of Ramden’s portable equatorial instrument, we think it may be acceptable to our readers to have the Hon. S. McKenie’s account of Mr. Ramden’s new refraction apparatus much improved, which was published in his anonymous pamphlet, (dated in the year 1791, a year after the professor’s treatise was published), together with the explanation of the principles on which the apparatus was constructed.—“Refraction or parallax,” says our author, “by changing the apparent altitude of a planet, may also change its apparent right ascension and declination. See fig. 21 of Plate XIII. (where the longitude may represent the horizon; E, Q, part of the equator; P, the pole of the equator; Z, the zenith; P E H, the meridian; Z V, an arm of a vertical drawn through I, the apparent place, and F, the true place of the planet; P A, a circle of declination, or hour-circle, drawn through the true place F; and P B, a circle of declination or hour-circle drawn through the apparent place I. The error in altitude from F to I alters the right ascension of the planet as much as the arm of the equator A B, or its parallel FC, amounts to. It also alters its declination from A F to B L, that is, from C to I. If a planet be in the meridian at L, the error, in declination from L to K, will be the same as the error in altitude; but there will be no error in right ascension, because the same circle of declination P E H, (perpendicular to the horizon,) passes through the apparent place K, and the true place L. In like manner, if by the construction of an instrument you have a vertical circle Z V, perpendicular to the horizon, it will pass through the apparent place I and the true place F, and there will be no error in right ascension; and if by the same instrument the error in altitude from F to I be determined, the true place F is found, and consequently there will be no error in declination. With Mr. Ramden’s new refraction apparatus you have just such a vertical circle as will appear from what follows.

In the focus of the telescope of the equatorial two fixed wires
wires are placed at right angles to each other; one, E Q, (see fig. 4.) represents part of a parallel of the equator; the other, P A, a portion of a meridian, or hour-circle. There are also two moveable cross wires at right angles to each other; one, H Q, represents a portion of a parallel to the horizon; the other, Z V, a portion of a vertical circle. These moveable wires have a motion round the axis of the telescope, by turning a pinion.

A small quadrant (see Plate XI. fig. 2, and also Plate XII. fig. 2.) is fixed on the part that carries the moveable wires, with divisions on each side; one expressing the degree of altitude of the object viewed, the other expressing the minutes and seconds of error occasioned by refraction, corresponding to that degree of altitude. To the index of this quadrant is fixed a small circular level, which being adjusted by its own pinion, gives the altitude; while by another pinion it ascertains the perpendicularity of one of the moveable wires, which gives the vertical circle above-mentioned, whereby the true right ascension may be determined, free from all error arising from refraction or parallax. Hence, in taking the moon's right ascension with an equatorial instrument, fitted with this refraction apparatus, in order to determine longitudes at land, there is no occasion to attend to her parallax, as the difference of her right ascension, caused by parallax or refraction, will only depress or elevate her on the same vertical circle, but will not change her right ascension from one hour-circle to another. In this refraction apparatus the centre of the fixed wires always remains in the line of collimation; whereas by the former construction, in raising or depressing that centre, it was moved out of that line; and as it was very difficult to replace it exactly, an error in the observation was liable thereby to be produced. In all observations made with this refraction apparatus, first adjust the circular-level, then set the centre of the moveable wires, by the micrometer screw, to the refraction corresponding to the altitude of the object viewed, as given by the small quadrant; and let one of the moveable wires be set always perpendicular. Since copying the preceding extract from Mr. M'Kenzie's pamphlet, we have been assured that it was published previously to professor Vince's treatise, and that the date 1771 is a typographical error for 1775; accordingly, we learn from Mr. Dollond, that Ramdlen's instrument preceded his, but our inquiries to obtain the precise time of its origin have not been successful. The two different sizes of Ramdlen's portable instrument were according to the following table of dimensions.

Portable Equatorial Instrument by Messrs. P. and J. Dollond.

Mr. Dollond informs us that his father contrived the instrument, which now comes under our notice, in or about the year 1775, and the readiness with which he communicated all the particulars we wished for respecting it deserves our grateful acknowledgment. This instrument, says the author, (in his quarto pamphlet,) which of all others is the most amusing to lovers of astronomy, is now rendered, by the following improvements, greatly superior to any hitherto produced. As the whole weight does not exceed thirty pounds, it may be said to be truly portable, yet, by the leadings of all the parts, and the perfection of the achromatic telescope, the observations may be made to a very great exactness. The focal length of the achromatic object-glasses is about 17 inches; it is composed of three glasses, and admits of an aperture of two inches. The tube being made as thin as possible, is easily balanced by the weight A, which is fixed in the semi-circle D B; (see fig. 3. of Plate XI.) then again all the parts above the horizontal axis (the end of which is seen as C) are balanced by the square weight D. By means of these balances the centre of gravity is preferred over the centre of the instrument in every position, and the different parts prevented from being strained when the instrument is put into any oblique position, which may be required in its various uses. This also tends to keep the telescope steady, which is of the greatest advantage in making an observation. Besides these very essential improvements, every part has been reduced to the most simple state; and several, which in other instruments of this kind, were found superfluous, have been entirely rejected.

The instrument is supported by three feet E, E, E; the screws a, a, a, are to raise or depress the feet, in order to bring the plate G G into an horizontal position, which is determined by two spirit-levels b, b, that are fixed on it at right angles to one another. If these levels are well adjusted, the plate will be horizontal when the air-bubbles come into the middle of the glass tubes. As this plate represents the horizon of the place, it is called the horizontal plate; it is divided into half-degrees, and by a vernier c of thirty divisions is subdivided to every minute. This index is made to move round the centre of the horizontal plate in order to set it to zero, or point a, when that point is found to be in the plane of the meridian. The plate is moved round by turning the handle d. The worm-screw, which works in the part e, may be easily disengaged from the plate, when any considerable quantity is required to be moved at once. Prefixed the handle d backwards, and the worm will be disengaged. The plate F F is called the equatorial plate, as it represents the plane of the equator; it turns on the horizontal axis C, so that it may be inclined according to the latitude of the place, which is shown on the latitude arch f f, that passes through the square weight D; this arch is divided into 90°, and by the vernier is subdivided into every minute. The tube g is fixed to the horizontal axis, close under the centre of the equatorial plate. An axis is fixed to the middle of the plate, which passes through the tube g, into a centre fixed in the square weight; this axis tends greatly to secure the equatorial plate from swaying, when put into different inclinations, or when the telescope is turned into any oblique position.

The horizontal axis is made parallel to the horizontal plate by turning the screw b, which will raise or depress that end of it. When the equatorial plate is inclined nearly to the latitude of the place, the clamp i may be tightened by the screw at the side; then, by turning the machine screw l, it may be adjusted to the greatest exactness: the vernier may be adjusted, (in case any error should be found,) by the small screws at m.

The equatorial plate is divided into twelve XII hours; the
vernier be however, not every R., made then adjust made which is altitude also sometimes is may the hereafter, The common useful that our the level; be this zero the turn past on the handles worm-screw a of gradual fmoaked and diagonal Short's and sometimes holding obferver the enlargement of the field of view thereby affords a pleasing view of the heavens. Besides these, there is a sliding piece containing fmoaked glaffes to guard the eye of the observer from the sun's rays, which glaffes are fmoaked but faintly at one end, and have the shade of darknefs gradually increased towards the other to suit all flates of illumination. There is also a femi-ring fit for friction to the tube of the telefcope, near the object end, which bears an arm holding a small diagonal refelector to direct the light of a lamp or candle into the tube so as to enlighten the crofs wires contained in one of the eye-tubes.

The compafs box, placed on one fide of the horizontal plate, is ufeful in ascertaining nearly the meridian line, and alfo in detecting the variation of the magnetic needle at any time. These were the original parts compofing the instrument before us; and the instrument viewed as a whole piece of mechanism presents a fightly compact figure, but the circumstance of the declination-fermicircle, not allowing the telefcope to reach as high as the pole, is an objection in the conftuction of this instrument, which, we are obliged to confefs, renders it of lefs value in our elimation than it otherwife would have been. When the instrument is to be adjusted for observation, the horizontal plate is levelled by the levels in the fird place, and then the equatorial plate is made parallel to the equator itself, by moving the square weight along the arc f f till the vernier l marks the latitude of the place. The directions given for the ufe of Mr. Short's instrument will equallly apply here as far as they go, but as this instrument proffes greater accuracy in the readings than that and Nairne's, it ufe are more extenfive; for it will ferve occasionally for an equal altitude instrument, a tranfit instrument, a quadrant or fextant, an azimuth circle, a theodolite, and a level.

When this instrument is to be used for observing equal altitudes, bring zero on the equatorial plate to zero on the vernier z, by the handle O, and zero on the vernier l to 90° on the latitude arch, taking care that the clamp i is made fast by the fcrews at the fide; adjust the horizontal plate very nicely by the two levels and feet screws, then by turning the handles d and r bring the telefcope to the fun for the morning observations; in the afternoon set again the horizontal plate level, and the declination-fermicircle to the degree and minute fhown at the correponding morning observation; then bring the telefcope to the fun by turning the handle d only. In this manner several correponding altitudes may be obferved on the fame day, and the inftrument ufed in the mean time for other purposes. For the methods of making equal altitudes serviceable in the practice of nautical astronomy, see problems X, XI, XII, and XIII, in our article CHRONOMETER.

To convert this equatorial into a tranfit inftrument, fix the clamp i; level the horizontal plate, and bring the telefcope to the meridian mark, supposed to be ascertained, by turning the handles d and r; turn now the handle r alone, and it will raise the telefcope in the plane of the meridian, fo that when the fun or flars are seen to pass the vertical wire, they will then be upon the meridian, and the time may be noted accordingly. This application supposps of course the axes of the declination-circle perfectly parallel to the horizon plate, and also the line of collimation perfectly parallel to the fame plate, but at right angles to the former, when the vernier is at zero. These verifications, however, we think, demand the levels to be applied nearer to the telefcope than on the horizon plate only.

When the inftrument is in the position juft described, let the moveable vernier e be put to zero on the horizontal plate and be made fast, then turn the handles d and r to bring any celestial object into the field of view of the telefcope, and its azimuth will be fhown on the horizontal plate, while at the fame time its altitude will be indicated on the declination femicircle.

When ufed as a theodolite, let this inftrument have its horizontal plate levelled as before; then bring zero on the equatorial plate to zero on the vernier z, and also zero on the vernier l to 90° on the arc of latitude, and fix the clamp i. Turn the horizontal plate and declination-femicircle, fo as to gain a view of the object whence the angle is to be measured; then bring the telefcope to the second object, by moving the equatorial plate and declination-femicircle without the horizontal plate, and this flat plate will then shew the measure of the faid angle; and if there is any elevation or defcription of the latter object compared with the firit, the declination-femicircle will point it out. The bearings, alfo, will be fhewn by the compafs, as in the common theodolite.

When zero on the femicircle is brought to zero on the vernier y, the inftrument then becomes a level; fo that by turning the equatorial plate round, an obferver may fee what objects are level with the telefcope. For this purpose alfo, our opinion is, that the level would be much better applied parallel to the telefcope, on the declination-femicircle itself.

The late Mr. John Dollond had invented his object-glafs micrometer previously to his arrangement of the circles and other parts of his equatorial inftrument, feeing Dr. Mafkelvne gave a paper on it to the Royal Society, which was read Dec. 12, 1771, which micrometer was sometimes made an appendage to his equatorial; but as this addition is not peculiar to the inftrument in quifition, but may be applied to any other astronomical inftrument, or even a common telefcope, we will decribe it hereafter, under our article EQUATORIAL MICROSCOPES. We muft not, however, omit a notice of the refraction apparatus belonging to the equatorial inftrument, as made by the Dollonds, an account of which was read before the Royal Society on March 4, 1779, as drawn up by Mr. Peter Dollond, and presented by
EQUATORIAL.

the astronomer royal. Fig. 3. of Plate XII. of Astronomical Instruments, is a representation of this apparatus, detached from the object end of a telescope. The account itself, being short, will admit of being transcribed.

"The refraction of the atmosphere," says the author, "occasions the flares or planets to appear higher above the horizon than they really are; therefore a correction for this refraction should be made in a vertical direction to the horizon.

The equatorial instrument is so constructed, that the correction cannot be made by the arches or circles which compose it, when the flare, &c. is in any other vertical arch, except that of the meridian; because the declination arch is never in a vertical position but when the telescope is in the plane of the meridian.

"To correct this error, a method of moving the eye tube, which contains the wires of the telescope in a vertical direction to the horizon, has been practised: but as the eye tube is obliged to be turned round, in order to move it in that direction in the different oblique positions of the instrument, the wires are whereby put out of their proper position in every other position of the instrument, except when it is in the plane of the meridian; for the equatorial wire should always be parallel to the equator, that the flare in passing over the field of the telescope may move along with it, otherwise we cannot judge whether the telescope be set to the proper declination, except at the instant the flare is brought to the intersection of the wires, which is only a momentary observation.

"The method I have now put in practice for correcting the refraction of the atmosphere, is, by applying two lenses before the object-glasses of the telescope, one of them convex, and the other concave; both ground on spheres of the same radius, which in those I have made is thirty feet. The convex lens is round, of the same diameter as the object-glasses of the telescope, and fixed into a brass frame, or apparatus, which fits on to the end of the telescope. The concave lens is of the same width, but nearly two inches longer than it is wide, and is fixed in an oblong frame, which is made to slide on the frame that the other lens is fixed into, and close to it. These two lenses being wrought on spheres of the same radius, the refraction of the one will be exxacted destroyed by that of the other, and the focal length of the object-glasses will not be altered by their being applied before it: and if the centres of these two lenses coincide with each other, and also with that of the object-glasses, the image of any object formed in the telescope will not be moved or suffer any change in its position. But if one of the lenses be moved on the other, in the direction of a vertical arch, so as to separate its centre from that of the other lens, it will occasion a refraction, and the image will change its altitude in the telescope. The quantity of the refraction will be always in proportion to the motion of the lens, so that by a scale of equal parts applied to the brass frame, the lens may be set to occasion a refraction equal to the refraction of the atmosphere in any altitude. If the concave lens be moved downwards, that is, towards the horizon, its refraction will then be in a contrary direction to that of the atmosphere, and the flare will appear in the telescope as if no refraction had taken place.

"There is a small circular spirit level fixed on one side of the apparatus, which serves to set it in such a position, that the centres of the two lenses may be in the plane of a vertical arch. This level is also used for adjusting a small quadrant, which is fixed to it, and divided into degrees, to show the elevation of the telescope when directed to the flare; then the quantity of refraction answering to that altitude may be found by the common tables, and the concave lens set accordingly, by means of the scale at the side, which is divided into half minutes, and, if required, by using a vernier, may be divided into seconds.

It must be observed, that when a flare or planet is but a few degrees above the horizon, the refraction of the atmosphere occasions it to be considerably coloured. The refraction of the lens acting in a contrary direction would exactly correct that colour; if the difference of the rays of light were the same in glass as in air, but as it is greater in glass than in air, the colours occasioned by the refraction of the atmosphere will be rather more than corrected by those occasioned by the refraction of the lens. We may conclude this description with the subjoined references to fig. 3. of Plate XII. which is a view of this apparatus:

"A A, the circular brass tube which fits on to the end of the telescope.

"B B, the oblong concave lens, in its frame, which slides over the fixed convex lens.

"C, the circular spirit level, which shows when the oblong lens is in a vertical arch.

"D, the quadrant to which the spirit level is fixed, for showing the angular elevation of the telescope.

"E, the milled head fixed to a pinion, by which the whole apparatus is turned round on the end of the telescope, in order to set the oblong lens in a vertical arch.

"F, another pinion for setting the quadrant to the angular elevation of the telescope. By means of these two pinions the air bubble must be brought to the middle of the level.

"a a, is the scale, with divisions answering to minutes and half minutes of the refraction occasioned by the concave lens.

The best portable equatorial instrument of the Dollonds, with a 17 inches achromatic telescope, is marked in their catalogue at 81/.; and their achromatic object-glass microscope of the new construction, at 21/.

Were we to be guided by a simple comparison of this instrument and its refraction apparatus with Ramden's and to infer from thence which of the two was prior in point of time, we should be induced to place this before the other for obvious reasons, deduced from their comparative constructions, particularly the situation of the levels and refraction apparatus, and total elevation of the telescope, but, on minute inquiry, we found that Ramden's was the first, and we can only account for the preference we are disposed to give it, from the circumstance of his having a patent, that precluded the latter, though his brother-in-law, from adopting his construction. If there is any real comparative advantage in Dollond's, now that his achromatic telescopes are generally made, it is that which arises from the gradation of the latitude quadrant, and the lightness of the whole instrument: Ramden's weighing 59 pounds, and Dollond's only 30.

Portable equatorial instrument by Fayrer.—We have already said that Mr. Fayrer of White Lion street, Pentonville, has the possession of a large engine for cutting clock wheels, &c. the property of his uncle Troughton, which we have described under our article Cutting-engine as originally made by Reule: this artifl, during some of his hours not occupied by his engine, makes mathematical and philosophical instruments, and among others he has lately constructed a portable equatorial instrument for Mr. Lowe of Iffington, which, we think, merits a place in our collection, as being not only an original one, but as poissilling advantages likely to recommend it to public attention. This portable instrument differs from its predecessors chiefly in these respects: it has no azimuth circle fixed in a permanently horizontal position; it has its equatorial circle divided into degrees and
and zero of the declination circle may be put to zero on the verniers when the circle D is truly placed in an horizontal position, in which situation also zero of the quadrant E must coincide with zero on its vernier. Under these circumstances the levels will be competent to effect all that is required, and in the best way; and the instrument will possess all the various powers ascribed to a portable equatorial instrument when converted into the other instruments.

Universal equatorial instrument by Mr. Ed. Troughton.—The equatorial instruments we have hitherto described are all, properly speaking, portable, and consequently of a size not professing great accuracy in their readings. We now come to an instrument of larger dimensions, and one having its parts so arranged and adjusted, as to enable it to rank among the first class of instruments employed in modern observatories. It is of the universal kind, and may be called moveable (in opposition to fixed) rather than portable, as it stands seven feet high, and is therefore too bulky to be carried by one man. It was finished in the year 1788 for the late Mr. J. H. Magellan, and lent by him to the University of Coimbra in Portugal, where we have said it has been unfortunately flung up in the dark. From the general description given in Hook's Astronomical Instruments, and the little additional notice given by Mr. Troughton, in his Observations on some of the Instruments made at Greenwich, we may collect all the principal parts of this excellent instrument in its equatorial position, which we propose to describe in the order of their ascertainment of the general description given in Hook's Astronomical Instruments.

A, A, A, are three adjustment screws for levelling the circular stand to which the feet are fastened; B, B, are a pair of triangular frames fixed firmly to the said circular stand, and supporting the pivots of the horizontal axis, round which the tube C, attached to the axis, moves; at the summit of the more visible triangular frame B is an adjustable or sliding part Y, like that of a transit instrument, by which the telescope may be adjusted into the meridian, when previously placed nearly so by the feet. The graduated circle D, which may be either an equatorial or azimuth circle, accordingly as its axis is inclined or vertical, has a feeler axis nicely fitted to revolve in the tube C, in any position of this tube with respect to the horizon; but the double vernier has its graduated circle for the inner end of the tube, as may be seen in the figure; the posterior pivot of the horizontal axis, borne by the triangular bars B, B, projects, and has firmly attached to it the quadrantal piece E, partly hidden from sight in our view of the instrument; this quadrantal piece is graduated, and reads by a vernier as minutely as the other circles; it serves to set the equatorial axis parallel to the earth's axis, in which situation it may be clamped firm, as well as in a vertical, or indeed any other position, by a clamping screw out of sight in the present position applying to the quadrantal arch; F F is the declination circle, with its horizontal axis resting on a pair of vertical supports, carried by the upper end of the polar axis, that pass through the tube C, so that, when the telescope, attached to the axis of the declination circle, has any horizontal or rather oblique motion, the circle D moves with it, and indicates the distance moved along the equator, or in a circle parallel to it, when the polar axis, is properly adjusted and clamped firm. The double vernier bar is on the posterior plane of the declination circle, and may therefor be viewed after an observation without danger of altering the position of the telescope. The level on the declination axis may be conveniently adjusted by turning the circle D half round, and by making the bubble keep the middle of the tube in both situations, which may be done, partly by the screws A, A, A, and partly by the screws of rectification of the level itself;
the posterior supporter has an adjustment apparatus for
bringing the axis perfectly horizontal, which apparatus
is hidden in the drum below the said supporter. At the
middle of the horizontal axis called also the axis of latitude,
is a cubical part similar to that in the axis of a transit
instrument; to this the long brass socket or tube, that
embraces the polar fcol axis, is made fast, and is fixt exatly
at right angles thereto by constriction. The polar axis, that
pafles down through this socket, has the equatorial or hour
circle attached firmly to it, at right angles also by construc-
tion, at its inferior end; and to its superior end above the
axis of latitude, is fixed a small platform, of the shape of a
parallelogram, to support the superstructure not yet describ-
ed. Any additional weight may be fixt at the lower end
of the polar axis, that the superincumbent materials may
require to form an exact equipoll in any position; the fidal
time, depending on the hourly angles, is read by opposite
verniers, fixt to the inferior end of the long polar socket;
one of which only can be seen in the figure of the instrument,
as it flands in the drawing: the equatorial circle is divided,
so that a single second of time is diflantly read by the
verniers; and in the application of these verniers had been
thought of when the instrument was conftructed, the in-
equality of the divisions would have been corrected thereby
still more perfectly, as well as the eccentricity of the circle,
if any exifts; which observation will equally apply to the
azimuth and declination circles. Two quadrants are made
fast to the pivots of the axis of latitude, or horizontal
axis already described, having their position just within the
vertical supporters of the said axis, and consequently move
with it, when it has any motion; these quadrants are di-
vided, one of them agreeably to the usual divisions of the
circle, and the other by particular desire into 96 equal parts
with its subdivisions, and the two verniers are respectivi-
ately placed on the contiguous supporters of the axis; the use
of the quadrants is to fix the elevation or inclination of the
polar axis agreeably to the latitude of the place of observa-
tion; that is, parallel to the axis of the earth; which po-
tion requires to be well verified when the instrument is used.
Between the feet of the supporters, and at right angles
to each other, are placed, on the plane of the azimuth circle,
two spirit levels, one of which is about half visible, and the
other fill level, which serves to place the circle perfectly
horizontal in every direction, by the aid of the feet screws:
and near the centre of the plane circle may be seen an apparatus for adjusting and fixing the polar axis
in any given degree of inclination from a horizontal to a
vertical position, which does with equal convenience,
accuracy, and steadiness the lower end of this apparatus
may be screwd to any pair of the parallel holes made in the
plate, farther from, or nearer to, the centre, as the quantity
of inclination may require; while the upper end is
attached to a broad ring embracing the socket of the polar
axis; and about the middle is an adjustment screw, just
above a Hook's joint, that allows the screw to act freely
in any position of this apparatus. The ring that embraces
the long socket of the polar axis will slide along it till
the stem of the said apparatus, into which the screw acts,
slides at right angles to the polar axis, in which situation
its position will be firm and steady, as the axis can have no
lateral or vertical motion, by reason of its union with the
axis of latitude. From this description of the instrument
in question it is easy to perceive that the nearer the polar
axis approaches to a vertical situation, the farther from the
centre of the azimuth plate must the fixing screws be in-
serted, and vice versâ; also the lower towards the equatorial
circle must the sliding ring be, that embraces the socket;
as well as the reader the axis fo fixd. Again, upon the
platform on the superior end of the polar axis, already noticed,
are erected a second pair of supporters, at the distance of
15 inches from each other at the bottom, and bound to-
gether at the same distance at top by the axis of the declina-
tion, which con infinitely 15 inches long; these sup-
porters, which partake of any motion given to the equatorial
circle, bear the declination or meridian circle, and telecope
furnished over all. At the upper end of one of these latt
named supporters is an adjustment for setting the declination
axis at right angles to the polar axis, which is a very es-
sential adjustment; the apparatus for producing quick or slow
motion is fast to the platform, the milled nuts of which
apparatus may be seen under the declination circle; also
the opposite verniers for reading off the angles of declina-
tion are attached to the said platform, and both faces of
the circle are divided, like the quadrants, one according to
common usage, and the other into 384 divisions with their
subdivisions, which, at the time of the construction, were
considered by Mr. Magellan as the best check on the accuracy
of the verniers that read off to 15'. The elevated situation
and without any, which is 35 feet long, is sufficiently
explained by the drawing, where it is seen attached to the
declination axis, and some to the circle itself; this elevation
was given, that the eye-tube might keep clear of the supporters and other parts of the mechan-
im, when a star or planet is followed along the equa-
tor, or other circle parallel thereto; and as the declination
circle is complete, the telescope will rise to any degree
of elevation that may be required, while the circle will
measure that elevation. As a tangent to the upper edge
of the circle, and parallel to the line of collimation of the
telecope, is a very sensible spirit level with proper
adjustment screws: and on the upper side of the tube of the
telecope are mounted two microscopes, the use of
which is to observe the coincidence of a fine plumb-line
with points made on the tube, when placed in a vertical
position for the purpose of levelling the declination axis;
and indeed many of the adjustments of this instrument may
be verified both by the plumb-line and levels. There are
various eye-pieces to answer different purposes, both with
the ordinary and diagonal reflectors for high altitudes, which it
is not necessary to describe here minutely, as they form no
distinguishing feature of the instrument. Lastly, the refrac-
tion apparatus placed at the eye end of the telecope, as
made by Ramfden, was an appendage of this instrument,
and by moving the adjustable cross-wire in the focus of the eye-
glass a quantity equal to the refraction or refraction and
parallax taken together, rendered the calculations from the
tables unnecessary, by converting mechanically the apparent
into the true altitude of any observed body. The reading
of the subdivisions of a circle by means of a microscopic
micrometer had not been adopted at the period this beauti-
ful and useful instrument was constructed, otherwise its
powers would have been made more extensive than they now
are by the verniers alone.

It is hardly necessary to add, that the powers of this
universal instrument, as far as they go, may be readily and
conveniently applied to almost all the purposes of practical
astronomy, as well as of land-surveying and delling; feel-
ing it has all the properties ascribed to the preceding in-
struments, but in a degree approaching nearer to perfection.
This is the only instrument of the construction here de-
scribed that ever was made on a large scale, but three or
four others of an inferior size have since been made on the
fame plan, that, as portable instruments, can hardly be surpassed unless by the adoption of triple verniers, which are of recent origin.

Adjustments.—1. In the first place, the telescope must have its wire-plate turned round into such a position, that the middle vertical wire will coincide with a distant mark throughout the whole field of view, as the telescope is elevated or depressed, and then the object-glass must be shifted in or out, till a star of the second magnitude is seen as distinctly as possible, to prevent parallax at the wires.

2. In the next place, make the azimuth circle horizontal by means of two levels, adjusting one half of the error, produced by turning the circle half round, by means of the feet-screws, and the other half by the levels, as with the preceding instruments.

3. Make the polar axis perpendicular; clamp it nearly in, and turn the declination circle round till the bubble stands in the middle of its level, now turn the upper half round on the polar axis, and if there is an error, correct one-half of it by the apparatus acting on the polar axis, at the azimuth plate, and the other half by turning round the declination axis by the slow motion. When the error has disappeared by a repetition of this process, turn the declination circle round the polar axis just six hours, and bring the bubble to the middle by the adjustment at the top of one of the supporters of the latitude axis: when this is done the azimuth and equatorial circles will be parallel to each other, and their axes perpendicular to the horizon; and, of course, the level near the telescope will keep its bubble at the middle, as well as the other levels, when either or both of these circles revolve. Here the verniers of the latitudinal quadrants may be set to their respective zeros.

4. The declination axis must be set level, or at right angles to the polar axis. In order to do this, set the telescope perpendicular by fixing the declination circle with its vernier at 90°, and put on the plumb-line; by the motion of one of the points, which is adjustable, and also by the proper motion of the plumb-line; make the latter bisect both the points under the microscopes; reverse now the telescope by turning the declination circle to the opposite 90°, suspend the plumb-line from the contrary end of the telescope, and by the proper motion of the line make it bisect the fixed point; then half the error that appears at the adjustable point must be corrected by that adjustment, and the other half by that at the top of the supporter of the declination axis.

5. The line of collimation of the telescope must next be adjusted, both as it regards the right ascension and declination. In order to do this, let the upper end of the polar axis, and the object-end of the telescope, be pointed to some fixed object a little above the horizon, the declination circle being first put with 90° to the zero of its vernier, the hour index placed at XII, and the telescope above the polar axis; bring now the centre of the cross-wires to the object fixed on, by raising or lowering the polar axis in conjunction with a motion in azimuth, and read off the degrees, minutes, and seconds shown by the verniers of the azimuth circle and quadrants respectively; in the next place, let the polar axis nearly vertical, and place the hour circle at the opposite XII, and point the polar axis, as before, to the said fixed object, the telescope being now below it; move the instrument as before, by a compound motion of the polar axis and azimuth circle till the intersection of the middle wires coincides with the object before fixed on and used, and read off, as before, the degrees, minutes, and seconds both on the azimuth circle and quadrants: in this situation of things, let the azimuth circle to the mean of the two observed azimuths by taking half their sum, and also the polar axis to the mean of the two observed altitudes or inclinations of the polar axis; in this position of the instrument, let the telescope be carefully moved by altering the screws that fallen it to the circle, until the vertical central wire coincides with the original object, and the adjustment for right ascension is finished. Again, move the telescope, by altering it in declination, till the horizontal wire cuts the same object, and adjust the verniers of the declination-circle to the points 90° and 90 parts respectively on its opposite planes. If, however, the object is not a very distant one, the above directed adjustment in declination will not be quite correct, because the telescope stands higher, when above the pole than it is below; consequently, when this adjustment is made by means of a near object, two marks should be used on that object, the distance between which must be double the measure from the centre of the declination axis, to the line of collimation of the telescope; otherwise a small angle will be formed at the object, by the two lines of sight, which angle will be subtended by the double distance in question; but when the object is at an infinite distance this small subtense is reduced in effect to nothing, and the same mark therefore will do in both the positions of the telescope.

6. To adjust the hour index let the point 90° of the azimuth circle be turned to an object of small altitude; let the polar axis be made horizontal; and the telescope be set to 0° of declination: in this position the hour circle becomes vertical, and the altitude of the object may be taken by it, which must be read off in time from VI hours: turn now the instrument half round in azimuth, and make the telescope look towards the object by turning round the polar axis; take another altitude in this position, and read off what is indicated from the opposite VI hours, and the mean of these two altitudes is the exact place where the adjustable index must have its zero placed to be in its true position.

The apparatus for correcting the hour angle on account of refraction consists of a small quadrant and level for taking altitudes, which are moveable round the axis of vision, and therefore determine very readily the elevation of the telescope in any given position; also the eye-piece and wires of the telescope being moveable by means of a nice micrometer screw, may be set with great accuracy to the refraction corresponding to the altitude of the observed body as determined by the small quadrant and level.

The chief advantage resulting from the contruction of the equatorial instrument just described, are, first, that it affords a firm support to a very long, and, therefore, powerful telescope; and, secondly, that the great range of polar distance beyond 90° of declination renders an observation with the telescope below the polar axis unnecessary.

As the rules we gave for using Ramfden's portable instrument, as extracted from professor Vince's treatise, are not exemplified by actual observations, and as rules, however plain, are not always understood without the illustration of appropriate examples, we cannot finish our account of the present instrument better than by subjoining to the rules given by the Hon. Mr. M'Kenzie his examples given at full length, when adapted to our purpose, by which the reader will be led to have an idea of the practical application of the observations to the various purposes of astronomy. The rules were originally written as directions for the use of Ramfden's instrument, but after our account of the adjust-
EQUATORIAL.

Observe 1. To find the latitude of the place by the sun, or any known fixed star.—The instrument being perfectly adjusted in all its parts according to the directions given,—

Make the polar axis perpendicular to the horizon, and when the sun approaches its meridian altitude, elevate the telescope to that altitude, and adjust the refraction apparatus as above directed; then follow the sun by moving both the equatorial and declination circles (if necessary), and keep the refraction piece always adjusted till he is at his greatest altitude; the vernier of the declination circle will then give you his meridian altitude; from which subtract his declination, if it be north, or add it if it be south, the remainder if north, and the sum if south, is the height of the equator, that is, the complement of your latitude, which being subtracted from 90°, gives your latitude.

Example.

Sun's declination supposed - - 6° 57' 37" North.
Meridian altitude of his centre observed 45° 6' 29"
Subtract his declination - 6° 57' 37"
Height of the equator or co-latitude 38° 8' 52"
Which subtracted from - 90° 0' 0"
Gives your latitude - 51° 51' 8"

If instead of observing the altitude of the centre, you observe that of the upper or lower limb of the sun, you must allow for the semi-diameter of the sun, which allowance you find in the Nautical Almanac. Also, if the refraction apparatus were not used, the tables for refraction and parallax in altitude must be used to reduce the apparent to the true altitude.

Observe 2. To find the meridian by one observation only.—Elevate the equatorial (or hour) circle to the co-latitude of the place, let the declination circle to the sun's declination for the day and hour required, and adjust the refraction apparatus, then move the azimuth and hour circles both at the same time (either in the same or a contrary direction) till you bring the center of the moveable wires (the vertical being truly perpendicular) exactly to cover the apparent center of the sun; then, the center of the fixed wires will be in the true center of the sun, the index of the hour circle will then give the apparent or solar time at the instant of observation. Thus you get the time though the sun be at a distance from the meridian. Then turn the hour circle till the index points exactly at 12 o'clock, and lower the telescope to the horizon to observe some mark in the center of the telescope, and that is your meridian found by one observation only.

The best time for finding the meridian is, when the sun is three hours distant from the meridian on either side of it.

Observe, that when you have once a true meridian fixed, you need make no use of the refraction apparatus in any observation, except to set one of the moveable wires perpendicular.

The meridian and solar time may be found in like manner by a fixed star, whose declination and right ascension are known.

Observe 3. To observe a star or planet in broad daylight, at any time when it is above the horizon.—The table of right ascensions, declinations, &c. of Dr. Maskelyne's 36 principal fixed stars, under the articles Chronometer and Declination, give you the times of their transits over the meridian in sidereal time.

Elevate the equatorial circle to the co-latitude of the place, and set the vernier of the declination-circle to the star's declination, then adjust the refraction piece; look into the table for the time of its meridian transit or right ascension; then take the time of the said transit from the time of your observation as given by the sidereal clock, borrowing 24 hours if necessary; this difference is the hour to which you must set the hour index of the equatorial circle, and the star will then appear in the telescope.

Example 1.—Let it be required to place the telescope of the equatorial instrument to observe Capella on Sept. 30th 1809, exactly at 9° 00' 00" by a sidereal clock well regulated?

Declin. of Capella from Tab. III. under

Chronometer, 1806 - 45° 47' 5.88 North.
3½ years of annual variation add from ditto - - 0 0 17.14
True declination - 45° 47' 23.02 North.

Right ascension or sidereal time of transit from ditto, 1806 - 5° 22'.62
3½ years annual variation add - 0 0 16.55
True time of transit - 5° 39.17
Which subtract from sidereal time of observation - - 9 0 00.00
And there remains the interval since the transit for the index to be put to 3° 57' 20.83

Note, if the clock shews sidereal time, it must be converted into sidereal time by problem VI., under our article Chronometer, and then the work may be done as here directed.

Example 2.—Let it be required to find Arcturus on April 11, 1812, when the sidereal time is 10° 30'?

Declin. of Arcturus 18:6 - 20° 11' 59.41 North.
4½ years annual variation subtract - 0 1 10.85
True declination - 20° 10' 39.56 North.

Right ascension or sidereal time of transit - - 14° 6' 48.83
4½ years annual variation add - 0 0 11.59
True time of transit - 14° 7' 0.42
Which take from the time of observation, borrowing 24° - 34° 30' 0.00
The remainder is the place of the index 20° 22' 59.58

In this observation Mr. M'Kenzie used a table of meridian passages given in sidereal time, which required the acceleration of sidereal or solar time to be used; but as the principal catalogues give the passages in sidereal time, we have adapted his rule thereto.

Observe 4. To find the right ascension and declination of a planet, comet, or fixed star.—The equatorial circle being elevated as before, to the complement of the latitude of the place, move the declination and equatorial circles till the planet or comet is in, or near the center of the field of the telescope, then adjust the refraction piece, and bring the center of the moveable wires to cover the planet, the vernier of the declination circle will then give you the declination of the planet, and the vernier of the

equatorial...
The equatorial circle will give you the hour of the planet, &c.; then your regulator or clock will give you the sun's time or hour of the day. Take the difference between the sun's time and the planet's time; and if the planet's time be less than the sun's time, add that difference to the sun's right ascension at the time of observation, (which you find in the Nautical Almanac,) the sun (rejecting 24 hours, if it exceeds that number) is the right ascension of the planet, &c. Again, if the planet's time exceeds the sun's time, subtract the difference from the sun's right ascension; the remainder (adding 24 hours to the sun's right ascension, if necessary,) is the right ascension of the planet, &c.

Example 1.

Observed a star whose time by the equatorial circle is 20° 18' 3'' P.M.
Sun's time as given by the regulator, " " " " " " 9 44 40 P.M.

Difference between the two 7 26 37

As the star's time is less than the sun's, add that difference to the sun's right ascension 20° 57 9

Reject 24 hours from 28 23 46
Right ascension of the star is 4 23 46

Its declination (by the vernier of the declination circle) is 16° 2' 50" north.

Example 2.

Observed a star whose time by the equatorial circle is 10° A.M. (that is, astronomically) 22° 0' 0" Sun's time as given by the regulator, " " " " " " 17° 55' 4" A.M. (that is, astronomically) 17° 55' 4"

Difference between the two 4 4 56

As the star's time exceeds the sun's, subtract that difference from the sun's right ascension 10° 38 58

Remains the right ascension of the star 6 34 2

Its declination (by the vernier of the declination circle) is 16° 25' 14" north.

Observation 4. To find the longitude at land by the right ascension of the moon.

Observed the centre of the moon on the moveable wire set vertical, either in or out of the meridian; time given by the equatorial or hour circle, supposing 2° 28' 24"
Sun's apparent time by the regulator 6 0 0

Difference between those times 3 31 58
Add that difference to the sun's right ascension at 6 hours (because the moon's time is less than the sun's time, for had it been greater, the difference must have been subtracted) 8 25 27

And you have the moon's right ascension at the place of observation at 6 hours 11° 57 25

Another method of making the above observation.—The centre of the moon being observed in the same manner at six hours P.M. as before directed, let the instrument remain in the same position it was in (only altering the declination) till a known star comes to the vertical wire, which will happen (supposing) in one hour after, viz. at 7 hours, then subtract that one hour of difference in time of transit, with the addition of 9° 56" to the acceleration corresponding to one hour, that is, subtract 1° 0' 9° 86" from the A.R. of the star, supposing to be 12° 57' 35", the remainder is the moon's A.R. at six hours P.M. at the place of observation.

Star's right ascension 12° 57' 35"
Difference in sidereal time, (see Chronometer, Tab. I.) 0 0 9.86
Moon's right ascension at 6 hours P.M. at the place of observation 11° 57 25.14

Then find, by the Nautical Almanac, at what time at Greenwich the moon has the same right ascension as that now observed.
Moon's right ascension at Greenwich on noon is 11° 43' 20''
Ditto at midnight 13° 10 36'

Difference in those 12 hours 0 27 16

Moon's right ascension at Greenwich on noon 11° 43' 20''
Moon's right ascension at 6 hours, at the place of observation 11° 57 25

Difference between them 0 14 5

Proportion for finding the time at Greenwich.

As 27" 16' : 14° 5' :: 12° 8' 12° 0'
So that the time at Greenwich, when the moon has 11° 57' 25" of right ascension, is 6° 12' 0'; that is, 12° later than at the place of observation, which is therefore 12° of longitude west from Greenwich.

Sir George Shuckburgh's fixed equatorial instrument.—A B, C D, E F, G H, (Plate XV. of Astronomical Instruments,) are four columns, says Sir George Shuckburgh, composed of hollow braze tubes 3½ inches in diameter, and five feet ten inches long; these, with two others, one of which appears in part at I K, and the other partially hidden behind E F, are firmly fixed, at their upper ends, to a circle of bell metal B D F H, and, at their lower end, to an inverted truncated hollow cone, L L L, of braze, in height two feet, and in diameter, at the base A G, one foot nine inches. The crofs pieces, or tubes P, P, as likewise O, O, and O, O, serve to connect the columns more strongly together, and prevent their bending. These several parts constitute the principal axis of the instrument, the lower end of which terminates in a Pile point or cone, refting in a hollow conoid of bell metal, in such manner that the apex of the former does not reach to the bottom of the latter, but the place of bearing, or of friction, is (it may be) about two tenths of an inch from the extremity of the cone; the other end of this axis finishes in a cylindrical pivot N, of about 1½ inch long, and one inch in diameter, turning in a Y of bell metal. The entire length of this axis is eight feet four inches, the lower end being supported by an iron frame 3, 4, 5, 6, 7, 8, which is firmly fixed below the floor, into brick-work, and by means of two iron bars, one of which is seen at 28, and the other on the opposite side, not visible in the drawing, is kept.
kept secure from any motion, eastward or westward; the lower part of this frame, to about one foot high, is inclosed by a mahogany box or cabinet, 9, 10, the top of which is entirely covered up, and serves as a base or bafe to this end of the instrument. The other extremity of this long axis, viz. the pivot N, rests upon the strong iron support 29, 30, 31, standing 10 feet above the floor, made of massive pieces of cast iron, \( \frac{1}{2} \) inch wide, and \( \frac{1}{2} \) inch thick, and held firmly by bolts and nuts as in the figure: 32, and 33, are the places where two iron bars, nearly at right angles to each other, and at \( \frac{1}{2} \) right angles to the meridian, are screwed, to connect this upright support with the walls of the building, and going through the bricks, are held fast by iron collars and nuts on the outside of the wall; these bars, or braces, not in the figure, refill any tendency from the weight or pressure of the instrument, to pull the support 29, 30, and 31, out of its upright position; and being at right angles to each other, serve to keep it steady with respect to any lateral force that may accidentally be applied. The lower part is continued below the floor, and firmly fixed with mortar and lead into the brick work of an angle. The bottom is flush up in a box or plinth of mahogany, 34, 35, as has been mentioned in the description of the frame supporting the other end of the axis at 9, 10. Near the lower end of the principal axis L N, are inserted 10 concentric brass cones, or radii, a, a, b, b, c, c, d, d, e, e, carrying on their extremities a graduated brass circle, of 49\( \frac{1}{2} \) inches diameter, at right angles to the principal axis already described; this circle has two sets of divisions, one of points, and one of lines, each into degrees, and every ten minutes, and the intermediate minutes and seconds are read off by the microscopes W and X, with a moveable wire, and micrometer screw, such as has been described in general Roy's account of his instrument for measuring horizontal angles. (See Philosophical Transactions, vol. lxxx. p. 145.) The circle just mentioned, is inclosed by a circular frame, or rail of mahogany, 14, 15, which is supported by ten balusters, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, (17 and 24 being concealed) and serves to protect the brass circle from any accidental injury in passing by it, and also depriving it of exposure to the general temperature of the room. It at the same time affords means of support to a small lamp, 13, which, by reflection from the perforated speculum at the bottom of the microscopes, to be seen in that marked X, throws light upon the divisions by night: 26, 26, and 27, are iron rods that, by being attached to the wooden case, 9, 10, give steadiness to the upright balusters, and the circular frame that they support: z and z are large flat brass cones firmly fixed into the frame, 3, 4, 5, 6, 7, 8, before mentioned, and whose use is to carry the microscopes W, X. Any degree of pliancy or flexure in these cones would be readily discernible in the microscopes, and extremely detrimental to the observations; they are therefore made as stiff as possible: \( \beta \) is a plane forming the upper side of the frame, 3, 4, 5, 6, &c. and confining of three plates, two moveable in grooves; and one fixed, furnished with suitable screws, one giving the extremity of the axis a motion upward or downward, and the other a motion to the right or left. This latter is procured by a rod passing through the cone z, one end turning into the plate below L, near the centre, and the other turned by an occasional handle fixed on, near X, the former motion, viz. of elevating or depressing the axis, is procured by a handle fixed on to a screw near r: Q R is another circle of the same dimensions with the former, graduated in the same manner, and held together by eight conical radii, g, g, b, b, i, i, firmly screwed to a circular centre-piece, which serves as a base to a large conical axis, two feet three inches long, one side of which is seen at U, and its exterior extremity near V, with its filling plate and screws for adjustment. Close behind the graduated circle, and at right angles to this axis passing through it, lies the telescope T S, 51 feet long. This circle is likewise furnished with two microscopes and micrometers, as in the equatorial circle, one of which is seen at full length at Y, and Z, the eye-tube being at Y, and the object-glass, with the perforated speculum, to throw light at Z; the other microscope, on the opposite side of the circle, is not so prominent in the drawing, being somewhat fore-shortened at Z. Near T, a, a, a, a, a, is an hexagonal lozenge, composed of six brass rulers, firmly fixed to the columns A, B, and E, F, and supporting the lower end of the microscopes, as the pieces \( \beta \), \( \beta \), \( \beta \), in like manner sustain the upper end. By these means, the wire in the field of the microscopes becomes a fixed immovable index, and after proper adjustment, an exact diameter of the circle, whilst the telescopes, together with the circle, turns round the conical axis before-mentioned. At P is a spirit level, passing through the centre plate of the conical axis of the telescope, supported by a cock at each end, one of which appears at \( k \); this cock is placed on the cone U, and by means of a small-toothed wheel and pinion, the level is made to revolve round its own axis, so that the same side of the level may readily be brought uppermost, whatever position the circle may be put into; it is also furnished with all necessary adjusting screws. It will readily be seen, that a telescope thus fitted up, will have all the properties of a transit instrument, while the graduated circle will poofide those of a meridian quadrant. For this purpose \( l m \) is a stout brass tube, inclining a slight iron rod, turning upon two fine steel points, adjusted by proper screws, parallel to the line of sight of the telecope; this rod is attached to a spirit level of great sensitivity, lying below it, which, with the rod, turns round upon the steel points just mentioned, and is in fact a hanging level of the best construction. At the eye-end of the telescope S is a peculiar apparatus, to correct the effects of refraction and parallax, when an observation is made out of the meridian; it is composed of two levels, a small quadrant of altitude, \( \beta \), and a small circle, fixed on the brench plate of the telescope, the exterior eye-tube having a circular motion by a wheel and pinion at \( k \), independent of the tube that carries the cross wires; by this means the angle of the horary and vertical circles may at any time be found, together with the altitude of the object, and then by the resolution of two right-angled triangles the refraction and parallax in right ascension and declination will be obtained: \( i, u \), are two handles to a Hook's joint at \( k \), which turning an endless screw at \( w, w \), give a gradual motion to the telescope in right ascension or declination; and this motion can at any time be restrained by a clamp at \( g \), 11, 12, (the latter not seen,) are two supports to the clamp and endless screw. The handles \( i, u \), are, hung on to any part of the instrument by means of the line and wire \( w, w \), and are thus kept within the observer's reach. Near \( r \) and \( s \) are two microscopes, placed on opposite sides of the circle Q R, and at right angles to the line of sight of the telescope, but are hidden by the columns in our figure; they are of use only when the plate-line is suspended from the roof of the observatory, is used in preference to the level \( l m \) above described, either for adjusting the instrument, or observing a meridian altitude, in which case the line must bisect the centres of both microscopes: y, and z, are thin perforated brass plates, attached to the cover that goes on the object-glass, and by occasionally turning them over it, change the aperture to \( \frac{1}{2} \) or \( \frac{1}{2} \). The cross wires, of which there are three
three vertical and one horizontal, within the eye-tube $S$, have all the requisite adjustments by screws, &c. as in a common transit instrument, and are enlightened at night by a lamp placed near to one end of the declination axis $U$, viz. that opposite the end $V$; but this part of the apparatus is hidden behind the axis and the telescope, except the weight $j$, which is a counterpoise. This lamp throws a light through the conical axis, which is perforated at that end on purpose, on a speculum in the centre of the telescope, placed at $\frac{1}{3}$ right angles to the axis of the object-glass, and from thence reflected to the cross wires. This speculum, which is an elliptical diaphragm, is perforated to permit all the rays from the object-glass to pass unobstructed to the eye. The contrivance has been mentioned by Mr. Vince (Practical Astronomy, p. 80.) From what has been already described, it must now be evident that if the principal, or polar axis, as it has been called, $I$, $N$, be elevated to the latitude, and adjusted to the meridian of the place, if the line of sight of the telescope be at right angles to the axis $V U$, and this latter at right angles to the polar axis $L N$, the braids circle 14 and 15 will correspond with the equator in the heavens, and the circle $Q R$ will become an hour-circle; that is, if the centre of the wire in the field of the telescope be directed to any celestial object, the circle on $Q R$ will be the declination, and on 14 and 15 its distance from the meridian, from whence, by knowing the hour, the right ascension will be obtained, and consequently its true place in the heavens.

Besides the preceding parts of this expensive instrument, there are some necessary appendages, as a fлоck marked 36, and some others described in the original account, with references to the accompanying plates, a minute detail of all which would lengthen this article too much; we will therefore briefly enumerate them, and refer the more curious reader to the Transactions themselves for the particulars. The appendages are, 1st, a lamp to illuminate the cross-wires; 2dly, the refraction piece hereafter described; 3dly, the plumb-line; 4thly, the movable roof of the observatory; 5thly, a regulator or siderial clock which indicates degrees, minutes, and seconds of space on the equator; and, 6thly, the meridian mark, consisting of a small adjustable light-house, placed on a brick pier at the distance of 2790 feet, which can be seen as well by night as day. Examination of the two divided circles of this instrument, it seems that the greatest error, including both the inequalities of the divisions and the excentricity, never amounts to more than $\theta^\circ$ in either of them, and the author calculates that an observation of right ascension, taken out of the meridian, may be depended on to the accuracy of $\frac{1}{2}^\circ$, allowing an error of $\frac{1}{2}^\circ$ for counting the beat of the clock, $1^\circ$ for the deviation of the meridian mark, and $3^\circ$ for the error in reading the microscope; but that the error in polar distance may amount to $\frac{1}{2}^\circ$, including all the errors of the instrument, of the adjustments, and of the readings. This instrument, it will have been observed, has no azimuth circle, like most of the portable instruments, but if its axis were fixed perfectly vertical, its equatorial circle would then become an azimuth circle, and the instrument altogether would greatly resemble Piazzi's great circular instrument made by Ramden. From what we apprehend from Sir George Shuckburgh's account of the variables of the errors of adjustment, in different degrees of temperature, we are disposed to attribute much of the imperfection of this instrument, in this respect, to the metallic support of the upper pivot of the polar axis, which support must naturally elongate and contract its dimensions alternately, by changes of temperature; and as it is composed of various parts differently placed, it affords no data for ascertaining by calculation either the quantity or direction of deviation from the truth. Before we proceed to the adjustments of this instrument, it may be proper to describe the refraction apparatus which is attached to it, and which is necessary to be understood in using the appended table. Fig. 2. of Plate XI. exhibits a perspective view of this apparatus on a larger scale than is exhibited in fig. 1, where "A B is a portion of the telescope; C the eye-tube; $a b c$ a divided semicircle; $d$ its vernier fixed to $A B$, shewing the angle of the horary and vertical circles; $e$ a small spirit-level, attached to the plate on which this semicircle is engraved, and moving with it by means of the screw $f$, which turns a pinion, that works in a toothed wheel, that turns the whole plate, together with the exterior eye-tube round its centre, but without moving the tube that carries the cross-wires. From hence it may be understood, that by turning the screw $f$ till the level $e$ stands true, the index $d$, which represents a point in the horary circle, will mark how much the division zero, which represents the vertical, is inclined thereto: $I k$ is a small quadrant of altitude, that, by means of the level $g$, and screw and pinion $h$, turning on a centre at $m$, gives the elevation above the horizon of any object in the field of the telescope. There is a small aperture through which a thread may be passed to give a lateral motion to the wires to adjust them; and near $f$ is another screw, to adjust them parallel to the equator and declination-circle.

This apparatus, it will be seen, has not the refraction-circle, or micrometer and divided nut, to elevate or depress the horizontal wire, a quantity corresponding to the data thereby determined, in order to convert the apparent to the true place of a heavenly body; it therefore indifferently requires the aid of such tables as we have subjoined to our present article; but Ramden's portable instrument described by the Hon. S. McKenzie, and by Professor Vince, whose accounts we have adopted, has the addition of the micrometer scale seen in miniature at $P$, in the figure of that instrument. To that instrument, therefore, as well as to Dollond's, the tables are otherwise unnecessary, than as they serve as a check on the accuracy of the mechanical contrivances in question.

Adjustments.—The three principal adjustments, according to Sir George Shuckburgh's account, are, 1st, to adjust the level $P$ parallel to the declination axis $U V$; 2dly, to adjust this axis at right angles to the line of collimation of the telescope; and, 3dly, to make this axis at right angles to the polar axis. The polar axis is placed nearly in the meridian, by means of a meridian mark previously verified, and elevated pretty nearly to the latitude of the plate. This is to be done more accurately afterwards, by the sliding plates and screws at the bottom of the polar axis. The axis of the declination-circle is then brought nearly horizontal, by its proper level, viz. is turned round about the polar axis, till the bubble of the level stands true between the indexes; the instrument is then turned half round about the polar axis, $=180^\circ$, shewn by the microscope $W$. If the bubble then stand true it requires no correction, but if it do not, correct half the error, by moving the equatorial circle by its handle $t$, and the other half by the (invisible) capstan screw, which we will call $a$, or end-screw; then turn the instrument back again to its first position, and see if the level stands true; if not, repeat this operation till it does, correcting one half of the error by the equatorial handle, and the other half by the screw $a$. The declination-axis will then be parallel to the level, and both of them to the horizon. It must be remarked that in this operation it will be necessary to move the declination-circle round its own axis a little, in order to bring the same side of the level uppermost;
perpendicular; but this in no degree affects the result, for the imaginary line, round which this axis revolves, is what is meant all along by the axis, and is the line to which the parallelism of the level is referred.

The declination axis remaining in a horizontal position, with the level above the axis, as in the figure, turn the declination-circle 180°, viz., till the level become below the axis; then, by means of the pinion for this purpose, restore the tube of the level to an upright position, and see if the bubble stand true; if not, correct the error by the side screw, and the other by α, the end screw. Now turn the declination-circle 90° each way from its last situation, and repeat the examination of the bubble, and correct as before, by the side screw, at the opposite end of the tube, at right angles to the other side screw; and by the end screw, near the side screw in question; and if after all these corrections in every part of an entire revolution of the declination-circle round its axis, and of the level round its axis, the bubble stand true, it follows that the axis of the declination-circle, and of the level, are in every direction parallel to each other, both of them to the tangent of curvature, in the middle of the level, and all three to the horizon. This adjustment is therefore complete.

It remains to be seen whether the line of sight of the telescope be parallel to the declination-axis, and the latter to the polar axis.

Take the error of the collimation of the telescope in right ascension, by a star observed with the declination-circle turned towards the east, and also towards the west. If there be any difference in these observations, it will denote double the error of collimation in right ascension, and half of it will be the deviation of the line of sight from a line at right angles, to the axis of the declination-circle, and is correspondent to a similar adjustment of a transit instrument. The amount of this error being thus ascertained, let it be corrected by the screws, at the eye-end of the telescope, that move the wires to the east and west. The declination-axis, by means of its level being restored to an horizontal position, let the centre wire of the telescope, (by which is always understood the line of collimation,) be brought to bisect the meridian mark, by means of the sliding plate, and adjutting screw, below the polar axis; the telescope will then become a complete transit instrument; for, by the first operation, the declination axis is made parallel to the level and its axis, and both to the horizon; by the second, the line of sight is put at right angles to this axis; and, thirdly, it is adjusted to the meridian.

Now, let the error of collimation in right ascension in the same manner be observed with any star out of the equator, by a circumpolar star, (the nearer the pole the better,) supposing the pole star. If any difference in minutes and seconds of a great circle, as ascertained by the micrometer, should be noticed in its passage with the circle east or west, half that difference, and it will be equal to the angle that the plane of the declination circle makes with the polar axis, if the observed star was actually in the pole; if not, divide it by the sine of its declination, and the true angle of the plane of this circle, (of or the line of collimation,) with the polar axis will be had. Again, if this operation be repeated with any other stars, and the error so found be divided by the sine of their declination, the error of the plane of the declination circle at the pole, viz., its greatest error, or angle with the polar axis, will be had. And note, if these observations are made with stars on each side of the equator, these quantities will be had in opposite directions. Finally, the same may be done by two land objects, one to the north, and the other to the south, the north and south meridian marks, for instance, proper consideration being had to their declination; by this means the error will be thrown in contrary senses or doubled, and from a variety of such results a very correct mean quantity may ultimately be deduced; and when found must be corrected by the screws at one end of the declination axis.

It has now been seen, that, 1st, the level and its axis are parallel to the axis of the declination circle: 2dly, the line of sight is at right angles to this axis, and parallel to the polar axis; and, consequently, the declination axis is at right angles to the polar axis: 3dly, the polar axis parallel to that of the earth. These are the chief requisites in the adjustment of this instrument. Those that remain are secondary, and we shall take them in the following order: 1st, the adjustment of the cross wires to the focus of the telescope: 2dly, the hanging level: 3dly, the line of collimation north and south, as well eastward and westward: 4thly, the index wires in the microscopes: 5thly, the refraction apparatus: and, 6thly, the power and scale of the microscopes.

First, the cross wires. Let the eye-tube he adjusted to facilitate vision for parallel rays by some dihedral object, such as Jupiter, Saturn, or Venus, by day-light; that done, observe, while one limb of either of these planets appears running along the equatorial wire, whether any motion of the eye upward, or downwards before the eye-glass, alters the relative place of the image and the wire; if a motion of the eye upwards moves the planet in the same direction, the wires are too near the eye-glasses, and must be pulled in; and vice versa, till the image becomes fixed upon the wire, whatever be the motion of the eye. When this point is obtained, the eye-screw, with its wires, must then be fixed, for that is its true place, viz., the correct focal point of the object-glasses; and whatever indistinctness may be found from the diversity of eyes of different observers, must be corrected by the motion of the eye-glasses only. Another point to be secured is the permanency, as far as may be, in the position of the object-glasses; for if this be not correctly centered, which is very rarely the case, and, indeed, never to be expected, that is, if its axis be not concentric with the axis of the cell, in which it is fixed, any motion of this latter, by screwing or unscrewing it, may not only change the place of the focus to which the wires are adjusted, but will needlessly move the line of collimation both in right ascension and declination. To obviate this, therefore, two corresponding marks should be made with a graver, both upon the cell into which the glass is burned, and also upon the tube of the telescope into which the cell is screwed, or otherwise inserted, that in case the object-glasses should ever be taken out to clean it, &c., it may be restored very nearly, if not exactly, to its former position.

The eye-glasses, object-glasses, and wires being thus settled in their respective places to each other, it will not be an improper time to measure the interval between the wires, which cannot be too accurately done, being of such constant use; this may be either, 1st, by observing the passage of a star in the equator, and making proper allowances for the rate of the clock, or by a star out of the equator, and making proper allowances for the declination in the proportion of the radius to the cosine, or, 2dly, by means of the equatorial circle, and a fixed hand object; and here the quantity must be diminished in the same ratio as the radius to the sine of the polar distance. We have made use of both methods as a confirmation of each other, and find the interval, which is equal in the three wires of my telescope, to be 7° 54′ 5″ = 30′ 3″ sidereal time; and these three
three wires divide the diameter of the field very nearly into four equal parts.

Second and third adjustments: the hanging level. By means of its proper handle, move the declination circle about its axis, till the bubble of the hanging level \(\ell \text{m} \) rests true between the indexes; then fix it by the clamp \(\alpha\), reverse the level by taking it out of its pivots, and turning it end for end; if the bubble now stand true, the level is adjusted; if not, correct \(\frac{1}{2}\) the error by the declination handle, and the other \(\frac{3}{4}\) by the small screw at the bottom of the level; then reverse the level and repeat this operation still it does. The level, or rather a tangent to its curvature at its middle, will be parallel to the axis on which it swings, and both will be horizontal. At this time look through the telescope, and see what land object is covered by the horizontal wire; now invert the telescope by turning it \(180^\circ\) round the declination axis, and \(180^\circ\) round the polar, and bringing the level true, it will then point to nearly the same place; and if exactly the same object as before be now covered by the horizontal wire, the axis of the level is adjusted parallel to the line of collimation in a vertical direction, if not, correct half the error by the little capstan screw at the bottom of the cock, or arm, that supports one end of the axis of the level, and the other half by the declination handle; invert the telescope, and repeat the operation, till the same object is covered in both positions, and the level is found true, then will the level and its axis be parallel to the line of collimation, and the object covered by the wire may be concluded to be in the horizon.

Fourth. The index wires of the microscopes.—The line of collimation, with respect to east and west, has been already adjusted as above. Let then the declination axis, by its level, be restored to a horizontal position; at this time adjust the index wires in the two equatorial microscopes \(W, X\), to bisect the two opposite divisions \(360^\circ\) and \(180^\circ\), then will these wires be rectified to their proper place. That being done, bring \(90^\circ\), or the division that represents the equator on the declination circle, under its respective microscopes, and turn the whole instrument one quarter round on the polar axis, viz. till \(90^\circ\) on the equatorial circle be bisected by the micrometer; and, if at this time, the bubble of the hanging level appear true, the index wire of the declination microscopes is correct; if not, correct \(\frac{1}{2}\) the error by the declination handle \(w\), and \(\frac{3}{4}\) by the little screws at the side of the hanging level, then reverse the telescope, viz. turn it \(270^\circ\) on the equatorial circle come under the micrometer wire, and if the level then rest true the adjustment is complete; if not, repeat the operation, as before, till it does; then by its proper screw bring the index wire of the declination microscopes to bisect the points \(90^\circ\) and \(90^\circ\). The indexes of both circles will be then adjusted, and the axis of the hanging level brought parallel to the line of collimation, with respect to east and west, as well as with respect to north or south. Note, this parallellism of the object of the level, to the line of collimation in a direction east and west, does not appear to be a very important rectification, but on some occasions may have its use.

Fifth. The refraction piece.—After what has been done, this apparatus will be adjusted. Bring the telescope, by means of its two levels \(P, P\), and \(l\), to point to the horizon, and in the meridian; then by the two points, \(f, b,\) Plate XI. fig. 2, of the refraction piece, bring its two levels \(c, c, d, d\) to rest true; move the nions \(d, d\) of the little semicircle of the horizon and vertical angles, \(a, b, c, c\), to the middle of the divisions, or \(o, o\, o, o\), and all that of the little quadrant of altitude, \(l, k\), to \(o, o\, o, o\). and this part is adjusted.

Sixth. The microscopes.—The magnifying power and scale of the microscopes is all that remains to be considered. The magnifying power of a compound microscope, as is well known, depends on the proportion between the distance of the object, and of its image from the object-glares, together with the proportion between the focus of the eye-glares and the ordinary focus of the eye looking at a small object (suppose) of \(\frac{1}{8}\) th or \(\frac{5}{8}\) th inch. These two ratios compounded give the power of the microscope. The former is called magnifying by distance, and is a material part in the construction of those microscopes; the scale of the micrometer being regulated by this part of the magnifying power. For example, let the distance of the object from the glass be \(a_1\), and the distance of its image \(a_2\), its power will be \(\frac{a_1}{a_2}\); and consequently the scale of the micrometer or motion of its screw, to answer to \(a_0\), (suppose) must be \(4\) times as great as the space occupied by \(a_0\), on the limb of the circle; and if the radius of the circle be two feet, an arc of \(10^\circ\) will be equal to 0.07 inch nearly on the limb, and \(= 0.28\) inch on the scale, viz. = to the same arc on a circle of 3 feet radius; and if each revolution of the micrometer screw be intended to describe \(1\), the screw must contain \(35\) threads in an inch. But as it would be difficult to adjust the screw exactly to the scale, the advantage of the construction of these microscopes is, the scale may at any time be adjusted to the screw; for let the interval between any two near points \(= 10^\circ\) on the limb, be measured by the screw, and, supposing, instead of being \(10^\circ\) or \(600^\circ\), it appears only \(570^\circ\); it is evident that the scale is bigger than it should be, or, which is the same thing, that the image is less by \(\frac{32}{5}\) or \(\frac{1}{5}\). In this case, increase the distance between the micrometer wires and the object-glares \(= \frac{3}{5}\), by unfurring or drawing out the tube that carries the micrometer and eye-glares, and the scale is adjusted. It will, at the same time, however, be right to readjust the object-glares of the microscope to distinct vision, by the screw of the cell that contains it, until the image and the wires have no relative change of place by any motion of the eye. This will again occasion some small alteration in the scale, and must be corrected by repeated trials, and the scale adapted to the divisions on the arc; and if the movable wire of the microscope be now brought to coincide exactly with the fixed one, and the movable index brought to zero on the screw-head, the micrometer is completely adjusted. This having been done with all the microscopes, and the opposite ones being made to agree, each with the other, in such manner, that the fixed wires may become a correct diameter, the whole instrument will have been completely adjusted.

Before taking an observation of right ascension and declination, the telescope must be adjusted to the meridian mark, so as that the centre wire may exactly bisect it, in which situation care must be taken to make the index wires of the equatorial micrometers bisect the points \(360^\circ\) and \(180^\circ\), by means of the adjusting screw of the polar axis; and when an observation is made out of the meridian the altitude and angle of the horizon and vertical circles must be taken by the refraction apparatus; then with these arguments, the refraction and parallax, in north polar distance, and in right ascension, may be found by inspection in the subjoined tables, by which any observation may be readily reduced to the meridian.

In this account of Sir George Shuckburgh, the reader may have observed, that the order of the adjustments proposed is not that which is best in practice; as some of the leading adjustments must necessarily be deranged by the subsequent ones as he has described them, and indeed so as to render
tender new adjustments necessary; but we were unwilling to transform the baronet's directions that have met with the approbation of the Royal Society, though we cannot dismiss the account without this remark for the reader's consideration; viz. the rectification of the telescope, levels, &c. ought certainly to precede the adjustments of the circles, that depend on their accuracy of position.

The Arnaugh equatorial instrument by Mr. E.L. Troughton.—The instrument which now claims our attention is represented in Plate XVI. of Astronomical Instruments, and, though similar to its predecessor shown in Plate XV, as to its use and properties, yet forms a striking contrast with it, in regard to compactness and beauty; too evident a contrast indeed to be overlooked at the first glance of comparative inspection. The arrangement of its principal parts is so novel, and at the same time so natural, as well as the connection of its smaller ones effected with such symmetrical precision, that the mind is struck with the contemplation of it, and spontaneously considers it as an instrument of a superior order, that seems to place at a distance every other individual of its kind; we therefore feel a peculiar pleasure in concluding our article with the account of an instrument, which, though it comes last, ought in our estimation to stand first as a model for future imitation. As the different component parts of the equatorial instrument are now become familiar to the reader, who has perused the preceding descriptions, we shall satisfy ourselves with a brief detail, unaccompanied by alphabetical references to the drawings, which presents a perspective view of all the leading features.

The horary or equatorial circle, without centre or radius, occupies the middle part of the instrument; and is held in its proper place by eight conical tubes of brass, four above and four below, which converge respectively towards the upper and lower poles, and which stand at the distance of a quadrant from each other. A strong and light frame is thus formed of the shape of two similar cones joining their bases at the horary circle, and connected near their fummits by two pieces of metal that terminate each with a hollow cylinder of about two inches diameter; this frame is further braced by cross connecting tubes, as well as by side braces, or props, in the manner sufficiently explained by the figure; and the whole frame, thus firmly united, supplies the place of a revolving axis, and carries the horary circle round with it, when it is made to turn on its cylindrical pivots. On these pivots the horary circle was finally turned true, after the frame was united and made fast in all its parts, so that the eccentricity of the circle, if it had any previously, was done away, by being turned on its own pivots. The inferior end of the polar axis or frame is supported by a solid stone, about 30 inches above the floor, with which it has no connection to produce untidiesses; this stone is capped by an apparatus of strong brass work, in which is produced the adjustment for bringing the instrument into the plane of the meridian, as well as for that giving the polar axis its proper elevation. This lower end of the axis terminates in a hemispherical button of hardened and finely polished steel, which presses edgewise against a plane of agate, and is kept central by two rollers that form an angle to receive it on the lower part of the apparatus; all which contrivances may be readily conceived without more minute description. The support for the elevated pole consists principally of a stone pier, reaching from the ground to the centre of the instrument; but on it is firmly fixed a strong frame of wrought iron, so contrived as to turn its edges towards the telescope hereafter described, in every direction; otherwise it would obstruct the field of view in elevations below the upper pole. The upper gudgeon is received between two rollers similar to those below, except that they are perforated, as well as the gudgeon, in order that as little light as possible may be intercepted when the telescope is pointed to the pole. At about six feet distance from each other, in the east and west line, upon the same solid foundation that supports the bearing stone and pier, are firmly fixed two pillars of stone, each nearly three feet high; and on the tops of these are placed half two strong cones of brass to support the microscopes for reading off the horary angles. The length of these two cones of brass is so proportioned as to correspond to the effective length of one half of the frame, or polar axis, in its inclined state, in all changes of temperature, by which means the microscopes preserve their relative situations at the horary circle. This circle is divided into 5' spaces, or spaces of 20 seconds of time, upon its extreme or exterior edge, which was made broad for this purpose, and the heads of the equatorial micrometers are divided as to subdivide the said spaces into tenths of a second of time. The axes of the microscopes of course are horizontal. At the tops of the conical parts of the pillars are adjustments for moving the microscopes; one with respect to perpendicular height, another with respect to the distance of the exterior edges of the horary circle, and a third along its plane. An apparatus also for quick or slow motion is attached to each of the cones in question, by means of which the instrument may be securely fixed, either in the meridian, or in any other given position, as it regards the meridian. The declination circle likewise occupies the middle of the frame, and has its centre precisely in the same point that is the centre also of the horary circle, these two circles being concentric, but having their planes exactly at right angles to each other, after the manner of the meridian and equatorial circles of a common ring-dial, when put into a plane for use. The declination circle is double, or composed of two complete circles united in several places by connecting pillars, and having each eight radii also connected in the same manner, after being inferred into the common axis, which is of the shape of a double cone. The telescope passes through the bases of the united cones of the axis, and has an aperture of 2½ inches, consequently the connecting pillars are long enough to admit such a telescope between the united circles, in which situation it is not very easily distinguishable in the figure. Its eye-piece, however, is discernible just under the declination circle. It is 4½ inches long, and revolves within the horary circle; consequently requires a diagonal or reflecting eye-piece when directed to the equator, in which situation the aperture admits light enough, notwithstanding the interposition of the horary circle. When the elevation is great, the head of the observer must necessarily be admitted between two out of the four lower conical pillars of the frame, which circumstance points out the scale of magnitude on which an instrument of this construction ought to be made, to be useful at all degrees of elevation of the telescope. The telescope has various magnifying powers, which may be used according to circumstances. Two opposite quadrantal arcs of the horary circle have chord-bars parallel to each other, at the middle points of both which are sockets for the gudgeons of the declination axis to work in as their supports; which bearings made the braces of the frame and horary circle essentially necessary to give strength and firmness to the whole. The declination axis, which is about three feet long, has an adjustment at one end for setting it at right angles to the polar axis, and carries also a very sensitive spirit-level parallel to itself; with another of which
the telescope is likewise furnished, which it cannot be necessary to particularize further, after our former descriptions of spirit-levels, except that in these the adjustment screws had divided heads, whereas in these there are divided scales of ivory, by means of which the half differences can be accurately estimated to the fraction of a second. The declination circle is divided into spaces of 5°, which are again subdivided by the microscopic micrometers into minutes and single seconds. One of these microscopes is seen above the horary circle and the other below, but both are supported by it, and point horizontally to opposite points of the declination circle, as one of the others is seen at the top of one of the pillars pointing to the exterior edge of the horary circle. The apparatus for quick or slow motion, to govern the declination circle, is attached to the lower part of the frame, or polar axis, as represented in the figure. The excellence of this instrument has been fully established in public estimation, by the use that has been made by Mr. Pond of the Armagh observations, taken with it in 1797, when he formed his catalogue of some of the principal stars, as we have already stated: in which catalogue (see our article Declination,) it will be seen that the accuracy of its measures accord very nearly with the results derived from an average of the best modern instruments: and we may add, that the coincidence would doubtless have been still more remarkable, had not the divisions, which are by dots, been injured by an accident. An intense frost, to which the instrument was exposed at the top of the maker's house, covered it with black spots, and corroded its surface so as almost to obliterate the dividing points, which were necessarily enlarged by hand, and of course might be altered a little by this annual operation, however carefully performed. The divisions of the other circle met also with an accident at the other side of the water, which, though of a different nature, has rendered the divisions less correct than they were before. Besides which, two other circumstances ought also to be named as drawbacks in this instrument, when compared with the circular instruments with which it has been contrived, namely, its verifications were not made with a plumb-line: and its polar position may be considered as somewhat unfavourable for taking declinations with the utmost nicety; but notwithstanding all these deductions, the accurate performance of the instrument has stood the test of a rigid comparison with the instruments of three modern observatories.

Adjustments. — 1. Turn the wire-plate round, if necessary, so as to make the middle vertical wire continue throughout the whole field of view, on some distant and well-defined point, while the telescope is elevated or depressed as it turns on the axis of the declination circle, to which the wire will in that case be perpendicular.

2. Slide the object-glass of the telescope in or out, while you view a star of the second magnitude, until the parallax of the wires is taken off, that is, until the vision is as distinct as possible.

3. To adjust the level of the declination axis. By the motion round the polar axis bring the bubble of the level to the middle of the tube, and in this situation make its scales or indices to coincide with both its ends; turn the level, end for end, and if it now stand in the middle, as before, the axis is level; if not, alter one half of the deviation from the truth by a slight motion of the polar axis, and the other half by the screws of the level itself; and repeat their rectifications till the bubble will stand always in the middle of the tube when its ends are reversed. But the bubble of a hanging level may also require a lateral adjustment; to examine it in this respect, turn it round on its own axis a little, and if the bubble has a tendency to go to either end of the tube it must be rectified by the side screws till this tendency is removed, and then if the bubble will yet bear reversing, the level is properly adjusted.

4. To adjust the pivot holes of the level parallel to the axis of the declination-circle, and the axis horizontal; bring the bubble of the level to the indices on the tube, with the level above the axis, by moving the instrument round the polar axis; then turn the declination-circle half round till the level is under its axis, and if the bubble now settles to the middle, as pointed out by the indices, the level is right; if not, alter one half of the error by turning the polar axis round, and the other half by the two screws that govern the pivot holes, in the mean time turn the telescope 90° round the declination-axis, and by these means move the other pivot-hole, bring the bubble to the indices, and the axis will be horizontal, as well as the pivot-holes parallel to it in all directions; for when the level itself is adjusted, as above directed, it is evident that if the bubble keeps its place at the indices during a revolution of the declination-circle, the axis itself must necessarily be horizontal.

5. To set the declination-axis at right angles to the polar axis, we may use the level itself instead of the declination-axis, after it has been set parallel thereto as just directed; for this purpose, bring the bubble to the indices by moving round the polar axis, and by opposite points of the equatorial circle by the two wires of the microscopes; turn the instrument exactly half round by the help of the microscopes so adjusted, and if the bubble now settles to the indices, the two axes are at right angles to each other; if not, alter one half of the error by the slow motion of the polar axis, effected by the equatorial tangent screw, and the other half by the two screws at one end of the declination-axis adapted for this purpose.

6. To set the line of collimation true in right ascension, let the bubble be brought to the middle of the tube, or to the indices as in the last adjustment, and look at any well-defined small object near the horizon, as bisected by the middle vertical wire; then having noted this mark, turn the instrument half round the polar axis, as indicated either by the level or equatorial microscopes, which are now adjusted to do the same thing; and when the telescope is turned back round the declination-axis, note if the same object or mark be intersected as before, if not, alter one half of the deviation by the equatorial tangent screw, and the other half by moving the wires of the eye-piece in the telescope; thus when the same mark is bisected by the middle vertical wire, in reversed positions of the telescope, the line of collimation will be right with respect to right ascension.

7. To place the indices of the declination-circle to read polar distances truly. Before we describe this adjustment, it may be proper to remark, that the microscopes themselves of this circle have each three separate adjustments, the first, that which alters the power by altering the distance of the object; the second, so as to make one minute on the circle equal to a revolution of the micrometer screw; the second, that which produces distinct vision by varying the distance of the entire microscope from the divisions of the circle; and the third, that which places zero on the scale of minutes to agree with zero on the declination-circle, and also zero on the scale of seconds, to agree with zero on the scale of minutes, as effected by the head of the micrometer being made to turn independently of the screw. These minor adjustments being understood, point the telescope to any distant land object, and let the middle horizontal wire bisect it, and read off the polar distances found by the indices, and take half their sum; make the
EQUATORIAL.

the same observation when the instrument is turned half round the polar axis, and take another mean of the angles now shown by the opposite indices; subtract the former mean from 180°, and add the difference to the latter mean, and half of this sum is the angular distance from the pole: of the instrument, to which quantity the indices must be put within the exactness of a minute or so, as this process must hitherto be considered as an approximation only; repeat the operation we have described of obtaining two means of polar distances more accurately by using the scales of minutes and seconds; thus, read off by the indices the quantity to the division next below the sub-divisions to be measured by the scales; then turn the micrometer head till the wire of the microscope bisects the next following point, taking care to count the notches passed over as minutes, and the seconds and parts on the micrometer scale to be added to the quantity given by the indices alone; and the supplement of the mean of the two measure by the microscopes, added to the mean read off in the same way, when turned half round the polar axis, being divided by two, will give the true angle from the pole of the instrument; and the scale of minutes, as well as scale of seconds on the micrometer head, must be finally adjusted thereto.

8. To place the declination-level parallel to the line of collimation of the telescope, bring the declination-axis level, or nearly so, and let the bubble of the declination-level be brought to the middle of its tube, by the motion round the polar axis, and let the indices be put to its ends; turn the level a small quantity round its own axis, and try if the bubble has any tendency to either end; if it has, adjust it laterally by the screws that move one of its pivots sidewise; till it is right in this respect; now reverse the level, and if the bubble does not stand in the middle, alter one half the error by moving the telescope in declination, by means of its screw for slow motion, and the other half by the screws that govern the pivots of the level, and the level itself will then be adjusted. In this situation of things look for some object in the centre of the field of the telescope, and note it; turn the instrument half round the polar axis, and as much round the declination axis as to bring the telescope exactly to the same object again; if the bubble now stands in the middle, the adjustment is right, but if otherwise, one half of the error must be altered by the motion of the telescope in declination, and the other half by altering the pivot-hole of the level. Lastly, turn the instrument the space of six hours round the polar axis, and adjust the other pivot hole till the bubble stands in the middle of its tube, and the adjustments are all complete, provided the polar axis of the instrument be exactly parallel to the axis of the earth, which we have all along taken for granted, and which may be effected by its own adjustments as pointed out by an observation of a circum-polar star, agreeably to our directions given under our article EQUATORIAL Setter.

× Secant of the Altitude.

Note. If the observation is on the ⎧east⎫ side of the Meridian, then is the true Meridian so many minutes to the ⎧west⎫ of that found by the Instrument.

- For the East side, use the correction from the EQUATORIAL table.
- For the West side, use the correction from the EQUATORIAL table as the negative value.

This table provides corrections for the observed time to account for the effect of refraction on the time shown by an equatorial instrument. The corrections are given in degrees and are added to or subtracted from the observed time, depending on whether the observation is on the east or west side of the meridian.

Vol. XIII.
EQUATORIAL.

Exposition and Use of the Tables.

The three first tables are particularly calculated for the use of a large equatorial instrument, for the purpose of clearing observations made with it from the effects of refraction and parallax, when neither Dollond's refraction apparatus is used, nor the micrometer circle of Ramfden's for adjusting the wire used in taking altitudes; but the four last are adapted more peculiarly for portable instruments. They are copied from Sir George Shuckburgh's account in the Philosophical Transactions, and, being adapted for all latitudes, are a suitable appendage to the descriptions we have given of the different instruments.

Table I. gives the correction of the refraction in north polar distance, by entering it with the altitude at the top, and the angle of the horizon and vertical circles on the left hand side; and in the common point of meeting is found a quantity in seconds and decimal parts, that is in all cases to be added to the apparent polar distance to give the true; but if it be entered with the angle of the horizon and vertical circle in the right hand column, it will give the refraction in right ascension, by multiplying the quantity here found by the secant of the declination to be found in Tab. IV., which is a readyer operation than dividing by the cosine, and amounts to the same thing.

Table II. gives the effect of the sun's parallax in right ascension and north polar distance, and is to be entered with the same arguments as Tab. I.; and the parallax in right ascension is to be multiplied by the secant of the declination as before; the sun's horizontal parallax being assumed = 8.06.

Table III. is a similar table, only calculated to an horizontal parallax of 10"; so that whatever be the parallax of the sun or planets, this correction may readily be found, almost by inspection, viz. by multiplying the tabular number by the exact quantity of parallax of the body observed, and cutting off the decimal quantity.

Table IV. contains the natural secants to each degree, extracted from Slerwin's tables, to be ready for the operations required above.

Table V. gives the correction of the time; viz. of the sun or star's distance from the meridian, as ascertained by a portable instrument not previously adjusted to the meridian; this quantity also is to be multiplied by the secant of the declination.

Table VI. gives the correction of the meridian line in minutes and decimals, which may be near enough for portable instruments; but the quantity here found must be multiplied by the secant of the altitude.

Table VII. (like Table I.) is adapted to seconds of time, and gives the refraction in right ascension in terms suited to such instruments as have the equatorial circle divided into hours and minutes.

Table VIII., in like manner, gives the refraction in declination. The arguments are the same in all the tables.

The tables were constructed by Sir G. S., in the year 1774, for his own use, and were founded on the principles explained by the Hon. S. M'Kenzie in fig. 4. of Plate XIII., where I F is a portion of a vertical circle = the refraction in altitude; C F a parallel to the equator; I C a portion of an horary circle = the refraction in declination, found by Tab. I. and Tab. VIII., the angle C I F, the angle of the horary and vertical circle; C F the refraction in right ascension, found by Tab. I. and Tab. VII.; D I (a parallel to the horizon) the correction of the meridian, found by Tab. VI.; and D F the correction of the time, found by Tab. V.; and as I F will hardly ever be found to exceed 30', these triangles have been considered all as plane; making due allowance, in the proportion of the sine to the radius, for the distances of the arcs D I, F C, and D F, from their respective poles, which has been noticed at the foot of each table. The refraction in altitude was taken from Mayer's Tables, 1770; London; which is calculated for a density of the air expressed by 29.6 inches of the barometer, and 50° of Fahrenheit's thermometer.

EQUATORIAL Micrometer, is an apparatus applied to a telescope, that has an equatorial motion, for the purpose of measuring small differences of right ascension and declination of any two heavenly bodies, the parts of either successively, or at the same time nearly, through the field of view, to as to be both visible at the same elevation of the telescope. This method requires no graduated circles with verniers or compound micrometers, and yet is capable of great accuracy within certain limits of difference between the relative situations of the bodies to be compared together; and if the right ascension and declination of one of the two observed bodies be previously known with sufficient accuracy, the place of the other can be determined therefrom by the observed differences. The common wire micrometer has been long in use as an appendage to the eye-piece of a telescope, and was used by Dr. Bradley in making astronomical observations, his manner of doing which was communicated to the Royal Society in the year 1772 (vol. xlii.) by Dr. Maskelyne; but as the telescopes then in use were from ten to fifteen feet long, for want of the achromatic object-glasses, an equatorial motion was given, not from one centre, but by means of supporters at each end of the wooden tubes, so contrived as to be manageable both in altitude and azimuth; which apparatus is still preferred at the Royal Observatory. The wires of the micrometer have been adapted differently by different makers, some making only one movable, and some more; but they all agreed in placing them in the focus of the eye-piece of the telescope. It is not, however, our intention to enter into a detail in this place of all the different constructions of the micrometer, as applied to various purposes, but to confine ourselves to a notice of those that have been more particularly applied to telescopes having an equatorial motion. For the other constructions, we refer to the article MICRO-METER.

Soon after the discovery of the properties of the achromatic object-glasses of a telescope had reduced the length of the astronomical telescope to a portable size, without diminishing either its power or size of its field of view, not only were equatorial instruments contrived of various constructions, as we have already described, but equatorial stands for simple telescopes were invented, and continue to be in use with the bell telescopes to the present day. To these telescopes the micrometers are a very necessary and useful appendage, inasmuch as they render it capable of being applied with advantage in ascertaining the right ascension and declination of a comet, planet, or other body out of the meridian, when they happen to be near enough to a known body to admit of being taken into the same field of view without altering the elevation. Though the wire micrometer was first invented, as applied to the focus of the eye-piece, and continues to be used in many instruments, yet since the invention of the achromatic object-glasses, Dollond's object-glass micrometer has by some astronomers been preferred, or at least deemed equally useful, particularly when the cross wires are also used in conjunction, as described by Dr. Maskelyne in his paper on this subject read to the Royal Society of London on Dec. 12, 1771, which was the year after Smeehon finished his wire micrometer, that had been begun about forty years before. If we give an
an account of these two kinds of micrometers in succession, the reader will perceive the varieties that may arise from them by slight deviations of construction. We will begin with Smeeaton's, as being of prior origin. We are not aware that Mr. Smeeaton has left behind him any perspective drawing of his equatorial micrometer, though we have heard that there is an underrubbed sketch of one among his papers, at present in the possession of Mr. Lloyd; but there is a fection of one accompanying his paper read to the Royal Society of London on June 7, 1787, which is sufficient for explaining the principle of its application. Fig. 3 of Plate XII. of Astronomical Instruments, is the said section, as viewed from the eye-end of the telescope. "This micrometer," says the author, "is furnished with five horary wires, denominated in their order, a, B, C, D, (B being the middle horary wire) and the two declination wires are denominated A, B, each movable by a separate and independent micrometer-screw, from the outside of the field to the centre, and a little beyond it; so that each wire can be moved into the place of the other, when at or near the centre." The field of view was only 1° 15', and the magnifying power as low as 20, with an eye-glass of 11 inch focus, and a double object-glass of 34' focal length; notwithstanding the author calculates that a difference of only 2" may be read by such apparatus, which he concluded was near enough for any instrument to read out of the meridian. In the construction of the hand every thing was done to ensure stability of position for any instrument to be moved about the meridian. With an apparatus so steady, it was not necessary to confine the observations to two bodies, to be compared, whose difference of right ascension was only a few minutes, but even hours could be admitted of for the interval of the successive transits, provided the difference of the declinations did not exceed the interval between the two adjustable cross wires. The difference of the right ascensions was easily ascertained by a regulator or chronometer, measuring the interval between the transits, and the distance between the bodies as measured by the interval between the cross wires, gave the difference of the declinations. The final trial of the fineness and accuracy of this apparatus was made with Saturn and Capricornus, from which it was found that the star had the same right ascension and declination, determined on two separate evenings, at the distance of 48 hours, though the instrument had not been touched during the interval. But the principal observations noticed in the memoir, are those relating to the elongation of Mercury, as taken from Sep. 23, to Oct. 13, 1786, the result of which was, that at 5° 22' 35' mean time on Sep. 23, A.M. Mercury's right ascension, deduced from a comparison with a Orionis, was 163° 59' 21", and its declination north 7° 44' 25'. For the particulars of the calculations and the tables of the observations, see the Phil. Trans. of 1787. Also for the manner in which a simple telescope may be moved to make in an equatorial direction, see our article Equatorial Stand of a telescope.

The object-glass micrometer of Dollond, of his most improved construction, is represented by fig. 4 of Plate XII. agreeably to a drawing given in Mr. Dollond's paraphlet that accompanies his equatorial instrument. By the improvement, says the author, this micrometer has received, it is rendered capable of being applied to telescopes of small aperture; the focal length of the object-glass being considerably increased, the scale by which the angles are measured is much enlarged. By this increase in the focal length of the object-glass of the micrometer, the perfection of the telescope is less injured; but the greatest advantage that is derived from the improvement, is the length of the segments, which admit of the whole aperture of the telescope, even in measuring the largest diameters of the sun or moon, and the object retains the same brightness in measuring the largest angles as in measuring the smallest.

Notwithstanding these several advantages, the instrument is greatly reduced in size, as will appear by inspecting the figure representing the micrometer on the end of the telescope; the description of which is as follows:—

1. and 2 are two long segments of an achromatic object-glasses, divided into separate pieces by a diametrical line, and fitted into separate frames, so that by sliding one or both the segments, they may be made to form in effect either one object-glass or two, it being the property of half a well ground glasses to give as distinct an image as the whole would do; the segment 1 is moved by turning the milled head c, and the segment 2 is moved by turning the handle d. When an observation is to be made, it is generally known what number of minutes the angle will contain nearly; suppose, for example, the diameter of the sun were to be measured, which is known to be about 32'; move the segment 1 till the index e comes to 32 on the scale f, then looking through the telescope, move the segment 2, by turning the handle a till the circumferences of the two images, formed respectively by the two segments, are brought to touch one another externally, and the quantity that the segments have moved will be measured by the scale g, g, and vernier h, by which an inch is divided into five hundred parts; the greatest exactness is required in this scale, as the angle is absolutely to be determined by the measure taken with it; the scale f being only of use to set the segment 1, so that in measuring the angle by moving the segment 2, they may both be moved nearly the same quantity.

The handle i is to turn the micrometer round, to bring the line dividing the two segments of the object-glasses into the plane passing through the two objects, whose distance is to be measured. It is necessary, in making observations with the micrometer, that the telescope, when the micrometer is on, be adjusted to the most perfect position of the object to be observed, as a small error in this respect may occasion a considerable difference in the observation. To find if there is any error in the adjustment of the micrometer scale g, g, turn the handle d, so as to make the two images perfectly unite, and the number shown by the scale and vernier will be the error of adjustment, if there is any; this error may either be allowed for in the observations, or be corrected by the vernier screws at k. The object proper to be used for adjusting the focus of the telescope with the micrometer on, may be any of the celestial bodies, or some distant well defined land object; but for adjusting the micrometer scale, the object may be nearer, such as a printed paper at two or three hundred feet distance, provided the focus be first well adjusted to this object. A table is usually given with the micrometer, which shows the number of minutes and seconds answering to the divisions on the scale. When the micrometer is on the end of the tube of the telescope, it is necessary that the screw at the centre of motion be tight, otherwise, which is better, that there be a counterpoise at the eye-end to preserve the equilibrium in any elevation. Also, as the object-glasses of the micrometer is concave, the common focus of the object-glasses of the telescope end of it is lengthened, which circumstance requires the tube of the eye-glass
to be longer than when the telescope is used without the
micrometer.

The properties peculiarly ascribable to the two kinds of
micrometers we have described are, that the one at the fo-
cus of the eye-glass is adapted for measuring the differences
of right ascensions and declinations of two bodies, one of
which has its place known; but the one placed at the ob-
ject end of the telescope is calculated, by means of its gra-
duated scale, to measure absolute small distances; and the
accuracy of its scale may be brought to the test by a com-
parison with a known interval between two stars or other
distant bodies. Dr. Maskelyne, in the paper we have
already noticed, has however shown how, by the addition
of two crofs-wires in the focus, the differences of right
ascensions and declinations may also be measured by Dol-
land's micrometer, thus: "Suppose it be required to mea-
sure the difference of right ascension and declination of two
stars, whose difference of declination does not exceed the
extent of the meridians passing through the stars does not exceed the

The EQUATORIAL.

of the equatorial sector, we propose to describe it agreeably
to its original construction; but as we have caused the dif-
ferent parts of the drawings, as given by Dr. Smith, to
be thrown into one perspective instrument, it becomes ne-
cessary to vary the detail accordingly. Fig. 1. of Plate
XIII. (of Astron. Infir.) is a perspective view of the prin-
cipal parts of the sector lying in its inclined stand or bed, which we have supposèd to be firmly fixed to a sloping pe-
deal, exactly parallel to the earth's axis. This inclined
bed, A B, is a strong brazen plate or bar, turned up at the
ends in a perpendicular direction at C and D; the lowerend C has a screw, entering it from below, strong enough
to bear the inferior end of the sector's axis E F G, the
conical hole made in the end of the latter at E, resting
on the conical point of the former; the upper end D
has a fit in it, into which the axis is demitted at the
cyllindrical part F, below the circular plate H attached
to the axis. The whole length of the axis is 13 inches,
of which the square part E F is 12. On the posterior
part of the bent end D of the inclined supporting plate
A B, is a clamp I, turning on two pivots, so that it may
be elevated or depressed without turning round in an
equatorial direction; this clamp fixes the circular plate H,
in any given place on its edge from turning round, but
adapts itself to the plate, so as to press equally on both
surfaces, by means of its vertical motion on pivots; conse-
quently the axis E F G, to which the plate H is attached,
may have a motion like the polar axis of the earth when
wanted, and may be firmly fixed by the clamp acting on its
plate in any given situation. At the superior end G of
the axis is fixed another circular brazen plate K L on one of
the flat sides of the squared axis, and having a motion round a
pin with screws and a tightening collar; on this plate a
cross of brafts is ferreved fall, composed of four bars at
right angles to each other, two of which bars constitute
an inverted cock, on the bent parts of this the long
radial bar M N is fixed, which is made strong by an edge-
bar on its under side. Whenever, therefore, the circular plate
K L moves round its central pin at G, the radial bar,
carried by it, partakes of its motion, and vice ver fo; this
plate has also a clamp Q, similar to the clamp I in every
respect, by which it may be made steady in any given
situation. The length of the radial bar is 2½ feet, and its
breadth at M and N 1½ and 2 inches respectively: at N is
a small arch of a circle, 6 inches long and 1½ broad, gradu-
ated into 10°, and subdivided into quarters, that read and
are figured both ways. Upon this radial bar is mounted
a telescope P, of 2½ feet in length, moveable on the point
M, as an axis of motion, near the object-end, and having a
vernier near the eye-end with 16 quarters of a degree
divided into fifteen equal parts, so as to read off exact
minutes. This vernier is moved by the nut of an endless
screw Q, that is adapted as an apparatus for fall or flow
motion, in the usual way. The diameters of the two cir-
cular plates are each 5 inches, and the plates are strong
enough to hold the telescope in any given position that an
observed body may require.

The Polar axis E F G of this instrument must be placed
truely in the meridian and parallel to the earth's axis, which
may be done by bringing the telescope parallel to the axis
itself, and, after fixing it, by following a circumpolar star
therewith, and noting the apparent path as it respects the
intersection of the crofs-wires of the telescope: the devi-
ation above or below the crofs-wire will point out the error
of elevation of the axis, and the difference in the times of
the star's passage through the two semicircles, east and west
respectively, will discover the deviation from the meridian

line;
EQUATORIAL.

line; then half these errors may be corrected by the fcrews that fix the inclined bar A B to the pedetial, and the other half by altering the position of the telescope, till, after several successive trials, the star will accompany the inter-

section of the wires through its entire circle. It is neces-

fary, however, that the polar axis be placed, by means of a small quadrant or other such contrivance, very nearly in its proper degree of elevation, as well as nearly in the meri-

dian on the pedetial previously to the adjustment by a cir-
cumpolar star. It is also necessary that the line of collina-
tion of the telescope be parallel to the plane of the fctor, as well as the latter at right angles to the circular plate H, which represents the equator; the former may have its truth examined by a dinted plumb-line suspended in a vertical position; for if the interfection of the crofs-wires of the telescope will pass along this line, when the plane of the fctor is vertical, and when the telescope derives its motion from the fcrews of the vernier alone, it may be concluded that the line of collimation is parallel to the plane of the fctor; but the plane of the fctor itself must be previously set right, as it regards the equatorial plate H, by the fcrews that fix it to the inverted cock of the fcrews, attached to the circular plate K L. From a consideration of this instru-

ment, as we have described it, it is obvious, that, provided the telescope, thus having a polar motion and bearing a graduated fctor, be made perfectly fteady, and placed in the true direction of an hour circle in the heavens, the dif-

ference of declination of any two bodies in the celestial regions, that does not exceed the extent of the fctor's limb, may be measured to the accuracy of a minute of apace, and that whether the two bodies pass the telescope together or successively, provided the elevation of the telescope does not vary in the mean time; and also the dif-

ference of right acfenion of any two bodies, similarly situated, may be had by noting the difference of ferial time, (by a regulator,) of their paffages over the horary wire; provided the situation of the fctor itself does not alter while the telescope is raised or depressed, but much of the accuracy of the results will depend on the fteadiness of the parts that are clamped. Were the equatorial fctor to be con-structed at this time, the reading by a microfcopec micro-

meter would greatly enlarge the powers of this instrument. If however well adapted this instrument may be to the purpofes for which it was intended," says profefor 

Vince (Treatife on Ptolemy, Afron. p. 141, and fee.) "yet it will not conveniently admite of a large telescope; Dr. Maclay, therefore, thought of a construction which would admit of one of a larger fize, and which has, be-

fides, several other advantages in refpect to the adjus-

ments, as will be evident when we come to defcribe them. The inftrument was made by Mr. Sifson, the conftuction of which we will first defcribe, and then proceed to its adjus-

ments."

EQUATORIAL fctor by Mr. Jonathan Sifson.—A B, in fig. 1.

of Plate XVII. (of Afron. Inf.) is a polar axis, II I a circle fixed upon, and at a small distance from it, on the centre of which is an axis, about which the telescope C D turns, carrying the indices a, b, each having a vernier which fubdivides to minutes, and the circle is graduated to fhow north polar diftances; this, which is called the crofs axis, goes through A B into a fixed cafe E on the other fide, and is moveable by a fcrew g in order to fix it perpendicular to the polar axis: L M is an arc of 2° fixed upon A B, and concentric with G; if g is a vernier whose whole arm K may be fcrewed to the axis on which the telescope turns, and conftantly in that cafe will turn with it, but if the fcrews be ope rated, the telescope will turn without it. N O P Q is a brafs frame, the two ends of which, O N, P Q, confift of two pieces, one of which goes over the are L M, and the other under, fo that by means of two fcrews at y and x to prefs them together, the frame may be fixed to the arc, in which cafe the fcrew e, passing through a nut at z on the arm K, will move the vernier v w; V is a brafs circle graduated on the edge, and moveable with the fcrew e, against which is fixed a piece of brafs r as an in-
dex; W is a piece of brafs fixed on an immovable piece of wood, on which is another piece not feen to receive the end of the axis B, and in which it turns, and this piece is move-
able call or well by a fcrew of adjustment; the end turns in a brafs focket e, moveable by a fcrew T in order to alter the inclination of the axis A B, and thence adjust it to the latitude; R S is an equatorial circle fixed perpendicular to A B, having a vernier m n; this circle is divided into 24.

The adjustments are three; firft, to set A B parallel to the earth's axis; fcondly, to adjust the line of collination parallel to the circle H I; thirdly, to adjust the crofs axis perpendicular to the polar axis. The firft adjustment confils of two parts, to set the axis at the proper angle, and to place it in the plane of the meridian. Now to adjust the axis to an angle equal to the latitude of the place, the instrument is suppofted to be at firft fixed as nearly as possible to the true angle, and then the error is to be corrected by adjustment; to do which, turn about the polar axis until the circle H I becomes perpendicular to the horizon, and direct the horizontal wire of the telescope to the pole star, or any other whole polar distance is known, when it comes above or below the pole; then turn the axis half round (which is shewn on the equatorial circle); in which cafe the circle becomes perpendicular to the horizon again; then if the axis be at the proper angle, it is manifeft that the telescope is now directed to a point as much below or above the pole as it was above or below be-

fore, that is, to the polar distance of the star increafed or diminished by the refraction of the star at the firft obser-

vation; hence, if we turn the telescope till the star be again obferved at the fame wire, the indices a, b, will have been moved over twice the refraction; supposing the star to be fo near to the pole, that the refraction may be con-

idered the fame both above and below; for if the star be firft obferved above, its apparent place is above the true, and therefore if the telescope and star revolve about the axis till they come below, the telescope is now directed to a point below the true place by the refraction, and as the ap-

parent place is now above the true place by refraction, the telescope is directed to a point diametral from the apparent place of the star by twice the refraction; but if it do not move over twice that distance, then half the difference is the error of the angle of the elevation of the axis; move the telescope therefore through twice the distance which the indices a or b will have moved over twice the refraction, which is supposing the star to be near to the pole, and we may imagine that the true distance of the star be demed by the index. If therefore the values of this instrument are to be true, we must make the index of the true distance of the star by the difference of the observed and true place.
bring it the other half, and the polar axis is truly adjusted. Secondly, to adjust the line of collimation parallel to the circle HI. Observe a star in the equator, and note the time of its transit over the middle wire of the telescope by a clock, adjust it to sidereal time, and note also the time shown by the vernier on the hour circle RS; turn the polar axis half way round according to the order of the figures on the hour circle RS, and the vernier shows a difference of 12 hours; now as the line of collimation is first directed to the equator, it must be perpendicular to the polar axis, and therefore by turning the polar axis about, it must continue to be directed to the equator, whether or not it be parallel to the plane of the circle HI; and if this could be done, and the telescope turned about, and the observation repeated without loss of time, the star would appear on the same wire, provided the line of collimation were parallel to the plane of the circle HI, for then the line of collimation in the second observation being parallel to what it was in the first, it must be directed to the same point in the heavens, the telescope being turned half round; but as this operation will take up some time, the polar axis must be turned a little more than half round in order to bring the star to the same wire, and the vernier would point out the same difference of times as the clock shews in the interval of the observations; but if these differences of times shown by the clock and the hour circle be not equal, the line of collimation is not parallel to the plane of the circle, and half that inequality of times is the error, which must be corrected by the adjustment for that purpose. Thirdly, to adjust the cross axis perpendicular to the polar axis, or to the line of collimation. By the last adjustment, the line of collimation was made to move in a plane; therefore, if that plane be adjusted to the polar axis, the line of collimation will describe a secondary to the equator. On this supposition, if we take a star of any declination, and note the time of its transit over the middle wire by the clock, and also the hour on the hour circle; then turn the polar axis half round, and observe again as in the last position, and the differences of the times of the two observations shewn by the clock, and on the hour circle diminished by 12, must be equal; but if the line of collimation do not describe a secondary, the differences will not be equal. To correct, therefore, this error, let $E_0$, fig. 2. Plate XVII. be the equator, $P, P'$ the great circle passing through the pole $P$, the great circle described by the line of collimation, and let the telescope be directed to a star at $b$, and let $d$ and $b$ be a portion of its parallel, take $a = b$, and draw the secondaries $P, d, m, P, b, c$. Now it is manifest, that if we turn the polar axis half round, the plane $P, E Q$ will then lie as much on the contrary side of $P, E Q$, and, therefore, when the telescope is directed to the star's parallel, it will cut it at $a$, and half $m, C$, or $E$, is the error of right ascension. Note the time on the hour circle, and continue to turn (in the present instance) the polar axis until the star, now at $a$, is brought to the middle wire, and note again the time on the hour circle, and we have the difference $m$ shown by the hour circle, from which subtract the time $e$, shewn by the clock between the observations, and we have $m, C$, the half of which is $E$. Now the star being on the middle wire, move the polar axis so as to cause the hour circle to move through an arc $e$, equal to $E$, and by the screw $g, f, g$, 1, alter the position of the cross axis, and consequently of the plane $P, E Q$ till the star appears again on the same wire, moving, if necessary, the telescope on the circle HI to bring the star into the field; and then as $g, f, g = a, b$, the line of collimation would have been corrected so as to make it pass through $P$, and the adjustment would have been truly made, provided the star had not moved in the time of this last operation. Correct again, therefore, and you will get the line of collimation to describe a secondary to the equator, when the telescope is moved on the circle HI. Thus the instrument is adjusted for use.

To find any object in the heavens, whose right ascension and declination are known. —Find its distance, at the time required, from the meridian in the usual way, and reduce it to sidereal time, and turn about the polar axis, that way the object lies from the meridian, until the hour circles points out that distance of the telescope from it; then turn the telescope till the indices $a, b$, shew the polar distance, and the object will be in the field of view. By this means we direct the telescope to a comet, or any other body whose place is known, which is invisible to the naked eye.

To find the true place of a body, and trace out its path in the heavens. —Screw the index $K$ to the cross axis of the telescope; bring the body upon the wire parallel to the equator, and take the time of its transit over the middle wire perpendicular to it, and note the degrees on the arc L.M, pointed out by the vernier $w$; then if there be any known fixed star near its parallel, move the telescope on the circle HI (the polar axis remaining fixed) to the star's parallel, wait till the star enters the field of view, and make it run along the same wire as the body did, and take the time of its transit at the middle wire, and the difference of these times will give the difference of their right ascensions, and the difference of the arcs on L.M, pointed out by the vernier $w$ at the times of the transits, gives the difference of their declinations; hence the right ascension and declination of the body is known. Continue these observations as long as the body is visible, and you will get its path in the heavens.

The utility and convenience of this method is, that we can at any time determine the place of a body without waiting for its coming to the meridian; where, besides the inconvenience of waiting, an observation might be hindered by the badness of the weather, or the body might come to the meridian in the day-time, when it could not be seen.

An instrument, somewhat similar in construction, but with considerable improvements, was begun by Mr. Bird in the last year of his life, or the year preceding, for the observatory at Oxford, and was finished by Mr. Troughton (the junior) about the year 1773, by order of Mr. Bird's executors. We regret that we have not had the means, in due time, of obtaining a peripeteic drawing of this instrument, that we might have gratified our readers with a description of it.

EQUATORIAL STAND of a telescope is a contrivance for making a common telescope follow a celestial body in its apparent path along, or parallel to, the equator; and answers the purpose of a polar axis of motion, while it adds but little to the expense of a simple stand for horizontal and vertical motions only. The thing required to be done to a common telescope, was to give the horizontal motion an equatorial direction, and then the vertical motion, of itself, becomes a motion in declination, or in an hourary circle, as well out of, as in the meridian. Various methods have been devised of effecting this purpose in the simplest way, but the contrivance invented by Mr. Smeaton, usually called Smeaton's Block, and which has all the advantages of cheapness, stability and simplicity, has been preferred to all others, and in our opinion merits a place, in our collection of altronomical instruments.

Fig. 5. of Plate XIII. of Aiton, Instr., is a representation of an equatorial stand of Smeaton's construction, in which the
the three legs are of mahogany, well braced together, and
shod at the lower extremities for the purpose of bring-
ing them within the plate. The part $a$, at the top of the
legs, in the shape of a blunt wedge, is of mahogany, and is
fast to the legs; the other smaller part $c$, above it, is also
mahogany, and sloped exactly like the part $a$; the two
parts taken together are called the block, the lower half of
which is fixed, and the upper movable on a strong cylind-
ric piece of brass fixed to the piece $c$, at right angles to
the line of section, or plane of contact, and passing through
the piece $a$ so as to be fixed, when necessary, by a finger
screw below the block, and within the junction of the three
legs. The plane of contact of the two halves of the block is
so sloped as to make an angle exactly equal to one half of
the co-latitude of the place of observation, with a hori-
zontal line, which the under-face of the block is sup-
poed to be by its position; but as the upper half of the
block is exactly similar to the other, its face, when in
the present equatorial position, makes an angle with the ho-

tizontal equal to the whole co-latitude of the place $i.e.$ when
in the meridian, is coincident with the plane of the equator.
When the part $c$ is turned half round, so that the point
$d$ may coincide with the point $a$, and the point $c$ with the
point $b$, the slopes of the two halves of the block are
then reversed, and the face of $c$ becomes horizontal;

hence it appears that a motion of the half block $c$ round
its axis of motion, will carry any telescope $g$, or other body,
placed on it parallel to its face, in the direction of the equa-

tor, provided it be placed in the meridian of the place when
it has the greatest elevation. Accordingly an axis of motion
of a small graduated equatorial circle $e$ is attached perpen-
dicularly to the face of the half block $c$, round which the
said circle is movable; and over this circle is mounted a
graduated semicircle of declination $f$, or of altitudes, when
the block is in its horizontal position, to which the tele-

cope is made fast. The circle $e$ is divided into half de-
grees, or two minutes of time, and is subdivided by a vernier
into $\frac{1}{60}$ of that quantity, which is, in minutes of space, and
four seconds of time; the declination-semicolon is also sub-
divided into minutes of space by a vernier; and by enlarg-
ing that circle, the subdivisions might be rendered still
minute; but the use of these gradations is merely to find a
star or planet, by its right ascension and declination, to
which purpose the instrument is quite competent. Mr. Troughton
informs us, that he has made this instrument universal sometimes, by dividing the block diagonally by an angle of
$45^\circ$., in which case it would take any degree of elevation
from a horizontal to a vertical position, and one of the
half blocks, being graduated into $360^\circ$, was read by a ver-

nier fixed to the other, so as to ascertain any given quantity
of elevation; but as the construction of the instrument does
not admit of great accuracy in its adjustments and motions,
he considered such addition rather as curious than really use-
ful in astronomy. Still, however, when the telescope is
fitted up with the best micrometer for measuring the difference of
right ascensions and declinations, and when the field is
made very steady, the instrument may be very serviceable in
an observatory, and is often made a part of its furniture.

The sliding tubes $b$ are sometimes superadded to brace the
eye-end of the telescope, and are found to answer a good
purpose, when well made, and fitted to any pair of the legs
that may happen to be turned towards this end of the tele-

scope. Both the equatorial circle $e$ and semicircle $f$ have
the usual apparatus for quick or slow motion; and when
the block is in the horizontal position, the telescope may
be fixed, by the finger screw under the block, to be conve-
niently used for viewing terrestrial objects; in which pos-
tion the instrument makes no contemptible theodolite, as
well as equal-altitude instrument, when a level is added.

EQUELA, in Geography, a town of Africa, on the Gold
coast.

EQUERY, or ECURY, a grand flable or lodge for
horses, furnished with all the conveniences thereof; as stalls,
manger, rack, &c.

The word is formed from the French, escurie, which
signifies the same thing. Some again derive escurie from the
Latin, festia, which not only denotes a place for bea-
fts to be put up in, but also a granary or barn. But a more
probable derivation is from equus, a flable for horses, of
equus, horse.

Some hold that the word flable, in propriety, relates only
to bullocks, cows, sheep, hogs, &c. ed equery, to horses,
mules, &c.

A simple equery is that provided for one row of horses;
a double equery that provided for two, with a passage in
the middle, or two passages; the horses being placed head
to head, as in the little equery at Versailles.

Under equery are sometimes also comprehended the lodg-
ings and apartments of the equerries, groomsmen, pages,
&c.

Equery, equery, is also an officer who has the care and
management of the horses of a king or prince.

Equeries, or Equerries, popularly called querries,
are particularly used amongst us for offices of the king's
flables, under the master of the horfe, five in number, who,
when his majesty goes abroad, ride in the leading-coach,
and in waiting, one at a time, monthly, and have a table
with the gentlemen-ushers during the time, and a salary of
$300l. a year each: that of the first equery and clerk-
martial being $500l.

They used to ride on horseback by the coach side when
the king travelled; but that being more expensive to them
than necessary to the sovereign, it has been discontinued.

Equerries of the crown flable, have that appellation,
as being employed in managing and breaking the saddle-
horses, and preparing them for the king's riding.

The equery of the crown flable has an annual salary of
$200l. and is, or always should be, in close waiting at court
and when his majesty rides holds the stirrup, while the
master of the horse, or one of the equerries in his absence,
sits in mounting him; and when his majesty rides, they
usually attend him. To the establishment of the queen's
household belong two equerries with a salary of $225l. each.
There are also two belonging to the prince of Wales's
household. Officers under the same denomination form a
part of the established households of the royal dukes, &c.

EQUES AURATUS, is used to signify a knight bachelor,
called auratus, q. d. gilt, because anciently none but knights
might gild or bestow their armour, or other habiliments
of war, with gold.

In law this term is not used, but instead of it milites, and
sometimes chevalier.

EQUESTRIA, among the Romans, a place in the
theatre where the equites or knights sat.

EQUESTRIAN, Equestrian, formed of the Latin,
eques, knight, horsemann, of equus, horse, a term chiefly used
in the phrase equestrian statue, which signifies a statue repre-
senting a person mounted on horseback.

The Fortune equerries, in ancient Rome, was a statue of
the goddess on horseback. We sometimes also say, eques-
trian column, which see.

Equestrian cohort, in Antiquity. See Cohors equi-

\[
\text{Equestrian games, ludii equestres, among the Romans,}
\text{horse-races, of which there were five kinds, the probumom,}
\]
or plain horse-race, the chariot race, the decursory race, about funeral piles, the ludus equinale, and the ludus neutrale.

Equestrian order, among the Romans, signified the order of the knights or equites.

EQUI, in Ancient Geography, a small town of Africa Propria, near a lake in the vicinity of Utica. According to Diodorus Siculus it was taken by Agathocles.

EQIANGULAR, in Geometry, is applied to figures whose whole angles are all equal; such are the square, and all regular figures.

All equilateral triangles are also equiangular.

An equiangular figure inscribed in a circle is always equiangular; but an equiangular figure inscribed in a circle is not always equilateral, except when it has an odd number of sides. If the number of the sides be even, then they may be either all equal, or else half of them will always be equal to each other, and the other half to each other; the equals being placed alternately. See Hutton's Math. Misc. P. 272.

EQIANGULAR is also applied to any two figures of the same kind, when each angle of the one is equal to a corresponding angle in the other, whether each figure, separately considered, be an equiangular figure or not, that is, having all its angles equal to each other. Thus, two triangles are equiangular to each other, if, e.g., one angle in each be of 30°, a second angle in each of 50°, and the third angle of each equal to 100°.

Equiangular triangles have not their like sides necessarily equal, but proportional to each other; and such triangles are always similar to each other.

EQUICRURAL Triangle, is what we more usually call an isosceles triangle.

EQUICULUS, Equileus, or Equus minor, in Astronomy, a constellation of the northern hemisphere. See Equuleus.

EQUIDIFFERENT, in Arithmetic. If in a series of three quantities there be the same difference between the first and second as between the second and third, they are said to be continually equidifferent; but, if in a series of four quantities, there be the same difference between the first and second as between the third and fourth, they are said to be discretely equidifferent.

Thus, 3, 6, 7, and 10, are discretely equidifferent, and 3, 6, and 9, continually equidifferent.

EQUIDISTANT, in Geometry, a term of relation between two things which are everywhere at an equal or the same distance from each other. Thus, parallel lines are said to be equidistant, as they neither approach nor recede.

EQUILATERAL, of equus, equal, and latus, side, is applied to any figure whose sides are all equal. Thus, an equilateral triangle is that whose sides are of equal length. In an equilateral triangle all the angles are likewise equal. See Equiangular.

All regular polygons and regular bodies are equilateral. See Polygon, Regular, &c.

EQUILATERAL Hyperbola, is that in which the conjugate axes, and every pair of conjugate diameters, are equal to each other. The asymptotes are also at right angles to each other, and each of them forms a right angle with the axis. Such an hyperbola is also equal to its opposite hyperbola, and likewise to its conjugate hyperbola, so that all the four conjugate hyperbolas are mutually equal to each other.

Hence, as the parameter is a third proportional to the conjugate axes, they are all mutually equal; consequently, if in the equation for the hyperbola \( y^2 = \frac{a^2}{b^2} \times \frac{x}{1 + x^2} \), or \( \frac{a^2}{b^2} \times \frac{x}{1 + x^2} \), in which \( a \) is the transverse axis, \( b \) the conjugate, \( p \) the parameter, \( x \) the abscissa, and \( y \) the ordinate, \( x, x^2 \) and \( y \) being made equal, the equation for the equilateral hyperbola becomes \( y^2 = \frac{a^2}{b^2} \times \frac{x}{1 + x^2} \); differing from that of the circle merely in the sign of the term \( x^2 \), which in the circle is +. See Hyperbola.

EQUILIBRUM, or Equipoise, in Mechanics, means an equality of forces acting in opposite directions, so that they mutually balance each other. Thus, the scales of a balance are said to be in equilibrio, when neither of them preponderates, in consequence of which the beam of the balance remains perfectly horizontal. But, it must not be imagined, that the equality of weights alone determines the equilibrium of mechanisms in general; for that is only the case when the velocities and directions are equal, as in the above-mentioned case of the balance, where the two arms of the beam being equal, the weights in the scales have equal velocities, supposing that the balance is made to vibrate, and move in vertical directions. Therefore, it has been said above, that the equilibrium takes place, when the forces, which act in opposite directions, are equal; for the forces are estimated from the weight of the bodies, their velocities, and directions conjointly. Thus, in the common mechanical powers, the equilibrium takes place, when the power is to the weight as the velocity of the weight is to the velocity of the power. The equilibrium of solids forms a considerable part of the science of statics, and the equilibrium of fluids forms a considerable part of hydrostatics.

Equilibrium is also used figuratively on other occasions. A painter must take care to observe the equilibrium of his figures, i.e., dispose them so that they present a centre of gravity, that they may not seem ill-supported, or ready to tumble. Thus, e.g., if an arm be moved forward, the other must be proportionally backward to poised the figure.

In a picture there should always be an equilibrium between one part and another; that is, the objects are to be distributed so as to balance and contrast each other; and not too many, e.g., be crowded on one side, and the other left bare.

EQUIMULTIPLE, in Arithmetic and Geometry, is applied to simple magnitudes when multiplied equally, i.e., by equal quantities or multipliers.

Thus, taking \( A \) as many times as \( B \), or multiplying them equally, there will still remain the same ratio between the magnitudes thus multiplied, as between the primitive magnitudes before multiplication.

Now those magnitudes, thus equally multiplied, are called equimultiples of the original ones \( A \) and \( B \); whence we say, that equimultiples have the same ratio as the simple quantities. In arithmetic, we generally use the term equimultiples for numbers which contain equally or an equal number of times their submultiples.

Thus 12 and 6 are equimultiples of their submultiples 3 and 2, inasmuch as each of them contains its submultiple three times.

EQUINA Sella. See Sella.

EQUINOCTIAL, in Astronomy, a great circle of the sphere, under which the equator moves in its diurnal motion.

The equinoctial is conceived by supposing a meridian of the sphere produced through a point of the equator, and there, by the rotation of the sphere about its axis, describing a circle on the immutable surface of the primum mobile.

The
The poles of this circle are the poles of the world. The sphere is divided by it into two equal parts, the northern and southern. It intersects the horizon of any place in the east and west points; and at the meridian its elevation above the horizon is equal to the co-latitude of the place.

When in the course of the sun, in his progress through the ecliptic, comes to this circle, it makes equal days and nights all around the globe: as he then rises due east and sets due west, which he never does at any other time of the year. And hence the denomination from **equus** and **nox**, night, *quod equal diem nulli*. All the stars that are under this circle, or that have no declination, do also rise due east and set due west.

The equinoctial, then, is the circle which the sun describes, or appears to describe, at the time of the equinoxes: that is, when the length of the day is every where equal to that of night, which happens twice a year. (See **Equinoctial**.) From this circle is the declination in the heavens or latitude of places on the earth counted in degrees of the meridian. Upon this circle is reckoned the longitude, 180° west and 180° east, in all 360°. Hence, 1° of longitude answers to 4° of time; 15° to 1° of time; and 1° to 4 seconds of time, &c.

The shadows of those who live under this circle are cast to the southward of them for one-half of the year, and to the northward of them during the other half; and twice in a year, viz. at the equinoxes, the sun at noon casts no shadow, being in their zenith.

**Equinoctial colline**, is that passing through the equinoctial points. See **Column**.

**Equinoctial dial**, is that whose plane lies parallel to the equinoctial. See **Dial**.

**Equinoctial hours, line, orient.** See the sublative.

**Equinoctial points**, are the two points wherein the equator and ecliptic intersect each other: the one, being in the third point of Aries, is called the vernal point, or equinox; and the other, in the third point of Libra, the autumnal point, or equinox.

The equinoctial points, and, indeed, all the other points of the ecliptic, are found, by observation, to be continually moving backwards, or in antecedentia, *i.e.* towards the west. This retrograde motion is called the **Precession of the equinoxes**, which see.

**EQUINOX, in Astronomy.,** the time when the sun enters one of the equinoctial points. The equinoxes happen when the sun is in the equinoctial circle, of consequence the days are equal to the nights throughout the world, which is the case twice a year, viz. about the 21st of March, and the 23rd of September, the first of which is the vernal, and the second the autumnal equinox.

As the sun's motion is unequal, that is, sometimes swifter and sometimes slower (from the causes already explained under the **Equation**), it comes to pass, that there are about eight days more from the vernal to the autumnal equinox than from the autumnal to the vernal, the sun spending so much more time in travelling through the northern than the southern signs.

According to the observations of M. Caffius, the sun is 186° 14' 53" in the northern signs, and only 178° 14' 56" in the southern. The difference of which is 7° 23' 57".

The sun, continually advancing forwards in the ecliptic and gaining a degree every day, makes no stay in the equinoctial points, but the moment he arrives in them he also leaves them.

Of course, therefore, though the day the sun enters the equinoctial point is called the equinox, it being reputed equal to the night; yet it is not precisely so, unless the sun enter the equator at mid-day: for if the sun rising, should enter the vernal equinox at setting, he will have departed from it, and have got northwards about 12°; consequently, that day will be somewhat longer than 12 hours, and the night proportionably shorter.

The time of the equinoxes, i.e. the moment in which the sun enters the equator, is found by observation, the latitude of the place of the observation being given.

Thus, in the equinoctial day, or near it, take the just meridian altitude of the sun; if this be equal to the altitude of the equator, or the complement of the latitude, the sun is at that very moment in the equator; if it be not equal, the difference is the sun's declination. The next day observe the meridian altitude as before, and find his declination; if the declination be of different kinds, viz. the one north and the other south, the equinox has happened in the interval of time between them; otherwise, the sun has not entered the equinoctial, or had passed it at first. From these observations a trigonometrical calculation gives the time of the equinox.

Thus, let D C (Plate XII. *Astronomy*, fig. 110.) represent the equator, A C the ecliptic, E the equinoctial point; the points A, B, C, the places of the sun at the times of observation; the arcs A D, B E, C O, the corresponding declinations; in the right-angled spherical triangles C E G, B E F, the obliquity of the ecliptic, and the declinations are known; whence may easily be found E C, E B; then B C, the sun or difference of E C, E B is the ecliptic arc described in 24 hours; these say as B C : B E :: 24 hours for B C : time for B E; and this time shews the distance of the equinox from the time of the middle observation.

**EQUINUS BARBATUS, a kind of comet.** See **Hippus**.

**Equinus ellipticus and quadrangularis.** See **Hippus**.

**Equinun ventor.** See **Venter equi**.

**EQUIP, To, in Naval Language.** A term borrowed from the French marine, and frequently applied to the business of fitting a ship for sea, or arming her for war. See **Fitting-out**.

**EQUIPAGE, in Navigation.** See **Crew and Fitting-out**.

**EQUIPAGE, Camp.** Under this term we confine ourselves entirely to what relates to the tents generally in use; remarking, that such as are admirably fitted for a cold climate, would be found totally unfervicesable in higher latitudes, where the air, confined in a small space, under a vertical sun, while probably not a leaf is in motion, could not fail to be unfit for repiration. Therefore, we shall give the regulations respecting tents, both according to the home service, and to what is found necessary for troops employed in the East Indies.

**Home Service, Laboratory Tent,** with mats, poles, pins, &c. should weigh 3 cwt. 24 lb.; and ought to be sustained on poles of 14 feet each in length; the ridge pole should be 18 feet. Some of these are made with half-walls; that is, their flies, or canopies, do not come within three feet of the ground, but are there fastened to a half-wall, or curtain, which being laced or hooked to the interior of the fly, hangs perpendicularly to the ground, to which it is secured by wooden pins, or pegs.

**India Service, Laboratory Tent.**—This class of tents is nearly similar, but they have commonly extra flies, flapping at about a yard distant from the inner shell, which are sometimes 3 feet well.
The proportions may seem very great, but they are found to be actually necessary in that climate. The total weight of a captain's marquee may be estimated, when dry, at 4 cwt.; when wet, at 6 cwt. A subaltern's marquee, when dry, 3 cwt.; and when wet, 5 cwt.

With respect to the larger classes of tents, such as are used by our colonels and general officers, they approach somewhat towards the construction of what, in the Indian service, are called field officers' sleeping tents, which generally have from 12 to 14 feet between two poles of 14 feet in height. They are chiefly composed of strong hells made of Ruffia-duck, with flies of canvas, and are ordinarily lined with perpet. The weight of such a tent may be computed at 5 cwt. when dry; and when wet at 7½ cwt. State tents may measure about 18 feet in the ridge, and have standards of full 16 feet in height. Their poles are generally made in two pieces, joining in their centres by means of a cylinder of iron; on the same principle as the folding ferris in ladies' parasols.

We have thus given some insight into the proportions between the tents appropriated to the several classes, so far as they could tend to instruct the reader; who will, of course, understand, that in proportion as the standards of a tent are lengthened, so will the several slopes of the fly be lengthened in a suitable ratio. The ordinary computation is, that the direct depth of the slope ought to be two-thirds the length of the poles where a full wall is to be attached; four-fifths where a half-wall is to be furnished; and that the pole should be one-quarter, or even a third, less in length than the direct slope of the fly is deep, if no walls whatever are to be added. The climate will indicate the necessity for more or less steepness in the slope; for if little rain falls, less declivity will answer; whereas, if, as in India, the rains are abundant and heavy, such a slope must be given as may infuse that the interior should remain dry.

It is of the utmost importance, that all camp equipage should be made not only conformably to a particular pattern, thereby to preserve uniformity of appearance; but, as nearly as practicable, of the same kind of materials, and of a given weight; so that a very correct estimate may be formed both of the bulk and gravity of the whole, when about to be conveyed either by land or by water. Besides, it is expedient, that the camp-colourmen, batmen, &c. should have a perfect understanding of this branch of military economy, and have the whole of the tents handed to them, when about to be laden, or conveyed; packed in a regular manner; so as to occupy as little space as possible; otherwise they never can flow to advantage, so as to be safe, and to afford as much space as can be spared for other articles.

**EQUIPAGE, in the Military Art, denotes all sorts of utensils, artillery, &c. necessary for commanding and procuring with ease and success any military operations.**

**EQUIPOLLENCE, in Logic, is when there is an equivalence between any two or more terms or propositions; i. e. when they signify one and the same thing, though they express it differently. Such propositions, &c. are said to be equipollent.**
EQUIPPE', in Heraldry, expresses a cavalier equipped, \textit{e.} \textit{e.} armed at all points.

EQUIRRA, in Antiquity, a festival instituted by Romulus, and celebrated on the 27th of February, in honour of Mars, at which there were horse-races.

EQUISELIS, in Natural History, the name of a large fly, of the size of a hornet, but having only two wings and no sting: it otherwise much resembles the common hornet in shape. This fly is found only in Macedonia. We have also in England flies which nearly resemble the hornet, wasp, and bee, but in their want of wings and having only two wings.

EQUISELIS, in Ichthyology, a name used by some authors for the fifth, caught on the Spanish shores, and supposed by many to be the same with the \textit{Aedes}, or \textit{Coryphaena}, with the forked tail of Arcted. See \textit{Coryphaena}.

Gen. Ch. Frutifications in an ovate-oblong terminal catkin, composed of whorled, filked scales. Each scale peltate, somewhat orbicular, but with many sids, bearing on its under side from four to seven tubular, angular, obtuse heads, parallel to and surrouding the flalk of two valves, burbling internally, containing numerous florets. Stam. Filament four, coiled up round the germin, in a spiral manner, while moilt, variaricated when dry; anthers terminal, simple, filactulate. Pfl. Germin globose, wrapped up in the flaments; style none; stigma obovate, acute. Seeds globose, deciduous, accompanied by the flaments. Eff. Ch. Catkin with peltate scales, fructifying on their infide. Partial involucrums tubular, of two valves. Seeds numerous, naked, surrounded by four spiral flaments. Many different opinions have existed concerning the fructification of this genus, but Hedwig's, as above given, seems to us the most satisfactory. In the artificial classification we retain it among the ferns, to which it is closely allied in natural affinity, though of itself a most natural and distinct genus; nor do we think Schreber's order, entitled \textit{Miscellanea}, lefens in any degree the difficulties respecting this tribe.

Seven species of \textit{Equisetum} are found in Britain, and two or three foreign ones are imperfectly known besides.

\textit{E.} \textit{fuso-vittatum}, Engl. Bot. t. 1874, known by its compound drooping branches, is one of the prettiest. It occurs chiefly in mountainous countries, in moisel, shady spots.

\textit{E.} \textit{hyemale}, Engl. Bot. t. 915, called Shave-grass or Dutch rush, is remarkable for the calous roughness of the ribs of its naked stem, which renders it useful in polishing wood, ivory, and even brads. Being rare in England, it has for these purposes been imported from Holland. Professor Davy has detected a large proportion of nitrous earth in the cuticle, to which its hardness and affinity are owing.

\textit{E.} \textit{variegatum}, Engl. Bot. t. 1887, found on the sandy sea-coast of Scotland, by Mr. G. Don, and a native also of Sweden, Denmark, Switzerland, &c. is a smaller species, nearly related to the last, and having a similar roughness.

\textit{Equisetum}, in Natural History, is the name by which some writers have denounced certain fossil plants, (phytolithirn,) which are found bearing some faint resemblance to the recent plant called horse-tail. Mr. William Mar-
EQUITY.

Far; I left we thereby destroy all law, and leave the decision of every question entirely in the breast of the judge. And law, without equity, though hard and disagreeable, is much more defirable for the public good, than equity without law; which would make every judge a legislator, and introduce infinite confusion, as there would then be almost as many different rules of action laid down in our courts, as there are differences of capacity and sentiment in the human mind.

Equity is of two kinds, and those of contrary effects; the one abridges, and takes from the latter of the law; and the other enlarges, and adds to it.

The first is defined the correction of a law, made generally in that part wherein it falls; as suppose a statute made, "that whosoever does such a thing shall be a felon, or suffer death;" yet if a mad-man, or an infant, who hath no discretion, do the same, he shall neither be a felon nor suffer death.

The other is defined an extension of the words of the law to cases which are not expressed, which yet come under the same reason; so that when one thing is enacted, all other things which are of the like degree are so too.

Thus, the statute which ordains, that in action of debt against executors, he who appears by dittress shall answer, extends by dittress to administrators; and thus of them as shall appear first by dittress, shall answer by the equity of the said act, "quia sunt in eisque generis."

Equity is also used for the virtue of justice. See Justice.

Equity, in our Laws, &c. is also frequently used for the Court of Chancery, (which fees,) where controversies are supposed to be determined according to the exact rules of equity and conscience, by mitigating the rigour of the common law.

"Equitas sequitur legem," is an old maxim in law; but, from the great increase of suits in chancery, some have thought fit to give it this construction, that in all cases after a man has been at law, he must go to equity.

Judge Blackstone has given a brief, but comprehensive view of the nature of equity, as it is now understood and practiced in our several courts of judicature. Equity, he says, in its true and genuine meaning, is the soul and spirit of all law; positive law is confined, and rational law is made by it. In this, equity is synonymous to justice; in that, to the true sense and found interpretation of the rule. But the very terms of a court of equity, and a court of laws, as contrasted to each other, are apt to confound and mislead us; as if the one judged without equity, and the other was not bound by any law. Whereas every definition or illustration to be met with, which now draws a line between the two jurisdictions, by setting law and equity in opposition to each other, will be found either totally erroneous, or erroneous to a certain degree. Thus, in the first place, it is said, that it is the business of a court of equity in England to abate the rigour of the common law; but no such power is contended for. The learned judge specifies various cases of positive law, in which the court of equity can give no relief, and in which it might as well as the courts of law, must say with Ulpian, "hoc quidem per quam juris eff, fed lex in scripta eff." Again it is said, that a court of equity determines according to the spirit of the rule, and not according to the strict letter of the act; but so also does a court of law. Both, for instance, are equally bound, and equally prosists, to interpret statutes according to the true intent of the legislature. In general, though not within the words of the legislator; and others, which may fall within the letter, may be contrary to his meaning, though not expressly excepted. These cases, thus out of the letter, are often said to be within the equity of an act of parliament; and so cases within the letter are frequently out of the equity. Here by equity we mean nothing but the sound interpretation of the law; though the words of the law itself may be too general, too special, or otherwise inaccurate or defective. These are the cases to which Grotius refers in the passage cited above. But there is not a single rule of interpreting laws, whether equitably or strictly, that is not equally used by the judges in the courts, both of law and equity; the construction must in both be the fame, or, if they differ, it is only as one court of law may also happen to differ from another, each endeavors to fix and adopt the true sense of the law in question; neither can enlarge, diminish, or alter that sense in a single tittle.

It has been further said, that fraud, accident, and truff, are the proper and peculiar objects of a court of equity. But every kind of fraud is equally cognizable, and equally adverted to, in a court of law. Many accidents are also supplied in a court of law. And, although a technical truff, created by the limitation of a second use, was forced into the courts of equity; and this species of trusts, extended by inference and construction, has ever since remained as a kind of peculiarity in these courts; yet there are other trusts which are cognizable in a court of law. Moreover, it has been said that a court of equity is not bound by rules or precedents, but acts from the opinion of the judge, founded on the circumstances of every particular case. Whereas the systems of our courts of equity is a laboured, connected system, governed by established rules, and bounded down by precedents, from which they do not depart, although the reason of some of them may perhaps be liable to objection.

In short, if a court of equity in England did really act, as many ingenious writers have supposed it (from theory) to do, it would rise above all law, either common or statute, and be a most arbitrary legislator in every particular case. Formerly, indeed, our courts of equity arrogated to themselves such an unlimited authority as hath totally been disclaimed by their successor for more than a century past. But the systems of jurisprudence, in our courts, both of law and equity, are now equally established systems, founded in the same principles of justice and positive law; but varied by different usages in the forms and mode of their proceedings; the one being originally derived (though much reformed and improved) from the feudal customs, as they prevailed in different ages in the Saxons and Norman judicatures; the other (but with equal improvements) from the imperial and pontifical formularies, introduced by their clerical chancellors.

The suggestion indeed of every bill, to give jurisdiction to the courts of equity (copied from those early times) is, that the complainant hath no remedy at the common law. But he, who should from thence conclude, that no case is justiciable in equity, when the law might have given relief, and, at the same time, calls his eye on the extent and variety of the cases in our equity reports, must think the law a dead letter indeed. The rules of property, rules of evidence, and rules of interpretation, in both courts, are, or should be, exactly the same; both ought to adopt the belt, or must cease to be courts of justice. Neither a court of equity nor of law can vary men's wills or agreements, or (in other words) make wills or agreements for them. Both are to understand them truly, and therefore both of them uniformly.
uniformly. The rules of decision are in both courts equally applicable to the subjects of which they take cognizance. Such then being the parity of law and reason which governs both species of courts, it may be asked what constitutes their essential difference? It principally consists in the different modes of administering justice in each; in the mode of proof, the mode of trial, and the mode of relief. Upon these, and upon two other accidental grounds of jurisdiction, which were formerly driven into these courts by narrow decisions of the courts of law, viz., on the true construction of securities for money lent, and the form and effect of a trust or second use; upon these main pillars hath been gradually erected that structure of jurisprudence which prevails in our courts of equity, and is inwardly bottomed upon the same feudal foundations as the whole system of law. As to the mode of proof, when facts, or their leading circumstances, rest only in the knowledge of the party, a court of equity applies it. If to his conscience, and pursues him upon oath with regard to the truth of the transaction; and, that being once discovered, the judgment is the same in equity as it would have been at law. But, for want of this discovery at law, the courts of equity have acquired a concurrent jurisdiction with every other court in all matters of account. From this composite discovery upon oath, the courts of equity have acquired a jurisdiction over all matters of fraud. As to the mode of trial, this is by interrogatories administered to the witnesses, upon which their depositions are taken in writing, wherever they happen to reside. With respect to the mode of relief, the want of a more specific remedy, than can be obtained in the courts of law, gives a concurrent jurisdiction to a court of equity in a great variety of cases. Thus it is in executory agreements, and in various kinds of frauds, &c. The true construction of securities for money lent is another fountain of jurisdiction in courts of equity. The form of a trust, or second use, gives the courts of equity an exclusive jurisdiction as to the subject-matter of all settlements and devises in that form, and of all the law terms created in the present complicated mode of conveyancing. This is a very ample source of jurisdiction, Black's Com. vol. iii.

Equity of redemption, on mortgages, is that right which a mortgagor has of redeeming his estate upon payment of the money borrowed. This enables a mortgagor to call on the mortgagor who has paid all of his estate to deliver it back, and account for the rents and profits received, on payment of his whole debt and interest; thereby turning the mort- 
mortgage into a kind of viceum radium. But on the other hand, the mortgagor may either compel the sale of the estate in order to get the whole of his money immediately, or else call upon the mortgagor to redeem his estate presently, or, in default thereof, to be foreclosed from redeeming the same, that is, to lose his equity of redemption without possibility of recall. And also in some cases of fraudulent mortgages, (flat. 4 & 5 W. & M. c. 16.) the fraudulent mortgagor forfeits all equity of redemption whatsoever. This is done by proceedings in the court of chancery. But the chancery cannot hinder the time of payment of the mort- 
gage money, where it is limited by express covenant, though it may lengthen it; and then upon non-payment, the practice is to foreclose the equity of redemption of the mort- 
gagor. 2 Vent. 564.

To foreclose the equity, a bill in chancery is exhibited, to which an answer is put in, and a decree being obtained, a master in chancery is to certify what is due for principal, interest, and costs, which are to be prefixed by the decree, whereupon the premises are to be re-conveyed to the mort- 
gagor; or, in default of payment, the mortgagor is orde- ed to be foreclosed from all equity of redemption, and to 
convey the premises absolutely to the mortgagee. Law of Securities, p. 129, 133.

By flat. 7 Gen. II. cap. 20, after payment or tender by the mortgagor of principal, interest, and costs, the mort- 
gagor can maintain no ejectment, but may be compelled to re-affign his securities.

Equity, in Mythology, sometimes confounded with Justice, a goddess among the Greeks and Romans, represented with a sword in one hand and a balance in the other.

Equivalence, is undervalued in something that is 
equal in value, force, or effect, to another.

Equivalence is of various kinds, in propositions, in terms, and in things.

Equivalent propositions. See Equivalence.

Equivalent terms, are several words that differ in 
sound have yet one and the same signification; as "every 
body was there," and "nobody was absent," nihil non, and 
onae.

Equivalent things, are either moral, physical, or flatical.

Moral, as when we say that the commanding or advising 
a murder is a guilt equivalent to that of the murderer. 
Physical, as when a man who has the strength of two men is said to be equivalent to two men. Statical, whereby a left 
weight becomes of equal force with a greater, by having its 
distance from the centre increased.

Equivocal, Equivocum, denotes a word or expression 
that is dubious and ambiguous, or that may have several 
meanings, one true and another false.

Equivocal terms answer to what are otherwise called 
omonymy, or homonymous terms.

Such is the word emperor, which is both the name of a 
dignity, the proper name of a person, and the name of a 
plant. So also the Latin gallus, which stands indifferently 
for a cock and a Frenchman.

In these cases, one word denotes two or more different 
ideas, or different forms of objects: whence that common 
definition of equivocals in the schools, "quorum nomen et 
commune ratio vero scientiae secundum illud nomen diversa." 
Philosophers distinguish equivocals into active and passive; 
or equivoca, equivocante, and equivocata.

In equivoca, equivocante, or those that denominate and signify 
things, are words common to several things in a very di-
fferent signification, i.e. to several things which have a similar ef-
fence corresponding to the similar denominations. E. gr. The 
word taurus, which stands for a bull, a mountain, and an 
animal; and in one signifies a lowing animal; in another, a 
heap of stones and earth; and in the third, a constellation 
or system of stars.

Equivoca, equivocata, or those that are called or denomi-
inated, are the things signified by ambiguous names, e. gr. 
a bull, a mountain, and an animal; which last species of 
equivocals alone Aristotle seems to have had in view in his 
definition, which agrees to those, and these only.

Equivocal action and cause. See Action and Cause.

Equivocal generation, is a method whereby animals 
and plants are supposed to be produced, not by the usual 
way of coition between male and female, but by some suppos-
ited power or virtue in the fun, &c.

Thus, insects, maggots, flies, spiders, frogs, &c. have 
usually been supposed to be produced by the heat of the 
fun warming, agitating, and impregnating the dust, earth, 
and putrid parts of animals.

This method of generation, which we also call spontane-
ous, was commonly affected and believed among the an-
cient philosophers; but the moderns, from more and better 
observations, unanimously reject it, and hold that all 
animals,
EQUUS

animals, ray, and vegetables too, are univocally produced; that is, from parent animals, and vegetables of the same species and denomination.

It were a thing, one would imagine, sufficient to dis
credit the Aristotelian, or rather the Egyptian doctrine of
equivocal generation, to find flies, frogs, lice, &c. to
be male and female, and accordingly to engender, lay eggs, &c.

The doctrine of equivocal generation we call an Egy
tian doctrine, as having, in all probability, had its rise in
Egypt, to solve the hypothesis of the original production
of men, and other animals, out of the earth, by the help of
the sun's heat.

To prove which, the Egyptians, as Diodorus Siculus
observes, produce this observation, that about Thebes,
when the earth is moistened by the Nile, and afterwards
impregnated by the intense heat of the solar rays, an in
numerable swarm of mice come forth; whence he
inferred, that all kinds of animals might equally have arisen
out of the earth at the beginning of things; and from
these bishop Stillingfleet takes the other writers and ad
herents to the doctrine of equivocal generation, Mela, Plin.
y, Ovid, &c. to have borrowed the hypothesis without
cap. 15. See Generation.

EQUIVOCATION, Equivocatio, the using a
term or expression that has a double signification.

Equivocations are expedients to evade telling the truth,
yet without telling a falsity. The fathers are great
patrons of equivocations and mental reservations, holding,
that the use of such shifts and ambiguities is in many cases
allowable.

St. Augustine, particularly, is reproached with endeav
ouring to vindicate his name for saying his wife from a crime
by an equivocation; "tacit aliquid veri, & non dixit alii
guod falsa." To advance a dubious proposition, knowing
it will be underlaid in a sene different from that you give
it in your mind, is an equivocation, and a breach of good
faith and sincerity.

In moral theology, it is strictly underlaid of a term or
phrase with two different significations, the common and
obvious, the other more unusual and remote; the latter of
which being underlaid by the speaker, but the former by
the hearers, they conceive something different from one
another.

Of this we have an instance in St. John, chap. xi. where
our Saviour is represented as saying, "Lazarus sleepest,"
for the disciples who took the word sleeping in the usual
signification, concluded that Lazarus, whom they had been
told, was sick, began to take relief, and would soon recover;
but Jesus, using the word in a less direct and usual signifi
cation, meant that Lazarus was dead.

When the equivocate confounds several words, it is pro
perly called an amphibology, (which fee,) of which we have
an instance in St. John, chap. ii. "Destroy this temple,"
says Jesus, speaking to the Jews, "and I will raise it again
in three days."

The lawfulness of the use of equivocations has been
greatly discredited among the modern casuists; many grave
authors deny that it is allowable to use them on any occa
sion whatever. Their reason is, that an equivocate is to all
intents and purposes the same thing with a lie.

EQUIVOQUE, L', in Mafs, is when a sharpt, by ex
traneous modulation, becomes a flat, and vice versa. As the
chord of D♭ becoming the chord of C♭ with a sharpt 3d,
&c. See Modulation, and Extraneous.

EQUELEUS, or EQUEUS, in Antiquity, a kind of
rack, or engine of torture, used for extorting the truth
at first chiefly on slaves, but afterwards turned against the
Christians.

The patient's arms and legs being fastened on the
equelsus with cords, he was hoisted aloft, and extended
in such manner that all his bones were dislocated. In
this state, red-hot plates were applied to his body, and
he was also goaded in the sides with an iron-forked instru
ment, called anguita.

The equesusus was of wood, and had holes at certain
distances, with a knife, by which the criminal was
stretched to the third, sometimes to the fourth or the
fifth hole; at intervals, the knife was flinched again,
by which he had no relief; but then he was tormented with
questions.

The equelsusus in more ancient times was constructed in
the form of a horse; the criminal was laid on his back,
and his arms were turned under the breast of the equelsusus,
his hands were bound, and his feet stretched out towards
his tail. A rope fastened to the feet was made to pass
over a smaller pulley between the hind-legs of the equelsusus,
and made to coil over another larger pulley fixed under
the belly by means of a handle, which the executioner
turned round till all the bones, &c. were dislocated. See
a learned dissertation on the form and use of this instru
ment, by Dr. Ward, in the Phil. Trans. vol. viii. Part iv.
p. 31, &c.

Hieronymus Magnus when a prisoner among the Turks,
written an epistle to "De Equelsus;" and another to Bells,
merely as it is paid from his memory, without any
affiliation of books. Sigismus had another treatise on the
same subject.

EQUUS, Equelusus, and Eguus minor, equus equus, the
Horse's Head, in Arisot., a constellation of the northern
hemisphere, whose stars in Ptolemy's Catalogue are 4 in
Tycho's 4, in Hevelius's 6, and in Mr. Flamsteed's 10.
See Constellation.

EQUUS, in Arts and Manufactures. See Horse.

EQUUS, in Zoology, a genus of the Bawus order. The
fore-teeth in the upper jaw are six, erect, and parallel; the
lower six, and more prominent; tusks solitary, included, re
mote; teeth two, incisal.

Species.

CABALLUS. Tail with long flowing hair. Equus cauda
undique fatoic, Linn. Equus auriculas breviscerer, juba longa, Briss. 12. Arifot. Athen. &c. Equus,
Rodi, Gofn. Horse.

FERUS. = equus ferus, Hafellq. Wilde Pferde, Gmel.
DOMESTICUS. & equus domesticus. Domestic norse.

This generous animal is cultivated in most parts of the
earth, and is found in a wild state in the deserts of Great
Asia, in the southern parts of Siberia, the banks of the
river Don, and other parts of Asia and Africa. See
Horse.

Hemionus. Longitudinal dorsal stripe without humeral
transverse band; tail hairs at the tip only. Equus hemi
t, Buff.

This curious animal, described by Pallas in the Transac
tions of the Royal Academy of Petersburgh, is supposed by
that naturalist to be the hemions of Arifotole, and which
appears, if this conjecture be correct, to have remained almost
unnoticed from the time of Pliny, who mentions it as a na
tive of Cappadocia.
This animal is described at length under the article Asinus.

The zebra is one of the most beautiful quadrupeds known; uniting to the grace of the horse, and vivacity of the flag, a peculiar combination of colours, that renders its appearance admirable. This animal is rather larger than the common ass, and bears some resemblance to the male. The head is of moderate size, and well formed, the ears long, the legs delicate, the body graceful, and the beauty of its shape heightened by the smoothness of the skin. The colour is either milk white, or faintly tinged with brown, or pale ferruginous, and the whole animal adorned with alternate pale and fuscous bands disposed with such amazing regularity as to have rather the appearance of art than nature. The stripes run in a transverse direction both on the body and limbs. The head is striped with fine bands of black and white, forming a centre in the forehead. The neck is adorned with stripes of the same, running in the same direction as those on the back, all which point perpendicularly towards the belly. The thighs and legs are decorated transversely with fuscous. The tail is of moderate length, round, rather slender, marked with black and white bands, and terminated by a thick tuft of brownish hair. The colours in the male are remarkably vivid, being sometimes of a fine yellow or yellowish, with the stripes nearly black, the female is almost white, with the stripes brown.

These animals are found in the hotter regions of Africa, from Ethiopia to the Cape of Good Hope; and are in particular met with in great plenty in the extensive solitary mountainous wastes of the latter tract of country. They live in large herds, and possess much of the manners both of the horse and the ass, and are exceedingly swift and vigilant, and prefer subsisting on the hard and dry herbage their Rerile haunts afford, to descending into the more fertile and more frequented plains. The disposition of the zebra is more unmanageable than that either of the horse or ass; and even such as have been taken when very young have evinced the same invincible degree of passion for liberty, when grown up, as those caught at an age of maturity. The Dutch have taken great pains to train them for domestic purposes, but with little success, and which is the more to be regretted as the domestication of these animals would be of essential utility to the colony. This is testified from the actual observations of many travellers. The zebra, transported into the temperate climates of Europe, have been known to produce young; but their offspring degenerates. It has been known to couple with the Arabian horse, and to give birth to a small mule not very unlike the hybrid creature formed between the horse and ass. According to Sparrmann, the zebra is hunted by the Hottentots for the sake of its flesh, which they deem excellent; but, in reality, it is in no respect superior to that of the horse. Le Vaillant describes the manners of these animals: the cry of the zebra, according to this writer, is very singular.

**Quagga.** Above chestnut fuscated with fuscous, sides footed; belly, legs, and thighs white. *Equus quagga, Gmel. Operra, or quagga, of the Hottentots. Mufton's Travels, Phil. Tran.

The quagga approaches in nearly resemblance to the zebra, as to have remained till very lately confounded with it, and from various circumstances to be considered as the female. This animal is inferior in size to the zebra. The prevailing...
prevailing colour reddish brown, and the upper part is marked with bands of black, but one of the principal differences consists in the belly, legs, and thighs being white, and the flanks, hanging, and buttocks, are also the flanks and buttocks. There is an obvious difference between the two sexes of this animal, the colours of the male being far more vivid than those of the female.

The more solitary regions in the southern parts of Africa are the haunts of this beautiful animal. They are of a pastoral disposition, and in a state of wildness, herd in troops of a hundred or more together; and it is observed that though they inhabit the same deserts as the zebra they never associate with that species. The quagga, unlike the zebra, is of a tractable nature; it is size is smaller, but stronger, and in proportion more robust. The attempts of the colonists of the Cape to reduce this animal to a state of servitude, like the horse, has been attended with some success; an instance of this is mentioned by Sparrmann. Quagga, openghla, and also cauchy, or cayabo, are the names by which the Hotentots distinguish this animal; its cry resembles the barking of a dog, in which sounds, similar to the latter words, are frequently repeated. Its flesh, which resembles that of the zebra, is eaten by the natives.

Appendix.

The cloven-footed, or Chiliee horse, is an animal of very ambiguous character, and which, if our suspicions be well founded, will be removed from the equus tribe whenever naturalists become better acquainted with this supposed species than they appear to be at present. The animal seems to have been unknown till observed by Wallis in the straits of Magellan. Molina, in his "Storia Naturale del Chili," describes it as a horse, under the title of Guemul or Huemul, and, as later writers depend on the authority of Molina for their description of this anomalous animal, it may not be amiss to repeat the particular information his account affords us. The guemul is described by him as resembling in different respects both the horse and the ass; it bears an affinity to both, but cannot appertain in either of the divisions of the hoofs above being sufficient to remove it from these apparently congenorous animals. In point of stature and appearance, the texture of the hair, and colour, the guemul, according to Molina, resembles the ass. The form and disposition of the teeth correspond with those of the horse. The ears are not long, as in the ass; they are short, straight, and pointed, as in the horse; neither is the back or shoulders of the guemul marked with the black stripe by which the ass is usually distinguished. The head is better formed than that of the ass, the chest more elegant, and the tail and buttocks more graceful. The internal conformation affords the most obvious diversity; and the voice, depending, in a material degree, on this interior organization, rather resembles the neighing of the horse than the bray of the ass. Gmelin is not correct in his translation from Molina, when he describes the "fractura interna," &c., as corresponding with that of the ass; this point may be thought material to the development of the true character of the animal, and should be therefore mentioned; and the more especially since the same mistake prevails in all the English descriptions of this cloven-footed, or Chiliee horse, that we have seen.

Molina speaks of the guemul as an animal of a vicious nature, wild, and of surprizing velocity. It inhabits the heights of the most inaccessible mountainous regions of the Andes of Chili; and it is said, besides, to be found in other Alpine tracts of South America.

The information upon which this animal is described appears to be not sufficiently explicit. We think the guemul ought not to be retained with the horse or equus tribe. Perhaps it is of the camelus tribe, or that, with still more propriety, it ought to be allowed to constitute a new genus. An ingenious writer observes, that "if only a single specimen of this animal had been described, we might have beffated it as admitting it otherwise than as an accidental variety." We could wish the other authorities alluded to had been adduced. The continental naturalists offer argument and speculation dependant on the description given by Molina only; any further information would therefore prove acceptable. In the Genelian "Systema Naturae" this animal is classed as a horse. Sommii considers it as allied to the llama, or camelus glama, and camelus viucagia. According to the character "pedes ungula indivisa," established by Linneus for the equus genus, nothing can be more absurd than a cloven-footed horse. Its affinity to the camel appears rather more evident, or, as before intimated, if it be not of that tribe, it is not improbable that it may constitute a new genus.

Equus Marinus, in Ornithology, the Fulmar of Pen- nant and Latham, and the Procercaria Glutulata of other writers, which see.

Equus Marinus, in Zoology, a name given by some to an animal very different from the hippopotamus, or river-horse, and more usually known by the name of the Maroje. See Trichechus Rafnius.

ERA, in Chronology. See ERA.

ERA, in Geography, a river of Tucuman, which runs into the Arro; 14 miles above Pife.

ERABA, a town of Peru, situated on the eastern bank of the river that answers to the Arabus of Alexander and Nearchus.

ERACLISSA, in Botany, so named by Forfkiill, from the Greek village near which he gathered it, according to Jullien, no other than Androchla telephobidei of Linneus. See Forf. Fl. Egypt. Arab. 208.

ERACTUM, in Ancient Geography, a town of European Sarmatia, in the country of the Balfarres, according to Ptolemy. It has been thought to be the modern Rawa, a small town of Podolia.

ERADICATIVE, in Medicine. See Radical.

ERAE, in Ancient Geography, a small maritime, fortified town of Aisia Minor, in Ionia, according to Strabo, who says that it was either founded or polleuted by the Teians.

ERAGE, a town of Africa, in the Penthapolis, according to Ptolemy.

ERAGISA, RAJEN, a town of Syria, in the Cyrrhai- tis territory, upon the banks of the Euphrates, according to Ptolemy, situated S. S. E. of Hierapolis.

ERAGROSTIS, in Botany, from τερας, love, and ζερας, great, the name of an elegant grass, Poa Fragrata of Linneus, called in Latin Gramen Amoris, and in French Amoureux. See Sm. Fl. Græc. Sib. t. 73, where the Linnean Briza Fragrata is given as a synonym.

ERANA, in Ancient Geography, a borough of Asia, in Cilicia; being the chief place of Mount Amans, upon which it was situated, on the same side with the altar of Alexander. Cicero says it resembled a town rather than a village.

ERANARCHA, formed of τερας, alms, contribution, and ζερας, command, a public officer among the ancient Greeks, whose business was to provide over and direct the alms given, and provisions made for the poor.

3 The
The cranacea was properly the administrator of reward of the poor; when any person was reduced to poverty, taken captive, or had a daughter to marry, which could not effect for want of money, &c. this officer called an assembly of friends and neighbours, and taxed each, according to his means and stature, to contribute towards his relief. This is what we learn from Cornelius Nepos, in his Life of Ekmanides. 

ERANG, in Geography, a town of the island of Certa. 

ERANGIA, in Botany, (Hesperus, the herald of spring,) a name given by Rennell in his Specimen Historicum Plantarum, 91, to the Snow-drop. See Galanthus. 

ERANNA, in Ancient Geography, a town of the Peloponnese, in Triphylia, a province of the Eide. Strabo calls it Eranis, and places it between Cyzippus and Pylos. 

ERANNOBS, or Erranobus, a river of India, according to Arrian, situated within the Ganges, into which it discharges itself near the town of Pilibothra. This river was of the third degree of magnitude among the Indian rivers, and inferior to none but the Ganges and Indus. Major Renell cannot apply the name Erranobus to any particular river. Pliny certainly says, that the Ionianas (Jamnas) entered the Ganges by Pilibothra, between Methora and Chilbarum (otherwise Chilphora and Cyphobara); but it is equally true, that in another place he mentions the confluence of the Ganges and Ionianas, and in the very next article says that Pilibothra is situated 452 miles below that very point of confluence. Strabo does not give the name of the adjoining river. See Pilibothra. 

ERANTHEMUM, in Botany, from Eranis, the herald, and corolla, a flower, according to Linnaeus (Phil. Bot. 177,) who is the author of the name; but such a derivation is, in the present instance, wholly defective of any appropriate meaning. We should have imposed it rather from hesperus, love, on account of the beauty of the flower, which might well justify such a denomination; and it is not impossible that Linnaeus might have had this idea in his mind when he wrote the Flora Zeylanica, but got it when composing his Philostrata Botanica. Linna. Pl. Zeyl. 6. Diff. Nov. Gen. Pl. 1. Am. Acad. v. 1. 384. Gen. Pl. ed. 4. 418. ed. 6. 11. Schreb. 15. Willd. Sp. Pl. v. 1. 51. Mart. Phil. Nat. Hist. v. 2. Joff. 110. 

Gen. Cun. Cal. Perniath five-cleft, tubular, very narrow, erect, short, pointed, permanent. Con. of one petal, funnel-shaped; tube very long and thread-shaped; limb deeply five-cleft, (occasionally four-cleft,) flat, its segments obovate. Stam. Filaments two, very short, in the mouth of the corolla; anthers nearly ovate, concealed, projecting beyond the tube. Pyl. German ovate, minute; style thread-shaped, reaching to the top of the flowers; stigma simple. Peric. and seeds not known. Linnaeus adds, that he had seen only a single specimen, (which by the mark ‡, was a dried one,) and therefore he left the genus to the attentive examination of other botanists. 

Such are the characters given by Linnaeus, and copied by Schreber, but the plant whence they were taken being no other than a Jafferia, very near, if not the same with J. palhella, Roxb. Corom. t. 177. Erantemum falls to the ground. Linnaeus indeed, in his own Gen. Pl. has made the following manuscript corrections: that the two upper segments of the calyx are the flornest; segments of the corolla not obovate but oblong, two of them joined together; anthers within the mouth of the tube. — Whence these corrections were taken we have no knowledge; probably from some of the plants he subsequently referred to Erantemum, for he certainly never again made any mention of it. He originally described from Hortus Hawaiianorum, and had he in his own any thing to illustrate the subject. In the species Plantarum, one species only is mentioned, by the name of E. calyculata, laid to grow in Ethiopia, and to have the habit of a Chinarum; yet he comprehends under it the plant of his Flora Zeylanica, which, as we have said, is Jafferia, and with this last the synonymy of Heron's Pae- 

thius, Amman and Ray have certainly no connection. In the thirteenth and fourteenth editions of the Systema Vegetabilium Selago dubia of Sp. Pl. having but two flornes and its fruit not afeerted, is called Erantemum angulifolium; while another species, called parvifolium, is adopted from Bergius, along with a synonym of Commelina, who figures it with four flornes and all the aspect of a Selago; indeed Linnaeus, in his own copy of Bergius, has expiated a confusion of its being such. E. fulvolis, from Teneriffe, the only supposed species besides is described in the Suppl. Pl. but wholly unknown to us. How far the above, and other suppos'd species of Selago, may constitute a genus by themselves, as Jaffieu supposes, we must leave in doubt; but if so, they cannot have any thing to do with the name or the above generic characters of Erantemum. S. 

ERANUSA, in Ancient Geography, a small town of Italy, placed by Pliny near the promontory of Lavinium. 

ERARIUM. See Herarium. 

ERAS, in Ancient Geography, a town of Asia Minor, in Ionia, in the vicinity of Epeusus, according to Thucydid. 

ERASED, in Heraldy, expresses any thing that seems violently torn off from its proper place. It is used in contradistinction to coupled, which signifies a thing clean cut off. The family of Card bears erasing, a damp lien rampant carved, azure, &c. 

ERASINUS, in Ancient Geography, a river of the Peloponneseus, in Arcadia, according to Strabo, who says that this river had its mouth near Burna, in the gulf of Corinth.—Also, a river of Greece, in Eoties. Strabo.—Also, a river of Greece, in Attica, near Brauron. Strabo.—Also, a river of Asia Minor, in Lycies.—Also, a river of the Argolid, towards the S. E. of Cenchrea, which formed a confluence with the Phryxus. 

ERASISTRATUS, in Biography, a physician of great reputation among the ancients, but of whole parentage and birthplace, as well as of the era in which he flourished, different accounts have been transmitted to us by different writers. It appears most probable, however, that he was born at Athens, in the time of Cusa and Cesa, (and not in Cos, the birthplace of Hippocrates, as has been affected,) that he was the most distinguished pupil of Crisippus, the Chian physician, and had attained a high character in his profession in the 123d Olympiad. His name acquired him the notice and esteem of Seleucus Nicolax, king of Syria, at whose court he is said to have evinced his ingenuity in the following manner. Antiochus, the king's son, was feigned to be a very madly, and the most ingenious physicians of the time were unable to discover the cause of it; until Erasistratus, observing the prince most attentively, remarked, that whenever Stratonice, his father's second wife, entered his apartment, he became considerably agitated, a blisth suffused his countenance, his voice grew more shrill, and his pulse quickened: whence the physician decided that his disorder was the effect of a concealed passion for Stratonice. In order to inform the king of this delicate affair, he flate that
Antiochus's disease was the result of a passion, the more unfortunate as it could not be gratified. The king, spurred at the impracticability of gratifying the inclinations of his son, demanded eagerly who was the object of his love. "My wife," replied Erasistratus, promptly. Sceclus having urged him strongly not to occasion the death of his son, by refusing to give up his wife, Erasistratus inquired, if he would give up Stratonice to save his son's life, were the object of his affection; with which the king expressed his ready compliance, and Erasistratus avowed that this would be the only means of prevailing the love of Antiochus. Seleucus immediately declared him king of the provinces in Upper Asia, and gave him Stratonice in marriage, although he had already had one child.

The great character of Erasistratus, however, is founded upon more solid ground than this anecdote displays. He may be considered as the father of anatomical science, at least conjointly with Herophilus. It seems to be clearly established, that, before the time of these physicians, no one had dared to dissect human bodies; anatomical examinations had been confined exclusively to the bodies of brutes. Human bodies had, indeed, been opened for the purpose of embalming, among the Egyptians, but no anatomical inquiry had resulted from that practice. The Ptolemies, especially Soter and Philadelphia, were defirous that the arts should be cultivated, and having surmounted the prejudices of the age, granted the bodies of malefactors to the physicians for dissection, of which opportunity Erasistratus and Herophilus availed themselves largely, and made several important discoveries. To what extent these discoveries were carried, it is not easy to ascertain, since the works of these physicians are lost; and what we learn respecting them is chiefly through the medium of Galen, who deeming Erasistratus in some sort a rival of his idol, Hippocrates, seldom quotes him but to confute him. It is asserted by Celsus (De Medicinâ, Præfat.), that the monarchs above-mentioned took the condemned criminals from prison, and gave them up to Erasistratus and Herophilus, who dissected them alive, in order to obtain a more accurate knowledge of the vital motions. (See Empiric.) It has been doubted, however, whether they were guilty of this barbarous practice, in consequence of their adoption of the opinion of Praxagoras, that the veins only received blood, and the arteries, and left ventricle, air; since, if they had opened the living body, they must have had ocular demonstration of the existence of blood in the latter: and this imputation is supposed to have been thrown upon them in a fabulous age; just as Medea is said to have boiled living men, because she was the sird who practised warm bathing. (See Eloy Dict. Hist.) It would appear, however, from the statement of Galen, that the evidence of their fenes, upon this subject, was contravened by this sort of Faberfuge: "As soon as the left ventricle of the heart is opened," they observed, "the air is dilated, and the ventricle is infamnaneously filled with blood." (Galen, De fanguis fit natura in arteriis.)

Erasistratus and Herophilus were the first who dissected the human brain accurately; according to the fragments preserved by Galen, Erasistratus described the brain minutely, its convolutions, the division of cerebrum and cerebellum, its cavities or ventricles, with their passageways of communication, and the origin of the nerves; and he inferred that the brain was the common fenitorium, or source of all the vital actions and sensations, which were effected through the medium of the nerves. (Galen, De Hippoc. et Platon. decret. lib. vii. cap. 3.) He also examined minutely the structure of the heart and of the great vessels, and was the first to point out the valvular apparatus, and its peculiar form in each of the cavities of that viscus. (Loc. cit. lib. i. cap. 10. and lib. vi. cap. 6.) He affirmed that the veins divided in the liver, for the purpose of secreting the bile; and knew that the urine was secreted by the kidneys.

His physiology, in general, was not, however, very profound, and his pathology necessarily imperfect; although he attempted to explain the causes of diseases from his knowledge of the structure of the body. The function of respiration served, in his opinion, merely to fill the arteries with air. "The thorax being dilated," he said, "the lungs expand at the same time, and receive air: this air passed to the extremities of the divisions of the trachea, and from them into the extremities of the pulmonary artery, whence it is pumped into the heart, by the dilatation of that organ, in order to be distributed to all parts of the body, by the great artery." He attributed digestion to attrition produced by the causes of the stomach; but he did not attempt to explain the particular manner in which the stomach accomplished such attrition.

The hypothesis, by which Erasistratus attempted to explain the origin of inflammation, seemed, in its leading feature, that modern supposition, which, sanctioned by the name of Boerhaave, was generally received in the medical world for a long series of years. (See Error loci.) He maintained, as we have already stated, that the great vein (vena aorta) was the reservoir of blood, and the great artery (aorta) the reservoir of air. "These reservoirs are divided and subdivided," he affirmed, "until they arrive at the surface, where the ramifications become so minute, that the blood cannot pass farther. Here the mouths or extremities of the arteries and veins close to each other, but the blood continues within its proper bounds, and does not enter the arterial or air-vessels, so that the body continues in the natural state. But when any canse of violence occurs to disturb this regularity, the blood is infused into the arteries, and hence the origin of diseases. Among the causes of disturbance just alluded to, too great abundance of blood is the principal; for by it the coats of the veins are preternaturally dilated, and their extremities, which are ordinarily impervious, open, and admit of the passage of the blood into the arteries. This transfused blood becomes an impediment to the course and motion of the arterial spirit or air, which is sent from the heart; and if the opposition of the two matters is direct, or if the blood are arrested near a vital part, a fever is produced; but if the air repel the blood, so that it pass not farther than the extremity of the artery, inflammation of that part is the consequence." (Galen, de vena fict. adver. Erasistrum.)

The practice of Erasistratus, like that of his master Chrysippus, was extremely simple. He did not employ bloodletting, nor purgatives; considering the former as hazardous in the operation, and debilitating in its effects, and the latter as not bringing away the proper humours of the body, but humours in a fort of corrupted state. He sometimes employed glypters, but thefe of the mildest qualities. All these remedies operated, in his opinion, by reducing plethora, which might be effected more safely and naturally by fasting, or abstinence in diet, especially when aided by exercise. He advised his patients, therefore, to use such articles of diet as contained little nutriment, as melons, cucumbers, and vegetables in general. He was exceedingly averse from the employment of compound medicines, and especially of the mixture of mineral, vegetable, and animal substances; and he exclaimed against the use of the antidotes of the physicians of his day, in which simplicity was altogether shunned.

From the fragments of his writings to be found in Galen and
and Cælius Aurelianus, it would appear, that Erasistratus wrote an accurate treatise on the disorder in which he disproved the operation of tapping; and that he had left books on the following subjects:— viz. on the Diseases of the abdomen, on the Preservation of Health, on wholesome Things, on Fevers, and Wounds, on Habit, on Palsy, and on Gout.

Having lived to extreme old age, and suffering severely from the pains of an ulcer in the foot, Erasistratus is said to have terminated his existence by swallowing the juice of eucalyptus, or hemlock. See Le Clerc, Hist. de la Medicine, Elyot, Dict. Hist. Cælius Aurelianus.

ERASMUS, Desiderius, a man of great celebrity in the republic of letters, was born at Rotterdam on the 28th of October, 1467. He was the natural son of Gerard, a native of Tergou, by Margaret the daughter of a physician, whom he intended to marry, but being deceived by the report of her death, he entered into the church, and on this account Erasimus has been called, by way of reproach, the son of a priest, though his father was not in orders at the time of his birth. When Erasimus was about nine years old he was sent to school at Deventer, where he made many considerable progress in learning, and was particularly distinguished by the excellence of his memory. His mother, who followed him to Deventer, to watch over his health, died of the plague when he was about 13 years of age. He was now left an orphan, and his guardians, forgetful of the sacred trust reposed in them, forced him into the church with a view of embezzling his property. Erasimus refuted their importance for a considerable time, but at last, when he was nineteen years old, he entered among the regular canons in the monastery of Stein, near Tergou. He was of a delicate constitution, and his health was not sufficiently robust for the life of a monk. His temper and sentiments were likewise averse from the habits of the profession; he accordingly, with the leave of his superiors, accepted, in his 25th year, an invitation to reside with the archbishop of Cambrai; but finding the patronage of that prelate not equal to his expectations, he went to Paris and studied in the college of Montaigne. Here he supported himself by giving private lectures to those who were less advanced in their learning than himself. His necessities required great exertion, and thus he acquired habits of industry which raised him to the highest pitch of literary excellence. Some of his pupils at Paris were the sons of Englishmen of considerable consequence, by whose liberality and constant request he visited their country, and contracted many valuable friendships. This was in the year 1497; from England he went to Italy, continued a year or more at Bologna, from thence to Venice, where he published his Adagia; afterwards to Pads, and at last he visited the capital, Rome, where his reputation was very high, and where he might have settled to great advantage, had he not determined, at the entreaties of his friends, and by the express invitation of Henry VIII., to return to England. Henry, while prince, had contracted a friendship, and high respect for Erasimus, and after a few months, after he succeeded to the crown, we find Erasimus at the court of London high in favour with the monarch, with Wolsey, with the archbishop of Canterbury, and with other persons of distinction.

At first he lived with Sir Thomas More, under whose roof he wrote his "Moriz Encomium," or "Praise of Polly," a witty and satirical composition. He afterwards went to Cambridge, and read lectures to the students in Greek and theology. For this he was remunerated with a living and many valuable presents, though not of so substantial a nature as to satisfy his expectations. He wished for an independence, and not being able to secure that in England, he went over to Flanders in 1514, and was shortly after elected nominal counsellor to prince Charles of Austria, with a stipend. Soon after this he paid a visit to Bafli, where he formed an intimacy with some valuable friends, which induced him to spend his latter days in that place. At Bafli he published, in the year 1516., his New Testament, in Greek and Latin, which was received with the utmost eagerness by all those whose minds were turned to theological pursuits. It was dedicated to Leo X. In the course of the same year, his edition of St. Jerome, a favourite author, made its appearance, which he inscribed to his generous patron, archbishop Warham. Erasimus was ever anxious to follow up the useful work of the ambitious rulers of mankind; he published, in 1517., a work entitled "Querela Pacis, unde quaestiones et factitanque," which is written with much strength of reasoning and true eloquence. By his contemporaries he was charged with maintaining the unlawfulness of war on all and every occasion: this, however, was a calumny invented by his enemies, of whom he had many, for, in the work alluded to, he expressly says he is speaking only of wars undertaken on trifling and unjustifiable occasions. "I think," says he, "very differently of wars, which are strictly and purely defensive, such as with an honest and affectionate zeal for the country, repel the violence of invaders, and at the hazard of life, prefer the public tranquillity." He was aware of the horrors and atrocities of a state of warfare, and thought almost any farce might be made by wise princes to prevent it. He undertook to vindicate the cause of peace, whom he makes the speaker on this occasion. But the arguments which he puts into her mouth, and the persuasive eloquence with which she addresses the sovereign princes of those dark times, as they are sometimes called, would scarcely be borne by the monarchs of Europe in this enlightened age. His descriptions are vivid, and his reflections but too just: "Exsurunt vicis, sallantur agris, diripiuntur templi, truncantur immortel civis, sum principes interim olim ludibulum, dum satitut, dum delectat se moriaribus, dum venatur, dum amat, dum potat. O Brutorum genus jam olim extitit! O fulmen Jovis aut oceum aut obtusum." To whom this is particularly applied it does not appear, but the "Querela Pacis" was occasioned by the following remarkable circumstance:

It was a favourite project at this period to assemble a congress of kings at Cambrai, conferring on the emperor of Germany, the kings of France, England, and the Low Countries; of which," says the author, "I am a native. They were to enter into mutual and indissoluble engagements to preserve peace with each other, and throughout Europe. This momentous business was very much promoted by William a Cerving, and by one, who seemed to have been born to advance the happiness of his country, and of human nature, John Sylvagius, chancellor of Burgundy. But certain persons, who get nothing by peace, and a great deal by war, threw obstacles in the way which prevented this truly kind and purposed from being carried into execution. After this great disappointment, I sat down and wrote, by desire of Sylvagius, my Querela Pacis." This work was dedicated to Philip of Burgundy, bishop of Utrecht, who was likewise a zealous promoter of peace, and who, so far from being offended with the free sentiments of the book, thanked the author, and even pressed him to accept a living, as a remuneration, which he civilly refused. Erasimus sought no preferment, though, says his biographer, he merited the highest: he fought the happiness of his fellow creatures, and felt himself abundantly rewarded by his own conscience.
Another antagonist with whom our author had to contend was Julius Caesar Scaliger, who had put himself at the head of those who were so fatalistic in the use of pure Latin as to reject every word not to be found in the works of Cicero, and who on that account had assumed the title of "Ciceronians." Erasmus, superior to this pedantry, employed new words for new ideas, and in justification of his conduct published, in 1528, a dialogue entitled "Ciceronians," in which he attacked the feats both with argument and ridicule. Scaliger wrote against him with all the malignity that human wit and learning could devise, and he was backed in his ferocity by others of the Ciceronians left able in the warfare, but not left invaeterate than their master. The nature of this controversy is fairly exhibited in the notes on the life of Erasmus by Baple.

Erasmus, wearied, perhaps, by disputations, published, in a short time after his "Ciceronians," had made its appearance, a treatise of much ability and learning, entitled "De Rea Latina Græcoque Formosis Pronuntiatione." In the year 1529, Erasmus left Basel for Frákburg, in order to shew his attachment to the church which had for some years been losing ground in Baslé, and so completely had the reformed religion gained an ascendancy there at this period, that all the images were taken from the town-house and other public places and burnt, which was supposed to have been the means of putting an end to the differences among the common people. Erasmus was now advancing in life, and feared, more than ever, fearful of being thought friendly to the reformation, and to shew his zeal for the opposite side he wrote and published an epistle against some "who falsely call themselves Evangelists," and as they, from his former works, had produced his authority against perdition, he began to maintain that there were certain cases in which they might lawfully be punished capitally as blasphemers and seditionists. Such were the unworthy reproaches to which he was led by an anxiety to keep on good terms with his patrons and protectors.

In 1533 he returned to Baslé, and so highly was he exalted by the church of Rome, that there was an intention to give him a place in the college of cardinals; but it was too late for him to accept of the high honour. His health rapidly declined, and on July 12, 1536, he died of a dysentery at the age of sixty-nine. He was buried with great funeral pomp in the cathedral church of Baslé, where his tomb still remains. By his will he left legacies to several friends, and the residue of his property he devoted to charitable purposes. In person he was below the middle size, well-shaped, of a fair complexion, with a cheerful countenance, a low voice, and agreeable elocution. He had assumed the name of Erasmus in conformity with the pedantic taste then prevailing among men of letters of taking names of Greek or Latin etymology; he translated his name of "Gerard," signifying "Amiable," into the equivalent ones of "Deziderius" in Latin, and "Erasmus" in Greek, making use of both, but the latter was his common and perpetual appellation.

Erasmus was a voluminous writer; and his works were published in nine volumes folio. They consist of numerous translations from the Greek; of grammatical and philological pieces; of poems, declamations, and orations; of a collection of apologies and apologetic: of works in divinity on various topics, moral, didactic, and controversial; of a version of the New Testament, paraphrases of the gospels and the epistles, and commentaries on some other parts of scripture; and of apologies, epitaphs to correspondents, &c. A new and beautiful edition of his works was published in Holland by Le Clerc in eleven volumes folio, 1705.
1703. Dr. Jortin, the biographer of Erasmus, speaking of his Latin style, says, it is that of a man who had a strong memory, a natural eloquence, a lively fancy, and a ready invention, who composed with great facility and rectitude, and who did not care for the trouble of revising and correcting; who had spent all his days in reading, writing, and talking Latin; for he seems to have had no turn for modern languages, and perhaps he had almost forgotten his mother-tongue. His style, therefore, is always unaffected, calm, copious, fluent, and clear; but not always perfectly pure and strictly classical.

No one contributed so much as Erasmus to throw discredit upon the barbarism and ignorance of the schools, or to make literature agreeable, and connect it with good sense and solid criticism. He was a great public benefactor; and therefore he is justly regarded as one of the principal glories of his age and country. His memory is equally honoured at the place of his birth and of his death. Several of his relics are preserved at the latter place, and at the former, the house in which he was born, is marked with an inscription, and his statue decorates the great square. Jortin's life of Erasmus. Bayle. Complaint of Peace. 1502.

ERASMUS, in Geography, a mountain of the island of Ceylon; 50 miles N.W. of Trincomaly.

ERASTIANS, in Ecclesiastical History, a religious sect or faction, which arose in England during the time of the civil wars, thus called from their leader, Thomas Erastus, a German divine of the sixteenth century, whose distinguishing doctrine was, that the church had no right to discipline, that is, no regular power to communicate, exclude, censure, absolve, decree, or the like. According to the founder of this sect, the pastoral office was only permissive, like a professor of the sciences over his students, without any power of the keys annexed. The Lord's supper and other ordinances of the gospel were to be free and open to all. The minister might distinguish the vicious and unqualified from the communion, but might not refuse it, or inflict any kind of censure; the punishment of all offences, either of a civil or religious nature, being referred to the magistrate. The pretended advantage of this scheme was, that it avoided erecting imperium in imperio, or two different powers in the same civil government; it effectually destroyed all that spiritual jurisdiction and coercive power over the consciences of men, which had been challenged by popes, prelates, presbyteries, &c. and made the government of the church "a creature of the state." Moll of our feril reformers adopted these sentiments so far as to maintain, that no one form of church government is preferred in scripture as a rule for future ages, as Cranmer, Redmayn, Cox, &c. and archbishop Whitgift, in his controversy with Cartwright, delivers the same opinion. The Erastians formed a party in the Assembly of Divines in 1643, and the chief leaders of it were Dr. Lightfoot, Mr. Colman, Mr. Selden, and Mr. Whitlock; and in the house of commons there were, besides Selden and Whitlock, Oliver St. John, esq. Sir Thomas Weldonington, John Crew, esq. Sir John Hliply, and others of distinguished reputation. In the assembly, the Erastians did not except against the presbyterian government as political institution, proper to be established by the civil magistrate, but they were against the claim of a "voice right." Accordingly the claim of divine right was hot in the house of commons. Neal's Hist. Part. vol. ii. 4to.

ERASTUS, Thomas, in Geography, a physician, was born, in 1523, at Augst, a village in the district of Badenweiler, in Switzerland. He studied at Basel, where he was seated with the plague in 1542, and narrowly escaped death. He suffered a long and tedious constiudecence, which, together with his poverty, threw an almost insurmountable impediment in the way of his studies; but he happily found a generous protector, who opened the door of the sciences to him, and furnished him with the means of travelling to Italy. He took up his residence at Bologna, where his proficiency in the study of philosophy and medicine was such, that he obtained the honour of the degree of doctor of these two sciences. Finding himself in a short time holding a distinguished situation among the men of learning, he followed the custom of the times by changing his name; giving a Greek turn to his original name, which was Liuter, (beloved,) he called himself Erastus. Under this appellation he became a teacher of medicine at Heidelberg, where he obtained considerable reputation; and in 1581 he was called to fill the medical chair in the university of Bafif. But this honourable situation he did not long enjoy; he died on the 18 of January, 1583.

He left many works behind him, of which some were printed during his life, and others have been published since his death; their contents, however, are not particularly interesting; the following is a list of their titles and editions.

1. "Disputationum de Medicina nova Philipippi Paracelsi," p. i. Basf, 1572, p. ii. ibid. 1572, p. iii. ibid. 1572, p. iv. ibid. 1573, all in 4to. In these volumes he refutes the doctrines which Paracelsus had previously taught at Basf, and had committed to writing.

5. "De Putredine Libri," 4to. ibid. 1580; Lijper, 1590.

ERATO, from you, I love, in Mythology, the name of one of the nine Muses who presided over love-poetry. "By Erato," says Callimachus in his epigram on the nine Muses, "the pious hymn was made." To this Muse some have ascribed the invention of the lyre and lute; but particularly the psaltery or long lyre of nine strings, and he is represented with a garland of myrtles and roses, holding a lyre in one hand, and a bow in the other, and at her side a Cupid, with his torch. In the portraits of Apollo and the Muses, dug out of Hercules, Erato is exhibited holding a plectrum or bow in her right hand, and leaning to play with the fingers of her left. The psaltery, or lyre, is more than twice the length of that in the hand of Tertipochore. (See Muses.) There is also a Nereid of the same name.

ERATONUS, in Ancient Geography, islands of the Arabic gulf. Piny designates their salubrity by the epithet Sitientes.

ERATOSTHENES, in Biography, an eminent Greek mathematician, philosopher, and chronologist, was born at Cyrene in the second year of the 920th Olympiad, or 275 B. C. He was educated under Aristo, the philosopher of Chios, and Callimachus, the poet; and he himself had several disciples who were eminent, and among the number was Arélophe of Byzantium, one of the most celebrated grammarians of his time. Such was the fame of Eratosthenes as a man of extensive erudition, that he was denominated klasos, i. e. victorious in five contests, alluding
to the five prizes of the Olympic games, and expressing his pre-eminent in all kinds of literary pursuits. He was also styled the cosmographer and father of chronology, the measurer of the universe, and the second Plato. On the invitation of Ptolemy Euergetes, he removed from Athens to Egypt, and succeeded Zenodotus in the office of librarian to the famous library at Alexandria. This office he retained under three successive princes, discharging his trust with singular honour, and acquiring high reputation for literature and science by his writings and discoveries. Availing himself of the multitude of historical memoirs, which the library furnished, he was both prompt and enabled to determine the dates of many distinct facts, by laying down certain chronological canons, for which see CHRONOLOGY. He also employed his eminent abilities and learning, with equal success, in reducing geography to a regular system, and laying its foundation upon clear and solid principles. He likewise first introduced into his map a regular parallel of latitude, which was a geographical outline traced over certain places, whose longest day was observed to be exactly of the same length. He began it from the straits of Gibraltar, and it thence passed through the Sicilian sea, and near the southern extremities of Peloponnesus, and was continued through the island of Rhodes and the bay of Tithys, and then entering Cilicia, and to crossing the Euphrates and Tigris, was extended to the mountains of India. By means of this line he endeavoured to rectify the errors in the ancient geographical map, supposed to be that of Anaximander. In drawing this parallel, he was regulated by observing when the longest day consisted of 14 1/2 hours, which Hipparchus afterwards determined to be the latitude of 36°. The running of this parallel through Rhodes was a happy thought of Eratosthenes, because it not only encouraged him to trace upon his map other parallels at certain intervals from his first, such as one through Alexandria, another through Syene, and another through Meroe, but he undertook to trace at right angles to these a meridian passing through Rhodes and Alexandria down to Syene and Meroe. His progress in this way enlarged his ideas with regard to the sciences of geography and astronomy, and induced him to attempt a more arduous task, which was that of determining the circumference of the globe by an actual measurement of one of its great circles, making his computation upon the whole by uniting certain accurate observations made in the heavens with a corresponding distance can fully surveyed, and taken upon a meridian of the earth. The segment of the meridian which he fixed upon for this purpose, was that between Alexandria and Syene, the distance of which was measured, and found to be 5000 itadas, and the angle of the shadow upon the obelisk, or funicular, which was observed at Alexandria, was equal to the 50th part of the circle; so at Syene there was no shadow from the gnomon at the mid-day of the summer solstice; and that this might be more accurately taken, they dug a deep well, which being perpendicular was completely illuminated at the bottom, when the sun was vertical. The fulness of this account was taken from Cledonides, who seems to have extracted it from Eratosthenes's original work, entitled Miteron. (See Fabr. Bell. Græc. vol. ii. p. 477.) And it is published as such at the end of the Oxford edition of Aratus in 1672, though under the title of Meteora 712 57 177. By this account Eratosthenes made the circumference of the earth amount only to 250,000 itadas; whereas a multitude of original authors, such as Strabo, Geminus, Vitruvius, Macrobius, Pliny, Capella, and Censorinus, have uniformly given the numbers to be 252,000. In order to reconcile these differences, Dr. Murdoch (Enquiries concerning Measures of length, prefixed to Burchard's Geography, vol. i.) has ingeniously supposed, that instead of 7 12', the difference of latitude was 7 80', which was the 15th of the circumference, which would bring the calculation to 252,000 itadas, and that Cleomedes neglected the small fractional part of the denominator; but that the principal mistake was in measuring the distance, and finding it to be 5000 itadas. Eratosthenes, by making the circumference to be 250,000 itadas, allowed 700 itadas to a degree, which, by the reduction of 8 itadas to a Roman mile of 5000 feet, amounted to 8 1/8 Roman miles to each degree. We shall return from this digression, after observing, that the map of Eratosthenes appears to have contained little more than the states of Greece, and the dominions of the successors of Alexander, digested from preceding surveys. He had been indeed, and has quoted the voyages of Pytheas into the great Atlantic ocean, which gave him some faint idea of the western parts of Europe: but they were so imperfect, that they could not be realised into the outline of a chart. Strabo tells us that he was extremely ignorant of Spain, Gaul, Germany, and Britain, as well as of the Gatti and Baffarni; he was equally ignorant of Italy, the coasts of the Adriatic, of Pontus, and of all the countries towards the north. And he mentions in another passage, that Eratosthenes had made the distance from Epidamnus, or Dyrrhachium, on the Adriatic, to the bay of Tharasia on the Aegean sea, quite aside Epirus, to be only 900 itadas, when it was really above 2000 itadas; and in another instance he had enlarged the distance from Carthage to Alexandria to 15,000 itadas, whereas it amounted to no more than 9000 itadas.

Eratosthenes also observed the obliquity of the ecliptic, which, in the year 270 B.C., he makes 23° 51'. (See Eratosth. In an epitome he kept Pythius a solution of the problem for the duplication of the cube; and he invented a convenient method of discovering the primary numbers, that is, such as have no common measure but unity, which has been called the sieve of Eratosthenes. He wrote also numerous treatises in grammar, astronomy, history, and geography, together with dialogues on the philosophical sects, and poems. Fragments merely of his different pieces have reached our times, some of which were published at Oxford in 1672, with brief annotations, in 4to. These fragments were also printed in the Uranologium of Petavius at Paris in 1630, and afterwards at Amsterdam in 1703. The most valuable remnant of his works is his "Catalogue of the kings of Thebes in Egypt, from Menes, who first peopled Egypt after the deluge, to the time of the Trojan war." This contains a series of 38 kings in a direct line of succession, taken not only from the records in the Alexandrian library, but from the sacred archives in Diodorus, or Thebes K Müslüman, and probably intended for supplying the defects, and correcting the errors of Manetho's dynamics. This has been used by some of our chief chronologers as an authority for founding the Egyptian chronology. Eratosthenes died at the advanced age of 80 or 81, having, as some authors report, starved himself to death, because he was unable to bear the depredation of spirits occasioned by the decay of his sight. Suidas. Vol. de Hist. Græc. Fab. Bib. Græc. More- ri. Anc. Un. Hist. Gen. Biog.

ERBACH, in Geography, a small town of Germany, in the circle of Franconia, anciently called Erdbach, with an old castle, belonging to the counts of Erbach, who, before the dissolution of the German empire, had two voices at the diet of Ratisbon, in the college of the imperial counts of Franconia. The whole county is about 25 miles in length, and 20 miles in breadth; its population does not exceed the number.
number of 30,000 individuals. It is a mountainous country, but tolerably fertile, and producing both corn and wine; of the latter, that of Schonberg, near the Berghaffe, is reckoned the best.

ERBAT, a town of Astatic Turkey, in the province of Diarbekin; 68 miles S.E. from Diarbek.

ERBAZ, a town of Astatic Turkey, in the province of Natafia; 36 miles W.S.W. from Doguzula.

ERBITA, in Ancient Geography, a town of Sicily, written Herbita by Cicero. It is thought to be the modern Nicofé.

ERBLSPACH, or ERBACH, in Geography, a town of Germany, in Lower Bavaria; 34 miles E.S.E. from Ingolstadt.

ERCBAM, in Ancient Geography, a town of European Sarmatia. Prokoné.

ERCE; in Geography, a town of France, in the department of the Ille and Vilaine, and district of Bain; 5 miles E. from Bain.

ERCEUS, of 1607, septum, in Mythology, the name by which those who were appointed to guard the walls of a city invoked Jupiter. This appellation, sometimes written Herceus, was given to Jupiter, because his altars, especially in the houses of princes, stood under the open air in places inclosed with walls.

ERCHEE, in Geography, a town of Perisa, in the province of Adirbeizan; 63 miles E.N.E. of Tauris.

ERCELLA Y ZUNIGA, Don Alonso de, in Biography, an eminent Spanish poet, was born at Madrid in 1533. His father, defended from a noble family, pursued the profession of the law, but dying while Alonso was an infant, the child and his mother were received into the household of Isabella, wife of Charles V. Alonso, as soon as his years permitted, was made page to the infant don Philip, whom he attended in his progress through the Low Countries, and part of Germany and Italy. He afterwards accompanied the same prince to England, to celebrate his marriage with queen Mary. During their stay here intelligence was received of a revolt in Chili, upon which troops were immediately sent off, with whom Ercilla embarked and proceeded to Lima. His duty required him personally to engage in a subterfuge with the Araucanians, whose courage and love of liberty he admired, and even applauded, though he was under the necessity of using all his efforts in subduing them. The intervals of warfare he employed in recording, in heroic verse, the interesting scenes to which he was witness. After he had escaped the dangers of the expedition, he had nearly lost his life at a tournament exhibited in honour of the accession of Philip II. During the fête a dispute arose between Ercilla and another gentleman; swords were drawn, and many joined in the conflict, which being continued into a plan of mutiny by the governor, he hastily, and without examining into the matter, commanded the principal disputants to be beheaded. Ercilla was led to the scaffold, and his innocence was demonstrated but just in time to save him from an ignominious death. He returned to Spain with his health very much impaired, in his twentieth year; but after a very short stay at home, he commenced a tour through various parts of Europe; but with what particular view has never been ascertained. In 1570 he married, and was made gentleman of the bed-chamber to the emperor Rodolph I. Ten years after this, he was found residing at Madrid, in retirement and poverty. The king whom he had served, and to whom he dedicated his poem "Araucana," made him no requital for his services, and little more is known of him, than the mention made by a contemporary of his being engaged, in 1596, in celebrating the victories of the marquis of Santa Cruz, in a poem that has never been published.

The "Araucana" is an historical poem, containing a narrative of real events, interspersed with fabulous circumstances. It contains 37 cantos, or round regular plan, but is an unconnected series of adventures. The verse is said to be flowing and spirited, though sometimes it is profane and impious. Mr. Hayley, in his Essay on Epic Poetry, has taken pains to make Ercilla known to the English reader, by translations of select parts, and an analysis of the whole poem. Gen. Brog. Hayley on Epic Poetry.

ERCYNA, a river of Greece, in Boetia, not far from the cave of Trophonius.

ERDENTI-CHAO, in Geography, a town of Chinese Tartary, in the country of the Elute; 680 miles N.W. of Pekin.

ERDER, a town of Germany, in the circle of Westphalia, and country of Lippe; 12 miles N.N.E. from Lemgow.

ERDMANSDORF, a town of Germany, in the circle of Upper Saxony, and circle of Erzgebühr; 5 miles E. of Chemnitz.

EREBBNUS, Eriônas, a name given by Galen and some other of the Greek writers, as a distinctive epithet for the black chameleon thistle, which was esteemed poisonous, and was by this word distinguished from the argens, or diyakon, or white chameleon, which was an ecficient plant, and used by some as an antidote. It has happened, however, that the white chameleon thistle has been by some called a poison, as well as the black; but this is only owing to a mistake of Pliny, in supposing the effects of birdlime to have been attributed to this plant, because of its yielding a viscous, but safe gum, at its root. It was called by some dyakon chameleon. See 11288.

EREBBINTHUS, in Botany, (1718, 2u), an ancient Greek name for some kind of thistle or legume, was applied by nachit to a supposed new genus of its own, which is the Galega virginiana of Linnéus. The latter in his Sp. Pl. inaccurately quotes Mich. Gen. which should mean Micheli, and professor Martyn, under his Galego, sp. 4, has Mant. Gen. both which would be unintelligible without an explanation.

EREBUS, from νυξ, night, in Mythology, a term denoting darknes. According to Hesiod, Chaos engendered Erebos and Night, from whose mixture was born neither the day. Aristophanes, ridiculing some ancient fable of theogony, in his comedy of the Birds, introduces one of his actors as saying, that in the beginning were the Chaos, the black Erebos, and the void Tartaros; but as yet there was neither earth, nor air, nor heavens. Night, with her fable wings, laid the first egg in the womb of Erebos, whence sprung, after some time, beneficent love, adorned with golden wings. From the union of love with chaos, arose men and animals. This was also the name of part of the inferi among the ancients: they had a peculiar exaption for those who were detained in Erebos.

Erebos was properly the gloomy region, and distinguished both from Tartarus, the place of torment, and Elysium, the region of bliss: according to the account given of it by Virgil, it forms the third grand division of the invisible world beyond the Styx, and comprehends several particular districts, as the limbus infantum, or receptacle for infants, the limbus for those who have been put to death without cause; that for those who have destroyed themselves; the fields of mourning, full of dark groves and woods, inhabited by
ERE

The erecting of a perpendicular on a line given, is a popular problem in geometry. See **Perpendicular.**

The term erection is also used figuratively; as the erection of a monument into a duchy; lithopries can only be erected by the king.

**Erection**, in **Physiology**, is the change in the state of the male parts, by which that organ is rendered capable of entering the vagina of the female, for the purposes of sexual intercourse. See **Generation.**

**ERECTOR**, in **Anatomy**, a name given to two muscles supplied to produce the power of bringing the organs with which they are connected into an erect state. They are the erector penis of the male, and erector clitoris of the female subject. See **Generation.**

**ERECTUM, Folium, in Botany.** See **Leaf.**

**RECTUS, CAULUS, an upright stem.** See **Caulis,** n. 6.

**EREGEM,** in **Geography,** a town of Flandres; 10 miles S.W. of Bruges.

**EREGNOS,** from **ergos,** I break, a word used by the ancients to express a beam decorticated and broken into small pieces, in order to be boiled in pits; and also applied indifferently to all the leguminous fruits broken in the manner.

**EREKLI, in Geography,** a town of Asiatic Turkey, in the province of Caramania; 60 miles E. of Cogni.

**EREMEGIKE,** a town of Asia, in Thibet; 25 miles S. of Turfan.

**EREMIT.** See **Hermit.**

**ERES, or Eris, in Geography,** a town of **Paxia,** in the province of Selchir, on the borders of Armenia; 86 miles S.W. of Derbend, and 120 S.E. of Tiflis.

**ERESIA,** in **Botany,** a name given by Plinius to a new African genus, Nov. Gen. S. t. 25, in honour of the Genian botanist Theophrastus Eresius; but Linneus, and all succeeding writers, have, with the greatest possible propriety, called the plant *Theophrastia*, which he.

**ERESMA,** in **Geography,** a river of Spain, which runs into the Duero, between Simancas and Tordesillas.

**ERESOS,** in **Ancient Geography,** a town of the island of Lesbos, which was the native place of Theophrastus.

**ERESUS,** or **Eubus,** a town of the island of Eubus, founded by a colony of Carthaginians. Its harbour was commodious, its walls very large, and its houses well built.

**ERETENUS,** a river of Italy, in Venetia, famous, according to Azilian, for its excellent cels, and supposed to be the present Retona.

**ERETHISMUS,** (from ergis, to irritate, or excite). Medical writers extend the general meaning of this term to every kind of irritation which has a tendency to weaken and destroy the vital powers.

In this article we intend to take particular notice of a dangerous affection of the constitution, well known among foreigners by the name of the mercurial erethismus.

Mr. Pearson acquaints us, that on his first succeeding to the situation of surgeon to the Lock hospital, he had occasion to remark, that almost every year one, and sometimes two instances of sudden death occurred among the patients of that charity. No cause could be assigned for these events, but the subjects were commonly observed to be men who had either nearly, or completely finisht a course of mercury. Messrs. Bromfield and Williams, on being consulted by Mr. Pearson, concerning the extraordinary cases, confessed themselves ignorant of the cause, mode of prevention, and treatment, and explained, that they had never been able to detect any difeased appearances in the bodies of such persons as had died in this sudden and unexpected manner.

Mr.
Mr. Pearson at length ascertained, that these unfortunate accidents were to be ascribed to mercury acting as a poison on the fyltem, quite unconnected with its operation as a remedy; and that its deleterious qualities were neither in proportion to the inflammation in the mouth, nor to the actual quantity of mercury absorbed into the constitution. The disordered state of the fyltem, implied by the mercurial erethismus, comes on after a long employment of mercury, and tends to a fatal termination. According to Mr. Pearson, it is characterized by great depression of strength, a fene of anxiety about the precordia, irregular action of the heart, frequent fighing, partial or universal trembling, in small, quick, and sometimes an intermitting pulse, occasional vomiting, a pales contracted countenance, a fene of coldnefs; but the tongue is felden furred, and the vital and natural functions are not much disordered.

Mr. Pearson observes, that when thefe, or the greater part of these symptoms are present, a sudden and violent exertion of the animal power will sometimes prove fatal. Walking hastily across the ward; vibrating suddenly in the bed to take food; or flightly struggling with some of the other patients, are circumstances noticed by the above gentleman as having commonly preceded the sudden death of fuch persons as have died of the mercurial erethismus.

In order to avert the perilous effects of this peculiar affection, Mr. Pearson flates, that the employment of mercury is, at all events, to be discontinued, whatever may be the fage, extent, or violence of the venereal symptoms. Every consideration must yield to the great object of extirpating the patient from a state of impending destruction; nor would a perfection in the ufe of mercury, under these circumstances, be of any avail, in regard even to the fphyllitic complaints.

The patient should be exposed to a dry, cool air, with out being subjected to any more fatigue than can be avoided. Mr. Pearson contends, that fitting in a room with a window open is not fufficient, but that the patient should go into a field or garden, and live as much as possible in the open air, till the above symptoms have disappeared. This plan should be conjoined with a generous diet. In this way patients have often been sufficiently relieved in the short pace of ten or fourteen days, to re-commence the employment of mercury, and to bear its exhibition effectually, without any bad consequences.

The gradual approach of the mercurial erethismus is commonly indicated (according to Mr. Pearson's account) by paleness of the countenance, a flate of general inquietude, and frequent fighing: the respiration becomes quicker, fometimes accompanied with a fene of conftiction across the chest; the pufle is small, frequent, and often intermitting, and there is a fene of fattering about the precordia. In this early stage the further progress of the mercurial erethismus may be frequently prevented by the exhibition of the camphor mixture with large doses of the volatile alkali, the employment of mercury being at the fame time fupended. Also, when the fkomac is not oppreced by farfamipilla, this medicine is productive of infinite benefit to perions afflicted with the mercurial erethismus. See Pearson on the "Effects of various Articles of the Materia Medica in the cure of Lues Venerea," edit. 2. p. 155 to 159.

ERETRIA, in Ancient Geography, a town of Greece, in the Phthiotide, a country of Thesaly.

ERETRIAS, a town of the island of Eubea, situated on the sea-coast at some distance to the south-east of Chaleis, opposite to the mouth of the Oropus, which, on the continent, separates the limits of Eubea from those of Attica. This town was probably built by the Athenians, as Strabo says, before, but according to Herodotus, after the war of Troy. It was for a long time a considerable place, and remained in a flourishing state under the reign of Darius, son of Hytkafes. It was destroyed by the Persians in the war of Greece, but was afterwards rebuilt, became very rich, and flourished in the time of Strabo. It was amply furnished with pictures, statues, and such ornaments. We cannot trace any remains, except a pefudation that it existed in a place called by the modern Greeks "Eretteboita."
at Ilkerton, common, of suffering the coal-owners to work their coal under the canal instead of paying large sums in order to have the same left, as the act had provided, and a great length has been thus excavated and the ground settled, with only a trifling and temporary inconvenience to the canal, in raising the banks; on the Nottingham canal the same was also successfully tried, even under the lock, on the recommendation of Mr. Thomas Waller, see Nottingham Canal.

A railway branch conducts from the head of this canal to B Peggy's, and another to Old Brindley colliery, in Nottinghamshire; and another, constructed in 1828, to the new collieries in Comberhurh-wood in Derbyshire.

ERFURT is a small town of France, in the department of the Sambre and Meuse, chief place of a canton in the district of Marche, with a population of 640 individuals. Its canton has a territorial extent of 272½ square miles, 13 communes, and 1,519 inhabitants.

ERFA, a town of the island of Corfu; 25 miles N. N.W. of Bafia.

ERFURT, or Erfurt, an anciently called Erpes, or Erpsifurt, a very old town of Germany, in Thuringia, on the river Gera, 63 miles N. by E. of Coburg. N. lat. 51° 6'.

It appears to have been founded in the beginning of the fifth century. The emperor Lewis held a diet at Erfurt in the year 827. The emperor Henry I. did the same in 935, and Rudolph I. in 1289. The last diet of the empire held at Erfurt was that of the year 1566. Erfurt was not an immediate free imperial city, but it enjoyed several considerable lordships and immunities, first under the protection of the landgraves of Thuringia, then of the princes of Brunswick, and lastly, from the year 1483, of the electoral house of Saxony; but the archbishops of Mentz claming the sovereignty over Erfurt, it was at last agreed, in 1667, that they should keep a governor in the city, on the express condition that the Protestant doctrine and worship should be respected. The professors' chairs of the university, which had been established in 1392, were allowed to be filled half with Roman Catholic and half with Protestant teachers. In 1754 an academy of sciences was founded, to which were subsequently added a botanical garden, an anatomical theatre, an astronomical observatory, a riding school, and a society of natural history. The public libraries are those of the Jesuits, of the Scottish convent, and of the Lutheran ministrum, which contained some valuable ancient manuscripts of the Hebrew bible.

The most remarkable public building at Erfurt is its cathedral church, which is reported to have been built in the year 753. Its celebrated great bell weighs 375 cwt. In more superstitious times, pilgrims used to flock to Erfurt from all parts of Germany on a particular day, to dance the dance of Death (den Todtentanz).

At the peace of Lunville, in 1801, the city of Erfurt, its territory and dependencies, and all the rights of sovereignty possessed by the ecclesiastical elector of Mentz, or Mayence, were ceded to the king of Prussia, as part of the indemnities to which this monarch was entitled for his losses on the right shore of the Rhine. The population of Erfurt and its territory, together with the Eischfeld, was, in 1802, reckoned at 121,400 individuals, and in the territory of Erfurt in particular, inclusive of the town, there were 35,171 individuals to the German square mile. The city of Erfurt, without the garrison, contained 16,500 inhabitants. But Prussia having declared war against France in 1806, Erfurt was one of the first towns which surrendered to the French after the unfortunate battle of Jena or Auerfiidt, in October 1806. The fort of Petersberg, which protects the city, and which had always been considered as very strong, did not even attempt a defence. At the peace of Tilsit, in 1807, Prussia was deprived of all the new acquisitions and old possessions beyond the Elbe; and Erfurt, by the conqueror's decree of the 18th of August, 1807, was form part of the new kingdom of Westphalia. But the French emperor having had a conference with the emperor Alexander I. of Russia at Erfurt in the month of October, 1808, this city was again transferred, by way of compliment, to the Russian emperor's brother-in-law, the present duke of Saxe-Weimar, who is a member of the Confederation of the Rhine. There is at Erfurt a considerable manufacture of ribbands, which employs above 500 individuals.

ERGALIA, of ipeps, opus, a word used by the Alchemists, to express that part of their treatises which explains the instruments employed in their operations.

ERGANE, in Mythology, the Invenstrefl, an epitaph of Minerva, because to her was ascribed the invention of several arts; since, besides that of the art of war, Lucian ascribes to her that of architecture; the art of spinning, of making cloth, tapestry, silk and woollen stuffs, is also ascribed to her by the ancients. She was also reckoned the first who taught man to plant and cultivate the olive. She is likewise honoured with the invention of chariots, and of the use of trumpets, and the first to teach the ancients to use a bow and arrow.

ERGASIMA, a name given by Dioscorides and other of the ancients to a very foul and coarse kind of myrrh.

ERGASTERIUM, a word used by the writers in Chemistry, sometimes to express the whole elaboratory, and sometimes that part of a furnace on which the bottom of the retort, copel, or crucible, is to rest in an operation.

ERGASTINE, or Ergasins, in Antiquity, a select number of virgins employed in weaving Minerva's peplos or robe, which was carried in procession at the Athenian festival Panathenaia. See Peplos, and panathenaic.

ERGASTULUM, among the Ancients, a house of correction, or workhouse, where slaves, by the private authority of their masters, were confined, and kept at hard labour for some offence. It was likewise called sophroniferum.

ERGATIA, or Ergasins, in Antiquity, a Laconian festival, in honour of Hercules.

ERGAVIA, in Ancient Geography, a town of Spain, in the Tarragonensis. Ptol.

ERGAVICA, town of Hither Spain, S. of Bilbilis.

This appears to have been a considerable place when it was taken by Graccus in his campaign. Several medals were struck here, which represented Augustus and Tiberius, with an ox upon the reverse.

ERGENE, in Geography, a river of European Turkey, which runs into the Mariza, near Demotica, in Romania.

ERGERS, a river of France, which runs into the Ill, about two miles east from Grispoltheim, in the department of the Lower Rhine.

ERGETIUM, in Ancient Geography, a town of Sicily, Ptol. and Steph. Byz.

ERGINUS, a river of Thrace, in the vicinity of the Anthas, which ran before Sarpedon.

ERGITIUM, a town of Italy, in that part of Magna Graecia called Apulia, situated on the Appian way, between Teamun N.W. and Sipontum S. E.

ERGOT, in the Mangle, is a hub, like a piece of soft horn, about the bignes of a chefent, placed behind and below the pattern joint, and commonly hidden under the tuft of the feltlock. To different lengths, or take it out, is to cleave it to the quick with an incisor-knife, in order to pull up a blisdder full of water that lies covered with the ergot. This operation is scarcely practised at Paris, but in Holland.
Ergot.

Land is frequently performed upon all four legs, with intent to prevent watery oases and foul ulcers.

Ergot, in Agriculture, is a vegetable disease which affects different sorts of grain, and other crops, swelling itself, according to the author of Phytologia, by the seeds growing out into large horns, having a black appearance without, as in fraude, rye, and in cereals. It very often attacks the rye in France, and occasionally in this country in such seasons as are very moist; the grain in these cases becoming considerably elongated, being either freighted or crooked, containing a black meal along with the white; and is ascribed to have the appearance of being pierced or perforated by insects, which are believed by some to be the cause of the affection. It has frequently other different appellations, such as clausus, or the fur, and horned; and no certain remedy or method of preventing it has, we believe, been yet discovered. See next article.

Ergot, in Medicine, a term originally applied, as we have seen, to a peculiar disease of corn, especially of rye, from the resemblance of the grains thus affected, to the fur of a cock; and, by metonymy, used to denote a disease in the human body, occasioned by taking this disease, or ergot rye as food.

The earliest account of this disease of rye, and of its pernicious influence on the human body, with which we are acquainted, is contained in a letter from M. Dodart to the editor of the Journal de l'Académie des Sciences. (Paris, March 17, 1769.) (See vol. iv. part ii. p. 79.) The facts were communicated a few years before by the physicians and surgeons of Sologne, in which district the disease had been very prevalent. The grains of rye, affected by the ergot, according to M. Dodart, are of a blackish colour externally, but white within, and when dry, they are harder and of a more compact substance than the natural grains, and have no bad taste. They are considerably longer than the other grains, some of them being fourteen or fifteen lines in length, and two in breadth; and even eight or ten of them are sometimes seen in one ear. They are obviously grafted on to the natural grains, and have no bad taste. They are considered as the cause of the disease. These grains were called ergots, prunts, in Sologne; and Gaffinois, where they also were known, they were termed bled corn. In various other places this diseased rye has been called seale corn, or cecale cornum, or cecale cornum, seale luxurians, clausus secalis, mater felaxis, or materkorn, (by the Germans,) &c.

It is stated by Tiffou, on the authority of Haller, that the ergot affects rye only, or two or three other Alpine plants of the grass-kind. (See Philos. Transact. vol. iv. for 1767, p. 112.) A minute description of the ergot was published by C. N. Langius in 1747, the substance of which may be found in the Acta Eruditorum for 1718, p. 309.)

The learned Tiffou, in his letter to Sir George Baker, just referred to, states that there are two other diseases which affect rye and wheat, and which have been confounded with each other, as well as with the ergot, or secale cornum, viz. the rubra, or mildew, and the scabula, bradur, or blight; the former being characterized by the appearance of a reddish yellow powder, of a glutinous nature, adhering to the stalk and head of the corn; and the latter by a blackness and degeneration of the corn. (See Fontana on this subject, and Sir Jof. Banks on the diseases of corn.)

The ergot was particularly observed in rye in wet seasons, and more especially when a wet spring was succeeded by excessive heat. M. Dodart remarks that the bread, which was made of ergot rye, did not differ from ordinary bread in point of taste; that this rye was most particularly pernicious when new; but that its effects were not observed until it had been eaten for a considerable time. M. Noel affirms that it losses its deleterious qualities altogether after being kept a few months in the field. (See a letter in Quenn de la Garenne, feche, p. 407, Paris, 1749.)

And writers in general agree in stating, that the disease, which the ergoted rye induces, is prevalent only at the conclusion of harvest, and cease before the commencement of winter; and that it was chiefly observed among the poor, who were unable to procure wheat or bread in those seasons of humidity and scarcity. (See Muller in Comment. Lips., anno 1752, p. 534, &c.)

The symptoms of the ergot in the human body are described somewhat differently by different writers; but they coincide in representing a dry gangrene, and ultimately death, as the ordinary result of the disease. It commences with a latitude and debility, but with little interruption to the function in general. A degree of torpor in the lower extremities is then observed, accompanied, according to some of the writers, with a sense of prickling, and of the creeping of insects (formicatio) upon the skin; a slight degree of swelling, but without inflammation, ensues, often accompanied by the most agonizing pains, and with a sense of burning heat; soon succeeded by that of extreme cold; and the limb and arms becomes shrivelled, and turns a dark hue, as if dried in fronds, afterwards black and detestable of feeling; in fact the limb dies, or is gangrenous, but in a dry state, which has been compared to that of a mummy. By degrees the dead parts separate from the living, as if they had been destroyed by cautery. In this mutilated condition, deprived of one, sometimes of both legs, more rarely of the hands or arms, some individuals have survived for months, or even years.

Besides this spontaneous gangrene of the limbs, another species of disease has been ascribed to the use of ergoted rye by Hoffmann, Tiffou, and some other writers; but with what justice or propriety may perhaps admit of a question. The disease alluded to was a febrile disease, said to be contagious and malignant, and to be accompanied and principally characterized by various spasmodic and convulsive symptoms, by which, or by a general epilepsy, the patients were frequently carried off. This disease is said to have been epidemic in Helifia, Westphalia, and other parts of Germany, at several different periods, in the 16th and 17th centuries; and a description of it by the professors of the university of Marburg, in the year 1597, is generally referred to, as the first complete account of the disease. But in that account, of which a translation is given by Gregorius Hortisius, no allusion whatever is made to the ergot, or cecal cornum; bad bread is mentioned only among other sorts of crude and unwholesome aliment, to which the disease (occurring in a time of dearth) is there ascribed. The whole of what is said respecting the exciting causes of that epidemic is contained in the compacts of these few lines. "Causes haud affectus quod attinet, ex aggrandizatio relatione sciere liet, quod externa causa commune su in alimento, ad nutrimentum minus idoneo et improportionato, conista, dum pauperes rebus ad vitam necessarium defulti, pause impropre et male coeunt longo tempore, in summa fama urgentia, devorant, interdum atiam poma acerba et acida, fungo loca et similia deglutientes, scire adulitis, immaturi, et artinginentibus ingurgitantes, de quorum depravatis concezione cruditates abortae, &c." (See Greg. Hort. Opera, vol. ii. lib. vii. obf. xxii.) A similar statement, respecting the origin of this epidemic, is given by Bennetius in his chapter, "De febre Magiinae cum Spafimo," probably

L 2
by gangrene of the lower extremities, preceded by pain and some feeling, at Waffisham in Suffolke, is given in the Philo. Trans. vol. iii. part ii. The date of this family, three months after the commencement of the disease, is thus represented: "1. Mary, the mother, dec. 40. The right foot off at the ankle; the left leg mortified, a mere bone, but not off. 2. Mary, dec. 15. One leg off below the knee; the other perfectly sacrificed; but not yet off. 3. Elizabeth, decat 13. Both legs off below the knees. 4. Sarah, decat. 10. One foot off at the ankle. 5. Robert, decat. 8. Both legs off below the knee. 6. Edward, decat 4. Both feet off at the ankles. 7. An infant, four months old, dead." The father also suffered slightly in the fingers. Although the symptoms were exactly those of the ergot, yet, in this case no rye was eaten, nor could any other circumstance in the diet or economy of the family be discovered, to which the gangrene could be attributed. See GANCRE.

ERIACH, in Antiquity, the name of a reconnoitered by the Irish Brehon law, in case of murder, to the friends, or to the child or wife of him that was slain, as a kind of composition between the murderer and his profecius.

ERIAMBO, in Geography, a river of Russia, which runs into the Oby; 70 miles above Obdorokoi.

ERIANTHUS, in Botany, from iepol, an eye, and anthera, a flower, Michaux Fl. Boreali-Amert. v. 1. 64. A genus of grasses established by Michaux, in its character very near Saccharum, but more naturally allied to Andropogon, to which, if the character of that genus were reformed, Michaux himself supposed the present might be referred. Andropogon indeed seems to require a thorough investigation, and probably a division into more than two genera.

ERIBANUM, in Ancient Geography, a town of Italy, in Campania, upon the Volturturn. Polybius.

ERIGBIA, a town of Macedonia, in the country of the Paeithes. Plut.-Alfo, a mountain of Macedonia, in the same country.—Alfo, a town of Asia, in Bithynia.

ERIBOLUM, the port of Nicomedes, a town of Bithynia.

ERIC, king of Denmark, in Biography. There were several princes of this name, though few of them have any claim to notice in this place. Eric the First was a sailor of the name of the "Good." A musician, celebrated for his great skill in the harp, asserted that he could deprive his hearers of their understanding by the powers of his instrument. Eric challenged him to the trial, and in the paroxysm of frenzy into which the performer threw the monarch, he killed four of his guards. Grieved at what he had done, he made all the reconnoiter he was able to the relations of the deceased, and to do penance for the bloody deed, he determined to undertake a pilgrimage to the Holy Land. His subjects remonstrated against his design, but he was not to be dissuaded from his purpose, set out on his journey, and died at the isle of Cyprus. This event took place in the year 1107.

ERIC X., king of Sweden and Norway, as well as of Denmark, the son of Wratifalus VII. duke of Pomerania, was declared successor to the crowns of Denmark and Norway in the year 1288, by his great aunt, queen Margaret; and when, in 1296, she annexed the crown of Sweden to her dominions, Eric was, by the treaty of the "Union of Calmar," declared successor to that state. This celebrated treaty consisted of three articles. 1. That the three kingdoms of Denmark, Sweden, and Norway, should thenceforward have but one king, who should be chosen alternately by each of them, and approved in a general assembly. 2. That the monarch should divide his residence equally between the three
three kingdoms, and appropriate the revenues of each to its particular exigencies. 3. That each kingdom should retain its own laws, customs, senate and privileges; and that the subjects of the one should not be elevated to offices of profit or power in another. These conditions, seemed at first sight, to have been dictated by wisdom, but they proved to be the source of wars that continued to rage during a whole century between the three kingdoms. On the death of the queen in 1412, Eric succeeded without opposition to the three united crowns. He had married the daughter of Henry IV., king of England, with whom he had a large portion of land, and thus might be regarded as one of the most potent kings of his time. Eric was soon involved in a war with the princes of Holstein, which for some time was carried on with doubtful success, but in 1424 the whole of South Jutland, including Sleswick and Gottorp, was adjudged to the Danish crown. This award, which was made by the emperor Sigismund, at Buda, determined Eric upon a pilgrimage to the Holy Land. During the expedition, he was made captive, and obliged to pay a large ransom for his liberty. His absence from home was attended by other evils. From his accession he had displeased the Swedes by refusing to call a general diet for the confirmation of their liberties, which excited much discontent, that at length broke out into open rebellion. In 1435 he met the Swedish diet at Stockholm, and agreed to a full redress of grievances. His promises, however, were of little avail to his people, who, after enduring much from his misconduct, deposed him in 1439, and chose, in his stead, his nephew Christopher of Bavaria. For ten years he made many attempts to regain his situation, but without success. After this he employed himself in compiling a history of Denmark from the public registers, comprising the period from the commencement of the monarchy to 1288. He afterwards repaired to the isle of Rugen, where he died in 1453.

Eric possessed quick natural parts, and was a lover of learning; but he was ambitious, detestable, irrefutable, and innumerable qualities which led him into many difficulties, and which rendered his reign truly disastrous. Univer Hilt.

Eric XIV., king of Sweden, son of Gustavus Vasa, ascended the throne of Sweden in 1560, at the age of twenty-seven, and was possessed of all the accomplishments proper to his elevated station. He spoke the modern languages, danced gracefully, showed animation in all his actions, and was eloquent and polite. But he suffered himself to be hurried away with gusts of passion, which sometimes obliterated every trace of reason, and rendered him furious. His father, who had witnessed these fits of rage, had once formed the design of excluding him from the throne, and of conferring the crown on his second son. For the same reason he refused to permit him to visit England to pay his court to the princes (afterwards queen) Elizabeth; but negotiated the business by means of his ambassador and second son John. Eric, however, almost immediately after his accession, determined to obtain an interview with Elizabeth, and set sail with a large fleet and splendid train, but the vessels being overtaken by a violent storm, were driven back upon his own coast, where he suffered shipwreck, and for a time relinquished his matrimonial project. He next fet propensities of marriage to Mary queen of Scotland, and almost before he could obtain any answer, solicited from the emperor the hand of the princes of Lorraine, daughter of Christian II., with whom he was enamoured by the description of some of his couriers. He received a favourable answer, but in the mean time he had changed his mind in favour of Elizabeth. His political conduct was as capricious as his amours, and involved him in continual quarrels with his neighbours, and a confedervy was formed against him by Muscovy, Poland, Denmark, and Lubeck. His brother John, who had married Catharine, daughter of the king of Poland, fell under his suspicion, and was driven to an open rupture. John was cited to Stockholm, to vindicate his conduct, and refusing to appear, an army was sent into Finland with orders to seize him and his wife, and to bring them to the capital. He was immediately thrown into prison, accompanied by his wife, who voluntarily chose to share in his sufferings. It is said that the king went frequently to the prison with the design of murdering his brother, but that on seeing him he felt his heart so moved with pity, as to prevent him from striking the fatal blow. Sometimes with tears in his eyes he would confide the anguish design which had prompted his visit, and added, "I know that the crown of Sweden is intended for you, and I requite that, when you are in possession of it, you will pardon my errors." This circumstance strongly displays the violence of contending passions in the mind of Eric, and has been brought to prove his infancy.

The early years of his reign were spent in wars chiefly with Denmark, carried on with vigour on the part of Eric, though without any permanent advantage. Domestic troubles at length withdrew his attention from foreign wars, and his capricious conduct destroyed all respect for him in the breasts of his subjects. Disappointed in his matrimonial projects, he entertained a number of concubines, one of whom, a peasant's daughter, gained such an ascendency over him that he married her. He was under the influence of his ministers and domestics of mean rank, who frequently excited his jealousies of the great families. He entertained a particular hatred of the Stures, an illusorius family, descended from the ancient regents. Eric had taken one of them into favour, though he had, on a former occasion, disgraced him, and made him contemptible in the eyes of the populace. He now sent him in the quality of embassador to Stralund, but he became once more the object of the king's abhorrence, who conceived that he was conspiring against his life and crown. The king took pains to convince the states that Sture carried on dangerous intrigues at Stralund, and he fomented witnesses to accuse him of treasonable designs. An infamous favourite, named Peerbon, perfused Eric to extirpate the whole family; sentence of death was accordingly pronounced against those unfortunate men, together with twenty fixed nobs, who were the pretended accomplices of a conspiracy laid to their charge. A public trial was afterwards allowed them, in which the Stures were able to vindicate their cause so completely, and to prove their innocence so undeniably, that the king himself apologized to them for their detention and long imprisonment; nevertheless, in a very short time, he robbed Nia Sture with his own hand. The unfortunate man drew the dagger from his breast, and presented it to the monarch, who, with the most savage barbarity, ordered his guards to accomplish that which he had failed to perform himself. The rest of the prisoners were all cruelly murdered at the same time. No sooner was this bloody scene over than Eric felt the pangs of a wounded conscience. He grew frantic, and, as if pursued by the avenging furies, fled into the woods, where he wandered for many days like a wild beast, refusing to take food or repose. On his return he endeavoured to compensate for his cruelty, by beholding large sums upon the friends and relations of the victims; and by giving up Peerbon to the hands of justice, who was condemned but not executed. Being threatened by the king of Denmark, Eric fled to liberty his brother John, to whom and to his other brother he proposed aligning lands
in Livonia, in lieu of those left them by their father Gut-
tavus. Shortly after he formed a dole of putting them to
death, and of conciliating the friendship of the earl of Man-
covy, by delminating him the wife of duke John, to whom
that prince had paid his addresses before her marriage. His
intentions were discovered in time to defeat the purpose,
and the brothers began to raise forces in their own defence.
Eric made a stand, and an accommodation was effected,
but by the treaty he bound himself to give up Peerlon, his fa-
vourite, who, being put to the torture, confessed a plot
driven by himself and the king, of pillaging Stockholm,
burning part of the ships in the harbour, and proceeding
with the rest loaded with spoil to Narva. The-dukes now
felt themselves justified in breaking the treaty, and they ob-
ligated Eric to capitulate in the citadel. He was put under
confineinent, loyally deposited by the flates, and duke John
elected in his stead. His children were declared incapable
of succession, and himself was condemned to perpetual im-
prisonment. His keepers were appointed from among the
relatives of those whom he had cruelly mafiacred, and who
did not fail to subject him to various inflicts and indignities,
and not unfrequently to the evils of cold and hunger.
After nine years imprisonment, he finished a wretched life
in 1578, in conquence, it was supposed, o f a dose of poi-
son administered by order of his brother John, who dreed
the possibility of his being liberated, and again fet upon the
throne. Eric was not deficient in talents; and he pro-
ferred great personal bravery; under his conduct the Swe-
dish troops repeatedly distinguished themselves in contend-
ing with and overcoming the Danish armies, and it has been
thought thai he would never have submitted to the hard
conditions which Denmark at length imposed on his successor.
(See John.) Univer. Hif.

ERICA, in Botany, synonym of Dioecories, the fame name,
variously corrupted, being applied to the several species of
this genus among the modern Greeks at present, according
to Dr. Sibthorp. See Prod. Fl. Græc. 256, 257.— Heath or
Cliffs and order, Odendria Mungynia. Nat. Ord. Bicornes,
Linn. Ericæ, Jul. Gen. Ch Cal. Perianth of four ovate-oblong, permanent,
upright, often coloured leaves. Car. of one petal, perma-
nent, four-cleft, regular, with an ovate or cylindrical tube,
more or less inflated. Stam. Filaments eight, capillary,
equal, inserted into the receptacle; anthers cloven at the
summit, opening by two pores, by which they laterally
cohene while young. PiJt. Germen superior, roundish;
style thread-shaped, straight, longer than the flarnes; flig-
ma capitata, in four or eight lobes. Peric. Capsule round-
ishes, smaller than the calyx, which covers it, of four cells
and four valves. Seeds numerous, affixed to the co-
olumella. Eff. Ch. Calyx of four leaves. Coroll; four-cleft. Sta-
mens inserted into the receptacle. Anthers with two pores.
Capsule superior, of four cells. Seeds numerous.
OfS. Some species appear to have a double calyx, but
the leaves spoken of by Linnaeus lately effected rather of
the nature of bristles. The shape of the corolla is ex-
tremely different in different species, its tube being in some
globular, in others ovate, in others again cylindrical and
much elongated; sometimes dilated at the orifice, some-
times contracted, in some inless curved. The anthers,
either included within the tube or projecting beyond it, are
in some finely cloven at the top, without any appendage
at the base; in some this latter part bears a pair of bristles,
in others a pair of notched leaflets, termed a crest, which, as
Mr. Salisbury remarks, originate rather from the filament
than from the anther.
This extensive and most elegant genus is confined to Eu-
ropc and the southern part of Africa, the country about the
Cape of Good Hope being, of all others, most abundant in
Heaths, whence the green-houses of Britain are continually
supplied with new species or varieties, to the great profit of
nurseriesmen, some of whom find it worth while to keep a
collector resident there. No Erica is found in America, in
New Holland, nor forsworn in the Torrid Zone. The habi-
t of the whole genus is shrubby, very rarely arborencent, with
small, opposite or whorled, usually narrow, leaves, and
bractated branked flowers, whose colours partake of all the
most exquisite tints of red, purple, yellow or orange, oc-
casionally variegated with green or white. Some are entirely
white, but the anthers are commonly dark brown or pur-
plish.
It is difficult to guess at the number of the real species
of Erica. Willdenow has 273, none of which are duplicates.
Our gardeners reckon about 200, many of which are merely
varieties, but there are several others only known hitherto
in a dried state, and probably not a few yet remain to be
discovered in the wilds of southern Africa.

The greater part blossom with us in the spring, but many
at various feasons. They are for the most part inodorous,
though a few of them are delightfully fragrant. They com-
monly keep well in an herbarium, provided they are dried
suddenly, so as not to throw off their leaves during the
process.

Few good figures of this genus, except of the European
kinds, are found in the older botanical works, but many
appear to great advantage in the more recent works of Ver-
tenat, Windland, Curtis's Botanical Magazine continued
by Dr. Sims, and especially in a folio publication by Mr.
Andrews, entirely devoted to the subject, as well as an oc-
tavo two, equally useful, by the same artist. The most
fuperb of all, however, are two thin fasciculi, published by
Mr. Atton, of coloured plates by Mr. Frederick Bauer,
but unhappily without any descriptions or even specific
characters.

In the scientific definition of the species of Erica much
yet remains to be done. The labours even of Linnaeus and
Thunberg are very far from perfection. Mr. Salisbury,
who has paid much attention to the subject, has given an
arrangement of 246 species, according to their natural affini-
ties, in the sixth volume of the Linnaean Society's Tran-
factions, with often expressive, if not classical, specific char-
acters, but with an unenriched change, and frequent perver-
sion, of names. This writer includes the Linnaean genus
Bleria, like Thunberg, under his Erica, while he excludes
E. vulgaris as a genus, by the name of Calluna, and sepa-
rates a few species (which have an irregular calyx, and
florid fruit, with three cells and three seeds) into another
genus, named, from its large fliguna, Salixis. To him we
are indebted for remarking that the corolla of Erica is per-
manent, which is not the case in Andromeda and Menziesia,
and that the anthers are united laterally to each other by
their back, before they discharge the pollen. He also confi-
ders all true Erica as having the partitions of the fruit originat-
ing from the centre of each valve.

Linnaeus and his followers distribute the species of this
genus into three principal sections by the structure of the
anthers; firstly, anthers aristated or furnished with a pair of
bristles at their base; secondly, anthers erectful, as above de-
scribed; thirdly, anthers simple, or destitute of any of those
appendages. The latter are subdivided into such as have
the anthers included within the corolla, and such as have
them projecting beyond its border. All these fections are
moreover separated into subordinate ones by the situation
of the leaves, whether opposite, or in three, four, or more
rows, or scattered, of which last E. glutinosa is perhaps the
only example. All these characters, however combined,
unfortunately prove but artificial, separating species natu-
really allied to or refembling each other; nor are some of
them, derived from the crusted anthers, or number of leaves,
constant or invariable, even in the same species. Still, as
no natural subdivisions have yet been suggested, we may be
elated of artificial and imperfect ones in fo vast a genus. Mr.
Salisbury, though he disposes the species in order, according
to what he conceives to be their natural affinity or resem-
lance, especially in the form and proportion of the corolla,
has not attempted to define or characterize many subdivi-
sions of the genus. As, however, it is very instructive to con-
template the species of such a genus in this light, and as this
writer's is the only attempt of the kind, we shall give exam-
pies of each of his subdivisions in the order in which he
places them. It is necessary to premise that these subdivi-
sions are considered as having in general no peculiar con-
nection, and that one or more species often come between
two of them, almost equally distant from both and each other.
Thus, in the very beginning, E. scoparia, (E.
coris folio quarto; Chus. Hist. v. 1. 42. f. 3.)—and E.
jejuciliosa, (Sm. Fl. Grac. Sib. t. 353. Prod. v. t. 257.)
fland as distinct from each other, and from three species
immediately following them, among which are abjunctoides
of Linnaeus;—and jetacea, Andrews, t. 62.—Next come
planifolia, Linn. (Pluk. t. 347. f. 1.) and oxyconecefully
of Mr. Salisbury, agreeing in their ovate dilated leaves, in
which are very much like their neighbours. Then again
(rather siccifolia), a new species, each plant separable, as
not immediately allied to any other.—We shall, in separate para-
graphs, mention one or more species of Mr. Salisburys
subdivisions, noticing likewise the separate anomalous
species, and introducing two or three new ones, to the bett
of our judgment, according to their several affinities. Many
still unfelt remain in every collection.

After siccifolia follows an assemblage of eight species.
Among these is E. pabstiana, Linn. Sp. Pl. ed. 2. 506,
pudica of Mr. Salisbury, thus characterized by him—Leaves
of a white; the anthers, crested, inflated.

Flowers terminal. Leaves Linear. Sides of the calyx
double backed. Corolla two lines long, downy on both
sides. Creists short.—Also F. ureocalcaris, Berg. Cap. 207.
Ait. and Bau. Ic. t. 16. (pentaphylla, Linn.)

Then 13 species with little or no affinity to each other,
among which are arcata (E. coris folio prima; Chus. Hist.
v. 1. 41.1.) and Thunbergii, Linn. Suppl. 2. 20. Curt. Mag.
t. 1214. a most beautiful species, conspicuous for its glaucid
white tube and large deep-orange limb, very rare at present
in the gardens.

Next appears a collection of eight, which is
volucella; another of three, including capitata and bru-
maidae (Andr. v. 61.) and a third of 18, among which are
fasciaria, Ait. and Bau. Ic. t. 111, with nigrica of Linn. and
Thunberg, so called from its conspicuous dark anthers,
elegantely contrived with the white corolla and calyx.
This last Mr. Salisbury is pleased to denominate volutecora.
These three subdivisions he indicates as not so distinct or
distinguishable as next.

The following section comprises five new species of Mr.
Salisbury's, named by him fabricii, diastatis, brevifolia,
champhydisora, and felaginifolia. They have all crested in-
cluded anthers, and terminal flowers.

His pinus, with a woolly corolla, stands alone.

Then follow 15 species, mostly Blaria according to Linneus,
having but four flurers; see Blaria. Nor can we much
object to the union of these two genera, except that in fo
valiant a tribe, we may be glad of even so flight a circumstance
as number to make a genus, when there is moreover such a
difference in habit as this very arrangement of Mr. Salisburys
implies. If indeed a few species of Erica, here and there
in their different natural subdivisions, were tetranodal, no-
body would think of separating them for such a reason.

E. nudisora, Linn. Mant. 2. 229. Sm. Plant. Ic. t. 57.
(accompanied by two others) follows. Mr. Salisbury exults
in having discovered its bracteas, which escaped Linneus,
Dryander, and the author of the present article, who in this
instance readily submits to his correction. They are in the
form of two or three excessively minute woolly scales, near
the base of each flower-flake.

The next five, or rather we would say seven, uniting two
of Mr. Salisbury's fections, are bicornus, Linn. Sp. Pl. 502.
Curt. Mag. t. 11, not at all different from carnea, Sp. Pl.
504; (this, according to Dr. Sibthorp, is the genuine
name of Disaccorides, extremely common everywhere in Greece;
mediterranea, Linn. Mant. 2. 229, Curt. Mag. t. 471—
nudisora, Sp. Pl. 503, (Garidel. t. 32), another beautiful
native of the south of Europe, long confounded with
vagans; manipulifolia, Sallb. (Sm. Fl. Grac. Sibth.
t. 352).—vagans, Linn. Mant. 2. 230, (Engl. Bot. t. 3)
common on all the heaths of Cornwall, either with red,
flame-coloured, or white flowers; umbrillata, Linn. Sp. Pl.
501, (Ait. and Bau. Ic. t. 5.), and lately nutans, Wendl.
and. Eric. fdec. 3. 5. The native country of this last we
know not, nor have we seen Wendland's publication.
The rest of this very natural assemblage grow in Europe
only.

-Californica and turgida, Salis. we have not ascertained to
our satisfaction.

Nine species, very naturally allied, having exceeedingly
long anthers, projecting from an elongated tubular corolla, are
placed next. Among these are E. Plakneti; Petiveri;
Bathia, Andr. v. 56; Sebana, Dryand. in Ait. and Bau.
Ic. t. 10; &c. mostly familiar to collectors.

Nine more comprehend imbricata, Linn. Sp. Pl. 503;—
and flexuosa, Andr. Eric. t. 33;—with lenatentis, Linn.
Suppl. 233;—and nolida, Berg. Cap. 64; the last name
is well retained by Mr. Salisbury, in preference to the in-
accurate one, paniculata, given by Linneus.

An assemblage of six more contains the beautiful baccates
Linn. Mant. 2. 233. Curt. Mag. t. 538; a good specimen of
the reft.

Five following ones are supposed to be little, if at all,
related. Among them are the beautiful glarea, Andr. t. 47.
Curt. Mag. t. 580; in the same section with which the
elegans, ibid. t. 966, should be interred. The flowers of the
latter are larger, and differently coloured, but they closely
agree in structure with those of glarea. E. Monimpanis,
Dryand. in Ait. and Bau. Ic. t. 7, (E. Monipanum; Linn.
Sp. Suppl. 2. 53), one of the most magnificent of all, is placed
by Mr. Salisbury, with a sign of incomplete affinity, after
Ic. t. 2, follows alone. Its corolla is of a pale uniform
yellow mixed with green.

Ten species, with a long tubular corolla and short included
anthers, are needlessly, we think, divided into three parcels.
These are mostly handsome flowers, very frequently to be
seen in gardens. Among them are vesiculata, Andr. Ic. t. 12,
which comprehends as a variety his esculenta, t. 46;—discolor of the same author, t. 3;—geminata, Ait. and Bau. t. 13;—abrinia, Linn. Sp. Pl. 506, (E. Pattersonia of Andr. t. 7, and the gardeners), remarkable for its thick-leaved and crowded golden blossoms, as well as its pulpy red-veined;—and concinna, Ait. Hort. Kew. v. 2, 23, first taken by Andrews, t. 64, for abrinia. For this last (concinna) Mr. Salisbury has, in our opinion with advantage, adopted the same paludiflora from Hermann, which indicates its place of growth, and consequently its requisite treatment in a garden.

Then follow 12 fine plants, needlessly, we again presume, divided into two parcels. Among them are tubiflora; curviflora; concinna, Ait. Hort. Kew. v. 2, 22. Ait. and Bau. t. 12; and fordica, Andr. t. 56; with several often confounded with these, (for it is rather an indistinct and perhaps variable tribe,) all which contribute much to adorn our green-houses, and are in general easily cultivated.

E. fusciflorus, Linn. Suppl. 210. Ait. and Bau. t. 6; and E. Maffani, Linn. Suppl. 221. Curt. Mag. t. 356; occupy a feaction by themselves. These are two of the most highly prized of the whole genus. The flowers of both are tipped with green.

The 12 next are, in general, scarcely less splendid, witness phavertiflora, Salisb. (exturgens, Andr. t. 13);—grandiflora, Linn. Suppl. 223. Curt. Mag. t. 189;—and terebriflora, remarkable for its tremendous leaves and the variation of colour in its flowers, instances of which are displayed in Andrews, t. 8, t. 20, and t. 33; likewise in Curt. Mag. t. 402. The deep scarlet is justly the most admired variety. We cannot but think fucis, Andr. t. 57, must be a distinct species.

To these are nearly allied the next five, comprehending feliflora, Linn. Suppl. 222, (fucis, Thunb. Diff. 43, t. 4, Andr. t. 6);—ulviflora, Salisb. called in the gardens gelida, which name aptly expresses the cool aspect of its snow-white corolla tipped with pea-green, and furely ought to have been retained;—and mammofa, Linn. Mant. 2. 234, Andr. t. 58. (abrinia, Schnee. t. 23); of which a beautiful scarlet variety is most common with us, called speciosa in Schneevooght, t. 3, and verticillata by Andrews, t. 21.

Of Mr. Salisbury's bractiflora, a solitary species, we have only seen a doubtful specimen.

E. cornua, Montin Nov. Adv. Upl. v. 2, 292. t. 9, f. 3. Linn. Suppl. 222, stands alone as does Mr. Salisbury's ulviflorina (mammofa, Thunb. Diff. de Ricä, ed. Salisb. 42, t. 21.)

E. australis, Linn. Mant. 2. 231, not uncommon in gardens;—and eliasi, Linn. Sp. Pl. 503. Curt. Mag. t. 384, follow next. These are both European species, and are immediately followed by two others, our elegant English E. Tetrolia, Curt. Lond. fusc. t. 21. Engl. Bot. t. 1014, (a name changed by Mr. Salisbury to unitiformis, fauage-shaped);—and his multicaulis, the fritia of Donn and Willdenow, native of Corsica.

Next comes by itself our common British cinerea, Curt. Lond. fusc. t. 25. Engl. Bot. t. 1015, more happily, but without any need, altered to mutabilis.

E. regermanii, Linn. Mant. 2. 232, only known in the

Linnian herbarium;—and pulchella, Andr. t. 56, occupy two separate sections. A very distinct and natural assemblage of four species next occurs, in which are empetrofilos, Linn. Sp. Pl. 57, known by its oary corolla;—and melchlinara, Salisb. (empetrofilos, Curt. Mag. t. 447.)

The four next seem scarcely to be separable from them, if we may judge by efiaria, Curt. Mant. 2. 22. Andr. t. 53, the only one of the four with which we are acquainted.

A difficult family of seven species, with a hoary habit, and small purplish downy flowers, is placed next, of which tardiflora, Salisb. (ambrosia, Curt. Mag. t. 446;—and birtiflora, Curt. Mag. t. 891, are examples. Both are distinct from, though nearly allied to, the real pultares of Bergias and Linnaeus, as well as from his parviflora.

A somewhat similar tribe, but smooth, and with larger more bell-shaped flowers, contains ten species. Among them is margaritacea, Ait. Hort. Kew. v. 2, 22. Andr. t. 54, very pretty when laden with its pearly blossoms.

E. Bergia, Linn. Mant. 2. 235, remarkable for its reflexed calyx, with two others, come next, and lead instinctively to the following section.

This comprehends pulchiflora, Linn. Sp. Pl. 407;—obliqua, Thunb. Diff. 44. And. and Bau. t. 3;—with phyfodes, Linn. Sp. Pl. 506. Curt. Mag. t. 443; with four more.

E. cornua, Andr. t. 48, stands alone, but between it and phyfodes we would introduce a new species, communicated by Mr. G. Hibbert among the rest of his dried specimens of this genus from the Cape, and by Messrs. Lee and Kennedy from their garden, where it first bloomed in 1809. We would name it E. rofurit. Leaves in four rows, obtuse, recurved, toothed. Anthers simple, included, with long pores. Corolla ovate, viscid. The leaves resemble those of phyfodes, but are more dilatant and recurved. Flowers about the ends of the branches, mostly axillary, long, viscid, fillets, with two or three oblong, pellucid, concave bracteas towards their middle; the flowers droop a little, and are remarkable for their fragrant scent, resembling otar of roses. The calyx-leaves are like the bracteas, and about one-third as long as the corolla, which is of a pale straw-colour, ovate, inflexed, viscid, its segments obtuse, crenate, but little spreading. Stamens about the length of the calyx; their filaments purple at the summit, without any crest or appendages; anthers brown, oblong, with pores two-thirds of their length. German turbinate, furrowed, smooth; style twice as long as the filaments; stigma capitate, dark coloured.

E. pulchella, Salisb. a new species, stands alone, the author being unacquainted with its affinity to any other.

Two others, unknown to us, occupy a section with gyniiflora, Berg. Cap. 58. Ait. and Bau. t. 17. (Andromeda dracoides, Linn. Mant. 2. 259.) This is a beautiful dress, with all the Mtt of an Eri, nor any thing but some occasional luxuriance of number in the parts of the flower to make it an Andromeda.

A very splendid and distinct assemblage follows, of six species, distinguished by their large flowers, with a long tube, always contracted at its mouth, and more or less inflated below. The border is spreading and ornamental. Among these are retorta, Linn. Suppl. 220. Curt. Mag. t. 362, first found at the Cape by Maffon, not by Thunberg;—ampullacea, Curt. Mag. t. 503; and Aitonia, Curt. Mag. t. 429. This last varies a little in the size and hue of its border, but strikingly resembles the Catalonian Jasmine, that we long ago named it Jasminet, nor is there any occasion for the uncoutch precision of Jasminiflora.—We have still some of this tribe, which appear to be nondescript.
Ten species with flowers of a somewhat similar form but smaller, and more slender needle-shaped leaves, constitute the next pair. To this belongs *fugiata*, Linn. Mant. 69, of which there are several elegant varieties, named E. *Hyme*, &c., in the gardens. Alto E. *Mucari*, Andr. t. 1, swelling like the Musty Hyacinth, which it imitates in colour; and *cana*, Linn. Mant. 233, Ait. and Bot. Ic. t. 18.

A tribe more splendid in general, of nine species, succeeds. To these belong *inflata*, Thunb. Diff. 41. t. 2; *ventricosa*, ibid. 27. t. 1. Curt. Mag. t. 320; *lutescens*, Linn. Mant. 234. Andr. t. 119; *articulata*, Linn. Mant. 65. Curt. Mag. t. 423; and *tisifolia*, Ait. and Bot. Ic. t. 19.

Two species, indicated as nearly related to the last, close Mr. Salisbury's list of 246 in all. These are *tetragona*, Thunb. Diff. t. 14. t. 4; and *albus*, Linn. Mant. 231. Curt. Mag. t. 440.

We turn, that those who may have occasion to describe new heaths in future, will, as far as they are competent, keep the above arrangement in view, as they will find it very instructive, however they may differ from Mr. Salisbury in principles of nomenclature. To this subject we have fearlessly found it necessary to advert, except occasionally, and we rather pass over in fleeting what we cannot approve. This botanical rejects all names of perons as applied to the species of any genus Mr. Dryander once began a more useful reformation in such names of Erica, making those which commemorate a writer on the subject end in *ana*, as *Scabia*; those which apply to a collector only, in the generic name, as *Moffia*. The greatest and most correct information is still to be expected from this able botanist, in the intended new edition of Mr. Aiton's *Horbus Kewenfis*, where the genus of Erica must always make a peculiar cfigure. S.

**ERICA.**

*In Gardening*, comprehends plants of the evergreen, flowering, herbby kind; mostly exotics; of which the species most in cultivation, according to Martyn, are: the crofted-leaved heath (E. *tetralix*); the fine-leaved heath (E. *cinerea*); the double-anthered heath (E. *dityma*); the tree heath (E. *ariorea*); the Spanish heath (E. *auritis*); the many-flowered heath (E. *multiflora*); the Mediterranean heath (E. *Mediterranea*); the yellow heath (E. *latca*); the purple-flaked heath (E. *halicaca*); the bladder-flowered heath (E. *mononaca*); the mucous heath (E. *mucosa*); the hairy-flowered heath (E. *voceola*); the marum-leaved heath (E. *mantonii*); the bloody-flowered heath (E. *crenata*); the flander-branched heath (E. *rumentacis*); the blue-flowered heath (E. *perfolia*); the three-flowered heath (E. *trifora*); the arbutus-flowered heath (E. *baccacus*); the flander-twigged heath (E. *corollata*); the crow berry-leaved heath (E. *petriofila*); the woolly heath (E. *capitata*); the tube-flowered heath (E. *lubri*); the long-tubed yellow heath (E. *conficcia*); the honeywort-flowered heath (E. *cerinioidea*); the tufted-flowered heath (E. *comosa*); the tall downy heath (E. *Maffoni*); the smooth-twigged pencil-flowered heath (E. *Phlox*); the downy twinged pencil-flowered heath (E. *Potevri*); the early-flowered dwarf heath (E. *herbacast*); and the great flowered heath (E. *grandiflora*). But there are many other species equally deserving of cultivation.

Concerning the first of these species, it is observed by the editor of Miller's dictionary, that it is not inferior to many of the foreign heaths in the beauty and delicacy of its flowers. It is distinguished from the other British heaths not only by the flowers growing in a kind of pendulous cluster on the tops of the stakes, but by the leaves growing in fours, and forming a sort of crosst.

The whole of the different species of heaths which are mentioned above, are plants of considerable beauty and elegance, but mosty tender and delicate in their habits of growth.

**Method of Culture.**—These very elegant plants must be treated in different methods, according to their nature and habits of growth.

The first three British forts are capable of being propagated by fowing the seeds either in the places where they are to remain, or in pots filled with peaty earth, in either the autumn or spring seasons; but this is a tedious method of practice. The better method is, therefore, to take them up from the places where they grow naturally, in the early autumn, with good balls of earth about their roots, planting them again immediately where they are to grow and remain for ornament.

They are found to succeed best where the soil is of the peaty or moory kind, and where it has not been enriched by manure; and as they protrude their roots chiefly near the top, it should be as little dug about them as possible, the surface only being kept clean and free from rubbish.

And the four following forts may be increased in the same manner as the above; but the best practice is by layers, cuttings, or slips, which should be laid down or planted out in pots filled with boggy earth either in the early spring or the latter end of summer, plunging them in a moderate hot-bed, and giving them proper shade and water. When they have taken full root, they should be carefully removed with balls of earth about them into separate pots, being replaced in the hot-bed till they become well established, when they will be capable of bearing the open air in mild weather when the weather is suitable.

All the other species may be increased either by cuttings or layers, but most of them by the former. The cuttings should be made from the best young shoots, and be planted in the spring season in pots filled with a composition of light boggy and loamy earth, being placed in the hot-bed, and covered with bell-glasses, and dusted shaded from the sun, flight waterings being given when necessary; the layers are laid down in the autumn, being managed in the same way as the cuttings. When the plants have become perfectly rooted, they should be removed into separate pots filled with the same sort of mould, being then put in the dry flore or greenhouse, where some of them require, to be constantly placed.

But the ninth, twentieth, and twenty-sixth species must be raised by layers, as they have not yet been increased by planting their cuttings in the manner directed above.

Where seeds are made use of in producing these plants, they should be sown in pots filled with the above sort of earth in the early spring, and plunged in the hot-bed of the flore. When the plants have acquired a few inches growth, they should be removed into single pots with a little earth about their roots, and be replunged in the hot-bed of the flore, being preferred in it, or the warmest part of the greenhouse, during the winter season, and whenever the weather is bad.

The first three forts afford an agreeable variety in the borders and clumps, as they continue long in flower. The four following kinds are likewise hardy, and afford variety among other potted plants in the open air during the summer months.

All the other species are more tender, but produce as agreeable an effect among the flore and greenhouse collection, from the great beauty and continuance of the flowers in many of the forts.

*ERICA marina*, *sea-heath*, a name given by many authors.

Vol. XIII.
to a very beautiful zoophyte of the fucus kind, called by Mr. Ray and some others the fucus ericae folio.

Erica, in botany, a name given by Gazz and some others, as the interpretation of the chilchis Arilbott, that is, as the name of the common herring.

ERICE, in Botany, the third natural order in the ninth class of the fyltem of Jullian, so named from the genus Erica which makes a part of it. This order consists of such dioxylenous monopetalous plants as have perigynous flaments, and the following distinguishing characters. Calyx of one leaf, permanent, sometimes superior, more frequently inferior and deeply divided. Corolla of one petal, sometimes deeply divided, inserted either into the upper part of the calyx, more commonly into its lower part, or into a gland at its base; mostly withering and permanent. Stem of a definite number, distinct, inserted into the same part, or rarely originating from the lower part of the corolla; anthers molly with two horns at the base. Germin superior, or rarely inferior; stile solitary; stigma generally simple. Fruit either superior or inferior, with many cells and many seeds, either pulpy, or more generally dry with many valves, fixed by their bases to the central axis, the partitions originating from the middle of each valve. Seeds, generally minute. Stem shrubby, of a more or less elevation, or herbaceous. Leaves alternate, or opposite, or whorled.

This order is in a great measure analogous to the Linnean Bisotenes, exclusive of the Rhododendra of Jullian, which differ from his Erica chiefly in having the partitions of the capsule formed of the inflexed margins of its valves, and not originating longitudinally from their centre. Ventenat retains the name of Bisotenes for the Erices.

The Erices are divided by Jullian into two sections, 1. Germin superior, consisting of Curyllia, Lium, (which being of the same genus as Itea, and having the capsule of the Rhododendron, it is to be removed thither); Bleria; Erica; Andromeda; Arbutus; Clethra; Pyrola; Epigea (removed to Rhododendron); Epacris (omitted by Ventenat); Gaultheria; and Brofse (Likewise omitted by Ventenat, a very uncertain plant). 2. Germin wholly or partly inferior, Argophyllum, Forst. and Lium. fil. Mefid, Forst; and Vaccinium.

A third section contains two genera allied to Erica, or supposed to be fo, Empetrum and Hufonia.

ERICALE, from ερις, the spring, and κάλους, beautiful, a name given by Renesm in his Specimen Hill. Plant. 75. t. 68. to the Gentiana vernus, a most elegant vernal plant. Linneus erroneously prints it Ericula.

ERICERUM, a name given by Actins and other authors to a fort of collylum, used in weakknees of the eyes, in which the herb erica or heath was an ingredient.

ERICERA, in Geography, a town of Portugal, in the province of Eftremadura, on the sea-coast; 20 miles N. W. of Lisbon.

ERICHTHONIUS, in Astronomy, a constellation, the same as Auriga.

ERICOLA, in Botany. See Ericale.

ERICU, a name given in Rhedus Hortus Malabartius, v. 2. $3. to the Ajilegias gigantea. It is corrupted from the Sanscrit name Rocys.

ERICUSA, in Ancient Geography, one of the seven Eolian islands, now Aitica.

ERIDANUS, in Astronomy, a constellation of the southern hemisphere, in form of a river.

The stars in the constellation Eridanus, in Ptolemy's Catalogue, are 341 in Tycho's, 19; in the British Catalogue, 84. See Constellation.

ERIDANUS, in Ancient Geography, a river of Italy, in Cilipine Gaul, now the Po, which see. Virgil describes it as the largest river of Italy, calling it the king of rivers:

"Fluviorum rex Eridanus."
the lake, and being composed of sand, is convenient for
hauling boats upon it, when the lake is too rough for fail-
ing and rowing. Towards the south side, however, on both
sides of the lake, it would be impossible to land, on account
of the perpendicular height of the rocks. There is a great
deficiency of good harbours along the shores of this lake:
on its northern side there are but two places which afford
shelter to vessels drawing more than seven feet water, viz.
Port Long Point, and Point Ahinean, and these afford only a
partial shelter. On the southern shore, the first harbour
you come to in going from fort Erie is that of Presqu’tel, 
which is situated at the distance from that fort of about six
miles, and where vessels drawing eight feet water may ride
in perfect safety. Beyond this, about midway between the
eastern and western extremities of the lake, there is
another harbour, capable of containing small vessels at the
mouth of Cayaghara river, and another at the mouth of
Sandusky river, which falls into the lake within the N.W.
territory of the States. British ships seldom use these har-
bours, but trade almost solely between fort Erie and Det-
roit river, and in case of contrary winds, they return to
fort Erie, if bound to Detroit river; or to some of the
points amidst the clusters of islands situated towards the
western extremity of the lake, if bound to fort Erie.

The navigation of this lake is very uncertain; and vessels
are often detained, at a considerable expense to passengers,
in some of the harbours. Lakes Huron and Michigan afford
communication with lake Erie, by vessels of eight feet
draught. There are fortes into the waters of this lake
from the Wabash, Great Miami, Maugan, and Alleg
gany, from two to sixteen miles. The islands at the west-
ern end of the lake, of various sizes, lie very close to each
other, and exhibit a very pleasing scenery; the largest of
them are not more than fourteen miles in circumference,
and many of them are very small. The largest islands pro-
duce a variety of fine timber, amongst which are found
oaks, beech, and red cedars, which latter, being
large, are sent for even from the Britich settlements on De-
troit river, at a distance of forty miles. Lake Erie has
a great variety of fine fish, such as flurgeon, eel, white fish,
trot, perch, &c. Amongst the woods are found racoons
and squirrels, and also bears, in the winter season, when the
lake is frozen between the main land and the islands.
All the islands are dreadfully infested with rapids, and
on some of them raffles are so numerous, that in the
height of summer it is dangerous to land. Two kinds
of raffles are found in this part of the country; the
one is of a deep brown colour, clouded with yellow, about
thirty inches in length, which frequents marshes and low
meadows, and does great mischief among cattle: the other
is of a greenish yellow colour, clouded with brown,
and nearly twice the size of the former. Many different
kinds of rapids, besides raffles, are found on the
islands in lake Erie. The ponds and marshes in the interior
parts of these islands abound with ducks and other wild
fowl, and the shores swarm with gulls; among the woods
are a few small birds, remarkable neither for their song nor
plumage. Weld’s Travels, vol. ii.

Erie, a county of Pennsylvania, on the south side of
lake Erie, containing 639,420 acres, and 1468 inhabitants.
Its chief town is Erie.

Erieux, a river of France, which runs into the
Rhone, at Beaucaillou.

Eriis, a name given to canary birds when about two
years old. See Canary Bird.

Erigena, John Scotus, in Biography, who flourished
in the ninth century, was probably born in Argyshire, Scot-
land, though some writers make him a native of Hereford-
shire, in England, and others suppute his birth-place to be
Ireland. He possessed an ardent thirst for literature, and
spared no pains in rendering himself accomplished in the
learning of the East, and from the extent of his erudition
he obtained the name of “Scotus the Wise.” He studied
several years at Athens, and became very conversant in Greek
philosophy. Upon his return, he accepted an invitation from
Charles the Bald of France, and lived for several years in
habits of intimacy and familiarity with his royal patron, who
allied him to him the direction of the university of Paris.
To the sovereign he was not only an instructor in literature
and science, but an adviser in the affairs of government.
The high rank which he obtained excited much jealousy,
particularly among the bigotted priests, who accused him of
maintaining heretical opinions. In the year 824, the Greek
emperor Michael the Stammerer, sent to the Western em-
peror, Lewis the Pious, a copy of the treatises of the sup-
pose Dionysius the Areopagite, which had long been held
in great veneration among the Greek Chrristians. Dionysius
was supposed to be the first Christian teacher in France,
and, on that account, the work in question was deemed of
great value, and the king, who was unable to read
the original Greek, employed Erigena to translate it into the
Latin language. Unfortunately this was performed with-
out licence from the pope, who, when he found the transla-
tion eagerly read, inquired that the French king should not
only banish Erigena from Paris, but should send him to Rome.
Charles refused to act in this ungenerous manner, neverthe-
less, it was deemed advisable, that Erigena should leave
the capital of France, and in a short time after he took refuge
in England. This translation of Dionysius’s treatises is
said to have caused the revival of the knowledge of the
Alexandrian Platonism in the West, and to have laid the
foundation of the mystical system of theology which afterwards
so generally prevailed. Of the original works of Eri-
gen, the principal was his treatise “On the Division of Na-
ture, or the Nature of Things,” which was published from
the author’s MS. by Dr. Thomas Gale, at Oxford, in 1681,
under the title of “Joannis Scoti Erigenae de Divin natural
Nature, Libri quinque, dui defiderati.” Erigena was employed
by our great king Alfred in the restoration of learning at
Oxford, where he was appointed professor of mathematics
and astronomy. In this situation he remained only about
three years, when some differences that took place in the
university obliged him to retire to the abbey of Malmsbury
in Wiltsire, where he opened a school. Here, it is affe-
tered, by many writers, that he was murdered by his own scholars,
either on account of his harshness and undue severity; or at
the inclination of the monks, who hated Erigena as being a
heretic, and much more learned than themselves. The par-
ticular time and place of his death have been the subjeets of
some dispute. Certain writers contend that his death took
place about the year 864 or 865, and others, who are ge-
erally followed, make it in 883. Some say he died in Eng-
land; and others, among whom is Dr. Henry, think that it
happened in France. He was certainly a very extraordinary
man for the times in which he lived, and after his decease
his name was, for a considerable time, to be found in the list
of the saints of the Roman church, till it was struck out
of the calendar, by Bonitus, on account of the heterodoxy
Enfield’s Hist. Phil.

Erigenae, a river of France, which runs into the
Rhone at Beauchastel.

Erigeron, in Botany, one of the ancient Greeks,
from εριγερον, an old man, because it is hoary
3 M 2

Pl.
universally appropriated to an animal, changed it to Hydnum.

ERINACEUS, in Zoology, a genus of the Feræ order, the hedge-hog of English authors. This tribe is distinguished principally by the teeth. The fore-teeth in the upper jaw are two, and dilatant, in the lower two approximate; the tusks in the upper jaw five each file, in the lower three; grinders four each side above and beneath; body above covered with spines.

Species.

The common hedge-hog, or as it is sometimes called erroneously the European hedge-hog, appears to be a native of the temperate parts of Asia, and to be found in Madagascar as well as Europe. It lives in thickets and bushes, forming a nest of moss, grafts, or leaves, of large size. When disturbed it rolls itself up into a globular form, prefenting on every part a formidable armament of spines, and this is indeed its principal means of defence; upon being immersed in cold water it expands, and swins with perfect facility. During the winter it is supposed to remain in a state of torpor.

Vegetables of various kinds, as the roots of plants, or fruits, reptiles, small birds and insects, constitute the principal food of this animal; the Calamine tame and keep it in their dwellings like the cat; and in this respect they become useful, as they destroy the cockroaches, and other obnoxious insects. They produce from three to five young at a birth. The flesh is very indifferent, yet is spoken of among the old writers as an article of food, with injunctions for roasting or otherwise preparing it for the table.

The hedge-hog is considered as an inoffensive animal, notwithstanding the vulgar supposition, that it feeds on cattle by night, and occasions ulcerations in those tender parts with the irritation of their prickles. The animal has a musky smell. Length ten inches.

Length eight inches. Inhabits South America. The head is thick, short; spines cumbrous tinged with yellow; hair soft, whitish, medullated over the eyes; tail short; claws long and crooked. Described on the authority of Seba.

Inhabits the lower parts of the Volga and Ural and extends from thence to the eastern parts beyond the lake Baikal. Its form resembles that of the common hedge-hog, but is smaller, the eyes larger, whiskers disposed in four rows; the feet longer, more slender; tail shorter, coma, ununcted, and nearly bared. The female is said to breed twice a year, and to produce from four to seven each time.

Extremely allied in its general appearance to the porcupine, and referred to the hedge-hog tribe chiefly on account of the number and arrangement of the teeth. Its size is supposed to be equal to that of the common porcupine. This animal is said to inhabit America, and to produce the precious stone called Reda del Porco, the imaginary virtues of which are so highly extolled in the old materia medica.

SETOUS. Ears shorter; top and hind head and shoulders beftet with spines; tail very short and spiny. Erinacea.
E. ERI

Native of India and Madagascar; length six inches; wallows in the mine, and granules like a hog, and forms burrows. Remains torpid for fixed months, during which the hair falls off.

CAUDATUS. No tail; stout very long and acute. Schreber. Tuarez, et le jeune tuarez, Buff. Madagascar Hedge-bug.

Inhabit India and Madagascar. In habit resembles the former, but is larger, measuring in length eight inches. The mouth and eyes are small; ears rounded and longer than the tetragus; the spine black, and covering the whole back and riles; hair yellowish and feet tawny.

The two last mentioned animals are considered by Pennant as the same species, on the premission that the former is the adult flate, the other in a less advanced stage of growth. Dr. Shaw seems inclined to adopt this supposition. There, nevertheless, appears in our mind no plausible reason for such conjecture, unless the descriptions be defective in the most essential particular; for, if one has a tail and the other none, they must be distinct. That the animal described by Buffon had not obtained its full growth is rendered extremely probable by the explanation afforded, but the production of a tail cannot be supposed to depend on the age of the animal. The taneers feeds on fruits, and remains torpid during about three months of the year.

ERINUS, in Ancient Geography, a people of Asiatic Sarmatia. Ptolemy.

ERINDES, a river of Asia, towards Hyrcania or Sparta, according to Tacticus.

ERINAEUS, one of the four cities of Doris, situate on the most northern verge of the kingdom, near the foot of the hills which part Doris from Macedonia. Alfo, a port of the sea of the Peloponnesus, in Achaia, between Aegium and the promontory Rhium. Phily. Alfo, a river of Sicily, according to Thucydides, called Orinos by Ptolemy.

ERINGO. See Eryngi.

ERINNA, in Biography, a Greek poet, mentioned by different writers as a native of Lefbos, of Teos, of Rhodes, and of Tenos in Laconia, is supposed to have been contemporary with Sappho, about the year 600 B.C. but she is placed by the Chronicle of Eusebius 250 years later. She was celebrated in ancient Greece, and several epigrams were written upon her, one of which speaks of her as inferior to Sappho in lyrics, and superior in hexameters. Some fragments are extant in her name, which are inserted in the "Carmina Novem Poetarum Flynnianum." Autw. 1565. Volf, Poet, Grece.

ERINUS, in Botany, a name adopted by Linnaeus from Dioscorides, the etymology of which is unknown. Neither is his "Eris" the same with the Linnaean plant, but rather, we presume to think, something which has hitherto eluded the fancy of commentators. His description accords in some points with Sambucus Eryngii. — Linn. Gen. 370; Schult. 4. 7. Willd. Sp. Pl. v. 3. 223. Mart. Dict. Hist. v. 2. tables. 102. Gen. 1. 55.—Cliffs and order, Diodynema Angioptera. Nat. Ord. Phragmata. Linn. Pediculare, Jaff.

Gen. Ch. Cal. Perianth in five deep, lanceolate, erect, nearly equal, permanent segments. Cor. of one petal, unequal; tube cylindrical, somewhat ovate, the length of the calyx, reflexed; limb flat, in five deli, nearly equal, inervertly heart-shaped segments. Stam. Filaments four, very short, within the tube of the corolla; two of them (the uppermost) a little longer than the others; anthers small. Pist. Germin inferior, ovate; style very short; stigma capitate. Peric. Capsule ovate, invested with the calyx, of two cells and two valves, the latter cloven half-way down when ripe; partition double. Seeds numerous, small. Recept. compressed.

E. Ch. Calyx of five leaves. Limb of the corolla in five, nearly equal, notched segments. Capsule of two cells. Seeds numerous.

Obit. By an unaccountable error in the Eff. Char. in all the editions of Linnaeus the upper lip is said to be very short and reflexed; though the whole limb of the corolla is truly described as (nearly) equally five-efect. Willdenow copies this, though the Hortus Kewensis had corrected it.

E. alpina is the best-known species. "Flowers raceme. Leaves spatulate." Linn. Sp. Pl. 878. Curt. Mag. t. 130. Native of the Alps of Switzerland, and the Pyrenean mountains, flowering in the middle of summer. It forms tufts, with several dwarf stems, bearing numerous purple flowers, and is a very ornamental plant for rock-work, requiring protection against severe frost and excessive moisture, like most alpine rock plants. It is increased by parting the roots, or by seed.

E. africana. "Flowers axillary, fertile. Leaves lanceolate, slightly toothed." Linn. Sp. Pl. 878. Lycine da villosa, formis ex alis floriferis, & c. Burm. Afr. t. 50. f. 1.) Native of the Cape of Good Hope. This has a taller, more branched stem, more oblong leaves, and axillary flowers, of what colour we know not, with a very long flender curved tube. It has not yet appeared in our gardens.

E. capensis. "Flowers spicate. Leaves linear, toothed." Linn. Mant. 272, excluding Burman's synonym. Gathered by Sparmann in fancy ground at the Cape of Good Hope. This is also a stranger to our gardens. The flowers are said to be yellow and very fragrant. In the dried plant they are black. The tube is an inch and half long; the segments of the limb deeply cloven, the lobes dilated, obtuse and divaricated.

E. triflora. "Leaves oblong, cut, toothed. Segments of the limb slightly cloven." Linn Suppl. 687. Found by Thunberg at the Cape. The flowers are said to be sweet-smelling, and of a dull colour.

E. porranus and Isatia us of Linnaeus, are both nearly related to Verbena Ambulata, and the former at least seems to be the very same species.

Gen. Ch. Umbel simple, of many short rays. Involute of many lanceolate, equal, undivided, coloured leaves, longer than the rays of the umbel, and densely clothed with wool. Cal. Perianth superior, in five deep, equal, concave, sometimes coloured, externally hairy, permanent leaves. Cor. none. Stam. Filaments five, as long as the calyx, equal, awl-shaped; anthers roundish, of two lobes. Pist. Germin inferior, obovate, compressed, furrowed, very hairy; styles two, capillary, spreading, longer than the calyx; stigmas simple. Peric. Fruit ovate, obtuse, compressed, furrowed, hairy, crowned with the calyx and stipes. Seed solitary?

E. Ch. Umbel simple. Involutum of many lanceolate,
late, equal, woolly, coloured leaves, longer than the unbelied. Fruit compressed, hairy. Petals none. Many flowers abortive.

This New Holland genus bears the most striking analogy to the European Abrantia, from which it differs in its woolly, not smooth, involucrum, but more essentially in having no petals, and in its hairy, not mucrinated, fruit. M. Labillardiere had, unknown to us, previously named it Abrantia, but that name being already long ago occupied in mineralogy, is untenable in botany.

The only species known are two.

1. E. major. Sm. Exot. Bot. v. 2. 57. t. 78. (Abrantia helianthus; Labill. Nov. Holl. 67. t. 92.) Segments of the leaves bluntish, flat, woolly on both sides. Flower-flakes somewhat coriaceous. — Native of the fancy country about Port Jackson, New South Wales, as well as of the west coast of New Holland, flowering in October. The root appears to be annual; it is woody and branching. Stem solitary, about two feet high, erect, leafy, round, woolly, but little branched except at the upper part, where the long flower-flakes, more or less numerous, grow in a coriaceous form. Leaves alternate, flaked, three-cleft, lobed and pinnatifid; their segments spreading, linear, entire, flat, a little dilated upward, and blunft; clothed with denfif wool, whitish beneath. Stipulas none. Flowers terminal, large and ornamental, all over white with a green or rusous tinge. Involucrum of eight or ten spreading leaves, each an inch or more in length, peculiarly soft and pliable, like velvet. Flowers very numerous, forming a convex compact fort of disk, those of the circumference males. Calyx white, so as to resemble petals. No aromatic or pungent flavour is perceptible in any part of the plant.

2. E. minor. Sm. Exot. Bot. v. 2. 39. t. 79. "Segments of the leaves acute, revolute; smoothish above; filly beneath. Flower-flakes scattered." — Found near Port Jackson, in a sandy or gravelly soil, flowering in March. — Much smaller than the last, and bearing the same analogy to it that Abrantia major, Sm. Exot. Bot. t. 77. does to the major, t. 76. — Root woody, branched, perhaps perennial. Stem a foot or two high, much branched, leafy, round, clothed with close-preflled hairs. Leaves on long foot-flakes, divided into three or five deep, spreading, dilated, acute, revolute, pinnatifid or three-cleft lobes; green, smooth, or slightly hairy, above; densely clothed with white silky hairs beneath. Flowers on long, solitary, terminal, naked flanks, scarcely a quarter so large as in the other. Calyx green, and not coloured. Involucrum almost naked underneath; hairy, somewhat silky, white or reddish above. This species is likewise without any peculiar flavour.

Gen. Ch. Common calyx globose, depressed, imbricated, many-flowered; its scales lanceolate or obvate, obtuse, scarious, equal, permanent; petals inferior, of two or three obtuse, permanent, mucrinated leaves. Male flowers several, in the middle of the disk. Cor. funnel-shaped; tube about as long as the calyx; limb in two deep, obtuse, mucrinated lobes. Stam. Filaments three or four, equal, inserted into the tube of the corolla, and rather longer than the limb; anthers vertical, roundish, of two lobes. Pet. German obsolete; style capillary, cloven; stigmas blunt. Female flowers several, in the circumference, between the calyx-scales. Cor. inferior, of two oblong, concave, obtuse petals, mucrinated at the upper part externally. Stam. none. Pet. German superior, of two or three lobes; style thread-shaped, shorter than the corolla, cloven; stigmas two or three, acute. Pericap. Roundish, of two or three lobes, with as many cells and valves. Seeds solitary.

Eff. Ch. Common calyx of many leaves, many-flowered; perianth superior, of two or three leaves. Male flowers central. Corolla of one petal, cloven. Female f. in the margin. Corolla of two petals. Stigmas two or three. Capsule of two or three cells. Seeds solitary.

The characters of this genus were so ill defined in the works of Linnaeus, that Hudson conceived our British Eriocaulus, confounded by Linnaeus with his detegulare, might be a distinct genus, and he therefore called it Nafnythia, in honour of Sir James Nafnyth, baronet; see Fl. Angl. ed. 2. 414. As however no genus can be more natural and distinct than Eriocaulus, and the fault appears to have been entirely in the descriptions of authors, its characters are now reformed. The above description is made from the only British species, E. septangulare, With. 184. Sm. Fl. Brit. 1010. Engl. Bot. t. 733. — "Stalk with seven angles. Leaves sharp-pointed, with an internal network of cells. Male flowers with four flaments." It grows in several lakes in the isle of Skye very abundantly, and was found in September 1801 by Dr. Wade, decorating the edges of all the lakes in Cumnamara, in the county of Galway, Ireland. The root is perennial, consisting of abundance of simple, white, shining fibres, composed internally of a series of cells, frequently interrupted by transverse partitions, which is the general structure of the whole herb. Stalk a spars high, solitary, upright, simple, naked, twilled, with seven angles and as many intermediate furrows, smooth, (so that in this instance the generic name does not well apply,) invested with a tubular sheath at the base. Leaves numerous, radical, sword-shaped, smooth, taper-pointed, about two inches long. Head of flowers terminal, solitary, hemispherical, about three lines broad, prettily variegated with dark purple and white, the calyx and anthers being of the former colour, as well as a few spots on the white corolla. The snow-white club-shaped protuberances, with which the extreme parts of the calyx and corolla are mucrinated, give the whole an elegant festalhy aspect.

Linnaeus knew about five species of Eriocaulus, but very imperfectly, and he was cautious of adopting Dr. Hope's accurate generic description of the above plant, published in the Philosophical Transactions, v. 59. 243. t. 12, left it should not accord with every species. As far as subsequent examination of the federal exotic ones has gone, it is found to confirm the account here given. Willdenow enumerates eight species in all; Lamarck describes 12 in his Encyclopedie, v. 3. 274—277, and figures 4, rather imperfectly, in his t. 5. This last author is, nevertheless, the best we have on the subject, though Willdenow heistated to follow him, and Vahl, in his Sp. Pl. v. 2. 210, removes his E. spadiceum, perhaps rightly enough, to Stelina.

Authors are very much confounded in their accounts of the native countries of several species. The genus was gathered by Thierry de Menouville in Hispaniola, not by Cobbmeron in the ile de Bourbon. E. spadiceum of the same author was found by Smeathman at Sierra Leone, from whom we have it in plenty, and whom Lamarck rightly quotes; yet Vahl mentions St. Domingo (Hispaniola) a its native country, on the authority of Lamarck's herbarium, without naming Smeathman.

The following 6 species we believe are hitherto entirely nondefcript. They will probably appear, with others, more fully illustrated hereafter from the pen of Mr. R. Brown.
Brown, when he has time to resume the study of this genus, of which we believe he has ascertained about 30 species. In the mean while, to secure his specific names and our own thus far, we shall attempt definitions of what we have determined from actual observation.

E. pygmeum, Soland. MSS.—Stalks aggregate, five-pointed. Leaves and sheaths smooth, of equal length. Head globoso. Calyx-styles obovate, pointed. Native of New Holland. Herb. Linn. fil. The flanks are about two inches high. Leaves about half an inch long, being rather shorter than the sheaths of the flanks, which is unusual.

Heads brownish.

E. scorpioidum.—Stalks aggregate, five-pointed. Leaves and sheaths smooth, of equal length. Head globoso. Calyx-styles obovate, acute. Communicated from New South Wales in 1792, by John White, M. D.—Stalks five or six inches high. Heads of a flivary white, scarcely so large as a pea, being about twice as big as the former.

E. fruticosum.—Stalk nearly solitary, five-pointed. Leaves and sheaths of equal length, densely woolly at the base. Head hemispherical. Calyx-styles obovate, acute. Gathered by Sonnerat at the Île de Bourbon. Stalks sometimes above a span high. Leaves spreading, involute when dry, smooth, or nearly so, but enveloped at the base, as well as the sheath of the flanks, by a dense integument of silky wool. Head much like that of E. septangulare.

E. laetiflorum.—Stalks somewhat aggregate, cylindric, furrowed. Leaves smooth, taller than the items. Head hemispherical. Outer calyx-styles rounded, obtuse; inner lanceolate, acute.—Gathered at Sierra Leone by Dr. Afzelius. The long and broad flat leaves, a span in length, are remarkable. The sheaths are also large, about half as long as the flanks. Head smaller than in the last, variegated with brown and white.

We have in our defcriptions substituted the word flak (scapus or pedunculus) for item, as being more correct. S. ERIOCEPHALUS, so named by Dillenius from scapus, wool, and e per, the head, in allusion to the remarkably woolly appearance, singular in the tribe to which it belongs, which this plant makes when in seed. Linn. Gen. 450. Schreb. 586. Willd. Sp. Pl. v. 3. 2384. Mart. Mill. Dict. v. 2. Iuf. 186. Gärtn. t. 168.—Cliffs and order, Syngenesia Polyanum-nectararia. Nat. Ord. Compositae nuncupatæ. Linn. Cor. Pseudore, Juff.

Gen. Ch. Common calyx erect, of ten ovate, equal, colori sheats; the five outermost keeled, the inner ones flat. Cor. compound, radiated; the perfect florets doubly numerous, confronting the disk; female ones five, making the radius; that of the perfect florets funnel-shaped, with a five-creep spreading border; of the radius flat, involvently heart-shaped, with three terminal lobes. Stem in the perfect florets, Filaments five, capillary, very short; stamens united in a cylindrical tube. Pijf, in the perfect florets, Germain oblong; style simple; stigma clavo, acute; in the female ones, Germain ovate, naked; style simple; stigma pointed, inflexed. Pericarp none, except the scarcely altered calyx. Seeds in the disk none; in the radius obovate, naked. Receptacle, flat, woolly, and the elongated wool which separates the two rows of calyx-styles, is moreover introduced between the perfect and female florets.

Obi. A small compressed body adheres to the bafe of eachscale of the calyx.

The species are two, both shrubs natives of the Cape of Good Hope, and to be met with, though rarely, in our green-houses.

1. E. africenua. Linn. Sp. Pl. 1310. Ait. Hort. Kew. v. 3. 278. Curtis Mag. t. 833. (E. tempervirens, folis faciulatus & digitatis; Dill. Ethn. v. 1. 132. t. 150. f. 134.)—Leaves lobed or undivided. Flowers corymbose. The leaves are faciulata, flat, and set anodially, as in the former. Flowers in long clusters or rather spires. Wool of the receptacle very long.—Dr. Sims in Curt. Mag. justly refers Gaertnner’s synonym to the foregoing species, not to this.

Gen. Ch. Cal. Perianth inferior, in fix deep, obovate, coloured, spreading segments, of which the three innermost are somewhat the largest. Cor. none. Stam. Filaments nine, occasionally eight or ten, rather longer than the calyx and inserted into its base, hairy in their lower part; anthers roundish, veritable, incumbent. Pijf. Germain inferior, oblong, triangular, with three furrows; illes three, the length of the flameus; filaments simple, obtuse. Pericarp triangular, membranous, not burting. Seed solitary, triangular, flat at each end, black, with a snow-white, small, farinaceous albumen, and large flat cotyledons. Eff. Ch. Calyx inferior, coloured, in fix deep segments, permanent. Capsule membranous. Seed solitary, triangular. Stigmas simple.

This genus in its parts of fruitification very nearly approaches Polygonum, but the above characters are sufficient to distinguish it, and the habit, more especially the absence of Hippeastrum, renders it totally distinct. We are possessed of three species, one of which only has been hitherto mentioned.

1. E. tomentosum. Michaux as above, t. 274. (Chryophleum? oppolitifolium; Walter Fl. Carolin. 140.) Calyx woolly, item-leaves whorled, seflate.—We have been acquainted with this plant ever since November, 1793, when a root brought by Mr. John Fraier from Carolina, flowered for the first time in his garden at Chelsea. It was drawn by Mr. Sowerby, but the figure remains unpublished. Michaux in the Meanwhile has named and described this genus as above, giving an indifferent plate of the only species known to him, which, he says, grows in the dryest fir woods of Carolina.
Carolina and Georgia, and which is the very fame as Mr. Fraser's, in whose herbarium we have seen a specimen from Mr. Walter, who named it, with a mark of doubt, Chrysophleum oppositifolium, not being furnished with sufficient materials to judge how far he was correct or not. Michaux has given a species character, a perilous attempt, and in place of a subord one, for a solitary species, as it can only by accident serve to contrast that species with others as yet unknown. The R. is perennial, rather woody, stem a foot or more in height, crept, round, woolly, finely-coloured, leafy, branched and forked, many-flowered. Leaves nearly entire, somewhat undulate; green, scattered with loofe, deciduous, rusty down above; densely woolly and whith, with rusty veins, beneath: the radical ones clustered, opposite, two inches in length, on broad, woolly footstalks about half as long, spreading: stem-leaves in numerous rather dilant whorls, three or four in a whorl, feifil, fearcely an inch long, unequal, pointed. Stipulas none. Bractea either terminal or from the forks of the stem, solitary, woolly, cup-shaped, bluntly toothed, woolly, containing eight, ten, or more inodorous flowers on simple, slender woolly footstalks, each joined in the middle, and dew-lining upwards. Segments of the calyx elliptical, broad, obtuse, white at the edge, green clothed with rusty wool beneath. Footstalks half as long as the leaves, very woolly, dilated at their base, but not quite embracing the stem. Flowers very numerous, in dense, globular, woolly tufts, one terminating each branch, and surmounted by another, on an elongation of the same branch, two inches above it. Flower-footstalks smooth. Calyx smooth, or very slightly downy at the back, its segments oblong, obtuse, keeled, entire, not wavy. We have not seen the radical leaves, nor been able to investigate the bractea. The round tufts of very copious flowers, and the flaked scattered small leaves, at once distinguishing this species.

2. E. parvifolium. Calyx naked. Stem-leaves flaked, alternate, ovate, revolute.-Gathered in California by Mr. Archibald Menzies. The stem is shrubby, branched, leafy, with a deciduous, nearly smooth bark. Leaves alternate or clustered, about a quarter of an inch long, ovate, obtuse, revolute, almost if not quite entire; smooth and shining above; densely clothed with rusty wool beneath. Footstalks half as long as the leaves, very woolly, dilated at their base, but not quite embracing the stem. Flowers very numerous, in dense, globular, woolly tufts, one terminating each branch, and surmounted by another, on an elongation of the same branch, two inches above it. Flower-footstalks smooth. Calyx smooth, or very slightly downy at the back, its segments oblong, obtuse, keeled, entire, not wavy. We have not seen the radial leaves, nor been able to investigate the bractea. The round tufts of very copious flowers, and the flaked scattered small leaves, at once distinguishing this species.

3. E. latifolium. Calyx naked. Stem-leaves flaked, alternate, heart-shaped, undulated. Foot-stalks embracing the stem. -Gathered in California by Mr. Menzies, with the leaf. Stem shrubby. Branches round, woolly, leafy. Leaves alternate, two inches long, heart-shaped, bluish, undulated, and crimped at the edge; covered with a web of deciduous white down above, very woolly and white beneath. Foot-stalks as long as the leaves, woolly, sheathing the stem with their dilated bases. Some leaves are clustered about the end of each branch. Flowers not larger than in E. parvifolium, and, as in that species, very numerous in globose woolly tufts, terminating elongated, naked, woolly branches. Segments of the calyx obvate, keeled, somewhat undulated.

The addition of the two species confirms the very natural genus of Eriogonum, which in the Linnaean system should immediately follow Rheum. Probably more species are to be found in the unexplored wilds of North America. Those we have described would all certainly bear the climate of Britain, and though not splendid plants, are worthy of cultivation for their singularity. Their qualities cannot be supposed different from Polygonum and Araphaxis. S.

Gen. Ch. Spike, or rather Catkin, imbricated every way: scales ovate-oblong, flat, slightly inflexed, pointed, membranous, loose, separating the flowers. Cor. none. Stam. Filaments three, capillary, anthers erect, oblong, Fil. German superior, very small: style thread-shaped, the length of the calyx-scale; stigma three, longer than the style, reflexed. Peric. none. * Seed triangular, pointed, surmounted at the base with numerous hairs longer than the spike.

Efl. Ch. Glumes sharply, imbricated every way. Corolla none. Seed one, invected with very long hair.

Six species are described by Willdenow, four of which are found in Britain, viz. E. vaginatum, Engl. Bot. t. 873; Polygonum, t. 563; angulifolium, t. 564, long confounded with the last; and alpinum, t. 511. The exotic species are, E. virginicum, Linn. Sp. Pl. 77.; and eurypermum, ibid.; both natives of North America. The latter has brown and shorter hairs to the seed than any other, so as to have nothing of their striking appearance. The whole genus grows in a turfly soil, generally in wet places, to which the first species is an occasional exception, being sometimes found on dry mountainous heaths. Some German botanists have lately distinguished from the vaginatum, one which they name E. Scheuchzeri. This is Eriophorum, n. 1332. Hall. Hist. v. 2. 175. (Juncus alpinus, capitulo tomentoso majori; Scheuchz. Prod. 27. t. 7. f. 2.) It has creeping roots, solitary stems, not half so tall, but much flouter than those of vaginatum, with a much less remarkable head. The leaves also are very short; the hairs of the seed very dense and remarkably delicate. It grows in the most elevated marshy pastures of the Alps, or about the boggy borders of Alpine lakes, as mentioned by Scheuchzer, and is undoubtedly a distinct species.

ERIOPHORUS, Bulbus, the Woolly Bulb, 3205. of Theophrastus, book vii. chap. 13, who mentions it as "growing on the shore, and having between its outer coats and the inner part, which is cattale, a woolly substance, of which various garments are woven." Pliny observes, that Theophrastus does not inform us in what country this is practiced. Dodonaeus, among the moderns first instituted an inquiry into this bulb, Hist. Stirp. 692, giving a figure, communicated by a friend of whose fidelity he is very unwilling to doubt, of a plant hitherto unseen by any other mortal. It has fealy bulbs, more resembling tuberous roots invested with the permanent bates of the foliage; long sword-shaped leaves: and large foliar flowers, unlike every thing known in the vegetable world, being formed of five densely flaggy ovate spreading petals, and a lithr standing upright in the place of the stamens and pillis. This cut has always been judged fictitious, and, if true, would not answer to the description of Theophrastus. Dodonaeus, in his botan. figures the Stellaria, and one kind of Bulbus eriphasus, and gives to Clusius, who, in his Hist. Plant. 173, gives Stellaria peruviana for another. Both these bulbs, and, indeed, some others, have, in fact, a woolliness about their upper part when the coats are torn asunder, apparently confining of their large and tenacious spiral-coated spavells; but the quantity or quality of this wool is not, in any instance that has come under our inspection, by any means adequate to the ues mentioned in Theophrastus.

Gen. Ch. Cal. none. Cor. bell-shaped, permanent, of six ovate, eri-leaved petals, three of which are exterior and most expanded. Stam. Filaments six, shorter than the corolla, awl-shaped, uniform, dilated at the base, smooth; anthers incumbent, oval, two-labaved. Pet. Germen superior, ovate, with six ribs; style erect, angular, as long as the flaments; stigma simple, obtuse. Pet. Capsule of three cells and three valves; partitions from the centre of each valve. Seeds several, affixed to the lower part of each partition, roundish, invested with long prominent woolly hairs.

This genus, than which none can be more natural, either with respect to character or habit, was established by Jacquin in the fifth or supplemental volume of his Collectanea, upon the Ornithogalum capense of Linnæus and Thunberg, with two other species. They all agree in their tuberos root; radical, flaked, solitary, elliptic-oblong, entire, involute leaves; and tall, naked, racemose, many-flowered flanks. The flowers are small; petals white with redtih, brown, or greenish keels.—They are all delineated in Jacquin's Icones Plant. Rarior. v. 2, as follows.

3. E. parvisfolium, t. 422. Leaves elliptical, obtuse, erect, flat. The leaves of this are glaucous, reticulated, and much smaller than in either of the former, being but from an inch and half to two inches long. Petals with a green rib. Partial-flanks an inch long, spreading.

All these species are natives of the Cape of Good Hope. We suspect that Bengal and the coast of Guiana may afford one or two more, but we are not furnished with materials sufficient to ascertain them completely.

Gen. Ch. Cal. Perianth inferior, in five deep segments, nearly equal, permanent. Cor. Petals five, ovate, sfiliform, regular and equal, somewhat spreading, mostly five times as long as the calyx, sometimes rough, inserted under a glabrous necarium, which surrounds the base of the germ. Stam. Filaments ten, awl-shaped, flat, clothed or fringed with fine spreading hairs; anthers on terminal stalks, roundish with a small point, two-lobed, incumbent, fimbriate. Pet. Germen of five lobes, superior, flanging on the necarium, each lobe somewhat ovate, triangular, acute, fimbriate spreading; style central, from the base of the germ, erect, cylindrical, elongated after flowering, smooth; stigma capitate, with five notches. Pet. Capsules five, connected by their base, ovate, compressed, coriaceous, of two valves, enclosing an achene, carinate, pinnate, bivalve arillus. Seeds solitary, kidney-shaped, brown, smooth.

Vol. XIII.

Obs. Some species have a four-crested flower, with but eight flaments, and others have five of their 10 flaments imperfect and abortive.—This genus differs from Boronia. Sm. Transf. on Nat. Hist. 257. t. 4-5, in having the anther upon terminal footstalks, and the style from the base of the germ; not to mention the flowers being generally five-crested and decandrous, and the leaves usually alternate. From Correa and Crevosen, see vol. 10, its differences are evident from the characters there given of those genera. We are happy here to mention that the long-stemmed Correa rubra flowered, for the first time in Europe, at Meirs. Lee and Kennedy's, Hammermüh, in June 1809.

The species of Eriostemon in our possession are six.

1. E. falicifolia. Willow-leaved Eriostemon. —Leaves linear-lanceolate, flat, straight, naked on both sides. Bracteas smooth. Flowers lateral. Gathered near Port Jackson, New South Wales, by John White, M.D., who communicated dried specimens to us in 1791, but it has not yet appeared in the garden. This is a very handsome flowering shrub, with numerous, alternate, wand-like, leafy, smooth, angular branches, having indeed much of the habit of Creosote fahgina. Bracteas alternate, from one to two inches long, but little spreading, linear-lanceolate, entire, bluish with a small point, thick and coriaceous, naked and smooth on both sides, beprinkled with glandular dots, scarcely veiny, but marked with an obsolete central rib; their base tapering down into a short flat footstalk. Stipules none. Flowers pink, resembling those of Correa lophia, on short, simple, solitary, axillary, angular, downy, bracteate flanks. Bracteas imbricated, roundish, obtuse, concave, pale, downy, fringed. Segments of the calyx much resembling the bracteas, about a line long, imbricated at their base. Petals alternate with them, and five or six times as long, broad, spreading, bluish, clothed with short, dense, finely pubescent, especially on the outside. Filaments about one-third as long as the corolla, red, all clothed from the base with dense, white, spreading hairs, and terminated by a naked, club-shaped, obtuse, red stalk, which is in the five innermost alternate ones is much longer, thicker, and more glabrous, than in the rest; these flaments conically the longest; anthers at the top of each flake, incumbent, uniform, all fertile, ovate, of two cells, burbling longitudinally on their inner side, tipped with a small, pale, reflexed scale or crest. Style shorter than the flaments.

2. E. busifolia. Box-leaved Eriostemon. —Leaves elliptical, keeled, revolute, with a recurved point. Branches hairy, round. Flowers lateral. Gathered near Port Jackson, by Dr. White. Of this we have two very distinct varieties, for considering the Protea-like nature of the leaves in New Holland plants, in which alone these differ, we dare not call them distinct species. In one the leaves are obvolute, narrow at the base, bluntly crested and glabrous at the edges; in the other they are broadly elliptical, heart-shaped, and embracing the frond at their base, generally even and entire at their edges, though occasionally furnished, in the very same manner, with blunt glandular teeth. In both the branches are round, clothed with short prominent hairs. Leaves numerous, scintillated, rather half the line long, coriaceous, nearly smooth, keeled, with a sharp recurved point, and a thick, slightly revolute, margin. Flowers towards the ends of the branches, axillary, solitary. Stalks rather shorter than the leaves, thickened upwards, slightly

3 N
ERIOSTEMON.

flattily hairy, with several minute, crowded, roundish, smooth bracteas a little above their base. Calyx much resembling the bracteas. Petals elliptish or oblong-coloured, almost as large as the former, but smooth or very slightly downy; more spreading and recurved. Filaments minutely fringed, their terminal flanks awl-shaped, bearing a few long scattered hairs; anthers much like the former but shorter, and with a shorter broader point. Germin smooth, with very pointed lobes; style shorter than the flaments.

3. E. fal/sfolius. Salt-trotted-leaved Eriostemon.—Leaves crowded, linear, obtuse; flattened above; convex beneath; rough-edged, straight. Flowers terminal.—Gathered by Dr. White near Port Jackson, with the leaf. It seems a more humble shrub than either of the foregoing, and has angular branches, all over scarred where former leaves have fallen; slightly hairy when very young. Leaves very numerous, somewhat imbricated, half an inch or less in length, flathily, linear inclining to obvolute, obtuse, flattish above, convex beneath, more or less rough-edged, and sometimes otherwise pubescent, dotted with flattened glandular points, which in the dried leaves are prominent tubercles. The base tapers down into a very short broad footstalk, articulated with a decurrent spreading of the bracteas. Flowers few, with footstalks, which are minutely bracteated at their base. Segments of the calyx short, broad and acute. Petals recurved, downy, white with a darker keen. Filaments smooth at the base, their upper part, and terminal flanks, densely clothed with long, upright, white hairs, almost concealing the anthers, which are oblong, with a very minute point or cleft. Germin smooth, with obtuse lobes.—The flaments in these three species would afford beautiful specific differences, were not those of the leaves more commodious and obvious.

4. E. unigera. Single-flowered Eriostemon.—Leaves scattered, elliptic-lanceolate, smooth; paler beneath. Flowers solitary, terminal, on short footstalks. Five of the flaments abortive. (Diosma unigera; Linn. Sp. Pl. 287, Alt. Hort. Kew. v. 1. 276. Mart. Mill. Dict. v. 2. n. 17. Curt. Mag. t. 253. Schrad. Sert. Hannov. 16. t. 8.)—Native of the Cape of Good Hope, from whence it was sent to the Kew garden, in 1775, by Mr. P. Maflof- and is now not uncommon in collections, being raised abundantly from the seeds of the dried flowers, produced abundantly in the spring and early part of summer. This is a shrub from one to two feet high, much branched, strongly, but not agreeably, aromatic in all its parts. Branches leafy, nearly smooth. Leaves scattered, on short, rather hairy, footstalks, elliptic-oblong, often nearly linear, obtuse, very glandular, paler beneath, very obscurely crenate, and somewhat fringed, varying in length from half an inch to an inch. Flowers solitary at the end of each branch, but from the number of the short branches they sometimes appear cymose. Stalks much shorter than the leaves, swelling upwards, downy, without bracteas. Segments of the calyx near half an inch long, lanceolate, purplish, fringed. Petals twice as long as the calyx, ovate, pointed, of a thinning varnished white, like porcelain, or often bluish-coloured above; purplish beneath. Stamens about the length of the calyx, their filaments all fringed; five of them short, bearing large heart-shaped anthers, with greenish glandular tips; live much longer and more slender, each terminating in a small round footstalk, with none another, varying in foot and shape. Germin globular, clothed with numerous flaked resembles others; style and filaments like the other species. Curtis and Schrader have well described this plant, but neither of them was sufficiently acquainted with the real species of Diosma, nor numerous in our gardens, to discover that it was generically distinct, and that the curious necary, essential to Diosma, was wanting. Schrader's description of that part agree with the generic character, but in this the accuracy would soon have discovered the truth, had we seen a real Diosma. The Henkes of Schmidt in Utter's Annals, f. 6. 117, to which Schrader refers, agrees in generic characters with Diosma barbigeria of Linnaeus, and not with our Eriostemon.

5. E. marginata. Bordered Eriostemon.—Leaves scattered, lanceolate, paler beneath. Flower-flanks axillary, twice as long as the leaves, coriaceous. Five of the flaments abortive. (Diosma marginata; Linn. Suppl. 157.) Native of the Cape of Good Hope, raised by Mellis, Lee and Kennedy, with whom it flowered in June 1839. It agrees very much in habit with the leaf, but has a more pleasant smell, like tallflax or myrth, when rubbed, and differs very essentially in the great length of its flower-flanks, which are not terminal, but spring from the borders of several of the uppermost leaves, and rising above the summit of the branch, make a sort of corona. A pair of lanceolate bracteas grow near the top of each flank, or tooth of the bracteas, and extend to the base. Their specific situation seems not characterizable of any specific difference. The segments of the calyx vary in breadth, and are often fringed, sometimes smooth. Petals mostly notched at the extremity, but otherwise like those of E. unigera, as are also the flaments. The leaves vary greatly in length and breadth. Their membraneous margin, whence the name is taken, is often very conspicuous in the dried plant, but we cannot perceive it in the living one, nor even in our garden specimens when dried, till we would not presume to change a name founded in truth, though not always applicable; otherwise pedunculata would be a more eligible one. Our remarks on this species are made from various specimens named and unnamed in the Linnaean herbarium, which vary greatly in the hairiness or smoothness of their branches and leaves, as well as in the form and breadth of the calyx; but we can find no positive specific distinction among them. The leaves in some are nearly opposite, but never constantly so. We know, from frequent observation, that the half species is extremely variable, and are persuaded that it will not be easy to adopt differences. The inflorescence, however, of each is so constant, that they can never be confounded together.

6. E. paradoxa. Various-leaved Eriostemon—Leaves lanceolate, revolute, downy beneath; simple, ternate, or pinnate. Flowers lateral, four-cleft. Stamens eight. Sent from Port Jackson, New South Wales, by Dr. White.—Stem: frabulose, with numerous, opposite, round, rough, leafy branches. Leaves an inch, more or less, in length, lanceolate, obtuse, entire, somewhat revolute; smooth and naked above; clothed with dense, white, entangled or flabby pubescence beneath. In one variety they are simple, almost perfectly opposite, on short footstalks; in another smaller, ternate, sessile on one common winged flank, which is about half the length of the lateral pair; in a third they are as large as in the first, and are either ternate or confluent of two pair and an odd one, all sessile on a similar, but longer, winged flank. The pinnate and the ternate kinds are unquestionably but varieties of each other, nor can we think the first a distinct species; our observation is, that the species may merge. The flowers of all are exactly alike. Flower-flanks copious, axillary, solitary, shorter than the leaves, simple, single-flowered, angular, clothed with rusty flabby scales or pubescence. Bracteas two, towards the middle of each flank, obvolute, rusty, small. Calyx downy and rusty, quadranular.
ERIAS, in Ancient Geography, a town of Spain, in Lusitania.

ERIKAY, in Geography, one of the western islands of Scotland, separated from South Veit by a narrow strait, called "Erikay Sound." About five miles in circumference.

ERISMA, in Botany, according to the name of the plant, is derived from ερις, to prop, or support, and from ηπις, to disperse, or content. Rudge Pl. Guiana. Clas and order, Monandria Monogynia. Nat. Ord. uncertain.

Gen. Ch. Cal. Perianth of one leaf, permanent, downy on both sides, in four deep unequal segments, one of which is much the longest, irregular, obtuse, behind the larger petal; the rest shorter, and half-lanceolate. Cal. Petals two, opposite, unequal, the uppermost united with the calyx by a cleft between its leaf segments, broad, roundish; its base ending in a horn-like, blunt spiny, the length of the petal, downy externally, like the calyx; the lowermost, almost as long as the other, and broader, infurrowed in the receptacle behind the perfect filament. Stam. Filaments five; one of them fertile, as long as the upper petal, incurved, inserted into the receptacle; the other four very short, abortive; another arrow-shaped, narrow. Pet. Germain inferior, oblong, of one cell; style thread-shaped, as long as the filament, ascending; stigma blunt. Peric. unknown. Rudiments of seeds two, oblong.

Eff. Ch. Calyx in four deep unequal segments. Petals two, unequal; the uppermost united with the calyx, splayed at its base; the lowermost inserted in the receptacle. Fruit with two seeds.

E. floribunda. Rudge, t. 1. Native of Guiana. A tree or shrub with round branches, when young clothed with flaky down of a brown colour. Leaves large, nearly opposite, elliptical or obovate, obtusely pointed, entire, smooth, with numerous parallel nerves. Sterile small, deciduous. Peduncles large, terminal. Branchlets in pairs, very unequal, downy, the finest about a line long, the other four lines long, broad and ovate. The flowers are very small, and concealed by the bract. Of their colour or properties we have no account.

ERISMATOLITHUS, in Natural History, and Mineralogy, is the name of a genus in the animal order of remains (relicium, or relics) of a former race of beings, which inhabited the earth or its waters, and includes the fulciments or plant-like supports which certain animals fabricated for their support and habitation, and which are preferred in a fossil state. According to Mr. William Martin (Outlines of the Knowledge of extraneous Fossils, p. 193), the essential characters or diagnostics of the permanent species in this genus are to be sought in various parts of the relicium, e.g. "in relicium of cellular fulciments, the flarp exhibiting the internal form or structure of the cells; in relicium of solid fulciments, the flarp exhibiting its external form." The temporary species of this genus are to comprise such cellular fulciments as do not shew the structure of their cells, and such solid imperfect specimens as are not reducible to known species. The fossil corals, corallines, pponges, &c. rank under this genus. See RELICIA.

ERISTALIS, the name of a flane, mentioned by Pliny and the ancients, and of which a very memorable quality is recorded by them, which, though it was naturally white, it would occasionally turn red.

ERISTICI, from Eristalis, in Botany, such authors as have attempted the study of that science in a philosophically way, and have been publicly engaged in disputes about the true foundation of its several distinctions, &c.

ERITHACE, a name given by the ancients to the yellow matter collected on the hinder legs of the bees after their excursions in search of the materials for their hives; we usually esteem this to be real wax, and the French call it circe, brute, or rough-wax; it is certain, however, that though the matter of which wax is to be formed is contained in this substance, yet the Dutch and some other nations have the most just idea of it, in calling it pain des abeilles, or the food of the bees.

This substance is only the sarina of flowers, and no experiment has been able to separate real wax from it. The most probable opinion concerning it is, that it serves the bees as food, and that after this it is converted in their hives into the substance called wax.

Gen. Ch. Cal. Perianth superior of one leaf, cup-shaped, with five teeth, permanent. Cor. of one petal, deeply five-cleft; tube very short; segments of the limb long, lanceolate, recurved. Stam. Filaments five, awl-shaped, spreading, scarcely so long as the corolla; anthers oblong. Pet. Germain inferior, rounded; style thread-shaped, compressed in the upper part, the length of the corolla; stigma acute. Peric. Berry globose, crowned with the base of the calyx, of ten cells (sometimes but eight, Gartner.) Seeds small, foliary, pendulous.

The species are,

1. E. fruticosa. Linn. Sp. Pl. 251. (E. odoriferum; Jacq. Amer. 72. t. 173. f. 23. E. fruticulosa; Brown. Jan. 165. t. 17. f. 3. Sambucus ligna duro odoratissimo; Plum. Ic. 247. t. 249. f. 2.)—Leaves obtuse. Flower-falts all cymocone, many-flowered.—Native of Jamaica, and of other West Indian islands, growing near the sea-fide, and very various in height and luxuriance, according to its situation. Stam. bristly, with round, smooth branches, kavy towards their extremities. Leaves opposite, falked, obturate, entire, about two inches long, various in breadth, obtuse, smooth and shining. Flowers white, smelling (according to Jacquin) like the common lilac, growing many together in long-falked, axillary, cymocone panicules, about the ends of the branches, but they are not terminal as Wildenow describes them. Berries purple, the size of a pea.—Jacquin

§ 392
ERI

deskibes another species or variety, he is doubtful which,
with inodorous flowers, white berries, and a more humble
flattish stem, growing on barren maritime rocks in the island
of Curacao. This we have never seen.

flowers cymose; perfect ones solitary. Gathered by For-
ller in the Society Islands. — That writer refers to the Ti-
namou, Rumph. Amb. v. 5. 216. t. 1435, as a narrower-
leaved variety of his plant. This is, indeed, to all appear-
ance, an Eriolitha. Rumphius informs us that it grows in
grassy open hilly places in Ambonya, and the neighboring
islands.

The stem is the height of a man. Leaves four or five
inches long, and as broad as two fingers, acute at each end.
Flowers of a dirty white. Berris yellowish-black, eaten
by starlings and other birds. The roots are used by the
natives to chew, along with a flight mixture of cloves, nut-
megs and ginger, in their maritime excursions, in which
they suffer much from cold and other inconveniences.

ERITRI, in Geography, a town of Astatic Turkey, in
the province of Natolia; 36 miles W. of Smyrna.

ERITZKA, a town of Ruffia, in the government of
Irkhutsh; 20 miles E. of Kireefk.

ERIVAN, called Persian Armenia, Greater Armenia,
and Eastern Armenia, a province of Persia, about 200
leagues in length, and 60 in breadth. See Armenia.

ERIVAN, Iravan, or Erivan, a city of Asia, and capital
of Greater Armenia, or Erivan; situated in a plain, sur-
rounded with mountains, and watered by two small rivers;
large, dirty, and ill built, but indifferently peopled:
the ramparts are of earth; the fortresses is encompassed
with a wall of bricks, in which are a palace for the governor,
and 800 houses, inhabited only by Persians; the Armenians
have shops there, but must not remain during the night.
The churches are small, and half buried in the ground, re-
sembling catacombs; in the town and its environs they reck
on 28 convents for devotees of both sexes, but they
are poorly endowed.

ERIX, or ERYX, in Ancient Geography, a mountain of
Sicyly, situated towards the western part, near the sea.
Solinus says, that it was consecrated to Venus. Polybius
places it between Drepana and Palermo. According to Apol-
lodorus, this mountain derived its name from a son of Venus,
called Erix. It is now called "Monte St. Giuliano," or
"Monte di Trapani." Also, a town of Sicyly, now
"Trapani del Monte," situated on the summit of mount
Eryx, difficult of access, and famous for a temple of Venus,
called Eryxina. Polybius and Strabo mention this town.
Minos decorated this temple with superb sculpture, and en-
riched it with such noble offerings, as have claimed for him
the honour of being its founder. The victims offered them-
selves voluntarily at the altar. The most beautiful women
in the world were the priestesses, and the Roman senators,
laying aside their characteristic severity, came hither to in-
dulge in pleasures with the beauteous Sicilian females, per-
suaded they should thus make their offerings acceptable to
the goddesses, and render her propitious. In the time of
Strabo the town and temple were much decayed. It is said
that Eryx was destroyed by Hamilcar, who, in the first
Punic war, A. D. 409, removed its inhabitants to Dre-
panum, which he had built not long before. Nothing now
remains but a palety village, and some foundations of a tem-
ple.

ERIZZO, SEBASTIAN, in Biography, a noble Vene-
tian, was particularly distinguished for his knowledge of the
medallical science. He published, in 1539, in Italian, "A

Discourse upon Ancient Medals," which has been highly
commended for its erudition. He contended for the difference
between the medals and coins of the ancients. Erizzo was
the author of a treatise on " Logic;" a translation of " Plato-
's Dialogues;" a discourse on "Civil Governments," and

ERKELENS, or EREKLENS, probably Hercules, in
Geography, in the days of the Romans, is an ancient town of
France, in the department of the Roer, chief place of a
canton, in the district of Crevelot, with a population of
14,000 individuals. It is Montee St. Michel, about three miles
from the river Roer. 15 miles north of Juliers; its ancient
fortifications were demolished by the French in 1674. The
canton contains 48 communes, and 17,853 inhabitants.

ERLA, a small town of the kingdom of Saxony, in
the circle of the Erzgebirge, at the foot of the mountain called
Rothenberg, remarkable for a rich mine of excellent iron,
the beet of the whole of this mountainous district. Its iron
works are celebrated for calling the best ovens and fyring-
pans in Saxony; there is also a manufactory of cannon-balls.
There was anciently a small town of the same name in Ruffia,
the government of Riga, not far from Dorpat; but it is now
in ruins.

ERLACH, in French Gerler, a small town of Switze-
land, in the canton of Berne, at a distance of about three
quarters of an English mile from the upper part of the bea-
utiful lake of Bienne, is situated on the declivity of the Julmont,
or Julius' mountain, for it is proved beyond contradiction
that Julius Cesar established upon this hill one of his strong
 entrenched camps. This elevation is also called Joumont,
pretty mount, from the beauty of the prospect, which can
be seen on no where more varied, or more interesting, on account of
the number of picturesque contrasts which it affords. Trav-
ellers who wish to visit the famous island of St. Pierre, in
the lake of Bienne, generally take a boat at Erlach. It
has an ancient castle, which gave the title of barons to the
illustrious Swift family of the Erlachs, who, from the time of
the intrepid Ulrich of Erlach, have held such a distingui-
ished place in the annals of their country.

ERLANG, or ERLANGE, a handson town of Ger-
many, in the circle of Frasconia, in that part of the mar-
grave of Anspach Baireuth which was called the prin-
cipality of Culmbach, on the river Rednitz, 18 miles N.W.
of Naremberg, and 50 miles S. of Bamberg. N. lat. 49° 38'.
Until the peace of Tiltil, concluded in July 1807, between
France and Prussia, this town, and the whole margrave
of Anspach Baireuth, belonged to the kings of Prussia,
whom it had been ceded by the last margrave, in 1792:
but it is now at the disposal of the French emperor.

Erlang is divided into the old and new town; the latter
is also called Chrlitian Erlang, from the name of its found-
er, the margrave Christian Erlent, who built it in the year
1686 to accommodate several families of Protestant French
refugees. The streets of both towns are regular and spa-
cious: there are two handsome squares, and some fine
churches. The principal manufactures established by the
French refugees were those of hoesery and of hats, which
are still flourishing. In 1742 the university of Baireuth was
also removed to Erlang.

ERLAU, in Latin Alter, or Agria, a town of Upper
Hungary, in the district of Heves, near which there is a
fine hot mineral spring, which is used for bathing. It is
the seat of a margrave, and the seat of a bishopric, and the
buildings of which are very fine: the professors are well
accommodated, the lecturing rooms very good, and the chapel, library,
and public hall extremely elegant. The see of Erlau is one of
the
ERM

the richest in the kingdom. The town is in general ill built, the only good houses are those of the canons of the cathedral. There is, however, a Turkish tower in good condition. The only remarkable manufactures are those of wax and of leather. The neighbourhood of Erlau is famous for an excellent sort of Hungarian wine, little inferior to the best Burgundy.

ERLEBACH, a river of Germany, which rives in the duky of Stiri; 6 miles below Ips.

ERLEBACH, a town of Germany, in the circle of the Lower Rhine, and electorate of Montz, on the Main; 3 miles N.N.W. of Clingenberg.

ERLENBACH, a town of Germany, in the circle of Franconia, and county of Wertheim; 10 miles N.N.E. of Wertheim.

ERMELAND, or ERMLAND, in Latin Vermicia, one of the four subdivisions of that part of the kingdom of Prussia which is called Eastern Prussia. In ancient times, two-thirds of this country belonged to the bishops of Ermland, who were princes of the German empire, and one-third to the chapter of the cathedral church of Frauenburg. The bishop enjoys still a very considerable income.

Ermland is particularly remarkable for its hemp and flax, and its linen yarn, great quantities of which three articles are annually exported to England in time of peace. The principal towns are Frauenburg, the see of the bishop; Braunsberg, the chief city, which alone exports yarn to nearly the annual amount of two millions of guineas; Heilberg, Allenstein, Rotter, Wolfen, &c.

ERMENEK, a town of Asiatic Turkey, in the province of Caramania; 83 miles S. of Cogni.

ERMENONVILLE, a small town of France, in the department of the Oise, chiefly remarkable for its beautiful park, and a castle, which derives some celebrity from having belonged to the hands of Gabrielle, mistress of king Henry IV. of France. But Ermenonville is become far more famous in modern times, for having been the last retreat of the eloquent and misanthropic Jean Jacques Roufseau, who died here on the 2d of July 1778, to whom a handsome monument has been erected in a small island called the island of poplars, which is in the middle of a fine lake. This monument is remarkable for the beautiful simplicity of its inscription.

"Ici reposé l'homme de la nature et de la vérité."

"Here reposés the man of nature and of truth.".

ERMESIA, a name given to a composition used among the ancients, and famous for its effects in making people get handome children. It consisted of honey, myrrh, saffron, and palm-wine, all beaten together. This mass was to be taken mixed in milk. The women took it as well as the men, and many had great faith as to its effects.

ERMISIA, in Geography, a town in Spain, in the province of Bilbao; 16 miles E.S.E. of Bilbao.

ERMIL, a town of Ruffa, in the government of Tambo; 44 miles S. of Tambo.

ERM, or ERME, in Heraldry, denotes a white field or fur, powdered or intermixed with black spots, called powdering. See FUR.

It is supposed to represent the skin of an animal of the same denomination. In effect, there is no animal whose skin naturally corresponds to the heraldic ermine.

The animal is milk white; and so far is it from having spots, that tradition reports, that it will rather die, or be taken, than fully its whitenees. Whence its symbolical use.

But white skins having for many ages been used for the linings of the robes of magistrates and great men; the furriers at length, to add to their beauty, used to few bits of the black tails of those creatures upon the white skins to render them the more conspicuous. Which alteration was introduced into armynery.

The fable spots in ermine are not of any determinate number, but they may be a greater or lesser, at the pleasure of the painter or furrier.

ERMINE, an order of knights, instituted in 1450 by Francis I. duke of Bretagne, and formerly publishing in France. The collar of this order was of gold, composed of ears of corn in faltier; at the end of which hung the ermin, with this inscription, a mea vie. But the order expired when the dukedom of Bretagne was annexed to the crown of France. ERMEINE, a crofs ermine is a crofs composed of four ermine spots.

It must be observed, that the colours in such arms are not to be expreffed, because neither the crofs nor the arms can be of any colour but a white and black.

Colombiere blazonz it quatre queues d'ermine en croix. The editor of Guillem describes it thus; a crofs of four ermines; or, more properly, four ermine spots in crofs. It is the coat of Hurfton in Cheffrey.

ERMINE, timbre of. See Timbre.

ERMINE, in Zoology. See MUSTELA ERMINIS.

ERMINES is used by some English writers for the reverse of ermine, i. e. for white spots on a black field; but on what foundation nobody can tell; for the French, from whom we have our heraldry, have no such term; but call this black powdered with white contre-ermine; as denoting the counter, or reverse of ermine, which is white powdered with black.

ERMINEUM Animal, flont, or ermine, the creature whose skin is the ermine, so much esteemed as a fine fur.

This creature is properly a species of weasel, and is called by Mr. Ray, and other authors, mystela candida, the white weasel, and by Linnaeus mystela ermines. It is in all respects like the common weasel, and is all over of a pure snow white, except the tip of the tail, which is of as beautiful a black, and it has a little yellowish grey about the eyes, and a mark or spot of the same colour on the head, another on the shoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the season of the year. It is frequent about rivers, and in meadows, in those countries which produce it, and feeds on moles, mice, and other small animals. The skins and tails are a very valuable article of commerce in Norway, Lapland, and Russia, and other cold countries, where they are found in prodigious numbers, and regularly change their colour in winter, becoming white. In Siberia, they burrow in the fields, and are taken in traps, baited with flesh. In Norway they are shot with blunt arrows, or taken in traps. The float is sometimes found white in Great Britain, and called the white weasel. See Mustela.

ERMENITES should seem a diminutive of ermines, and naturally to signify little ermines; but it is otherwise. Erminites expresses a white field powdered with black; only that every spot has a little red hair therein.

Some authors use the word erminis for a yellow field powdered with black, which the French express much better by, or, femee d'ermiines de faulbe.

ERMENOIS expresses au or field, with fable powdering.

ERMS, in Geography, a river of Germany, which runs into the Danube, four miles S. W. of Nurtlingen, in the circle of Swabia.

ERMSLEBEN, a town of Germany, in the circle of Lower
ERN, in Geography. See MANSTEDT.

ERNEST, in Biography. See MANSFIELD.

ERNESTIN, in Geography, was born in August, 1707, at Tennstatt, where his father was Superintendent. He studied at Pforta, and soon displayed uncommon talents; he afterwards applied himself to the study of theology at Leipic, and took his degree of M. A. in the year 1730. In 1734, having been elected rector of Thomas's school in the room of Geiner, ancient literature, and those branches of knowledge connected with it, became the principal objects of his pursuit. The successful application of his talents in this department enabled him to be chosen, in 1742, extraordinary professor of ancient literature, in 1756 he was elected public professor of eloquence, and in 1758, he was made doctor and professor of theology. He died in the year 1781, having, till within the last two or three years, been incessantly engaged in the laborious discharge of his public duties. For twenty years and more he paled the greater part of each day in instructing others, yet he found ample time for the publication of many original works, and for editing various ancient authors. Among the latter may be mentioned, 1st, theMemorabilia of Xenophon, which has since been frequently republished in this and other countries. 2d, Cicero's Opera omnia in clav equipment, in 6 vols. The Clavis has been published separately. Ernici, in preparing this work for the press, employed the best and oldest editions of Cicero, as well as several MSS.; he examined critically the text of Cruter, corrected it in a great many faults, and in his short notes, he has in various places illustrated, and in others refuted the original. He also gave the world new editions with notes of Suctontius, Tactus, Homer, &c. He published Aristophani Nubes, cum scholiis antiquis et Prafat; He-derici Lexicon, multis vocabularum multif. &c. ; a New Theological Library, in 11 volumes; and "Institutio interpretis Novi Testamenti," which has passed through several editions. Alberti of Leyden was so much delighted with this, that he called it "The Golden Work." A new edition of it was published in Holland within a few months after it was printed at Leipic. The extensive talents and noble judgment of Ernici enabled him not only to embrace every department of literature, in which to examine and illustrate many of its obscurities and difficulties, but to read with the most acute and retentive memory; and, above all, an honest and upright heart. "Though," says his biographer, "the fulness of his countenance bespoke a character noble to every kind of levity, and born for labours that require great vigour and exertion, he was a friend to cheerfulness, and his company, on account of his easy behaviour and good humour, which was often heightened by Ciceronian wit, but confined within the boundaries of decency and decorum, made his conversation much sought after, and highly agreeable." Gen. Biog.

Gen. Ch. Cal. Perianth small, superior, in four deep, upright, acute, equal, permanent segments. Cor. of one petal, falver-shaped; tube elongated, quadrangular; limb in four deep, lanceolate, recurved segments. Stam. Filaments four, inserted into the tube two, attached, an- shielded, longer than the tube; anthers ereect. Fil. German fquare, inferior; fyle thread-shaped, about as long as, or longer than the stamens; stigma oblong, pointed. Peric. Berry roundish, crowned with the calyx, having a furrow at each side, and confluting of two cells. Seeds solitary, hemispherical, fringed.

1. E. littoralis. Swartz. Fl. Ind. Occ. v. 1. 224. t. 4. Vahl. Symb. v. 1. 28. (Thymelca humilior, folis acutis atroviretibus; Sloane Jan. v. 2. 93. t. 189. f. 1. 2.) Stem square, smooth. Leaves nearly sessile, acute, with a spiny point. Gathered by Sloane, Browne, and Swartz, in Jamaica. The latter informs us that it grows in gravelly places by the shore, or on calcareous rocks. Root pro- perennial. Stems procumbent, creeping, rather woody, with numerous, long, creeping or pendulous branches, which are straight, fquare, smooth, forked at joints, sometimes divided, but bearing numerous, alternate, short, leafy, fimple, lateral branches. Leaves crowded, opposite, crossing each other.
either in pairs, nearly sessile, about an inch or more in length, elliptic-lanceolate, acute at both ends, entire, very smooth, ribbed, rigid, of a dark green, tipped with a spinous point. Stipules united with a stem between the very short footstalks, each crowned with three bristles, the middle one longest. Flowers axillary, solitary, sessile, yellowish. Many of them, according to Dr. Swartz, have no petals.

2. E. montana. Sm. Fl. Graec. Sib. v. 2. t. 14.; unpublished. Prod. n. 3.45. (Asperula calabrica; Linn. Suppl. 190. Wildl. Sp. Pl. v. 1. 577. L'Hér. Stirp. v. 1. 65. t. 32. Kubelead. strictifolia Drude constifolia, flore magno suaverebente; Tourn. Cor. 5.)—Stem round, downy. Leaves stalked, blunt, pointed.—Native of mountainous places in Crete, Sicily, and the south of Italy. Much smaller than the last, except in its flowers, which are larger, clustered about the ends of the branches, and of a fine rose-colour. The stems are much branched, woody, decumbent. Leaves on short stalks, opposite, about half an inch long, elliptic-lanceolate, bluish at both ends, entire, revolute, without any terminal spine, much more pliable than the former; dark green above; pale below; roughish; occasionally. When bruised they have a very disagreeable pinnaceous smell. Stipulas with a simple lanceolate point. Branches more or less downy when young.—Authors have greatly differed about the genus of this plant. By the older ones it has been taken for a Rubia, a Valeria, a Thymelea, and a Neriium or Wolfia; by modern writers it has been referred to Asperula, Scabiosa and Paprika. We hope to be nearer the truth than our predecessors; at least its technical generative characters agree well with Swartz's Ernaldes, nor do we find any great discordance in the habit.—This beautiful plant emulates the Daphne Cneorum in colour and general aspect, and would be fearlessly Lifts admired in our gardens, to which it is, as yet, a stranger.

ERNSPACH, in Geography, a town of Germany, in the circle of Franconia, and principality of Hohenlohe; six miles N. of Okingen.

ERNESTEIN, a small town of Germany, in the circle of the Lower Rhine, and electorate of Cologne; eight miles E. of Ernsthofen.

ERNSTHOVEN, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse Darmstadt; 10 miles S. of Darmstadt.

ERNSTHAL, a small town of the kingdom of Saxony, in the county of Schonburg, close by Hofehof, at the foot of a mountain called the Pfaffenberg, with a population of about 4,000 individuals. It has a few cotton and linen manufactories.—Alfo, a small town of Germany, in the duchy of Saxo-Coburg, which has a considerable glass factor in the space of thirteen weeks, or three calendar months, they make 216,000 glasses, 1,000 of which used to be sold, in 1788, for 3 rix dollars, or not quite twelve shillings each.

ERODINUM, a word used by some of the enthusiastic writers in alchemy, to signify the prophetic, good or bad, of any operation.

Gen. Ch. Cal. Perianth inferior, of five ovate, pointed, concave, permanent leaves. Cor. Petals five, oblong, spreading, rather longer than the calyx, generally more or less irregular. Nectar of five glands between the petals. Stam. Filaments 5, awl-shaped, united by their base into a short peduncle, five of these fertile, nearly as long as the petals; the alternate five shorter and barren; anthers five, oblong, valvatile. Pist. Gynoecium superior, with five stigmas, blocked; style central, awl-shaped, spirally furrowed, as long as the stamens, permanent; style five, reflexed. Pet. Capsules five, aggregate, membranous, oblong, vertical, separating at its base, formed by each tipped at its summit with a long, linear, flat, pointed, rigid awn, hairy on its base, and at length spirally twisted, adhering by its point to the summit of the flanks. Seeds one or two, erect, ovate-oblong.

Linnaeus in his Genera Plantarum had long ago indicated a division of his genus Geranium into several natural sections, disbelieving by characters in their fructification and inflorescence. The late learned botanist Montf. L'Heritière, purifying the idea, divided that genus into three, each of them as naturally and distinctly defined as any in the whole system, and although the convulsions of his country, and his own premature death, prevented his publishing an elaborated work on the subject, he had fortunately conferred by letter with the intelligent editors of the Hortus Kewensis, and with the writer of the present article, so that his intention has been carried into effect, both in that work and the Flora Britannica. Of these three genera Geranium with its five fertile filaments, regular flower, and recurved naked awns, consists of what are usually called European Geraniums, bearing but one or two flowers on a stalk; Pelargonium with its seven fertile filaments, irregular flower, tubular nectary, and spiral bearded awns, comprehends what are generally called Cape Geraniums; while the present genus is made up of the Linnaean Gerania circum.aria.

Three species of Erodium are natives of Britain.

1. E. circum.aria. Engl. Bot. t. 1560. Hernh. Stork's-bill. Geranium circum.aria; Linn. Sp. Pl. 951. Curt. Lond. falc. t. 7. t. 51.) "Flower-flakas many-flowered. Leaves pinnate; leaflets sessile, pinnatifid, cut." Common in waffle ground. In sandy places near the sea its petals are generally white, or their usual rose-colour is elegantly diversified with a green spot on two or three of them. The herba is fetid, prostrate and annual, with finely divided leaves.

2. E. nesophorum, Engl. Bot. t. 502. bulky Stork's-bill. Geranium nesophorum; Linn. Sp. Pl. 951.) "Flower-flacks many-flowered. Leaves pinnate; leaflets nearly sessile, elliptical, unequally cut." Wild in the mountainous pastures of Yorkshire and Wellmoreland, but in other places it is usually the outcast of gardens, where it has often been cultivated for the sake of its strong musky scent of its heritage. The flowers are smaller and less ornamented than those of the preceding; leaves larger, paler, and more viscid.

Wildenow has 34 species of this genus in all. Most of them
them abound in the warmer countries of Europe, and the northern part of Africa, and several are cultivated with us for ornament, as *E. grbinum*, (Geranium creticum; Gen. em. 943), a hardy annual with large blue flowers; *E. lyr"nulae*; Andr. Repof. t. 443, which requires a greenhouse, and is perennial. Three species are natives of the Cape of Good Hope, viz. the most beautiful *E. incarnatum*, Ait. H. Kew. v. 2. 415. Curt. Mag. t. 261. (Geranium incarnatum; Linn. Suppl. 306.) This is a tender greenhouse plant, and therefore not very common, but worthy of all attention for the delicate hues, and eye-like pencilling, of its blossoms. The other two Cape species are *arduinum*, (Geranium arduinum; Linn. Sp. Pl. 952.) very little known to botanists, and never introduced into the gardens of Europe; and *rdbifolium*, Jac. Ic. Rar. v. 3. t. 509.) an inconspicuous flower, not much likely to exite the attention of cultivators.

**ERODIUS**, in Entomology, a genus of the Coleopterous kind, establisht by Fabricius. These insects are generally distinguished by the following character: the antenee moniliform; feelers four; jaws horny, truncated, and bifid; lip horny and emarginate. This is the Fabrician definition, to which may be added that the body is roundish, gibbous, and emarginate; thorax transverse; wing-cages closely united, and longer than the abdomen.

**Species.**

**Testudinarius.** Black; wing-cages rough, the sides covered with whitish dust. Fabr.

An insect of large size, found at the Cape of Good Hope; the wing-cages are very gibbous, with small raised dots.

**Gibbus.** Black; wing-cages with three raised lines. Fabr. Remarkable for the gibbosity of its form, and the obtusity of the wing-cages; it is of moderate size; and has the anterior flanks armed with a strong tooth in the middle and at the tip. The species inhabits Arabia.

**Planus.** Black; wing-cages with a single raised line. Fabr.

Native of the same country as the former. The anterior flanks not armed with a spine.

**Minutus.** Black; wing-cages perfectly smooth. Fabr. Small thorax with two impressed dots on the back; legs unarmed. Inhabits the easter parts of the world.

**Mucicatus.** Gibbous, black; wing-cages minute.

**Faber.** A species described in the Fabrician Suppl. Ent. from the cabinet of Lundi. It is a native of the Cape of Good Hope; in size and appearance resembles E. gibbus. The head and thorax smooth.

**Erophlevo**, in Geography, a town of Rusia, in the government of Iukutich; 60 miles N. of Balagankoi.

**Eros**, of *ερως*, love, in Mythology, one of the two chiefs over all the other cupidus, being the caue of love. See *Anteros*.

**Erosion**, in books of Surgery, we often find this expression used synonymously with the term ulceration.

**Erosion**, in Geology, according to Mr. Kirwan, (Geol. Ed. 230 and 285,) denotes a solution or melting of the softer calcareous particles by water, by which he accounts for the formation of the vast caverns and grottoes to be found in the Derbyshire line-flone rocks, and those of other countries.

M. de Sauntifii, in his Agenda (Journal des Mines, N° 202,) directs the attention of geological travelers to the sides of valleys (§ 12.) to search for the vestiges of the erosion of water: by which we might understand a mechanical sweeping or washing away of strata, as well as a solution or melting as above.

**EROSUM Foliurn, among Botanists. See Linat.**

**Erotesis**, *ερωτησις*, in Rhétor., the same figure with *Inversion*. Every interrogation or question is but figurative; but it becomes figurative, when the same thing may be expressed in a direct manner; but the putting it by way of question gives it much greater life and spirit. As when Cicero says (in Catal. i. c. 1.) "Cataline, how long will you abuse our patience? Do not you perceive your designs are discovered?" He might have said, "You abuse our patience a long while; you must be sensible your designs are discovered." But it is evident how much this latter mode of expression fails short of the force and vehemence of the former. Thus also, when Medea says, "I could fave; and do you ask, if I can destroy?" Had the merely said, "I could fave, and I can destroy," the sentence would have been flat, and very unfit to express the rage and fury in which the poet there represents her. (Quint. Init. Orat. I. viii. c. 5.) This figure is suited to express molt passions and emotions of the mind, as anger, disdain, fear, desire, etc. It serves allo to press and bear down an adversary. This figure likewise diversifies a discourse, and gives it a beautiful variety, by altering the form of expression, providing it to be neither too frequent, nor continued too long. Besides, the warm and eager manner in which it is expressed enlivens the hearers, and quickens their attention.

**Erotem, in Botany, perhaps from ερωτησις, to question, in allusion to its doubtful nature at first sight, being very like *Trac* till the fruit is investigated. Swartz. Prod. 5.** The author, however, being himself, as it seems, dissatisfied with this name, has, in his Fl. Ind. Occ. v. 1. 971, changed it to *Freziaria*, which fee.

**Erotia, *ερωτια*, a festival among the Greeks, in honour of Cupid, being celebrated every fifth year with sports and games.

**Erotianus, in Biography, the author of a glosary, containing an explanation of all the words used in the writings of Hippocrates, lived in the first century of the Chriftian era, in the reign of Nero, and dedicated his work to Andromachus of Crete, who was physician to that emperor. It was printed at Venice, in 1556, in 4to, with the notes of Barth. Eufentius, under the title of "Vocum, quae ad Hippocratem, colleci, et ejus operum in septem foliios divisitum."" The glossary of Erotian was also annexed to the edition of Hippocrates, published by Fœbusi at Geneva, in 1657. Haller. Bibl. Med. Eloy.

**Erotic, derived from ερως, love; whence ερωτησις, is applied to any thing which has a relation to the passion of love. In Medicus, we particularly use the phrase delirium eroticum, for a kind of melancholy contracted through excess of love.

Though, among the several species of pulses, there be no amorous pulse, that is, no pulse peculiar to that passion; yet we can certainly discover where the disorder is erotic, by the beating of the pulfe, which, in that cafe, is changeable, unequal, turbulent, and irregular. Speak to the patient of the person he loves, and his pulse instantly changes, becoming higher and quicker; and the minute you change the conversation, the pulse is loft again, and is disturbed anew.

**Erotidma, *ερωτιαδα*, the name with erotica.

**Erotomania, in Medicin, a term used by some writers to denote that modification of infancy, of which the passion of love is the origin, and in which the love of a particular individual constitutes the predominant idea. Sauvages treats of this form of derangement under the name of *melancholia amorata*; (see bis Nolof. Meth. Clafs viii. Gen. xix. Spec. 2.) Sennertus under that of *amor infantus*,
EROTYLOS, in Natural History, the name of a stone, of which we have no description left us, but which the ancients are said to have used in divination.

EROTYLUS, in Entomology, a genus of Coleoptera in the Fabrician system, allied, and in some degree confounded, with the two Linnean genera Chrysolina and Coccinella, and arranged by Gmelin under that of Cryptoccephalus. The antennae are filiform; feelers four and unequal, the anterior longer and hatchet-shaped: jaws horny and bifid; lip horns, short, dilated at the tip, truncated, and somewhat emergent from the furca. The transformations of these insects are unknown in the perfect state; they are found generally on flowers. Three of the species are described by Linneus, the remainder principally by Fabricius.

Species.

CANCELLATUS. Black; wing-cases yellow, reticulated with black. Fabr. Large and roundish; inhabits Brazil.

HISTRO. Deep black; wing-cases barred with black and yellow, a scarlet spot at the base and tip. Fabr.

A species of large size, an inhabitant of Cayenne.

LUQUEUS. Tectaceous; antennae and hands black. Fabr. Native of America.

CIBUS. Black; wing-cases yellowish with black spots; band in the middle and at the end black. Fabr. Chrysolina gigas fo, Linna. Coccinella, Grouv. An insect of considerable magnitude, the wing-cases of which are remarkably gibbous, and the thorax impregnated on each side; it is a native of South America.

FASCICATUS. Oval, black; wing-cases with fine waved fulvous bands, the anterior one interrupted. Fabr.

Inhabits Cayenne.

NOTATUS. Black; wing-cases with a yellow band in the middle spotted with black, and marked with red at the base. Fabr. Native of South America.

CONCATENUS. Black; wing-cases reticulated with yellow and black, and marked with two black bands. Fabr. Mant. Inf. Country unknown; the body large.

PUNCTATUS. Oval; wing-cases black with five red dots. Fabr. Inhabits America.

PUNCTATISSimus. Black; wing-cases yellow with numerous black dots. Fabr. Vol. XIII.

Described from the Hunterian cabinet: an American species.

VARIOUS. Black; wing-cases punctured, spotted with fulvous in the middle. Fabr. Inhabits Surinam.

GENMASSUS. Black; wing-cases with numerous fulvous dots; thorax variegated. Fabr.

A species of moderate size, found in Cayenne.

MACROCHEIRUS. Black; wing-cases with alternate black and yellow bands; fore legs very long. Fabr.

Native of India.

AEDOMENALIS. Black; wing-cases yellow with four waved black bands and a bright black dot. Fabr.

A Brazilian species, in size resembling E. fasciatus, and having the abdomen yellow with two lines of black dots.

FASCICUS. Black; wing-cases with three yellowish bands. Fabr.

From the Bankian cabinet; the native place unknown: size moderate.

ZEUS. Yellowish; head, base of the thorax, and three bands on the wing-cases with the legs black. Fabr. Mant. Alternavus. Black; wing-cases with two yellow bands, the anterior one dotted with black. Fabr.

SUINAMENSIS. Black; wing-cases red and immaculate. Fabr. Native of Surinam.

LIMBATUS. Oblong, black; margin of the thorax and border of the wing-cases yellow. Fabr.

South American species; head yellowish with a black frontal spot; thorax smooth with a broad, indefinite lateral margin.

NEBULOSUS. Black; thorax, and wing-cases varied with ferruginous. Fabr.

Inhabits the same country as the preceding.

DILATATUS. Oblong, black; thorax and wing-cases ferruginous. Fabr.

Native of the Cape of Good Hope. The antennae are brown, at the base ferruginous; wing-cases smooth, and much broader than the body.

MORIO. Oblong, black, and immaculate. Fabr.

This, and the four following species, are natives of New Holland. These are described by Fabricius from the Bankian cabinet, and are represented in the volume of "Donovan's General Illustration of Entomology, devoted to the Insects of the Australasian regions."

SOMARIGULUS. Oblong, black; wing-cases ferruginous and green.

AMETHYSTINUS. Oblong, black; thorax and wing-cases blue; resembles the last; front retina; wing-cases with punctured striae.

BICOLOR. Oblong, black; bronzed above.

CUPREUS. Oblong, black; thorax and wing-cases coppery.

FLAVIPES. Oblong, glossy green; antennae and legs yellow. Native of Jamaica, in the Bankian cabinet.

EROWA, the name of a kind of nettle which grows in the mountains at Otaheite in the South Sea, with which the inhabitants make fishing lines, which serve to hold the strongest and most active fish, and are much stronger than our silk lines of twice the thickness.

ERPACH, in Geography. See EREBCH.

ERPEniUS, Thomas, in Biography, was born at Ypres, in Holland, in the year 1684. His parents, natives of Bois-le-Duc, were, on account of their conversion to the Protestant religion, obliged to withdraw from that place, to one more favourable to the rights of private judgment. They provided their son with a good education in the rudiments of learning, and when they discovered in him a pre-
penity for literary pursuits they sent him to Leyden, where he felt so difficult of succeeding in his studies, that for some time he determined to relinquish them. Fortunately his desire for knowledge overcame his modesty, and he applied himself with so much diligence, that he obtained the highest praise of his different tutors, and excited their surprise at his extraordinary progress. He excelled in metaphysics, but his fame with politeness is built on the skill which he acquired in the oriental languages. After avoiding himself of all the advantages which the university of Leyden afforded, he travelled for farther improvement in foreign countries. In England he became acquainted with Bedell, who was celebrated for his knowledge in Hebrew and rabbinical learning. In France he improved himself in his knowledge of the Arabic tongue; and in Italy he improved his acquaintance with the Hebrew language, by conversing with some learned Jews, and made himself master of the Perfan, Turkish, and Ethiopic tongues. After spending several years in foreign countries, Erpenius returned to Holland, where he was elected professor of the oriental languages in the university of Leyden. This was in the year 1612, and very shortly after his appointment he set up a press for the printing of works in the Eastern literature. In the year 1620 he was sent by the States General on different journeys into France, to engage Peter du Moulin, or Andrew Rivet, to undertake the theological professorship at Leyden. After this he was appointed oriental interpreter to the States, and was employed to translate the letters addressed to them from Asia and Africa, and to write such as were sent by them to the sovereigns in those parts of the world. He was frequently invited into Spain by the sovereigns of that country, to explain certain inscriptions in the Arabic language on the Moorish buildings and monuments in that country, and the emperor of Morocco is said to have been highly pleased with the purity and beauty of his style, and to have exhibited his letters as objects of real curiosity. He died in the year 1624, when he was only 43 years of age. His works are numerous, and have given him a high reputation among the learned. They are enumerated by Moret, and other biographical writers, and we are informed that he projected an edition of the Koran, with a Latin version and notes, likewise an Arabic grammar and lexicon, which his death prevented him from executing. Gerard Jean Vollius pronounced over him a funeral oration. Moret.

ERRIS, or ERPIIS, in Ancient Geography, a town of Africa, in Mauritania Tingitana. Polemy.

ERRA, in Geography, a town of Portugal, in the province of Estremadura, on a river of the same name; 22 miles S.E. of Santarem.—Algo, a river, which runs into the Lulas, 12 miles E. of Salvateira, in the province of Estremadura.

ERRABARI, a town of Egypt; 10 miles N.W. of Cairo.

ERRAINE, a town of Egypt; two miles E. of Tahta.

ERRANT, in Law, the same with itinerant; the term is attributed to judges who go the circuit; and to bailiffs at large.

ERRANT, Knight. See Knighth.

ERRATA, a list usually placed at the beginning or end of a book, containing the faults that have escaped in the impression, and, sometimes, even in the composition of the work.

Lindenburg has an express dissertation on typographical errors, "De Erroribus Typographici"; in which he observes, that there is no book exempt from them, not even the sacred books. He sets himself to enquire into all the causes thereof; and proposes means to prevent them, but he advances nothing on that article but what is either common, or impracticable.

ERRATIC, in Astronomy, an epithet applied to the planets, which are called erratic, or wandering stars, in contradistinction to the fixed stars.

ERRATIC fevers, in Medicine, a term used to express such fevers as, according to the language of medical writers, observe no regular type, that is, are not determinate either in their attacks, or in their general period. They are thus called by way of distinction from the typhic fevers, which are regular in both. See Fever.

ERRATIC winds. See Wind.

ERRHINE, in the Materia Medic, from ἡ ἑρήνη, Erinanni, the nose, is a term applied to those substances which are introduced into the nose, for the purpose of exciting a discharge from the passages. When they excite freezing, the medicines of this class have been called pterygine, and stercorarii; and, from the discharge which they occasion, they have been termed apophlogistic, and, in barbarous Latin, caput-purgum.

Erhines, by stimulating the exhalant vessels and the mucous follicles of the Schneidarian membrane, which lines the internal surface of the nose, and the cavities adjoining it, excite those vessels and follicles to pour out their fluids more copiously than usual. The discharge is sometimes of a mucous, and sometimes of a thinner fluid; it is often attended with freezing, but sometimes is procured without. This, however, implies no difference in the operation, except into the stronger or weaker irritation of the medicine employed. For although when freezing is excited a larger evacuation is often produced, yet the effects of erhines are not altogether proportional to the sensible irritation which they occasion. See Allon, Mat. Med. vol. i. sect. 8.

The evacuation produced by these medicines consists not in emptying the mucous follicles or bringing a membrane of the nose of their contents, but in augmenting the secretion: whence, agreeably to the laws of the circulation, a greater influx of fluids to those parts is necessarily occasioned, and therefore a diminution of the fluids in the neighbouring vessels. In this way Dr. Cullen explains the fact, that erhines often give relief to rheumatic pains in the neighbouring parts, especially to the tooth-ach, as well as to some forms of head-ach, pains of the ear, and ophtalmia. "How far their effects may extend," he says, "cannot be exactly determined; but it is probable that they may operate more or less on the whole vessels of the head, as even a branch of the carotid puts into the nose: and independent of this, it is not improbable that our erhines may have been of use in preventing apoplexy and palsy; which at least is to be attended to so far, that whenever any approach to these diseases is suspected, the drying up of the mucous discharge should be attended to, and, if possible, refraeled." Cullen's Mat. Med. vol. ii. p. 436.

The nicotians, or tobacco, as it is commonly prepared for use, who summer themselves by snuffing may be conveniently employed, with people accustomed to it, as an erhine; but repetition soon diminishes its power, and renders it useless. It produces a different degree of discharge in different people, even of those who use it habitually; and Dr. Cullen states, from his own experience, "that whenever the discharge has been considerable, the laying aside snuffing, and therefore suspending that discharge, may have very bad effects."

The article most commonly employed as an erhine, is the Afromojarabosco, snuffed up the nose every evening, for a short time, in the quantity of three grains. Quincy observes,
serves, that its pungency is not immediately felt upon taking, but after some time it makes the nose run very much. In larger quantities it sometimes brings blood, and even occasions a swelling of the whole head. This last effect, however, has been oftener produced by the Euphorbiun, a hill more acrid erhine. Dr. Cullen, speaking of these severe effects, says, "I have seen some infallacies of mægrims, ophtalmias, and particularly tooth-aches, cured by the violent operation of erhines; but I never thought it safe to imitate the practice." The white belliiore, in very small quantity, is also an acrid erhine.

ERRA, in Geography, a province of Africa, in the country of Per. See that.

ERRORISIUS, from which, I precipitate, in Medicine, is used in different senses, sometimes for a weakness of the whole body, sometimes only of some one part. When applied to the whole body, it expresses that utter dejection and prostration of strength which makes a man fall down like a dead carcass; and, when applied to the eyes, it expresses such a debility, as renders it impossible to keep them open.

ERRAOD, in Geography, a town of India, in the country of Coimbatore; 39 miles E. S. E. of Dacomatic, and 48 N. E. of Coimbatore.

ERROL, a small uninhabited town of America on lake Umbagog, on the north-easternmost settled part of Grafton county, in New Hampshire, incorporated in 1724.

ERROMANGO, an island in the Southern Pacific ocean, being one of those called the "New Hebrides," 18 leagues from Sandwich island, and 24 or 25 leagues in circuit. The middle of it lies in S. lat. 18° 34' E. long. 169° 19'; and it is of a good height. Captain Cook anchored in a bay of this island; and he found that although the behaviour of the inhabitants was at first friendly, their real intentions were very different. They were armed with clubs, spears, darts, bows and arrows, and seemed determined to employ them in a hostile manner. On this account it became necessary for the captain to give orders to his men to fire upon the assailants. At length they were so terrified as to withdraw and make no farther appearance. These islanders, it was observed, seemed to be of a different race from those of Mallicolco, and they spoke a different language. They are of a middle size, with a good shape, and tolerable features. Their colour is very dark, and their aspect is not improved by their custom of painting their faces, some with a black, and others with a red pigment. Their hair is curly and crisp, and somewhat woolly. The few women, who were seen and who appeared to be ugly, wore a kind of petticoat, made either of palm leaves, or of a similar plant; but the men, like those of Mallicolco, were almost entirely naked. On account of the treacherous behaviour of the inhabitants of Erramongo, captain Cook called a promontory, or peninsula, near which the skirmish happened, "Traitor's Head." This is in the N. E. point of the island, and is situated in S. lat. 18° 34' and E. long. 169° 28'.

ERRONAN, or Pootova, the most easterly island of all the Hebrides, appeared to captain Cook to be about five leagues in circuit, of a considerable height, and flat at top. On the N. E. side is a little peak seemingly disjoined from the isle; but which was thought to be connected by low land. It is distant in the direction of N. by E. 3/ E. 11 leagues from Port Reolution in the island of Tanna.

ERROR, a mistake of the mind in giving assent to, or a proposition, which is not true. See Fallacy.

Some philosophers define error an act of the mind, whereby things that should be joined are separated; or, things that should be separated, are joined; or a wrong judgment, disagreeing with the things whereon it is placed.

Error stands in opposition to truth, which consists in an agreement between the proposition and the thing whereof it is affirmed or denied.

However, a bare failure, or non-attainment of truth, does not constitute error; that being common both to ignorance and doubting.

Error only stands distinguished from falsity, in that the former is in the mind, and the latter only in the proposition.

The great origin of all error, i.e., of believing that to be true which is false, is a liberty, or power, in the human mind, of giving its affent to ideas, to propositions, that are obscure, as if they were periphrastic and plain.

Particular causes of error are, inadvertency, ignorance, impatience, interest, authority, education, &c. See FAITH, Probability, Opinion.

Against all which, there is this one general rule or caution laid down by F. Malbranche and others, viz., never to give our full assent to any proposition, unless the evidence for it be so strong, as that we can no longer withhold it, without incurring the secret reproaches of our own reason.

Mr. Locke reduces the causes of all our errors to these four; viz. 1. Want of proofs. 2. Want of ability to use them. 3. Want of will to use them. And, 4. Wrong measures of probability.

F. Malbranche considers five occasional causes of error, or rather of five different kinds of errors, accommodated to the different manners we have of perceiving things. 1. Errors of sense. 2. Of the imagination. 3. Of the understanding. 4. Of our inclinations. And, 5. Of the passions. See Sense, Imagination, Understanding, Inclination, and Passion.

ERRORS, popular. See Popular.

Error, in Law, generally denotes a fault, or oversight, either in pleading, or in process; upon either of which is brought a writ, by way of remedy, called a writ of error; in Latin, de errore corrigitae.

A writ of error lies for some supposed mistake in the proceedings of a court of record; for, to amend errors in a false court, not of record, a writ of "false judgment" lies. The writ of error only lies upon matter of law arising upon the face of the proceedings; so that no evidence is required to substantiate or support it; there being no method of reverting an error in the determination of facts, but by an attaint, or a new trial, to correct the mistakes of the former verdict. A writ of error may be brought for notorious mistakes in the judgment or other parts of the record; as where a man is found guilty of perjury, and receives the judgment of felony, or for other leas palpable errors, such as any irregularity, omission, or want of form in the process of outlawry, or proclamation; the want of a proper addition to the defendant's name, according to the statute of additions; for not properly naming the sheriff, or other officer of the court, or not duly delivering where his county or court was held; for laying an offence committed in the time of the late king, to be done against the peace and public good; and for many other similar cases, which (though allowed out of tenders to life and liberty) are not much to the credit or advancement of the national justice. These writs of error to reverse judgments in case of misdemeanours are not to be allowed of course, but on sufficient probable cause shown to the attorney-general; and then they are understood to be grantable of common right, and "ex debito jactantis," but writs of error to reverse attenders in capital cases are only allowed "ex gratia," and not without express warrant under the king's sign manual, or at least by the consent of the attorney-general.

1 Vern. 170, 175.
If a writ of error be brought to reverse any judgment of an inferior court of record, where the damages are less than ten pounds; or, if it be brought to reverse the judgment of any superior court after verdict, he that brings the writ, or that is plaintiff in error, must (except in some peculiar cases) find substantial pledges of prosecution, or bail (rat. 3 Jac. I. c. 8. 13 Car. II. c. 2. 16 and 17 Car. II. c. 8. 10 Geo. III. c. 57.): to prevent delays by frivolous pretences to appeal; and for securing payment of costs and damages, which are now payable by the vanquished party in all, except a few particular instances, by virtue of the several statutes here recited. 3 Hen. VII. c. 10. 13 Car. II. c. 2. 8 and 9 W. III. c. 11. 3 and 5 Ann. c. 16.

A writ of error lies from the inferior courts of record in England into the king's bench, and not into the common pleas. (Finch. L. 480. Dyer 250.) Also from the king's bench in Ireland to the king's bench in England. It likewise may be brought from the common pleas at Westminster to the king's bench; and then from the king's bench the cause is removable to the house of lords. From proceedings on the law side of the exchequer, a writ of error lies into the court of exchequer chamber, before the lord chancellor, lord treasurer, and the judges of the court of king's bench and common pleas; and from thence it lies to the house of peers. From proceedings in the king's bench in debt, detinue, covenant, account, cafe, ejectment, or trespass, originally begun there by bill (except when the king is party) it lies to the exchequer chamber, before the justices of the common pleas, and barons of the exchequer; and from thence also to the house of lords (rat. 27 Eliz. c. 8.); but when the proceedings in the king's bench do not first commence therein by bill, but by original writ issued out of chancery, this takes the case out of the general rule laid down by the statute (1 Rolls Rep. 264. 1 Sid. 424. 1 Saund. 346. Carth. 80. Comb. 295.): so that the writ of error then lies, without any intermediate stage of appeal, directly to the house of lords, the dernier resort for the ultimate decision of every civil action. Each court of appeal, in their respective stages, may, upon hearing the matter of law in which the error is alleged, reverse or affirm the judgment of the inferior courts; but none of them are bound, save only the house of peers, to whose judicial decisions all other tribunals must therefore submit, and conform their own. Blackl. C. 3. book iii.

Error, to ass. See Assign.

Errors, Clerk of the. See Clerk.

Error loci, literally error of place, a doctrine of considerable importance in the theory of diseases, taught by the celebrated Boerhaave. It was deemed the principal cause of those obstructions to the circulation of the blood, on which inflammation, in all its varieties, was supposed to depend. The parts of a fluid," says Boerhaave, "become unable to pass by error of place (per errorem loci), when a copulal in the diluted state of the blood, as it enters the conical canal, and cannot pass through the narrow end of it." (Aphorism 118.) This doctrine is founded upon these three circumstances: the series of particles, of which the blood is composed; the series of progressively diminishing vessels; and the conical form of these vessels: and it is thus explained by the comment of Van Swieten.

The largest particles in the blood are the red globules, which are to be found naturally in the larger vessels only. Now the extremities of the arteries carrying red blood, transmit the red globules freely, according to the observations made with microscopes on the pellicular parts of living animals. The finer parts of the blood are conveyed into the smaller lateral vessels, and the red vein receives the red blood only. The vessel of the next magnitude receives all the fluids except the red globules, and retaining the larger particles only, (viz. the serous globules) transmits the remaining thinner liquids into the still smaller vessels, that arise from the artery. This law obtains, then, in all the decreasing series of vessels. The red arteries can receive and transmit all the humours; the serous arteries exclude the red part of the blood, but transmit the serous globules, and every other thinner fluid, and so on. Now, should the diameter of a lateral vessel arising from a larger one be by any means increased, for example, the aperture of a serous artery, which arises from a red one, a red globule might be able to enter its orifice when thus dilated; but as a conical canal always grows narrower, it will shortly sink fall, and be by no means able to pass through its extremity, and consequently will cause an obfuscation, as the bulk of the particle to be carried through exceeds the capacity of the transmitting vessel.

This error loci of the fluids was considered as the proximate cause of inflammation by Boerhaave, and his commentator illustrates the dilatation and dilution of the lymphatic and serous vessels by the red blood in the case of inflammations of the eye; in which the vessels of the surface of the eye, which are naturally transparent, become red, and visible, sometimes even giving a red colour to the whole of the surface. See Van Swieten, Comment. ad Apil. 118—573, &c.

ERRUCA, in Ancient Geography, a town of Italy, belonging to the Volsci, according to Diodorus Siculus.

ERSE, in Geography, a river of Germany, in the circle of Lower Saxony, which runs into the Fulde, 8 miles S. of Zelle.

ERSH, in Agriculture, is a term signifying land in the rate of rubble after the grain has been taken off. Hence we have pea, bean, and different sorts of grain ephes.

Ersh-Crop, is such a crop as is grown after some of these sorts of rubbles have been turned down by the plough.

ERSTEN, in Geography, a small town of France, in the department of the Lower Rhine, chief place of a canton in the district of Harrow, with a population of 2,344 individuals. The canton contains 14 communes and 8,991 inhabitants, on a territorial extent of 137½ kilometres.

ERTA, a town of Aix, in Parthia.

ERTHOLM, a small island, about three leagues from the coast of Schanen, and half a league from Boraholm. It belongs to the Danes; and till of late was garrisoned only with 50 men: the force has been since augmented to 500. This island may be easily captured and retained by that power, which, during the interval of naval operations in the Baltic, has the superior fleet.

ERTEO del FERRO, a town of Italy, in the kingdom of Naples, and province of Calabria Citera; 10 miles W. of Umbratone.

ERZGEBIRGE, or rather ERTZEBURG, (arch-mountains country,) is the fifth of the ten circles into which that part of the kingdom of Saxony, which is called Saxony Proper, or formerly Electoral Saxony, is divided. As the rest, it is an arch-mountains country, which was nothing but an impervious forest, called Miriquido, or Miriquidi, few spots of which began to be cleared in i.2d. It is bounded to the north by the circles of Mifdia, Menfien and Leipzig, and by the principality of Altenburg, to the west by the same principality, the circles of Neustadt and Voigtländ, and the dominions of the princes of Reuss; to the south and east by the kingdom of Bohemia. Its principal rivers are the Zschopau, the Flöhe, the Pöhl, the Prebischitz, and the Schwartzwasser. The
The territorial extent of the Erzgebirge is 131 German square miles, and its population, in 1785, amounted to 405,600 individuals, which gives 3322 inhab. to the German square mile. It produces corn, potatoes, vegetables, and timber, and its chief products are coal, iron, and silver. The whole circle of the Erzgebirge contains 61 towns and 723 villages. It is subdivided into 13 districts, viz., Freyberg, Angkuburg, Chemnitz, Riesa, Freudenstein, Altenberg, Lautenfels, Wolkenstein, Annaberg, Grünhain, Schwartenberg, Weißersberg, and Zwickau.

**Eruca**, a town of Aisch Minor, in the province of Saxony, is chiefly known for its excellent potatoes and its town hall, which was rebuilt in 1747.

**ERUCA, in Zoology.** See CATERPILLAR.

**ERUCA Marina grjina fasca.** See APPHODITA.

**ERUCAGO, in Botany.** T. vol. ii. p. 103, see BUNIA, spec. 3.

**ERUCATION, Belching, the same as action.**

**ERUDE, in Botany.** T. vol. ii. p. 103, see BUNIA, spec. 3.

**ERUDITION, Belching, the same as action.**

**ERUPTION,** denotes learning or knowledge; and chiefly that of history and antiquity, of languages and of books, which is the result of hard study, and extensive reading. The Scaligers were men of deep erudition: the writings of M. Launoy, a priest of the Oratory, are full of erudition.

Mr. Locke says, it is of more use to fill the head with reflections than with points of erudition. If the mind be not just and right, ignorance is better than erudition, which only produces confusion and obscurity. M. Balzac calls a heap of ill chosen erudition the luggage of antiquity.

**ERUDEIRA, in Geography, a town of Portugal, in the province of Estremadura: 12 miles N.N.W. of Lissabon.**

**ERVILLA, in Botany.** An ancient name for a kind of vetch or pea. See PISUM OCHRUS, also ERUV.

**ERUPA, in Ancient Geography, a town of Arabia Deserta.**

**ERUPT, in general, a burbling forth, or exclusion of anything which was before covered, or concealed.**

The eruption of volcanoes, or burning mountains, is frequently the effect of fine of earthquakes. See EARTHQUAKE, VOLCANO, &c. For an account of the erupions of Mount Atins and Vesuvius, see ATINS and VESUVIUS.

**ERUPTION, in Medicine, denotes the appearance of various spots and discolourations of the skin, whether pulvular, papular, &c.; thus, we speak of an eruption of small-pox, or of measles; and, by a figure of speech, those pulvular, papular, &c., are often denominated eruptions, or cutaneous eruptions.**

**ERUPTION IN INFANTS.** See INFANTS.

**ERUPTIVE DISEASES, a term nearly synonymous with CUTANEOUS DISEASES, (which see).** Eruptive fevers are those febrile diseases which are accompanied by an eruption of spots or thorns on the skin, by which they are principally characterized: such as small-pox, measles, chicken-pox, cow-pox, scarlet fever, erythema, mumps, &c.

ERY

chiefly differs in being rather larger, and in having more rounded and not emarginate leaves. Nothing however is more variable than the termination of the leaves in *Vicia* and its allies. The *pods* are called silky, which is perhaps equally applicable to *E. bifidum*. All things considered, we much doubt of the permanency of this species, which, we, like Willdenow, adopt entirely from the excellent work of Desfontaines. We tolerate, but cannot approve the mixture of Greek and Latin in the name *siculus*, which if the species should remain, ought to be made *vicidicus*.

3. *E. bifidum*. Hairy-podded Tare. Linn. Sp. Pl. 1630. Curtis Lond. f. 4. t. 54. Excl. Bot. t. 66. c. — Stalks many-flowered. Pods hairy, two-seeded. Leaves emarginate.—A pernicious weed in cornfields and pastures throughout Europe. It much resembles the first species, but the *stems* is usually smoother, the ends of the leaves more abrupt and notched, the *flowers* and *pods* more numerous on each stalk. The most essential difference consists in the shorter, somewhat rhomboid, hairy *pods*, with only two seeds.—Mr. Curtis observes that he has "in wet feaons, seen whole fields of corn overpowered and totally destroyed by this plant, which is stronger and more prolific than *E. tetraerisum*." He does nut, however, suggest any remedy. These weeds are too minute and inconsiderable when young to be eradicated, and when they have fixed their tendrils upon the crop, they can no longer be separated without "rooting up also the wheat with them." S. ERYUM. See Sophora.

ERY, in Geography, a small town of France, in the department of the Aube, chief place of a canton in the district of Troyes, with a population of 1752 individuals. It is 9 miles S. of St. Florentin, and has some manufactures of linen-cloth. The canton contains 14 communes and 11,999 inhabitants, on a territorial extent of 222.4 kilometres.

EWRASH, a river of England, which rises in the county of Nottingham, and almost in its whole course separates that county from Derbyshire, and falls into the Trent, 4 miles S. W. of Nottingham. See Erewash.

ERWITE, a town of Germany, in the circle of the Lower Rhine, and duchy of Westphalia; 5 miles S. of Lippstadt.

ERXLEBEN, John Christian Polycarp, in Biography, was born in June, 1734, at Quedlingburg, where his father was dean of St. Nicholas's church. He studied medicine at Gottingen, where he took the degree of master of arts in 1755, and shortly after gave lectures on natural history and the veterinary science. Having published his introductory lectures, he undertook, at the expense of the Hanoverian government, a tour through France, Holland, Denmark, and a great part of Germany, in the course of which he acquired much practical knowledge in the veterinary art. On his return he lectured on the several sciences connected with natural history, and natural and experimental philosophy. In 1774, and the following years, he was elected a member of most of the learned societies on the continent. He died in August, 1777, when he had but just attained his thirty-third year. Erxleben published many works which were highly esteemed, among these are "Principles of Natural History;" "Principles of Natural Philosophy;" "An Introduction to the Veterinary Art." Gen. Biog.

ERYANNOS, in Ancient Geography, a river of Asia Minor, in the Troade, which had its source in mount Ida.

ERYBIUM, a town of Greece, in the Doride, situated, according to Diodorus Siculus, at the foot of mount Parthenius.

ERYCEIRA, Francis de Menezes, Count of, in Biography, born at Lisbon in 1614, was brought up to the use of arms, and obtained some important offices under government; but in the midst of his usual occupations he cultivated literature, and published a number of works, particularly histories of Tangier and Portugal; and the life of John I. king of Portugal.

ERYCEIRA, Francis Xavier de Menezes, was grandson of the preceding, and, like him, united a literary with an active and military life. He was born at Lisbon in 1672, and rose to eminence in the State. He was chosen member of various learned societies. From his ancestor he inherited a valuable and extensive library, to which he made many great additions. He is said to have been the author of more than a hundred different works, of these, however, but few seem entitled to notice. The best known are, "Memoirs on the Value of the Monies of Portugal," 4to. 1738; "Reflection on Academical Studies;" "Parallels on Illustrious Men and Women;" and "A Translation of the Henriade." He died in the year 1743. Nouv. Dict. Hist.

ERYCINA, in Mythology, a surname given to Venus, from Erix, a mountain in Sicily, where she had a temple. Venus Erycina had also a temple at Rome, which was deemed very ancient even in the time of Thucydides. See Erix.

ERYMANTHUS, in Ancient Geography, a mountain or forest of the Peloponnesus, in Arcadia, E. of a river of the same name, which had its source towards the north, on the confines of the Elide and of Arcadia, in mount Lampie. The wood of Erymanthus was full of boars, which made great devastation in the country. Hercules was employed to give chase to them, which he did with such success, that he slew with his own hands the largest of them. See Hercules—Als, a town of the Peloponnesus, in Arcadia, called Phlegia and Pyrophyllus, according to Paufanias.

ERYMI, a people of Scythia, on this side of the Imaus. Ptolem.

ERYNNE, a town of Asia Minor, in Lydia. Step. Byz.—Als, a town of Greece, in Thessaly; placed by Pliny in Magnesia.

Gen. Ch. Common Receptacle conical. Flowers all fertile, sessile, with scales between them. *Involucrum* of the whole receptacle of many leaves, flat, spreading beyond the flowers. Cal. Perianth inferior, of five upright, acute leaves, sessile on the germen, shorter than the corolla. Cor. in the aggregate uniform, roundish. Petals five, equal, either with a linear longitudinal striation, their points bent in, so as nearly to reach the base. Stam. Filaments five, capillary, straight, projecting far above the corolla; anthers oblong, vertebrate. Pfi. Germen inferior, brilly; styles five, thread-shaped, a little spreading, somewhat shorter than the filaments; stigma simple. Peric. Fruit ovate, separable perpendicularly into two parts. Seeds oblong, cylindrical; in some species remaining shut up in the crust of the pericarp, in others deciduous from it.

A most singular and very natural genus, having the habit and aspect of a thistle, the herbage rigid, thorny, either
Ery

either more or less tinged with vivid blue, or pallid and whitish; while the fructification is exactly that of an umbelliferous plant, though the florescence is capitule. Willdenow has eleven species, but they and their synonyms require a thorough investigation. Two are natives of Britain, viz., E. maritimum, Engl. Bot. t. 718, (in which plate we are sorry to remark that the petals are drawn reflected instead of inflexed, an error that till now escaped us.)—This frequent on sandy fdy shores throughout Europe, flowering in July and August. The long creeping perennial roots are aromatic and somewhat acid; they are esteemed diuretic and restorative, and are sometimes sold candied. The herbage is glaucous variegated with a permanent blue. Leaves round, pointed, lobed, with spinous teeth. Flowers blue, in dense terminal heads, encompassed with a large leafy involucre. Scales of the receptacle three-cleft. The other British species is E. campyloides, Engl. Bot. t. 57, found very rarely in England, though common on the continent. Its leaves are much more narrowly divided than the first, and pinnatifid. Flowers greenish-white, with narrow involucral leaves and undivided scales. This appears to be r. 270 of Dioscorides.

Among the exotic kinds E. amethystinum, Linn. Sp. Pl. 337, a native of Syria; E. alpinum, ibid. Curt. Mag. t. 925, from the Swifs alps; and E. planum, Jacq. Auct. t. 391; are all hardy perennials, frequently cultivated for ornament. E. amethystinum is indeed nearly hirsute, but, on account of its many-leaved, finely divided, blue involucrum. The following five species are not in Willdenow.

E. cyanum. Sm. Prod. Fl. Grac. Sibth. v. t. 175. Fl. Grac. v. 3. t. 258. unpublished. "Radical leaves in five deep pinnatifid segments. Stem much branched and divaricated. Involute of about five leaves."—Common in Greece and the islands of the Archipelago. The root is perennial. Stem 12 or 18 inches high, of a fine blue, as well as the involucrum and foliage, many-flowered and divaricated. Leaves small, in linear, narrow, pinnatifid segments. Heads of flowers small, blue, with prominent, conspicuous, white anthers. This most resembles E. triquetrum, Vahl. Symb. v. 2. 46, in habit, but the flowers and involucrum are very different.

E. multifidum, ibid. Fl. Grac. v. 3. t. 259. "Leaves doubly pinnatifid, somewhat lyrate; radiated at the extremity. Stem corymbose. Involute pinnatifid."—Gathered by Dr. Sibthorpe in the Morea. Taller than the last, with a bright blue stem and flowers. The finely pinnatifid leaves give it the aspect of an Echinops. This is presumed to be Eryngium curvipes ericetum, Schreb. multifido, caule et ramis amethyfthinum; Tourn. Cor. 23.

E. parciflorum, ibid. (E. folis lacinios, capulis flororum exiguis et dense congestis; Tourn. Cor. 23.) "Leaves bipinnatifid. Stem corymbose. Involute three- or simple, four times as long as the head." Of this no figure is extant, nor is it known where Dr. Sibthorpe gathered the specimen found in his herbarium. The root is perennial. Herb whitish. Stem densely clothed with leaves, and bearing numerous flowers at the summit. Leaves twice or thrice pinnatifid, their segments narrow and divaricated. Heads of flowers very small, with large involucra, generally of five leaves, which are either undivided or three-cleft.

E. purpureum. Leaves all pinnatifid, their lower part fringed with capillary teeth. Stem nearly simple, with few flowers. Involute of about seven undivided leaves. Gathered near Tangier by the late M. Broussonet and the Abbé Durand, who formerly sent specimens to Dr. Smith. Root perennial. Stems a foon high, round, furrowed, leafy, fearlessly branched, but bearing about three dark-blue heads of flowers, with very spinous calyces. Leaves all nearly alike, pinnatifid, with decurrent, sometimes lobed, segments; their lower part clasping the stem, pectinated, fringed with fine long capillary teeth. Great part of the stem, and the upper side of each leaf of the involucrum, are tinged with a rich deep bluish purple, hardly equalled in any other of the genus.

E. carthusioides. Leaves oblong, toothed, undivided, heart-shaped and clasping the stem at their base. Stem nearly simple, with few flowers. Involute of several ovate leaves. Gathered by J. Broussonet in the neighbourhood of Algers, flowering in June. Stem a foot high, strong, round, leafy, sometimes purplish, simple, except at the summit, where it bears from three to five large heads of blueish flowers, whose involucrum consists of several large, ovate, purplish, spinous-toothed leaves, much resembling those of a Carthusioides. The radical and stem-leaves are all simple, oblong, wavy, with large spinous teeth, veinzy and pale-green.

ERYNGO, in the Materia Medica. The root of eryngo is an extinguent and deobliguent, and is therefore esteemed a good hepatic, urticae, and nephritic. Its whole virtue, it is to be observed, consists in the external or cortical part. Their virtues, however, appear to be but weak; and they are now scarcely otherwise used than as made into a sweetmeat.

The London college directs it to be candied in the following manner: boil the roots till the rind will easily peel off; when peeled, slice them through the middle, and the pith being taken out, wash them three or four times in cold water; then for every pound of roots thus prepared, take two pounds of double-refined sugar; disolve the sugar in water, let it on a fire, and as soon as it begins to boil, put in the roots, and continue the boiling till they become soft.

These candied roots are an ingredient in artificial ajis milk, which is thus made: take of candied eryngo root one ounce, pear barley half an ounce, liquorice root three drams; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil them gently together, then strain the liquor for use, of which half a pint should be drunk three times a day.

ERYNYS, q. d. 4; 12; 15; contentio mentis, or before, as Paulinus remarks, iuxta significat to fall into a fury, or Furius, a name given to Ceres by the Sicilians.

Gen. Ch. Cal. Periainus in five deep, roundish, concave, permanent segments. Cor. of one petal, falver-shaped; the length of the calyx; tube cylindrical, pervious; limb the length of the tube, in 10 roundish segments, spreading. Stam. Filaments five, very short, inserted into the lower part of the tube; anthers erect, ovate, shorter than the tube. Pfyt. German superior, ovate; style none; stigma five-lobed. Peric. Berry oval, of one cell. Seed solitary, large.

E. paniculata. Roxb. Coromand. t. 159. The only known species, a native of the mountain forests of India, from whence Dr. Roxburgh sent us specimens in 1789. A very large climbing shrub. Branches alternate, leafy, round, clothed when young with copious rusty down. Leaves alternate, three or four inches long, spreading and 2-3-lobed.
deflected, elliptic-oblong, pointed, entire, velvety; smooth and shining above; paler and opaque beneath. Posterior half an inch long, angular, finely. Stipulas none. Peduncles many-flowered, terminal, erect, much branched, about a span long, their flanks, small oblong feathered bracteoles, and the calyx, all deflexely clothed with tubby down. Tube of the corolla greenish; limb yellow, about three lines in diameter. Berry the size of a small cherry, black, pulpy, containing one large seed.

Of the uses or qualities of this plant or its fruit we have no account. From its botanical affinity to Chrysocephalum, Achara, &c. it may certainly be eaten with safety. 'The flowers are not inedible.'

ERYSIMA, in Ancient Geography, a town of Asia, in Cappadocia.

Gen. Ch. Cal. Perianth of four ovate-oblong, colored, parallel, cohering, deciduous leaves. Cor. cruciform, of four oblong flat, very obtuse petals, whose claws are the length of the calyx and erect. Nectary a gland between each of the shorter filaments and the germen. Stam. Filaments fix, the length of the calyx; of which two opposite ones are shorter than the rest; anthers simple. Pet. Germen superior, linear, square, the length of the flanum; style very short; stigma small, capitate, permanent. Peric. Pod long, linear, straight, exactly square, of two cells and two valves. Seeds numerous, small, roundish.

Willdenow has 14 species, of which five are British.

1. E. officinale. Linn. Sp. Pl. 922. Curt. Lond. fabe. 3. t. 50. Eng. Bot. t. 753. "Pods close-pressed to the main flaks. Leaves ruminate." Common in wakie ground and about hedges. This is usually taken for the species of Dioecorides, whose description, more full than usual with that writer, is very applicable to it. Dr. Sibthorp, however, decidedly considered Sibemmium polycocorum as the plant Dioecorides meant, and this, perhaps, will be found to accord ill better with his description, which compares the horn-like pods to fængreck. See its figure in Mathiolius, Ed. Valgr. fol. v. 1. 524. The species of Theophrastus is supposed to be a still different plant, as he reckons it among the various kinds of grain.

In this and similar cases, therefore, though the Linnean generic name is adopted from ancient writers, it does not follow that their plant is of the same genus, which matter is frequently impossible to be ascertained. It is sufficient that such names are established by common consent amongst systematical botanists, from whom they acquire a new stamp of authority; nor ought they to be changed, whatever new light may be thrown upon them by future commentators. We study by the arrangements of Linnaeus or Jussieu, not by those of Theophrastus or Dioscorides. It is only in case any species requires to be separated from an established genus, that we are glad to recur to its ancient appellation for a generic name; as in the cases of Cyamus, Sm. Exot Bot. v. 1. 50. t. 51. 32 (see Cyamus); and Nuphar, Prod. Pl. Grec. v. 1. 361.

"Lower leaves lyrate; their terminal lobe rounded; upper ones obovate, toothed."—Common in wakie ground, either dry or wet, flowering most in the spring. Its numerous flowers of a full yellow, often seen double in gardens, and its dark flowering broad leaves easily distinguish it. The whole plant has a nauseous, bitter, fanny flavour.

3. E. procera. Sm. Fl. Brit. 757. Eng. Bot. t. 129. "Lower leaves lyrate; upper ones pinnatifid, their segments linear, oblong, and entire."—Found in Devonshire by the Rev. Dr. Becke. The narrow lobes of the flower, smaller flowers, and much longer pods, distinguishes this from the last, with which we believe Linnaeus confounded it. The distinction is highly important, as we are convinced the present is the very same with the American Cystis, as it is called, or rather Winter Cystis, of the gardens, an agreeable and wholesome pungent herb for salads, &c.

The exotic species are not quite so well ascertained as ours. Elberhart and Roth have taken pains to elucidate them, and the result is given by Willdenow. We know not that any of them is worthy of the attention of the cultivator except for botanical curiosity. They are all either annual or biennial, perfectly hardy in our climate, and bear narrow lanceolate leaves, with small yellow flowers. As weeds their copious seeds render them rather troublesome.

ERYSIPELAS, from σεπελας, to draw, and ευος, near, from the diffusion of the affection to draw the adjacent parts into the same state; or from σεπελας, red, and μαλα, black, a dark red. The generality of surgical authors have considered erysipelas as a species of inflammation, and every reflection induces us to entertain the same opinion, notwithstanding the opposite sentiment of one of the lectors on surgery in this metropolis. The immortal Celsius has observed: 'notas vero inflammationis sunt quatuor: rubor, et tumor, cum calor et dolore,' lib. 3. cap. 10. According to this definition, erysipelas is certainly an inflammation, although the degree of swelling is not so great, nor the pain exactly of the same kind, as in cases of phlegmon, or common inflammation.

With many distinguished surgical authors, we regard erysipelas as a particular kind of inflammation, most frequently affecting the small veins on the surface of the body. It is, as Mr. Hunter describes, more commonly a cutaneous inflammation, than one situated in deeper parts; although it is probable, that in some confections, every inflammation, wherever it exists, will be of this kind. However, there can be no doubt of the fact laid down by this accurate observer, viz., that the skin appears to be the most susceptible of erysipelas, because this affection will spread over a prodigious extent of the surface of the body, while (at least, in common instances) the cellular membrane underneath remains free from disorder. (See Hunter on Inflammation, p. 270.)

Mr. Hunter taught surgeons, that one of the uses of the adhesions,
ERYSIPELAS.

Adhesions, which form in cases of common inflammation, is to circumcise and bound the matter, in the event of suppuration taking place. Now, in erysipelas, the extravasation in the place affected is not so considerable as in phlegmon, nor is it of that kind, which produces adhesions among the inflamed parts. Indeed, since erysipelas seldom ends in suppuration, such adhesions, according to Mr. Hunter's view of the subject, would in general be unnecessary. Perhaps, also, the circumference of there being no adhesions in erysipeltal cases, may account for the terrible diffusion of mischief, which always happens, when adhesions do occur; and make the disease take place. Then, we know, that the matter makes its way extensively through the cellular subismence, in every direction under the skin, under fat, and between the muscles, producing, wherever it goes, what has been often named a gangrenous suppuration. When erysipelas is of an unmixed kind, it has not the dark red colour which common inflammations have, but a lighter red, with a yellow tinge, which is particularly observable towards the termination of the disorder. The swelling which occurs is unattended with any remarkable induration, and forms a very inconsiderable prominence. The skin of the inflamed part has a shining appearance, and, on being touched with the finger, turns white at the spot where the pressure is made; but the bright red colour immediately afterwards returns. The pain is usually of a burning, shooting description, and the patient frequently complains of a fort of itching, which is found to be particularly annoying. The swelling, which happens in cases of erysipelas, is not only not so hard and elevated as that which arises in examples of phlegmonous inflammation, it is at the same time not so clearly circumscribed.

Another remarkable feature of erysipelas, is the manner in which this inflammation often changes its situation, by getting well on one side, while it is spreading in some other direction. The great celerity with which the affection spreads, and the large surface which it in a very little while covers, may also be set down among its most striking peculiarities. When the affection is intimately dependent on the state of the constitution, we very often see all the local symptoms recede in one place, and the disease make its attack in some other part of the body. Such instances are not uncommonly mentioned by writers as metagales, just as if it were a real fact, that, when the erysipelatous symptoms get well on one leg, and the other leg becomes affected in a similar way, these events happen, in consequence of the first identical disease actually moving from one limb to the other. From this absurd doctrine originates all the cant about the danger of using such applications as are likely to repel the inflammation. The truth is, that the second attack of the erysipelas is not at all connected with the termination of the first; but arises from some different, and probably inexplicable cause, just as encysted tumours will often form, one after another, in various parts of the body, as regularly as they are cut out. In this latter instance, no one is abjured enough even to suspect that the growth of one tumour is the effect of a previous one being cured.

In true erysipelas, there is no throbbing of the part affected, as in cases of phlegmon; and when erysipelatous inflammation runs along the skin, the affection has a determinate edge, and does not lose itself gradually and insensibly in the surrounding parts, as common inflammation does.

The alteration which the skin undergoes in erysipelas consists in its feeling at the part affected less pliable than in the natural state, and a little thickened.

Such are the ordinary local symptoms of erysipelas.

They are subject, however, to some variety, depending on the mildness or violence of the attack, and on the circumstance of the disorder being either simple, or complicated with another affection; for instance, oedema, phlegmon, &c.

With respect to violence, erysipelas may be very properly divided into three degrees. In the first, or mildest form of the complaint, the erysipelas makes its appearance, without any preceding illness, or with only a slight indisposition of short duration, and confounding of latitude, disturbed sleep, loss of appetite, &c. Their complaints very soon go off, when the erysipelas comes out, which happens in about a couple of days. For two days more the local symptoms remain the same, and then the erysipelas turns pale and yellow, gradually disappearing altogether, with a detachment of the cuticles. During the whole course of the disorder there is no fever of any consequence; but a little while before the redness occurs the pulse is sometimes rather disturbed.

In the second, or more severe degree of the disorder, the patient is troubled, about two days before the erysipelas makes its appearance, with an unusual prostration of strength, heaviness in all his limbs, headache, loss of appetite, nausea, and even actual vomiting, complaints in the stomach, &c. Besides these inconveniences, the patient is affected with a fever, and all its usual symptoms. After a couple of days, commonly on the third day from the commencement of all indisposition, the erysipelas comes out, attended with a gentle sweat, and a moderate increase in the secretion of urine, after which circumstances the fever, with all its attendant symptoms, goes off. The rest of the progress of the case is similar to what we have related, as happening in the first, or mildest attack of erysipelas.

In the third, or most violent degree of the disorder, particularly in those cases in which erysipelas makes its attack on the face, the patient is affected with severe febrile symptoms, headache, loss of sleep, delirium, sickness, &c. These complaints do not diminish, as in the milder cases of erysipelas, when the local redness, heat, &c. take place on the third day; but continue with unabated vehemence, until the erysipelas itself subsides. The last desirable event commonly happens, according to Richter, on the eleventh day, accompanied with an increase in the secretions from the skin and kidneys.

The most dangerous cases of erysipelas are those in which the face is affected. Of this form of the disorder, the celebrated Cullen has left us a matchless description, which we think is highly deserving of repetition in this Cyclopaedia. The erysipelas of the face, (says this interesting author,) comes on with a cold Sweating, and other symptoms of pyrexia. The hot state of this is frequently attended with a confusion of head and some degree of delirium; and almost always with drowsiness, or perhaps coma. The pulse is always frequent, and commonly full and hard.

When these symptoms have continued for one, two, or at most three days, there appears on some part of the face a redness, such as that of erythema. This redness at first is of no great extent; but, gradually spreads from the part it first occupied, to other parts of the face, commonly till it has affected the whole; and frequently from the face it spreads over the hairy scalp, or descends on some part of the neck. As the redness spreads it commonly disappears, or, at least decreases in the parts it had before occupied. All the parts upon which the redness appears are at the same time affected with some swelling, which continues for some time after the redness has abated. The whole face becomes considerably turgid; and the eye-lids are often so much swelled, as entirely to shut up the eyes.

3 P
To continue Dr. Cullen’s account: when the redness and swelling have proceeded for some time, there commonly arise, sooner or later, blisters of a larger or smaller size on several parts of the face; these contain a thin yellowish, or almost a colourless liquor, which sooner or later runs out. The surface of the skin in the blistered places sometimes becomes livid and blackish, but this livor sordidus goes deeper than the surface, or discovers any degree of gangrene affecting the skin. On the parts of the face not affected with blisters the cuticle suffers, towards the end of the disease, a considerable desquamation.

Sometimes the tumours of the eyelids end in a suppuration. The inflammation coming upon the face does not produce any remission of the fever which had before prevailed; and sometimes the fever increases with the increasing and spreading inflammation.

The inflammation usually continues for eight or ten days; and, for the same time, the fever and symptoms attending it also continue.

In the progress of the inflammation, the delirium and coma attending it sometimes go on increasing, and the patient dies apoplectically, on the seventh, ninth, or eleventh day of the disease. In such cases, it has been commonly supposed that the disease is translated from the external to the internal parts. But, Dr. Cullen observes, that he never met with any instance in which it did not appear to him, that the affection of the brain was merely a communication of the external affection, as this continued increasing at the same time with the internal.

When the fatal event does not take place, the inflammation, after having affected a part, commonly the whole of the face, and, perhaps, the other external parts of the head, ceases. With the inflammation the fever also ceases; and, (says Cullen,) without any evident crisis, the patient returns to his ordinary state of health.

The same distinguished writer represents the disease as being not commonly contagious; but he conceived it possible that it might sometimes be communicated from one person to another; and, he adds, that persons who have once laboured under the disorder are liable to return of it.

According to Cullen, the event of the disease may be foretold from the state of the symptoms which denote more or less affection of the brain. If neither delirium nor coma comes on, the disease is seldom attended with any danger; but when these symptoms appear early in the disease, and in a considerable degree, the utmost danger is to be apprehended.

We have already remarked that, in cases of erysipelas, suppuration does not frequently happen; but that when it does, owing to the matter not being confined by the adhesive inflammation, very bad consequences follow. Whenever the matter spreads, it occasions under the skin an extensive sloughing of the skin, tendons, and cellular substance, all which kind of mischief may take place, while the skin itself, which is very vascular and highly organized, remains unimpaired in its texture. This combination of suppuration and mortification is more likely to happen when the erysipelatous inflammation extends to a greater depth than common, so as to affect the cellular membrane. In this state, as Mr. Hunter has well described, air, matter, and floughs, are all produced together under the skin, and, in handling the part, a strange feel is communicated, neither like that of a fluctuation, or a crepitation. Mr. John Pearson very whimsically, we will not say unaptly, compares the sensation with that excited by a quagram or moras. Frequently, the practitioner may observe in some opening, made either by ulceration or the lancet, a small black flougy point, and, on taking hold of it with a pair of forceps, and drawing it out, he finds, to his great surprize, that a whole mortified tendon, of considerable length, follows his instrument.

Erysipelas is to be met with more frequently in summer than winter, and more commonly in hospitals than other places. Wounds of the head, more often than any other kind of accident, give rise to the disorder.

Erysipelas has sometimes been observed on the skin of new-born infants. Several instances of this kind are mentioned in the Medical Communications, as having occurred in the British Lying-in-Hospital. In one of these examples the child was born with its whole face swollen and inflamed, the left side being affected with a true erysipelas. There was also an inflammation on the legs, feet, and left hand. On each side, there appeared an oblong slough, of a dark brown colour, almost livid; the one on the leg was exceedingly large. The cure was attempted by employing embrocations, emollient poultices, and fomentations, and applying camphorated spirit of wine. This child appears to have swallowed the decoction of bark with great ease, as it took four ounces of it every day from the very time of birth. In three days the swelling of the face and other parts had considerably subsided; but, on the third day, a vesication began to form on the left cheek, and another just above the eye-brow, on the same side. These vesications increased in number and size, especially on the legs, where they extended over the whole limb. Some confluent carbuncles were added to the decoction of bark, and pledgets, dipped in oil of turpentine, were put on all the parts affected, previously to the application of the poultice. The vesications began to break on the sixth day, and a painless yellowish matter issued from them; yellow flakes also now made their appearance in different parts. The child remained much debilitated, and, for the last three or four days, had taken eight ounces of the decoction of bark, with one dram of the confluent carbuncles every twenty-four hours. The pledgets, applied to the fores, were dipped in a digestive ointment, with oil of turpentine, and some calamina e cymno. Under this mode of treatment, the floughs were soon detached, and the child recovered though not without the loss of the little finger, two joints of the ring finger, and one of the middle one.

The distemper, which we have just been describing, for some time proved extremely fatal, none of the infants recovering who were attacked. However, bark is stated to have acted quite as a specific remedy for the disease, as soon as it was tried, and almost all the children are said to have got well who took this medicine. Mortification always took place in such subjects as died; and the danger was regularly observed to be the greatest in the infancies in which the genitals were the parts first attacked. The disease was also noticed to affect the children of weakly women, and of such as were addicted to drinking spirits.

To return, however, to our account of the common forms of erysipelas, we have to apprise the reader, that the term "St. Anthony’s fire," which is so frequently mentioned by all sorts of persons, is strictly applied by medical writers and practitioners to that species of the affection in which vesicles arise upon the surface of the skin; while other infirmities, not accompanied with vesications, are named simple erysipelas.

The division of the subject, however, cannot be properly comprehended under these two varieties; and the generality of authors have found it necessary to observe other distinctions.

Mr.
ERYSIPELAS.

Mr. Pearson, in his Principles of Surgery, has noticed the following species of the complaint:

1. The acute erysipelas.
2. The edematous erysipelas.
3. The malignant, or gangrenous erysipelas.

Each of these species may be an idiopathic, or symptomatid disease.

Mr. Pearson remarks, that the acute erysipelas is most commonly seen in those of a faduluous and choleric temperament; it is generally sudden in its attack, and usually affects the face. Febrile symptoms are often present immediately after the accession of the diseased; but they gradually diminish as the erysipelas becomes more distinctly formed. Considerable heat, and great uneasiness, take place in the part affected; the skin is also of a brighter red colour than in the other species. If pus-tules appear, they are distinct; but sometimes there are no evolutions on the surface.

Suppuration very rarely occurs in this kind of erysipelas, and the violence of the disease usually subsides in three or four days; the part then grows yellowish, and throws off furfuraceous scales. The disease terminates about the twentieth day. A tenderness of the hairy scalp will often continue for a considerable time after the disease has disappeared.

The acute erysipelas, as we have already observed, is sometimes an idiopathic affection; frequently it is symptomatic, or, in other words, the consequence of a wound, especially one of the head. Persons who have once been attacked with the acute erysipelas, in a spontaneous manner, are particularly liable to suffer again from future attacks of the same disorder.

Mr. Pearson states, that the edematous erysipelas is not, in general, so sudden in its attack, nor so severe on its accession, as the acute erysipelas. The disease increases gradually, is more diffused, and is attended with less burning pain. If febrile symptoms should arise, they never run high, nor are they of long duration; most commonly the strength is depressed, attended with a soft, frequent, perhaps, irregular pulse. In this species of erysipelas no constitutional relief is derived from the appearance of the local affection; on the contrary, the danger increases with the progress of the external disease.

When the face is the seat of the edematous erysipelas the whole countenance has a bloated appearance. The red colour of the skin is mingled with yellow or brown, and the complaint is attended with flouriness, vomiting, and more or less disturbance of the functions of the brain. Mr. Pearson further remarks, that the vesicles are often small and numerous, and, that when they have been exposed for a few days to the air, the countenance becomes covered with a dark-coloured crust, very much resembling the appearance which arises in the confluent fsmall-pox. Though the face is very much swollen, it is not firm to the touch, and easily yields to pressure.

The edematous erysipelas is deemed highly dangerous. Patients often die, in a delirious or comatose state, about the seventh day, sometimes a little later.

It is common to see many people afflicted with this species of erysipelas about the same time. Mr. Pearson informs us that, in hospitals, he has seen several persons successively attacked with the complaint in the same ward. Some conjectures have been entertained of the disorder being contagious.

All ages and constitutions may be affected with the edematous erysipelas. However, subjects weakened by age, or intemperance, are most frequently attacked. Dropical patients, children, and new-born infants, are also seen affected with the complaint.

According to Mr. Pearson, the edematous erysipelas, when symptomatic, is much less dangerous than when idiopathic; but, says this author, whenever the face is considerably affected, the disease is always to be regarded as a serious one, whatever be the remote cause. On the limbs the disease is seldom dangerous, or very afflicting, unless treated in an improper way. Mr. Pearson mentions his having seen the edematous erysipelas make its first appearance upon the face, and, by a gradual and regular progression, proceed downward to the extremities, successively appearing upon an inferior portion of the body, as it disappeared from a superior part. Each renewed accession of the complaint was less and less severe, as it receded to a greater distance from the part that was primarily affected.

The malignant, or gangrenous erysipelas, makes its first appearance somewhat like the edematous form of the disorder. Its progress, however, is much quicker. Phlyctenous, with a livid base,soon occur on the skin, together with gangrenous symptoms. The disease, at a very early period, becomes attended with a stench of the constitution, resembling that which exists in putrid fevers.

The gangrenous erysipelas mostly occurs on the face, neck, breast, and shoulders: the danger of the disease depends very much on the state of the constitution.

When an erysipelatous inflammation, particularly one of the legs has been cured, a degree of edema will frequently continue about the lower part of the limb for some time afterwards.

Erysipelatous inflammation differs from phlegmon in the following respects. The swelling is less prominent; and is never distinctly circumscribed. The skin often has the appearance of being scorched, or burnt. The redness is quite circumscribed, has a very determinate edge, is frequently tinged with yellow, and, on being touched with the end of the finger, a white spot is produced for a short time in the place where the pressure was made. The pain is not of the lancinating, throbbing kind, which attends phlegmonous inflammation; but is such as causes a sense of heat and burning in the part, together with a violent degree of itching. The part affected does not present the feel of, what surgeons understand by, tenesmus; but only seems to the touch as if the skin were a little thickened. Except in the acute erysipelas, there is no hardness of the pulse, as in cases of phlegmon, and instead of being attended, as the latter affection, with rather an increase of strength, erysipelas is almost always accompanied with more or less debility.

With respect to the causes of erysipelas our knowledge is very imperfect, and every observation on this subject must be received with doubt. We do not mean to state, that the remote causes are not very often sufficiently obvious. We frequently have occasion to remark, in the practice of surgery, that certain punctured wounds, and injuries of the external parts of the head give rise to erysipelas. Indeed, we may state, as a general remark, that the same class of irritations, termed remote causes, which in one constitution would occasion phlegmonous inflammation, in another would excite erysipelas. What is far more difficult of investigation, is the cause why erysipelas should take place rather than common inflammation; in other words, the exact particularity, to which the origin of erysipelatous inflammation is to be ascribed, is involved in much more obscurity. Sometimes even the remote cause cannot be discovered, the affection having the appearance of originating in a spontaneous manner.
ERYSIPELAS.

It was one of the ancient doctrines, established by Galen, and maintained down to the present time, that what is understood by a bilious habit is particularly subject to erysipelas inflammation. Many parts of the writings of the celebrated Pett, the experienced Richter, and other noted modern writers, evince their belief in this opinion. Weak and irritable constitutions appear to us to be most subject to erysipelas; while strong, phlegmonic persons most frequently undergo common phlegmonic inflammation. We think, that there is every reason to believe, that, in general, erysipelas is intimately dependant on the state of the constitution, or on some peculiarity of temperament. This opinion is somewhat confirmed by the fact, that while persons, who lead drunken, intemperate lives, are particularly often afflicted with erysipelas inflammation, in consequence of local injuries, other people, who lead more regular lives, generally have phlegmonic inflammation after similar injuries.

It must be admitted, however, that erysipelas occasionally makes its appearance in constitutions with which we can find no evident fault. Indeed, Hunter seems to have considerable reason for his inference, that the affection may, in some instances, be altogether independent of constitutional causes, since it is the common course of the disease to be actually getting well on one side as fast as it is spreading on another.

If we can sometimes assign particular circumstances, which operate as causes conducive to erysipelas, it is all that we can hope to do. To trace the proximate cause in every example which presents itself, is far beyond our pretensions; neither do we believe that it is to be done by the powers of human research. We might adopt the language of Cullen, and talk of erysipelas depending "on a matter generated within the body, and thrown out, in consequence of fever, upon the surface of the body." We might also join Mr. Pearson in representing erysipelas as being sometimes the "critical termination of another disease, such as obstructed menstruation, quartan ague, suppressed suppuration, phlegmonic and convulsive diseases." However, we should shew just as much devotion for truth, were we to offer any other wild, vague suppositions, unsupported by rational evidence.

Left aspiring in our attempts, we shall only aim at pointing out circumstances which seem to act as causes, conducive to the disorder, in some instances. If many women of temperate lives, and young children, are occasionally affected with erysipelas, as they undoubtedly are, the fact only proves, that there are other causes besides intemperance which may be concerned in giving rise to the complaint. The sources of the disease must, we believe, on some occasions, be regarded as among the mysterious and inaccesible secrets of nature. When drunkenness and other kinds of intemperance are assigned as causes conducive to erysipelas, it is not meant that they are exclusively so. There are, probably, hundreds of other causes in existence, though we may not be able to detect them.

With regard to women of temperate regular lives, and to children being occasionally affected with erysipelas inflammation, the fact cannot be called in question. But, still, no experienced man will contend that such subjects are attacked with erysipelas, on meeting with local injuries, half so frequently as persons with constitutions impaired by any kind of intemperance, habits, or modes of life.

Richter and some other writers, have described erysipelas as depending very much on a suppressed state of the periphraxis; but we are inclined to think that they have ascribed the importance of a canse to a mere effect of the fever, with which erysipelas is connected.

Treatment of the acute or phlegmonic erysipelas.—This species of the disase being commonly attended with a full, and frequently, a hard pulse; the blood drawn flowing upon its surface the buffy coat to be seen in all inflammatory complaints; and lastly, the swelling of the eyelids, frequently ending in suppuration; there can be no doubt, that the affection should be treated very much in the same manner as phlegmonic inflammation. Blood-letting, cooling purgatives, and every part of the antiphlogistic regimen, are advised by Cullen, who affirms, that his experience has confirmed the fitness of this method of cure. The evacuations of blood-letting and purging are to be employed, more or less, according to the urgency of the symptoms, particularly the febrile ones, and those which mark an affection of the brain.

Although Mr. Pearson mentions general and topical bleeding as being indicated in the treatment of the acute erysipelas, yet he observes, that cases very rarely occur in large towns where bleeding is at all admissible, and a repetition of the operation can very seldom be proper.

Professor Richter strongly praises the good effect of emetics on erysipelas; but some other writers, probably in a strain of ignorance, or prejudice, represent such medicines as having sometimes occasioned fatal confusions.

Another indication is to promote a gentle degree of periphraxis. For this purpose, we may exhibit small doses of the antimonium tartaratum, or the pulvis ippecanus, comp. ator vitriolicum; false draughts with volatile alcali, &c.

Opium and camphor are also proper remedies for allaying irritation.

Whoever has been in the habit of consulting the writings of several celebrated medical authors, will perceive that they place great reliance in bark, as a medicine tending very powerfully to check and cure erysipelas inflammations. When we mention Mr. John Hunter among such authors, our readers will be inclined, perhaps, to suspect that there must be some foundation for the repute into which this medicine has risen for the complaints under consideration. However, we must confess our own belief, that bark gained credit for its good effects on erysipelas entirely in consequence of the general enthusiasm which once depicted it as a cure for almost every disease of the human frame. The sentiment is corroborated, if not confirmed, by the fact, that the best modern practitioners seem now to consider bark no longer of eminent service in cases of acute erysipelas.

With respect to local applications, in these instances, several kinds have been used by different practitioners. Cold astringent lotions, oily substances, rubefacients, farinaceous, or earthy powders, and enollient poultices, have all been tried. As far as our experience extends, the lotio aqua lasthgyri acetati is as good an application as can be made to a part affected with the acute species of erysipelas. However, it becomes us to apprise the reader, that the majority of medical writers below the greatest praise on the employment of dry mealy powders, such as flour, starch, &c. for topical remedies, with which the inflamed part is to be covered.

Mr. Pearson, strangely enough, speaks in favour of rubefacients, as if the skin were not already reddened enough by the disease; but reserves his highest recommendations for mild warm poultices. Let the surgeon, however, consider the ill consequences and terrible mischief which always occurs when suppuration supervenes, and let him beware of the injudicious plan of promoting the latter event.

Treatment of the adematous erysipelas.—In this case topical bleeding may be practiced; but venesection is hardly ever
ever allowable. The bowels should be kept open with fa-
firm purgatives, of the mildest description, and a gentle per-
spiration ought to be excited, by means of small doses of
purgative ipecacuanha, &c. For the purpose of appeasing pain and irritation, the prac-
titioner may prescribe camphor, opium, aether, &c.
When the patient's constitution is in a debilitated con-
tition, tonics are indicated, together with the most nour-
ishing food. Bark, wine, port, brandy, the confectionary
mixture may now be found of the utmost service.

Treatment of the malignant or gangrenous erysipelas.—
Little need be said here on this subject, as the mode of treat-
ment is the same as that of mortification in general. See

Gangrene.
The grand objects are: to support the patient's strength;
to cover the parts affected with exfoliative poultices;
to foment them two or three times a day with a decoction
of poppy-heads; to make depending openings for the escape
of the matter and fluids, and remove the dead parts, as
soon as it can be done without occasioning the least irrita-
tion and pain.

We have frequently seen the gangrenous mischief so ex-
traordinary in these cases, that amputation of the limb was
the only means of saving the patient from destruction.
See Richter's Anfangsgründe der Wundartzneykunst.
Cullen's First Lines of the Practice of Physic. Cooper's
First Lines of the Practice of Surgery.

ERYSPHE, in Agriculture, a term applied by some to
that vegetable disease generally known by the name of
mildew. See Mildew.

ERYSTHIA, in Ancient Geography, a town of the
island of Cyprus. Steph. Byz.

ERYTHIETA, an island of Iberia, in the ocean. Ac-
cording to Strabo, it was separated from the continent by
a large strait of a strait, or, according to Pliny, of 160
paces. It was near Gades. Its name was derived from the
Phcenicians, who, having inhabited the banks of the Ery-
threan sea, came to settle here. It was also called Aprodi-
tus, or the Isle of Venus, and the Isle of Juno. See Gades.

ERYTHHEMA, in Surgery, (from ερυθρόζ, red.) The
celebrated Cullen distinguished two classes of erysipela-
ous inflammations. When the disease was an affection of
the skin alone, and very little of the whole system, or when
the affection of the system was only symptomatic of the ex-
ternal inflammation, he called the disease erythema; but when
the external inflammation was an exanthema, and symp-
tomatic of an affection of the whole system, he named the
disease erysipelas, which see.

An Erythema, Rose, or St. Anthony's Fire, (says
Dr. Cullen) is an inflammatory affection of the skin, with
hardly any evident swelling; of a mixed, and not very
bright red colour, readily disappearing upon pressure, but
quickly returning again; the redness of no regular circum-
scription, but spreading unevenly, and continuing almost
constantly to spread upon the neighbouring part; with a
pain like to that from burning; producing blisters, some-
times of a small, sometimes of a large size, and always
ending in a desquamation of the scarlet-kin, sometimes in
gangrene.

We need not enlarge on the subject of erythema, in the
sense of an erysipelas not originating from a constitutional
inflammation, as every useful information, concerning erysipela-
ous inflammations in general, is to be found in the article
Erysipelas.

The chief object which we have in view in the present
part of this work, is to describe a particular affection of the
skin, named, in consequence of its being occasioned by the
use of mercury, the mercurial erythema, or eczema.

It was perhaps, for the first time, distinctly noticed and
described by Mr. Benjamin Bell in his Treatise on the
Venerial Disease. "It is not an uncommon effect of
mercury (says this author) to excite an eruption upon the
surface of the body. In some, this appears as a military
raff, somewhat resembling measts; while in others it is
considerably elevated, and seems to be produced by a serous
effusion between the cuts and scarlet-kin. In some the
eruption is partial, being confined to particular spots; while
in others it prevails generally over the whole body.

This eruption, or efflorescence, is not attended with
pain; but the heat and itchiness which accompany it are,
in some instances, so distressful, that it keeps the patient at
all times very uneasy, and deprives him entirely of rest.

The remedies, (observes Mr. B. Bell) which I have
found to answer the best, are the internal use of opiates,
conjoined with the application of flour or flour-powder to
the parts affected. The skin is kept sufficiently cool and
easly by one or the other of these powders being from time
to time freely applied to the eruption; and, by a proper ex-
hibition of opiates we secure rest during the night. In
some instances, however, we are obliged to avoid the use of
opiates; for although they may answer the purpose of pro-
curing sleep, they tend evidently to increase the heat and
itchiness of the eruption. We find, indeed, that, in some
instances, opium excites an uneasy itch, and sensation
over the whole body, even where an eruption has previously
been taken place: and it is, perhaps, with such patients only,
that it cannot be employed in the treatment of this eruption.

The eruption to which I allude, (adds Mr. Bell) ap-
pears to arise entirely from the effect of mercury upon the
system; but it does not seem to depend upon any particu-
lar preparation of the remedy. It takes place indiscrimi-
ately from all of them; and not more readily from unclean
than from those preparations that are used internally." See a
Treatise on Gonorrhoea Virulenta; and Eczema Venerea; by

Since this gentleman published the foregoing work, the
mercurial erythema has excited considerable attention, and
several writers, viz. Drs. Moriarty, McMillain, and Spens,
and Mefias Alley and Pearson, have endeavoured to render
our knowledge of the subject more extensive.

Dr. McMillain judiciously observes, that eruptions of
various kinds are very common symptoms of syphilis, but
a very unusual effect of mercury. Hence, until the real
nature of the mercurial erythema was ascertained, whenever
the affection occurred in patients undergoing a mercurial
course for syphilitic complaints, it was naturally enough con-
sidered as an anomalous form of leuc venerea. The mercury
was consequently pushed to a greater extent, in proportion
to the violence of the symptoms, and from the cause of the
derese being thus unconsciously applied for its removal,
it could not fail to be aggravated, and hurried on to a fatal
termination. At length, the observation of this fact, and
of another truth, that a similar eruption did sometimes ap-
ppear in patients who were using mercury for other com-
plaints, and in whom no suspicion of syphilis could be en-
tertained, led to the important discovery that the eruption
was entirely an effect of mercury, and not at all connected
with the original disease.

Dr. McMillain imputes the first explanation of the nature of
the mercurial erythema to Drs. Moriarty and Spens, and
Mr. George Alley, all which writers published in the
course of the same year, viz. 1804. However, the passage
which we have quoted above, from Mr. B. Bell's work on the
the venereal disease, clearly evinces that though the above
 gentlemen have undoubtedly great merit in having increa
 our information concerning the disease, yet the latter writer
 had noticed the affection before them. Indeed, Dr. Spens
 has had the liberty to make this acknowledgment him
 self.

 According to Dr. M‘Mullin, the different appearances
 which this disease assumes, from its severity and duration, may
 be best understood by describing it as consisting of three dif
 tinct stages. The first stage, says this gentleman, com
 mences with languor, languitude, and cold shiverings. These
 symptoms are succeeded by increased temperature of the
 body, quick pulse, nausea, headache, and thirst. The pa
 tient is troubled with a dry cough, and complains of dif
 cult respiration, anxiety, and sense of itching about the
 precordial. The tongue is usually moist, and covered with
 a white glutinous film. It sometimes appears clean
 and of a bright red colour in the centre, while the margins
 remain foul. The skin feels unusually hot and itchy,
 with a sense of prickling, not unlike the sensation ex
 perienced from the application of nettles. The belly is
 generally colitive; but a diarrhoea is often produced by very
 flight causes.

 To continue Dr. M‘Mullin’s description: on the first,
or second day, an eruption most commonly appears, the colour
 of which is either dark or bright red. The papulae
 are at first distinct and elevated, very much like those which
 occur in rubella. Sometimes, but not often, the eruption
 appears like urticaria, and in such instances the disease is
 observed to be very mild. The papule very speedily run
 together in such a manner as to form a suffused redness,
 which disappears on pressure. In mott cases, it first begins
 on the forehead, inside of the thighs, forearm, or within
 mercurial frictions have been made, and the skin of the
 parts affected becomes considerably swollen. Infficences
 have also been seen in which an eruption of a purplish col
 our, and accompanied by papule, has suddenly diffused it
 self over the whole body. (See Moriarty on Lepra Mercu
 rialis.) Dr. M‘Mullin remarks, however, that the latter
 form of the affection may be considered as uncommon. In
 every instance which Dr. M‘Mullin has seen the eruption
 was at first confined to a few places, and thence gradually
 extended, until the different portions of the eruption had
 united. The papule were also rough to the feel. But, in
 such cases as releave urticaria, many minute vehicles, inter
 spersed among the papule, and containing a serous fluid,
 make their appearance from the very first. Contrary to
 what happens in most diseases, accompanied with cutaneous
 affections, the febrile symptoms are much aggravated, and
 continue to increase, after the eruption is complete. The
 pulse in general beats from 120 to 150 in a minute, the
 thirst continues urgent, and the patient, who is extremely
 rellves, seldom enjoys quiet sleep. Dr. M‘Mullin further
 informs us, that when the eruption has continued in this
 manner, for a certain period, the cuticle begins to peel off in
 thin, whitish, scurvy exfoliations, not unlike those ob
 served in rubula. This desquamation first begins where
 the eruption made its earliest appearance, and in this order
 spreads to other parts. About this period the faucies
 become fore, the tongue swells, and the eyes appear somewhat
 inflamed.

 The duration of this stage is very various; sometimes it
 continues from ten to fourteen days, and in other cases it
 terminates in half that time. When the disease has ap
 peared in its mildest form, the patient recovers immediately
 after this desquamation, a new cuticle having formed under
 neath. When the disease is severe, however, he has only
 experienced the smallest part of his sufferings, and the skin
 now affumes a new appearance, which Dr. M‘Mullin has
 considered as the second stage.

 This author represents the skin as appearing at this pe
 riod as it studded with innumerable minute vehicles, which
 are filled with a pellucid fluid. These vehicles (he observes)
 may be expected, if the patient, at the close of the first
 stage, should complain of increased itching, and a sense of
 a burning heat in the parts, from which the cuticular exfo
 liations have fallen. The vehicles sometimes remain for a
day or two; but in general they are burst immediately after
 their formation, by the patient rubbing the parts, in or
 der to relieve his strong impatient. The sufferers
 a serous serous fluid is discharged, whichpossesses to dif
 figurable fluid, that it induces nausea in the patient
 self, and those who approach his bedside. The smell
 is said to be peculiar, that it can be easily recognised
 by any person who has once perceived it. Dr. M‘Mullin
 states, that this fluid is poured out most copiously from the
 scrotum, groin, inside of the thighs, or wherever the skin
 forms folds, and sebaceous glands are most numerous. The
 feroe discharger from the vehicles forms, with the cuticle,
crustations, which Dr. M‘Mullin regards as the criterion of
 the third or last stage.

 The same writer observes, that the crusts are generally
 very large, and when detached retain the figure of the
 parts from which they have fallen. Their colour is in
 general reddish, but it sometimes appears dark and dirty.
 Dr. M‘Mullin conceives, that this period of the disease
 might be termed, with much propriety, the stage of de
 cration, in order to distinguish it more fully from the de
 quamation, which has been already noticed. When the
 stage of decration appears, the faucies become more af
 fected, the eyes intolerant of light, and the tars tendon
 inflamed, and sometimes turned inward. The crusts formed
 on the face, as in other parts of the body, before falling
 off, break off as to leave cracks and fissures, which horridly
decom the countenance; and in consequence of the great
 swelling of the face the eye-lids are also completely closed.
 The back and hairy scalp are said to be the parts most
 backward in becoming affected; and, according to Dr. M‘Mu
 lin’s account, they even sometimes escape entirely in very
 severe cases.

 In this stage of the mercurial erythema the patient is
 under the necessity of avoiding every kind of motion, on
 account of the pain which it occasions, and which he
 compares with such a fermentation as one may fancy would
 be produced by a cracking of the flesh. The crusts also fall off
 in such abundance, that the bed seems as if strewn with the
 cones of hops.

 While the eruption is only making its appearance in one
 place, it may have attained its most advanced form in another
 part, so that all the different stages of the disease may be
 present at once, in the same individual. Typhus prevails through
out the whole course of the complaint; but, what is curious, the appetite continues
 in most cases unimpaired, and sometimes is even voracious.

 Dr. M‘Mullin also remarks, that when the catarrhal
 symptoms have continued during the progress of the com
 plaint, they are particularly aggravated in the advanced
 stage of the cafe. The anxiety and pain in the breast
 are likewise flared to be very severe, attended with cough and
 bloody expectoration, the patient invariably feeling languid
 and dejected. The pufhe becomes frequent, feeble, and
 irregular; the tongue black and parched; and, at length,
adiphora, delirium, convulsions, gangrene of the surface
 of the body, and death, ensue.

 The
ERYTHEMA.

The mild form of the disease only goes through the first stage, and ends, as we have already described, in a slight desquamation, after a few days. When the affection is severe, however, it is often protracted more than two months, every stage of the eruption continuing proportionally longer; and when, in this manner, it has run its course, it repeatedly breaks out on the new surface, and passes through the same stages.

For the preceding history of the symptoms of the mercurial erythema, we feel ourselves highly indebted to Dr. McMillan. See Edinburgh Medical and Surgical Journal, vol. ii. p. 25, &c.

With the exception of one case, which Dr. Rutter has inserted in the eighteenth number of the journal just now mentioned, we have no notice recorded, in which the present disorder originated, without the patient being under the influence of mercury. Whether Dr. Rutter's example is to be considered as the same identical disease as the one which we have been describing, we shall not undertake to investigate. We shall only observe, that since it is very possible to mistake other complaints for the real mercurial erythema, we do not consider one solitary fact, resting on the judgment of an individual, who might differ in opinion concerning the nature of the disease, with the next medical practitioner consulted, a sufficient ground for implicitly believing, that such a disease as the mercurial erythema can be produced quite independently of the use of mercury.

In certain habits, every preparation of mercury, and every form of employing this medicine, seem capable of bringing on the disease. As the complaint was first taken notice of in patients who were afflicted with syphilis, it was supposed to be an anomalous form of the venerial disease. But, at last, the repeated appearance of the eruption in persons exempt from all suspicion of having any syphilitic symptoms, made surgeons convinced, that what is now commonly named the mercurial erythema had nothing venerial in its nature. However, since few out of the great number of patients, continually employing mercury, are afflicted with this erythema, medical writers have attempted a further explanation of the difficult subject of caufoes, by flating, that the mercurial erythema only takes place in such patients as have a certain undefinable peculiarity of constitution. The contemplative reader will at once perceive, that this is a vague and an unphilosophical mode of accounting for the production of the disease, as the same sorry kind of explanation may be generally adopted in regard to every disorder, the immediate cause of which is totally unknown.

Is it not a greater mark of prudence and good sense to confess our ignorance, under these circumstances, than to offer statements, wishing them to be considered as explanatory, while they do not convey any information whatever on the subject?

It has been supposed by some, among whom is Dr. Gregory of Edinburgh, that the application of cold to the body, while under the influence of mercury, is absolutely essential to the production of the disorder under consideration. Notwithstanding there can be so reasonable doubt that the mercurial erythema is commonly excited by the use of mercury in some form or another, yet, it appears from what Mr. Pearson has stated, that the disease is not always excited, and it is not possible to avoid it in the employment of the medicine. On some particular occasions, when this gentleman judged it to be of great moment to continue the mercurial friction, the eruption neither spread universally, nor was it materially increased. The patients, however, did not get rid of the rash till the mercury was discontinued.

We have already noticed the opinion of Dr. Gregory and some other practitioners, that exposure of the body to cold, at a time when the system is under the influence of mercury, is absolutely necessary for the production of the mercurial erythema. Mr. Pearson seems to entertain a very different sentiment; for, he observes, that he is not aware of any other cause, than the action of mercury on a particular kind of constitution being concerned. He acquaints us, that he has seen this cutaneous disease occur in private practice as well as the Lock hospital, where the strictest attention has been paid to the temperature of the apartment, to regimen, and to personal cleanliness. He has had no reason to believe that any one season of the year is more conducive to the disease than another; and he states that free exposure to the air, either in winter or summer, has not the least perceptible effect in exciting the eruption.

Mr. Pearson, as a general rule, recommends the employment of mercury to be immediately left off on the first appearance of the eruption; and though he seems to admit that the affection may be relieved by remedies, yet he is doubtful whether any plan of treatment has the power of interrupting its regular course, or abridging its duration. Mr. Pearson would by no means wish to inicate, however, that the patient may not derive considerable benefit from medical assistance; his sufferings (he says) may be greatly mitigated; many inconveniences may be remedied; his strength may be supported; and, in short, (says Mr. Pearson,) he may be conducted through the disease, that his general state of health shall not suffer any material or permanent injury.

It is not enough to discontinue the employment of mercury. In large hospitals, and particularly those as are appropriated to venereal cases, the patient should be immediately removed from those wards which may have their atmosphere vitiated by the breathing of persons charged in general with mercury.

In the early stage of the mercurial erythema, Mr. Pearson recommends small doses, of antimonial powder, with coffee draughts, or elixir the ammoniac acetata. A gentle purgative should be given every three or four days, and opium is proper for appeasing the pain and irritation, and procuring sleep. Sometimes, says Mr. Pearson, opium mixed with camphor, or Hoffman's anodyne liquor, will have a better effect than when administered alone. When the discharge is no longer ichorous, and the tumefaction is subsiding, the same surgeon prefers the liberal exhibition of farfapilla and bark. He has also thought, that the general sense of uneasiness has been lessened by the vitriolic acid, which proves at the same time grateful and refreshing.

The diet should be of a light and nourishing quality; but no fermenting liquors can be prudently allowed till the desquamation of the cuticle is somewhat advanced.

In order to diminish the pain arising from the irritation of the skin, the warm bath may be used, as often as the patient's strength will permit. His linen and sheets, which are soon rendered hard and stiff by the discharge, should be very frequently changed. Mr. Pearson is also in the habit of covering every part, where excoriations occur, with a soft mild crape, made of litcharse phalter, yellow wax, and olive oil. This application is to be thickly spread on rollers, by which means it may be conveniently put wherever it is needed. The dressing should be changed twice a day.

Dr. McMillan has noticed, that, though in the early stage of the mercurial erythema, diaphoreses are indicated, yet the bowels are so irritable, that such medicines can scarcely be employed. For the same reason, he recommends...
mends us to be very cautious in giving mineral acids, ripe fruits, &c. This gentleman approves of the patient being kept in rather a warm temperature, and in a place where he can derive the advantage of a quick circulation of air. The bowels being weak, Dr. McMullin advises us only to employ the mildest purgatives, when medicines of this class are required.

With regard to the topical treatment, the latter gentleman says, that solutions of sulphate of zinc, and acetate of lead, sulphur ointment, and the decoction of oak-bark, have all been tried, but without any particular good, and he seems to prefer sprinkling the parts with powdered tar. To alay the cough and looseness of the fauces, he advises mucilaginous mixtures, containing a small proportion of opium.

When the incrustations become general, the fever always assumes more of the typhoid type. In this stage bark has been universally preferred, with a view of supporting the strength; but Dr. McMullin remarks, that this medicine cannot be given in sufficient quantity, owing to its affecting the stomatch, or occasioning diarrhoea. In some instances, he observes, the cold infusion, compounded with aromatics, has been well retained, and a little opium may be added to the dose. Opium, which this gentleman describes as improper in the first stage, may be given without any risk of unpleasant consequences. He states, that the wish is the best remedy in this stage of the disease. Porter and diluted spirit are also proper, and the thirst must be allayed with whey, light broths, and nourishing drinks of every kind. Owing to there being now a large extent of the skin in an excoriated state, the patient cannot at this time generally bear warm bathing, which often brings on a state of syncope, and all that can be done is to wash the parts, in the most tender manner, with tepid water.

For the ophthalmia tarbi, the unguentum zinci vitriolati is recommended, and the hiemcum aqua caulis is said to relieve most effectually the pain which makes the patient feel as if his flesh were cracking.

ERYTHRAE, in Ancient Geography, a town of Greece, in Boeotia. Pliny. It was situated near mount Citheron, according to Eupirides. Some authors place it in the territory of Phocis, to the east of this town.—Alfo, a town of Greece, in Thessaly, situated upon the river Eryphus, according to Strabo.—Alfo, a town of Greece, in Eolus, near Eupallus.—Alfo, a town in the ille of Cyprus, called Paphos.—Alfo, one of the twelve towns of Asia Minor, in Ionia, according to Pliny Strabo says, that it gave name to the Erythraean Sibyl. He says also, that it had a port, called Cyllus, in which were four islands called Hippa. The town was built by Nepheus, the son of Ceduus. In the town was a temple of Hercules, one of the most stately edifices in all Asia. Erythrae took part, on all occasions, with the Romans, who rewarded its fidelity with ample privi-

legs, and considerably enlarged its territory. It is now a village, named Brethri.—Alfo, a town of Africa, in Liby.

ERYTHREAN, in Botany, Cythera, red, a name given by Rennell to the Chironia Centaurium, (Centauria Centauriurn of Linnaeus), on account of its red colour, unusual in the Gentian tribe. This writer contemplates the universally received opinion of its being the Cythera purpurata of Dioscorides, because the latter is said to prefer watery situations. But neither this, nor indeed any other of his arguments, is of much weight; for the Chironia Centauriun often occurs in low and wet places, and according to Dr. Sibthorp is very frequent throughout Greece. Chironia purpurea, which Dioscorides would hardly distinguish from it always grows in marshy spots, and is found on the coasts of Greece, as may also Chironia pallescens, though scarcely distinguished by any body from the common kind when Dr. Sibthorp visited that country, and therefore not noted by him.

ERYTHREAN SEA, in Ancient Geography, is the ancient name of the Red Sea. Indeed, the ancients gave this name to the whole expanse of water that extends from the coast of Ethiopia to the Land of Tarsus. This appellation is probably derived from Edom or Edan, whose descendants were called Idumæans, and inhabited the northern part of Arabia. The Idumæans navigated upon the Red sea and the Periphan gulf, and also upon the Indian sea, and the oriental name Idumæae signified—Red. Whence the sea of the Idumæans was called the Red sea, and the Erythraean sea.

ERYTHREAN Sibyl. See STEVIN.

ERYTHRINA, is an appellation given to Heraclea, from a temple which he had at Erythres, in Arcadia.

Gen. Ch. Cal. Perianth of one leaf, entire, tubular; its margins more or less two-lobed; its base on the lower side furnished with a honey-bearing pore, Cor. papilionaceous, generally of five petals; standard much the longest, lanceolate, acuminate, hisps bent downwards; wings mitate, somewhat ovate, scarcely longer than the calyx, and hardly reaching beyond the claw of the standard; keel subequal, usually about the length of the wings, sometimes longer, of two petals either separate or united, notched at the end. Stam. Filaments ten, unequal, united below into a tube, fitt at the upper edge, a little incurved, half as long as the standard, one of them occasionally separate; anthers ten, oblong. Pf. Germin superior, falcate,awl-shaped, tapering into an awl-shaped style, as long as the stamens; stigma terminal, simple. Pdr. Legume very long, protuberant from the seeds, pointed, of one cell. Seed several, kidney-shaped.

Eff. Ch. Calyx two-lobed, standard much longer than the keel. Wings minute. Legume cylindrical, with many convex seeds.

Obf. E. berbacea has the tenth flamen separate; which is also the case with E. Carya-gallii, whose keel moreover has its petals united into one, and is much longer than in the generality of the species. The species of this splendid genus are, for the most part, natives of very hot climates in the East or West Indies, and amount in Wildenow, who has paid particular attention to them, and described two new ones, to twelve.

E. berbacea, Linn. Sp. Pl. 992. Trew. Ehret. t. 58. found
in Carolina, will support our winters in a green-hous, nor
does its stem always die down to the root. The flowers
form long and very handsome spikes, being of a most vivid
though deep scarlet, with purplish stalks and calyx. Stamens
scarlet with a black eye.

E. Carolinianus, Linn. Sp. Pl. 992, brought from the
West Indies, requires a flower. It has an arborecent
prickly stem, with flowers much like the former.

E. mitra, Jacq. Hort. Schoenbr. v. 2, 1756, is another
familiar species in its flowers, but different of prickles.
It was sent to the Imperial garden from seeds brought from the East Indies, prob-
bably from the garden at Calcutta. It was in 1805 but a
slender prickly shrub about six feet high, with serrate
prickly-ribbed leaves. Flowers in large terminal clusters, of
a rich unpolished deep scarlet, their standards much broader,
and keels much longer, than is usual in this genus; the wings
very small and three-lobed, of a greenish white. Tenth
filament separate to the very base.

E. speciosa, Andr. Repof. t. 443, a plant we have never
seen, flowered in the garden of A. B. Lambert, esq., and
though supposed to be a native of South America, is said
to be perfectly hardy, and to thrive very freely from cuttings.
Whether it be comprehended under any of Willdenow's
species, we are not at all certain. The stem is prickly,
thick and strong. Leaves very broad, with prickly ribs.
Flowers scarlet, in very dense spikes. Wings half as long
as the standard, which is narrow like the third species; keel
not half so long as the wings. If these circumstances are
constant, the generic character will require correction.

ERYTHRINUS, in Ichthyology, a species of Spurds
and allies of Salmo, which see respectively.

ERYTHROCEANEUS, in Ornithology, the red and
blue macaw, with a wedge-like tail, and the sides of the
head naked and rough. See Psittacus.

ERYTHRODANUM, in the Materia Medica, a name by which some authors have called the rubia tinctorum,
or madder.

ERYTHROIDES, in Anatomy, from ἔρυθρος, red, and
ῥόδα, form, a name given by some anatomists to the first proper
covering of the telodics. It is not now admitted that these
bodies are the true Rubia. Some say the thorns of the
creosylvus and cellular subsidence of the scrotum, to which,
the perhaps, above-mentioned name may have been ap-
plied.

ERYTHRONIUM, in Botany, from ἕρυθρον, red, in al-
ibus to either the colour of the flower, or to the more
unusual blood-like stain in the leaves. Dog's-tongue Violet.
Mart. Mill. Dict. v. 2. Juifi. 48. (Den's canis; Tourneuf.
t. 202.) Clafs and order, Hexandria Monogynia. Nat.

Gen. Ch. Cal. none. Cor. Petals six, regular, lanceo-
late, pointed, lying over one another alternately towards the
base, spreading gradually, reflexed from about the middle ;
three of them external, three internal. Nectary two scars,
or little scales, at the base of each of the inner petals. Stam.
Filaments six, uniform, awl-shaped, shorter; anthers oblong,
erec, as long as the filaments. Petal. German superior,
roundish or oblong, with three angles; ryle simple, shorter
than the corolla, taper at the base, and a little bent at that
part, otherwise fringed; stigmas three, spreading, somewhat
cylindrical, furrowed, or notched. Peric. Capsule nearly
globular, contracted at the base, of three cells and three
values. Seeds numerous, ovate, pointed.

Eff. Ch. Corolla bell-shaped, of six reflexed petals. Nect-
ary two scales at the base of the three inner ones. Cap-
tule globose, contracted at the bottom. Seeds ovate.

31. append. t. 9. Curt. Mag. t. 5. Leaves with a blunt
flat point. Style cylindrical. German globule, obtuse.
Native of mountainous places in Italy, Switzerland, Carinthia,
Styria, Carinthia and Tartary, flowering in the spring.
In our gardens it is a hardy perennial, distinguished by its
elliptical radical leaves, very various in breadth, elegantly
flared, and separated with purple, and its solitary drooping crimson or
whitish flowers, with pendant dark purple anthers. No
remains of the botany are to be found after the end of June.
Leaves and several botanists of his time professed this to be the
real genus of Dioscorides, not does it ill accord with
the description, though Dr. Sibthorp feems not to have met
with the plant in Greece. It cannot, however, be made
to agree with the sapio of the same author, though
the latter appellation feems to have given rise to its
present generic name. The old authors made two species
on account of the various dimensions of the leaves, which
Linnæus reduced to one, but he very improperly made a
third variety of the following species.

2. E. florum. (E. americanum; Curt. Mag. t. 1113. E.
Dens canis v.; Linn. Sp. Pl. 437.) Leaves involute at
the point. Style club-shaped. Native of the colder parts of
North America. It flowered in April 1828, in the gar-
dens of Mr. Lodigges at Hackney, and Mr. Salisbury at
Brompton, and was fiill well determined by Mr. Gawler in
Curtis's Mag. The leaves resemble the former, except in
having a hooded termination, from the involute edges of the
point. Flower deep yellow spotted with red. Anthers
and pollen yellow. Style very thick in the upper half.
German obovate.

German elliptic-oblong, acute.—Gathered by Mr. A.
Menzies on the west coast of North America. The leaves
are broadly elliptical, and in our specimens appear pale,
and scarcely spotted. Petals purplish, very much rolled
back, as in the Martagon Lily. Stamina with unusually
long taper-pointed filaments, and pale or yellowish, not
dark purple, anthers. German elliptic-lanceolate, pointed.
Style contracted at the base, but otherwise pretty exactly
cylindrical, with much longer stigmas than either of the
foregoing.—The whole plant also is larger, and appears to
us unquestionably distinct. The discovery of this species in
America renders the original name of the latt fo exception-
able, that we hope we may be pardoned for changing it be-
fore it is adopted in any regular systematic work, other-
wise it would be too late. S.

ERYTHROPHTHALMUS, in Ichthyology. See Cy-
prinus.

ERYTHROCHRIZA, in Botany, εἴρυθρος, χρίς, a red root;-
Michaels Fl. Boracii-Antv. v. 2. 36. t. 36, is Galax
aphylos, which see.

ERYTHROXYLUM, εἴρυθρον, χρύον, red wood. Brown.
v. 2. 746. Mart. Mill. Dict. v. 2. Jull. 233. Clafs and
Malpighia, Jull.

Gen. Ch. Cal. Perianth of one leaf, turbinate, very small,
withering, in five ovate acumen segments. Cor. Petals five,
short, concave, spreading. Nectary an upright, coloured, notched
scale, attached to the base of each petal. Stam. Filaments
10, the length of the corolla, connected at the base by an
abrupt
abstract membrane; anthers heart-shaped. *Pig. Tomentum*, ovate, superior; filaments, thread-shape, distant, the length of the stamens filiform thickish and obtuse. *Peric. Drupa* ovate, of one cell. *Seed.* Not oblong, with four obtuse angles.

Eff. Ch. Calyx turbinate. Petals five, each with a notched nectariferous scale at its base. Stamens connected at their base. Drupa of one cell.

This genus, founded by Browne, consists of two species only in his work. 1. *E. arcelatum*, Linn. Sp. Pl. 612. Brown. Jam. t. 38. f. 2. and t. 14. f. 3. (E. carthaginense; Jacq. Amer. 134. t. 87. f. 1.) This is called, in Jamaica, Red Wood, or Iron Wood, and is said to be excellent for the fize of the tree, which is not above five or six inches in diameter. The leaves are obovate, two inches long, marked with two lines at the back, which circumferbe the part that was exposed before each leaf expanded. *Flegetes* harry, white, fragrant, on simple, clustered, lateral flanks.

2. The second species of Browne has been neglected by following authors, probably as a variety of the first. He describes it as different in its manner of growth, with smaller rounder leaves.

Cavanius and Lamanck have much increased the number of species, so that they now amount in Wildenow's work to 12, all except the above unknown to Linnaeus. They are natives either of South America, Madagascar, or the islands of Mauritius and Bourbon, and were chiefly gathered by Commerson. The French call many of them Bois d'Uhu. The wood is, in some instances, said to have a very strong and disagreeable smell when burning.

ERYX, in Ancient Geography. See ERYX.

ERYX, in Zoology, a species of Anquis, being the Anquis doys trilímato of Boddaert, above comneous, with three black lines, and light bluish beneath. It is found in England, and in America.

ERZ, or ERZI, in the Botanical Writings of the Ancients, a word usually confided by the Hebrews, and by them made the name of the cedar.

ERZEN, in Geography, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, seated on the Hümme, 7 miles S.W. of Hameln.

ERZERUM, or ARZERUM, a city of Asiatic Turkey, and capital of a pachalic to which it gives name, and is a part of Armenia, situated near the head of the Euphrates, at the foot of a chain of mountains which are usually covered with snow till the latter end of spring. The town is surrounded with a double wall, and defended with some square towers; the houses are mean, and none of them large. The suburbs are inhabited by Christians. Of the inhabitants, they count 18,000 Turks, of whom two-thirds are Janizaries; 6,000 Armenians, who have an archbishop, and two churches; and 400 Greeks, who have a bishop, and one main church. The Greeks are mostly employed in the manufacture of copper, brought from some mines three days journey from the city; this, and the manufacture of the skin of a species of marten, are the only articles of their commerce. Erzerum is the staple of the merchandize of India, especially when the Armenians infest the environs of Aleppo and Bagdad. This merchandize consists of silk from Persia, cotton, painted linens, spices, rhubarb from Bucharia, madder from Persia, zedoary, &c. This town was one of the laft which was taken from the Greek emperors by the Arabs; 250 miles N.N.E. of Aleppo, and 510 E. of Constantinople.

erzgebirg. See ERTZGEBIRGE.

ESAPHE, from the word, I feel with the fingers, a word used by Hippocrates, to express the touching of the mouth of the uterus, in order to discover its state of disease.

ESAU, in Biography, the son of Isaac and Rebecca, and the twin-brother of Jacob, whom he succeeded at his birth, was born in the year 1836 B.C. At his birth he was covered with hair, indicating great bodily strength, by which he was fitted for the kind of life to which he afterwards devoted himself. As he was fond of hunting, he supplied his father with a variety of delicious food, and became his favourite. Jacob, however, was the favourite of his mother, and by means of a circumstance mentioned in his history, supplanted Esau of his birth-right, which he contested to barter for a mess of red pottage, that had been prepared for their father, during his absence. Hence he and his posterity derived the appellation of Edom, signifying red. At the age of 40 years Esau divorced his parents by marrying two wives out of idolatrous Canaanish families, with which the posterity of Abraham were prohibited from forming any connection. In process of time, he regained his father's favour, and as death approached, Isaac determined to confer his last prophetic benediction on Esau, as his first-born son and heir. The artifice of his mother, however, counteracted his purpose; and she contrived to impose upon Isaac, and to obtain the father's parental blessing for his son Jacob. Esau was irascible on account of the treatment of his brother; and determined to kill him as soon as their father should die.

Rebecca again interposed, and sent Jacob away to her brother Laban, with whom he might be secure from the threatened vengeance of his brother. During the period of separation, which lasted several years, Esau married a wife of the family of Ishmael, and removing to mount Seir, acquired great power and wealth. When Jacob returned, after long absence, to his father's country, with a numerous family, and large flocks and herds, he dreaded his brother's displeasure; and though they had an amicable and affectionate interview, he entertained suspicion of remaining resentment, and instead of complying with the wishes of his brother, who was desirous that he would settle in his neighbourhood, he dwelt in Shechem. After their father's death they lived in peace and amity; but as their possessions enlarged, and there was not sufficient room for them in the land in which they were strangers, Esau returned to mount Seir, where his posterity multiplied under the denomination of Edomites. (See Edom.) The time of his death is not mentioned, but bishop Cumberland thinks it probable that he died about the same time with his brother Jacob, at the age of about 147 years. Genesis, ch. xxv—xxxvi.

ESAU, in Geography, a mountain of Arabia, in the country of Yemen, 4 miles N. of Uden.

ESALOVO, a town of Kaffian Sibere, in the government of Kelifan; 36 miles E.S.E. of Kafanoiarik.

ESBONITE, in Ancient Geography, a people of Arabia Petraea, who took their name from the capital, which was founded in the mountains over-against Jericho.

ESBUS. See HEBSON.

ESCADENA, in Geography, a town of Spain, in the country of Sevilla; 20 miles W. of Sevilla.

ESCAILLON, in Geography, a river of France, which runs into the Seidelt, about two miles above Valenciennes.

ESCALA, A, a town of Spain, in the province of Catalonia, on the coast of the Mediterranean; 22 miles E. of Gerona.

ESCALADE, or Scalaede, in the Military Art, a furious attack of a wall or a rampart; carried on with ladders, to pass the ditch, or mount the rampart; without proceeding in form, breaking ground, or carrying on regular works to secure the men.

When the troops are prepared to pass the ditch, either with
with the abundance of boards, hurdles, and fashions, when it
is muddy, or with small boats of tin, or buckets covered
with skins, or oil-cloth when it is deep, and filled with water,
that a party must be placed on the counterfear, opposite to the
landing-place, ready to fire at the garrison if they are alarmed,
and oppose the mounting on the rampart. If the ditch
is dry, the ladders are fixed in some place farthest distant
day the centry; and as soon as they get upon the rampart,
they put themselves in order to receive the enemy; if the
centry should be surprised, and flently overcome, the
detachment fences to break open the gate, and to let in the
rest of the party. If the ditch is wet, the rampart high,
and provided with a revetment, it will be difficult to
brake the town in this way; but if there is no revetment,
the troops may hide themselves along the outsid of the
rampart till all are over. Since the invention and use of
gunpowder, and the walls of cities have been flanked, they
are seldom taken by escalade.

ESCALANA, in Geography, a town of Spain, in Old
Castile; 14 miles N. N.E. of Segovia.

ESCALANTE, a town of Spain, in the province of
Biscay; 15 miles E. of Santander.

ESCALON, a town of Portugal, in the province of
Barr; 16 miles N. of Almeida.

ESCALLON, in Botany. See Scallion.

ESCALLONIA, so called by the younger Lin-
neus, at the recommendation of Mutis, in honour of a
learned Spaniard named Escalón, the pupil of Mutis in
botany, mathematics and philosophy, and his indefatigable
compassion during his abode in New Spain. This gentle-
dman discovered the shrubs in question, as well as a num-
ber of new or rare plants besides, in his various journeys
through New Granada, most of which were, by Mutis or
himself, communicated to Linnaeus or his son. A very
fine plant was originally chosen by Mutis for the above
purpose, of which a specimen and drawing were sent to Lin-
neus; but it proved, on a careful examination, to be a Lo-
rincus, and remains undescribed in the Linnaean herbarium.

Mart. Mill. Dict. v. 2. Juff. 321. Clas. and order, Ponta-

Gen. Ch. Cal. Perioph of one leaf, inferior, hemisphé-
rical, with five large, spreading, oval, acute, permanent
tooth. Cer. Petals five, equal, inserted into the calyx,
tongue-shaped or ovate, obtuse, a little dilated from each
other, longer than the calyx-teeth. Stem. Filaments five,
equal, erect, awl-shaped, inserted into the calyx between
the petals, opposite to its teeth and about the same
length; authors incident. Pfl. German half involuted with the calyx,
globular; style cylindrical, straight, the length of the flau-
ment; stigma capitulate, umbonate. Petio. Berry roundish,
of two cells, crowned with the calyx-teeth. Seeds very nu-
merous, minute.

Eff. Ch. Berry of two cells, with many seeds. Calyx
encompassing the fruit. Stigma capitulate. Petals five,
inserted into the calyx.

Leaves evenly ferrat, minutely pointed, veiny beneath.
Flowers flally.—Gathered in New Granada by Escallon.
—Stem ferraty, branched, slightly angular, with a smooth
deciduous bark. Young branches numerous, alternate,
short, simple, leafy, each terminated by a solitary, flaked,
terminal flower. Leaves alternate, spreading, about three-
quarters of an inch long, ovate, obtuse with a minute
point, minutely ferrate, especially towards the end, smooth,
deciduous; with no perceptible veins on the upper side;
paier ad veiny beneath; the base tapering down into a
short, often fringed, footstalk, each of whose edges unites at
their base with a glandular toothed angle or rib in the
branch. Stipulas none. Flower-stalks angular and glandu-
lar. Petals about thrice as long as the calyx-teeth, ap-
parently white, erect, their extremities reflexed. Berry back
the size of a large pea, or bigger, crowned with the calyx
and base of the style.

2. E. ferrata. Sm. Pl. Ec. t. 31. Leaves ferrate, some-
what abrupt, smooth and without veins at the base.
Flowers flally.—Gathered about the strows of Magellan,
by Commeron; in Staten Island, (not Terra del Fuego,) by
Mr. Archibald Menzies.—A humble, branched smooth branch,
with something of the aspect of a Simarum. Branches
erect, somewhat zig-zag, angular, with a pale ferratus
back, those of the perfect blossom green, fleshy, shorter,
each bearing a solitary, terminal, flaked flower. Leaves
deciduous, alternate, oblong, obtuse, often abrupt or tu-
rufes, with a minute central point or tooth, equally ferrata
or somewhat erect, very smooth; slightly veiny above;
pale and definite of lateral veins beneath, though furnished
like the former with a strong central rib. Footstalks smooth
and entire, as are the angles of the branches. Stipulas none.
Flower-stalk smooth. Petals white, spreading, not recur-
ved. Top of the germ violet. All the parts of fruitifica-
tion, except the petals, are but one-third the size of the
former. The little berries, crowned with the permanent
style, appear to remain through the winter, and their upper
part, above the calyx-teeth, easily separates like a lid as
they ripen, exposing the pulp full of small seeds, with its
transverse partition.

3. E. glandulosa. Leaves double ferrate, acute, glandu-
lar at the back like the branches. Flowers somewhat
covered. —Gathered in Chile by Mr. A. Menzies.
Branches wandy-like, roundish, leathery; when young,
covered with abundance of prominent glandular tubercles.
Leaves alternate, when fully grown an inch and half long,
obviate, pointed, strongly and doubly ferrate; smooth or
slightly downy above; veiny, and rough with innumerable
prominent resinous glands, beneath; tapering at the base
into a shortish glandular footstalk. Each leaf is accompa-
nied by an axillary tuft of smaller ones, the rudiments of future
branches. Stipulas none. Flower-stalks several about the
tops of the branches, axillary and terminal, simple or subdi-
vided, each about an inch long, angular, glandular like the
branches, as is also the base of the calyx. Bractes
few, at the base or subdivision of each stalk, linear, glandu-
lar. Calyx about the size of the leaf. Petals more like the
former, and somewhat longer, with rounded, reflexed
extremities, Style furrowed, surrounded at its base with an
amphial lobed gland or necary, of which we can find no
traces in the other species. Germin of two cells. The fruit
we have not seen.

ESCALONA, in Geography, a small, tolerably built,
walled town of Spain, in the province of New Castile,
with several suburbs, situated on an eminence defended by a castle, in
a fruitful spot watered by the Alberche, 20 miles N.W. of
Toledo, and 32 S.W. of Madrid. It has four churches, and
two convents.

ESCALOP Foil Shells, in Conchology, are described by
Da Costa (Concil. p. 247.) as found in the lime-stone
quarries at Thame in Oxfordshire; Mr. Walcot, in his
Petitions found near Bath, 2 has also described a similar
kind of shell, as found in the clay on the side of the road
between Cherveton and village, and in the free-stone at
the quarries near King’s Down; and another kind found
in a flint zone at the lime-stone quarry near the Cresent
in Bath.
ESCAMBIA, one of the most considerable rivers that fall into the bay of Pensacola, in West Florida, discharges itself near the head of the north branch, about 12 or 15 miles from Pensacola, through several marshes and channels which have a number of islands between them, that are overflowed when the water is high. The course of this river from an unknown source is very winding. The lands on each side are, in general, rich, low, or swampy, and well adapted for the culture of rice or corn. The numerous rivulets that fall into this river from the high country about it may be led over every part of the rice lands, at any season of the year. The islands at the mouth of the river, of which some are considerable in extent, are not inferior for rice to any in America.

ESCAMBIO, from the Spanish cambier, to change, was anciently a licence granted any one for making a remittance, or giving a bill of exchange to another, beyond fees. For, by Stat. 5 Rich. II. no person might exchange, or return money beyond fees, without the king's licence.

ESCAMS, in Ancient Geography, a river of Massia, which has its source in mount Himus.

ESCAPE, Fire. See Fire-Escape.

ESCAPE, in Law, an evasion out of some lawful restraint, either by violence or health.

Escapes are either voluntary, or negligent. Voluntary, are such as are, by the express consent of the keeper to whose custody, in civil actions, the debtor has been committed; after which, he can never retake his prisoner again. (3 Rep. 51. 1 Sid. 330.) though the plaintiff may retake him at any time, (stat. 8 or 9 W. III. c. 27.) but the sheriff must answer for the debt.

Negligent escapes are where the prisoner escapes without his keeper's knowledge or consent; and then upon fresh pursuit the defendant may be retaken, and the sheriff shall be excused, if he has him again before any action brought against himself for the escape. (F. N. B. 130.) A rel ease of a prisoner in execution, (which fees,) either going to gaol or in gaol, or a breach of prison will not excuse the sheriff from being guilty of and answering for the escape; for he ought to have sufficient force to keep him, since he may command the power of the county. (Cro. Jac. 419.)

An escape of a person arrested upon criminal processes, by eluding the vigilance of his keepers before he is put in hold, is an offence against public justice; and the party himself is punishable by fine or imprisonment. (2 Hawk. P. C. c. 122.) But the officer permitting such escape, either by negligence or connivance, is much more culpable than the prisoner. Officers, therefore, who, after arrest, negligently permit a felon to escape, are punishable by fine. (1 Hal. P. C. 630.) but voluntary escapes, by consent and connivance of the officer, are a much more serious offence: for it is generally agreed that such escapes amount to the same kind of offence, and are punishable in the same degree, as the offence of which the prisoner is guilty, and for which he is in custody, whether treason, felony, or trespas; and this, whether he was actually committed to gaol, or only under a bare arrest. (1 Hal. P. C. 500. 2 Hawk. P. C. 134.) But the officer cannot be thus punished, till the original delinquency has actually received judgment or been attained, upon vertíc, confession, or outlawry, of the crime for which he was so committed or arrested; other wise it might happen, that the officer might be punished for treason or felony, and the person arrested, and escaping, might turn out to be an innocent man. But before the conviction of the principal party, the officer thus neglecting his duty may be fined and imprisoned for a misdemeanor. (1 Hal. P. C. 568, 9. 2 Hawk. P. C. 134; 5.) See Rescue.

ESCAPE WARRANT. If any person committed or charged in custody in the king's bench, or Fleet prison, in execution, or on mesne process, &c. go at large, on oath thereof before a judge of the court where the action was brought, an escape warrant shall be granted, directed to all sheriffs, &c. throughout England, to retake the prisoner, and commit him to gaol when taken, there to remain until the debt is satisfied; and a perdon may be taken on a Sunday upon an escape warrant. Stat. 1 Anne, cap. 6.

ESCAPEMENT, in Horology, is an ingenious mechanical contrivance for transmitting, in a modified way, and at equidistant intervals of time, the maintaining power of a clock or watch to the regulator, whether balance or pendulum, in order to restore that loss of motion in every vibration or oscillation, which necessarily arises from the friction of the acting parts, and the resistance of the air in every machine. It has been said, under the article Clock, that the maintaining power, whether consisting of a weight or spring, when suffered to expand itself unrestrained, would make the wheel-work run on with an increasing velocity, until the obstacles to motion, such as the friction in the teeth and at the pivots, the resistance of the air, &c. fixed the maximum of velocity with which it could expand itself; at which period the friction and resistance would jointly operate as a regulator, whilst they and the maintaining power remained unaltered, and the machine so circumstanced would greatly resemble a common kitchen-jack; and if an index were inserted on the arbor of the first or slowly moving wheel, it would indicate such portions of time as the ratio between the maintaining power and the regulating friction and resistance of the air taken together would produce; but it is obvious, that every alteration produced in the friction by wear, founfns, &c. or in the density of the air by the state of the atmosphere, would affect the indication so much, as to render it extremely irregular; hence the balance and the pendulum were successively invented and applied to regulate the indication of time by their isochronous vibrations; but then as both these regulators have alternate motions backwards and forwards, they could neither of them be applied immediately to check a wheel that moves continually in one direction, without the intervention of some contrivance, connected both with the wheel and regulator, which should convert a direct circular motion into a motion changing its direction by perpetual alternations. To devise and execute a piece of mechanism that should perform such an office flexibly and accurately, required much science as well as mechanical skill, and the invention once executed was denominated an escape, or by contraction among the workmen escape, because it suffers a tooth of the wheel, with which it acts, to escape, or pass on, at such intervals of time as are measured by the regulator, which wheel is therefore also called the escape wheel.

From this short account of the origin and office of an escape, the reader will perceive, that the accuracy of its construction constitutes one of the most essential considerations in an horometrical machine, it being an indispensible condition, that the successive impulses taken from the maintaining power through the medium of the wheel-work, and given to the regulator, should be so modified, as to disturb as little as possible the natural isochronism of the regulator, or, if it do disturb it, that it should somehow compensate that disturbance. Hence it becomes necessary, that the workman, or mechanician, should be fully acquainted with the theory of the natural isochronism of his proposed regulator, when he undertakes to design and execute his escape; he must not only know how much of the
maintaining power will be sufficient to balance the loss sustained in the natural length of a vibration, by reason of friction and the resistance of the fluid medium, but he must consider and indeed ascertain, by theory or experiment, or both, at what point of the arc of vibration the power must be applied; likewise how long the impulsion shall continue to act, and whether that action ought to be uniform, increasing, or decreasing in its intensity. These and similar considerations have produced, as might be expected, a great variety of constructions of an escapement, both with regard to their external shape and names. As a general observation it is one of the utmost importance in the useful art of clock-making, and as we have no author in the English language has given us the different constructions in historical order, together with such remarks as may enable the reader to judge of their respective excellence, we will devote some time to the detail of both the theory and practical construction of such different escapements as seem to merit a general notice.

But before we enter upon our description and examination of different escapements of clocks and watches, as the reader has not yet had an opportunity of perusing the article Pendulum, and as all escapements depend upon the shape and manner of action from the relation they bear either to the laws of its motion, or to those of a moving balance, it will contribute greatly to his better understanding the subject, if we premise first some of the chief circumstances which relate to the theory of a free pendulum. We have observed that any influence that any external impulse will have on it when applied to become the regulator of a clock; and secondly, if we explain the theory of a balance's motion, which we have purposely reserved for this place by reason of its intimate connection with the escapement.

1. In fig. 1. of Plate XXXI. of Horology, let C D represent a free pendulum, or pendulum that has no weight but what is collected at the centre of oscillation or point D, and let the arc D B represent a semi-oscillation round the point C, taken as the centre of motion or point of suspension, at which we will suppose there is no friction, then if the resistance of the air and rigidity of the string or rod were not to interfere, when the pendulum was once removed from its natural or perpendicular suspension C D to B, and suffered to descend again by the sole force of gravity, it would acquire such a velocity at its lowest point D, by means of the accelerating force of gravity, as would, under these circumstances, carry it up an equal semi-oscillation or arc D G, which relate to the theory of a free pendulum. If we subtract from the equal arc D G, the same reasoning would apply in the returning vibration from G to B; the velocity acquired at D by the descent from G to D would carry the pendulum again up to B, and the consequence would be, under such natural circumstances, if they could be effected, that there would be a perpetual alternation of vibrations of the same length, which would consequently be isochronal with respect to each other, so long as the pendulum remained of the same length; and such a pendulum would of itself be a perfect time-measurer, and would only want a register to indicate the number of its vibrations, to make it a complete regulator or chronometer; but the fact is, the friction and rigidity at the point of suspension cannot by human art be entirely annihilated, though ingeniously can greatly diminish it; nor can the obstacle to free motion arising from the resistance of the air be removed, or even rendered uniform; hence it is found that when a pendulum is drawn aside from its point of rest, every succeeding vibration, after motion has commenced, is somewhat shorter than the preceding one, until after some hours have been spent in alternate vibrations continually shortening, the pendulum finds its original point of rest; the time expended in doing this is longer in proportion to the diminution of friction, the air and other circumstances remaining unchanged. Perdriouille Bérthoud, the famous French clock-maker, made some experiments to ascertain this fact, and constructed the knife-edge suspension of a French's pendulum, with a heavy lenticular ball, so free from friction, that the vibration of 15° was not reduced to 15 till 29° 45' had elapsed; but notwithstanding every attempt to reduce the friction, the pendulum came to rest at last. From this short view of the tendency of a pendulum to come to rest after it has had a motion communicated to it, we clearly perceive the necessity of making some auxiliary additions to the natural force of gravity, in order that the pendulum may keep up the length of its original vibration in every succeeding one, notwithstanding the obstructions which continually oppose the operation of gravity; these auxiliary additions to the motion, produced by gravity only, constitute the operation of the maintaining power, modified by the wheel-work and escapement, in every pendulum clock; and hence arises a disturbance in the theory of the free pendulum, which makes such a theory no farther of use in clock-work, than as it affords certain laws and a scale of forces, such as the mechanical man may labour to imitate, by modifying the joint agency of his auxiliary additions and of the operation of gravity, so that they shall act in concert, and the imitation is to be effected principally, as to its mode, by the escapement, the maintaining power being considered only as to the gravity of any additional power to be applied in aid of gravity.

Now, if we suppose the pendulum at the situation B, or extremity of its arc, and draw A B perpendicular to the vertical line C D, and B E = C B perpendicular to the line A B, or, which is the same thing, parallel to the line C D; also, if we draw B F a tangent to the arc at the point B, and from the point E emit the line E F upon it, to form a right angle at F, in which case the line F E will be parallel to the line C B. B E will represent the force of gravity, which, by the resolution of forces, is equivalent to B F and F E; but F E is perpendicular to the tangent, or is in the direction C B of the radius, and therefore can neither accelerate nor retard the motion, whilst B F, being in the direction of the tangent, or perpendicular to the radius, is wholly employed in accelerating or retarding the pendulum's motion; hence, the line B E = B F : the force of gravity : the accelerating force, but from the familiar triangles B E F, C B A, B E is = C B, and B F = B A, therefore, by substitution, C B : B A :: force of gravity : accelerating force, and consequently the accelerating force = \[
\frac{C B}{B A}
\] in which expression gravity and the radius C B are invariable, therefore the accelerating force varies as the line B A of the arc of vibration. From this law of variation of the accelerating force of a body moving in a circular arc, it follows, that the longer arcs require longer times than the shorter arcs in the proportion of 34 : 29, as Huygens has demonstrated; for the line does not increase so fast as the arc, which it ought to do, to make the vibrations of the same pendulum in different arcs isochronal: if, however, the body could be made to move along the chord or straight line B D, instead of the arc B D, then the vibrations of different lengths would be isochronal, because two similar bodies will run down each a separate chord of different lengths to the lowest point of the same circle in the same time, namely, in the time that each would take in falling through
through the whole diameter of the circle, and the acquired velocity of each, at the lowest point, would be in proportion to the length of its chord. But the mechanician has not attempted to make his pendulum vibrate in chord lines, which probably is impracticable, but has invented another curve, called the cycloid, generated by a point in a circle revolving on a straight line, which curve possesses this peculiar property, that the accelerating forces, which a body acquires by moving along it, are exactly proportional to the arc, (see Cycloids,) so that a pendulum vibrating in this kind of curve, will perform its long and short vibrations in the same time. This property of the cycloid was first discovered by the celebrated Huygens, who owed much of his celebrity to it, and adopted a contrivance for making a pendulum move in such a curve, which will be described under our article Pendulum, and also the reasons will be given why it was laid aside in the practice of clock-making. It may be proper, however, to remark here, that with a pendulum vibrating in the arc of a cycloid, with all its weight collected in the ball, and its length rendered variable, if such a pendulum could be made, it would, notwithstanding, be of consequence what the nature of the escapement were, because though the variations in the arc, arising from varied gravity alone, would not affect the times of the successive vibrations, yet, when additional force is applied in aid of gravity, by means of the maintaining power and escapement, the uniform law of acceleration just described would be partially disturbed by such addition, though the disturbance would be less perceptible than in circular arcs of considerable extent.

When, however, a pendulum vibrates in a small arc, it is demonstrable that such an arc differs very little from a cycloidal arc near its lowest point, may almost coincide with it; it is also found from experience, that a heavy ball is less disturbed by the requisite additional force, communicated by the maintaining power, than a light one, as might be inferred from theory; on which two accounts the prevailing practice among clock-makers is, to make such escapements for a pendulum as require but short vibrations, and, in order to gain momentum, to appeal a heavy ball; and it has been discovered, and is now indeed an acknowledged fact, that a regulator with an exact compensation for the effects of variable temperature in its pendulum, and that vibrates by means of a good escapement in small arcs, with a heavy lenticular ball, goes with a degree of accuracy beyond what Huygens durst even hope for from his cycloidal contrivance; in effecting which, theory and practice were found to be greatly at variance.

But the cycloidal theory, which, considered as a theory, is not only ingenious, but illustrative of the principal circumstances which relate to the motion of a pendulum, will furnish us with a concise and clear notion how the natural arc and time of a vibration will be altered by an accension of external force to the force of gravity, without some knowledge of which alteration no mechanician can proceed on scientific principles in the construction of an escapement.

Supposing now the pendulum in fig. 2, similar to that in the preceding figure, and the arc to be so small as nearly to coincide with the cycloidal curve, let the arc G B be bent into the straight line H I, and with the semi-arc D H, as a radius, describe the semi-circle H L b; let the line A B from H to M, and from b to m perpendicular to the line b H, and join m M, which line will pass through the centre D; from any other points i and k in the semi-arc or radius, draw the lines I N and K O parallel to H M, and also the corresponding ones i n and k o parallel to b m, and we shall obtain the following relations of the properties of the pendulum's motion.

1st. The forces of gravity urging the pendulum towards D from B, at the points I and K of the semi-vibration, will be represented by, and proportional to, the ordinates J N and K O of the straight line M D m; and the corresponding ordinates i n and k o will represent, and be proportional to, the retarding forces of the same gravity, at the points i and k of the other semi-vibration, and vice versa in each half of the returning vibration.

2dly. The velocities acquired by the uniform action of gravity at the points K and i, will be respectively proportional to the ordinates K q, and i p, of the semi-circle H L b, hence the velocity of the pendulum at the lowest point D, is to its velocity at any other point of the arc I, as D L (= D H, or whole semi-arc) is to I P.

3dly. The times of the pendulums vibrating through the portions H I, I K, K D, &c. of its arc, will be represented by, and proportional to their corresponding areas H P, P Q, Q L, &c. respectively in the semi-circle H L b; which proportions will be equally applicable in the ascending portions of the arc D k, k i, and i b, which will also be moved through in times proportional to the arcs L q, q p, and p b, respectively; if the pendulum is projected from the lowest point D with the initial velocity D L, this velocity will be reduced at the point k to k q, at i to i p, and at b to nothing, whence the pendulum will return, and the operation of gravity will begin to be reversed.

4thly. If one pendulum describe the arc represented by H D b, and another describe the arc K D b, (still supposing them to be cycloidal or very nearly so,) they will describe them in equal times, but their velocities at D, or greatest velocities, will be respectively proportional to H D and K D, or length of their semi-arc; that is, while a pendulum, projected with the initial velocity D L, from the lowest point, ascends to the point b, or extremity of its semi-vibration, another similar pendulum, projected with the initial velocity R D, will ascend to the point k, or extremity of its arc, D R being = D k, and the same will be true in the deficient, where the increments of motion exactly balance the ascending decrements.

5thly. The areas M H I N, M H K O, &c. are proportional to the squares of the velocities acquired in moving down the arcs H I, H K, &c. or to the diminution of the squares of the velocities effected by the retardation of gravity in the returning or ascending semi-vibration.

From a due examination of the relations exhibited in the preceding illustration of the principles of a pendulum's motion, the reader will readily perceive that there is a certain length of the arc of every vibration, whether performed in a circle or cycloidal curve, which corresponds to its maximum of velocity, or velocity at the lowest point; which length, in large circular arcs, is determined by the greatest chord line, but in cycloidal curves, or small circular arcs, is the whole arc itself; he will also understand how, when the weight of a pendulum is given, its accelerating action in any given point of the arc may be ascertained; from which and similar considerations he will be able to form something like an estimate of the effect that will be produced in the above natural relations by the application of an external force of an ascertained quantity, acting in a given manner; for instance, let us suppose that a maintaining power is applied to keep up the vibrations of a pendulum, as in our last figure; that the quantum of power to be added to gravity be to its accelerating force at H or b, as b m is to m r, which we will suppose to be a number of grains to some number of ounces; and that this additional power
power is applied through the agency of an escapeinent, which so modifies it, that its action is exerted but a short time, and at the extremity of the arc: the rough conjuncture which the reader would be apt to form would be, that as the two forces began to act in concert, a pendulum actuated by them would obey a compound scale of forces, differing in quantity but not in quality from the simple scale of gravity, and that therefore little or no alteration would take place in the time of its vibration; let us see what would be the result according to our theory; from the point m of the line m b, of the greatest acceleration or retardation, as the case may be, set off m r equal to its representative, for so many times of augmenting or retarding force, and then b r will be the whole force urging the pendulum towards D: do the same for every point of b D, and we get a new scale of forces represented by the dotted line r s t D, and the space m D r, contained between the two scales m D and D r, will represent the addition made to the square of the velocity in moving over b D by the joint action of gravity and of the maintaining power. Then if we make the area D v u equal to the area D b m, by leaving out as much space parallel to the perpendicular b m, as we take in behind the hypothetic m D, the point v will have the excursion or extent of the returning, as well as of every succeeding vibration, because the area of the triangle D u v is proportional to the square of the velocity, and v is therefore the point where the initial velocity D L will be extinguished. Lastly, if the arc b v of the semi-circle be bisected, its half will very nearly represent the contraction effected in the time of the outward semi-vibration, agreeably both to theory and practice; and in a similar manner might be calculated the effect to be produced on a natural vibration, or vibration from simple gravity, by any accession of external force differently applied: in the instance we have given, a temporary impulsion would evidently make a greater derangement when given at the extremity of the arc, than if it had been given at L, and greater at L than at K, and consequently the least derangement would have arisen if the impulsion had been given at the lowest point D, which is worthy of recollection; though the fact is, that most of the eescapsements, the arcs of the detached kind, continue to act for a sensible time, and, after all, the thing principally aimed at in modern practice is, to construct all the parts of an horological machine so, that the arc of vibration may vary as little as possible under the different influences which affect the pendulum’s motion; for then, whatever the length of the arc be, whilst there is no variation in it, the vibrations will be isochronal, whatever be the nature of the curve; but completely to effect so definable a purpose can hardly be expected under all the combinations of variable refractions arising from friction, oil, air, &c., however detached the eescapements may be, i.e. however small the continuance of each of their impulsions. Hence, certain ingenious artists have attempted such a compound scale of forces, connoting of gravity and maintaining power conjointly, as shall render even circular vibrations of different lengths isochronal among themselves, when they shall happen to vary in length, which plan would certainly make the best compensation for the effects of variable refractions, but such plan could be completely executed at pleasure; and the compound scale of forces to do this, must be to the scale of gravity alone, as the arc of semi-vibration is to the line of the same in every point of the excursions. For in fig. 1, if B F be supposed equal to the semi-arc B D, then B E, the whole compound force at the point B, will be greater than C B or force of gravity alone, and will be to it, by similar triangles, as B F is to the line A B, as has been demonstrated; therefore the whole compound force at any point B of either semi-vibration should be to the force of gravity alone in that point, as the arc B D is to the line A B, which compound scale consequently will demand as a certain limited variation, or scale, in the auxiliary force derived from the maintaining power through the modifying medium of the escapement.

2. When a balance was first applied as a regulating power, it possessed no natural property, like the pendulum, of perpetuating its own oscillations, but had its motion produced by an artificial force acting alternately on its opposite pallets, and derived entirely from the maintaining power at certain intervals; so that to perform all the oscillations in equal times, the action of the force applied was required to be the same in mode, quantity, and duration, in each oscillation, which conditions could not be fulfilled by reason of the constant changes that took place in the friction of the works, and in the density and confrequent resistance of the air; a simple balance therefore was no otherwise better than a continued fly, except that its alternate oscillations prevented the acceleration of motion that would ensue, if there were no such frequent checks as the balance experienced. Dr. Hooke's invention of a regulating spring, to be an auxiliary balance what gravity is to a pendulum, was an important one, to which all the excellence of an ordinary watch may have its origin imputed, and without which the compensations for different temperatures in the best chronometers would not be of any utility. The discovery of a spring’s force being as its tension, or dilance moved from the point of red, (ut tensio sit vis,) was the first step towards a theory of motion by which the balance and its regulating spring, taken conjointly, may have their effect estimated, and by which such a balance with the belt compensation and escapement now vies in accuracy even with the pendulum itself.

George Atwood, eqf. of Cambridge, has published an excellent memoir in the Philosophical Transactions of London, vol. 84, part i. 1794, intituled "Investigations founded on the Theory of motion, for determining the times of Vibration of Watch Balances," from which we beg leave to extract so much as falls within our purpose in this place.

Let PM N S, fig. 3. of our plate, represent the circumference of a watch balance, which vibrates by the action of a spiral (or helical) spring, on an axis passing through the centre C. Let O D B E be the circumference of a concentric circle, considered as fixed, to which the motion of the balance may be referred. In the circumference of this circle let any point O be affixed, and when the balance is in its quiescent position, suppose a line to be drawn through C and O, intersecting the circumference of the balance in the point A; the radius CA will be an index, by which the position of the balance, and its motion through any different arcs of vibration, will be truly defined. In the sequel, the motion of the balance, and the motion of the index CA, will be used indifferently, as terms conveying the same meaning. Since the balance is in its quiescent position when the index CA is directed to the fixed point O, on this account O is called the point of quiescence of the balance, or balance spring, indicating the position when the balance is not impelled by the spring’s elastic force either in one direction or the other. If the balance should be turned through any angle C B, the spiral spring being wound through the same angle, endeavours its elastic force to restore itself, and when at liberty, impels the balance through the arc B O with an accelerated velocity to the instant at which the position O, where the force of acceleration ceases: with the velocity,
city acquired at 0, the balance proceeds in its vibration, describing the arc OE with a retarded motion. The elastic forces of the spring at equal distances, on the opposite sides of the point O, are assumed to be equal; it is also allowed that the effects of friction, and other irregular resistances, which retard the motion of the balance, are compensated by the maintaining power, so that the time of describing the first arc of vibration BO, by an accelerated motion, shall be equal to the time of describing the latter arc OE, by a retarded motion, and that the entire arc of vibration BOE is bisected by the point O.

To render the construction of fig. 3. more distinct, the fixed circle ODBE is represented to be at a small distance from the circumference of the balance, but is to be considered as coincident with it, so that the arc BO, subtending the angle BCO, may be of the same length with an arc of the circumference of the balance, which subtends the same angle BCO; on this principle CO or CA may be taken indifferently as the radius of the balance.

The determination of the time in which the balance vibrates, from the theory of motion, requires the following particulars to be known, viz.

First. The spring's elastic force, which impels the circumference of the balance, when it is at a given angular distance OD, (fig. 3.) from the quiescent point O.

Secondly. The law or ratio observed in the variation of the spring's force, while the balance is impelled from the extremity of the semi-arc B to the point of quiescence O, where all acceleration ceases.

Thirdly. The weight of the balance, including the parts which vibrate with it.

Fourthly. The radius of the balance CO, and the distance of the centre of gyration from the axis of motion CG.

Fifthly. The length of the semi-arc BO.

Suppose the plane of the balance to be placed vertically, and let a weight P, (fig. 4.) be applied by means of a line suspended freely from the circumference at T, to counterpoise the elastic force of the spring when the balance is wound through an angle from quiescence OCD. This weight P (the weight of the line being allowed for,) will be the force tending to accelerate the balance, either at rest or in motion, when at the angular distance OD from the quiescent position. It appears from many experiments (of Berthoud) that the weights necessary to counterpoise a small spring's elastic force, when the balance is wound to the several distances from the quiescent point, represented by the arcs OOG, OH, OI, &c. fig. 4, are nearly in the ratio of those several arcs. It also appears, that the shape, the length, and number of turns of the spiral, may be so adjusted to each other, that the forces of elasticity shall be counterpoised by weights, which are in the precise ratio of the angular distances from the quiescent point, or, as it is sometimes expressed, in the ratio of the spring's tensions; at least as nearly as can be ascertained by experiment: this law of elastic force is affirmed in the subsequent investigation.

The position of the centre of gyration may be always determined when the figure of the vibrating body is regular, by calculating the sum of the products, which arise from multiplying each particle into the square of its distance from the axis of motion, and dividing the sum by the weight of the vibrating body; the square root of the result will be the distance of the centre of gyration from the axis of motion. When the figure of a vibrating body is irregular, recourse must be had to experimental methods, in order to determine the position of the centre of gyration. See Airwood's treatise "On the Rectilinear Motion and Rotation of Bodies."

Let the radius of the balance CA or CO = rs, fig. 3; the semi-arc BO = b; let the spring's elastic force, acting on the circumference of the balance, when wound to any given angle OCD, from the quiescent position, be P, and let the arc OCD = a; the weight of the balance and the parts which vibrate with it = W; the distance of the centre of gyration from the axis of motion CG = g. These notations being premised, the resistance of inertia, by which the mass contained in the balance opposes the communication of motion to the circumference, is \( \frac{W^2}{r^2} \), and consequently the force which accelerates the circumference at the angular distance OCD from the quiescent position is \( \frac{P \cdot x}{W^2} \). This quantity remaining invariably the same, while the balance describes the arc of vibration BOE, may be denoted by the letter F, so that \( F = \frac{P \cdot x}{W^2} \); supposing the radius CA commencing a vibration from the point B to have described the arc BH, and let OHD = a, since the force which accelerates the circumference at the angular distance OHD from quiescence \( O = F \), and the forces of acceleration are supposed to vary in the proportion of the angular distances from the quiescent point O, the force which accelerates the circumference of the balance at the point H will be \( F = \frac{x}{a} \); let u be the space through which a body falls freely from rest by the acceleration of gravity, to acquire the velocity of the circumference at the point H; the principles of acceleration give this equation \( u = \frac{-F \cdot x^2}{a} \); (Newtonii Princip. vol. i. prop. xxxix.) and taking the fluents while \( x \) decreases from b to a, \( u = \frac{F \cdot x \cdot b - b^2}{2a} \); if therefore \( l \) is made = 193 inches, being the space which bodies falling freely from rest, by the force of gravity near the earth's surface describe in one second of time, the velocity of the circumference, when the extremity A of the index CA has arrived at the point H, will be \( \sqrt{\frac{2l}{a}} \times \sqrt{b - \frac{b^2}{a}} \). Let \( t \) represent the time in which the circumference describes the arc BH; then \( t = \sqrt{\frac{2l}{a}} \times \sqrt{\frac{b - \frac{b^2}{a}}{b}} \); and \( l = \sqrt{\frac{a}{2l}} \times a \) a circular arc, of which the cosine \( \frac{n}{b} \) to radius = 1, which is the time of describing the arc BH expressed in parts of a second; when \( x = 9 \), that is, when the circumference has described the entire semi-arc BO, the circular arc of which the cosine = \( \frac{9}{b} \) is a quadrant of a circle to radius = 1. Let \( p = 5.14439 \); &c. the time \( t \) of describing the semi-arc BO = \( \sqrt{\frac{a}{2l}} \times 2 \), and this quantity being substituted for \( a \), the
Let the given arc $\alpha = 90^\circ$ in this case $t = \sqrt{\frac{p r^2}{8 l r^2 + 180^2}}$.

Agreeably to this expression, Mr. Atwood wished to try the practical results of a chronometer made by Kendall, to prove how far his theory agrees with practice, and assuming the centre of gravity to be the same as in the balance were a cylindrical plate, he obtained from Mr. Earnshaw the following data, viz.:

W, the weight of the balance and vibrating parts = 42 grains.

P, the force at the circumference of the balance, which counterpoises the force of the spring when wound to the distance of $90^\circ$ = 24 grains.

$r$, the radius of the balance = 1.125 inches.

$t$, the space described in one second of time by bodies which descend freely from rest by the acceleration of gravity = 93 inches.

$\beta$, the circumference of a circle to radius $r = 3.14159$, &c.

The balance, when adjusted to mean time, made full five vibrations in a second; the actual time of a semi-vibration is therefore $0.1150$.

Then $t$, the time of a semi-vibration by the theory,

$$t = \sqrt{\frac{p r^2}{8 l r^2 + 180^2}} = 0.0994 \text{ parts of a second}$$

and hence $0.1150 - 0.0994 = 0.0156$ is the difference between the actual time and the time by calculation from the theory; and the near coincidence of the two results proves that the supposition of the centre of gravity being nearly as in a cylindrical plate, is near the truth.

It is observable," says our author, "that the semi-arc of vibration $BO = b$, does not enter into these expressions for the time of a semi-vibration; if, therefore, instead of the semi-arc $BO$, an arc of any other length $LO$, terminating in the point of quiescence, (fig. 3) should be substituted in the preceding investigation, the time of describing $LO$ would be

$$t = \frac{\frac{p r^2}{8 l r^2 + 180^2}}{11}$$

or, $\sqrt{\frac{p r^2}{8 l r^2 + 180^2}}$ equal to the time of describing the other semi-arc $BO$; consequently, whether the balance vibrates in the largest or smallest arcs, the times of vibration will be the same. From the preceding investigations it appears, continues our author, that when the force by which the circumference of the balance is accelerated at the given angular distance $\varepsilon$ from the quiescent position is $F$, the time of a semi-vibration

$$t = \sqrt{\frac{\frac{p r^2}{8 l r^2 + 180^2}}{11}}$$

and conversely, when the time of a semi-vibration $t = \sqrt{\frac{p r^2}{8 l r^2 + 180^2}}$; the force which accelerates the circumference to the given angular distance $\varepsilon$ from the quiescent position, that is, $F = \sqrt{\frac{p r^2}{8 l r^2 + 180^2}}$.

Since time-keepers are usually adjusted to mean time when the balance makes five vibrations in a second, the time of a semi-vibration will be $\frac{1}{(10)^\circ}$ th part of a second; the substitution of $\frac{1}{(10)^\circ}$ in place of $\frac{1}{5}$ being made in the preceding equation, the force which accelerates the circumference of the balance, when at any given angular distance $\varepsilon$ from the quiescent position, will be determined for all time-keepers adjusted to mean time, in which the balance makes five vibrations in a second. Suppose the given angle $\varepsilon = 90^\circ$, then making $e = 90^\circ$, $p = 3.14159$, &c. $l = 193. t = \frac{1}{10}$, the accelerative force at the angular distance from quiescence $90^\circ$ or $F = \sqrt{\frac{p r^2}{8 l r^2 + 180^2}} = r = 1.00408925$. We have therefore arrived at the following conclusion; if the radius of the balance is equal to one inch, and the time-keeper is adjusted to mean time when the balance makes five vibrations in a second, the force which accelerates the circumference of the balance at the distance of $90^\circ$ from the quiescent position is $1.00408925$, the accelerative force of gravity being $1$. And if the radius of the balance is greater or less than one inch, the force by which the circumference is accelerated at the distance of $90^\circ$ from quiescence will be greater or less than $1.00408925$ in proportion to the radii.

According to the principles assumed in the preceding solution, the spring’s elastic force is supposed to vary in the proportion of the angular distances from the quiescent position, and on this condition the vibrations are shown to be isochronous, whether they are performed in longer or shorter arcs; but if the spring’s elastic force at different distances from quiescence should not be precisely in the ratio here assumed, the longer and shorter arcs may be altered in the time differing in any proporitons of inequality. If, for instance, the spring’s force, instead of varying in the ratio of the aforesaid distances, should vary in the $3/90$, $4/90$, &c. power of the distances, it does not appear from the preceding solution what alteration in the daily rate would be caused by this change in the law of the force’s variation, when the semi-arc of vibration is increased or diminished by a given arc. To ascertain this point fully, other researches will be necessary, by which it may be known, what alteration of the daily rate of a time-keeper is occasioned by a given increase or diminution of the arc of vibration, when the spring’s elastic force varies in a ratio of the distances from the quiescent position, the general index or exponent of which is any number or fraction $n$.

"The force which accelerates the balance being assumed to be in that power of the distances, the exponent of which is $r$, let $BO = b$, (fig. 5.) be the semi-arc of vibration when the time-keeper is adjusted to mean time; let $DO = a$; the accelerative force on the circumference at the distance from quiescence $OD = F$; suppose the circumference to have described the arc $BH$ from the extremity of the arc $B$; and let $HO = x$; then the force by which the circumference is accelerated when at the angular distance from the quiescent position $OH = \frac{F x}{a}$; let $u$ be the space through which a body falls freely from rest by the acceleration of gravity, to acquire the velocity of the circumference when it has described the arc $BH$; the principles of acceleration gave this equation $u = \frac{F x}{a^2} \times 11$; taking the flu-
ESCAPEMENT.

The watch will be obtained from the preceding theorem, by making the following substitutions; \( BO = 135^\circ; IO = 127^\circ; \) the alteration of the daily rate \( = 24^\circ \times \frac{\tan 135^\circ - \tan 127^\circ}{127} \).

From this theory of the balance and balance spring it is evident, that when there is a very minute alteration in the law of the force's variation, amounting to no more than \( \frac{\pi}{400} \) th part of the entire ratio of the distances, an acceleration is caused in the daily rate of more than \( 2^\circ \); when the diminution of the semi-arc is only \( 8^\circ \), and as this alteration in the force is left, probably, than can be detected by actual measurement of the force by mechanical means, it is very probable that a much greater acceleration or retardation of the rate, than in the example before us, may occur from the same cause, which can only be corrected by a corresponding alteration either in the length or strength of the balance spring, or both, as the case may require, and the best way of detecting the law of force by which the spring acts at different distances from the quiescent position, is by increasing or diminishing the maintaining power, so as to render the arc of vibration unequal in successive trials for a limited time. The necessary conclusion, from such trials with different maintaining powers, will be, that when an acceleration of the daily rate accompanies a diminution of the arc of vibration, the elastic force of the spring used varies in a ratio than that of the distances from the quiescent position; but on the contrary, when a retardation takes place, the balance and balance spring, the said elastic force varies in a higher ratio than the of the distances from the point of quiescence. We here suppose the same efeapebility to be used in all the trials, and that the impuluse given to the balance is no more than sufficient to overcome the inertia of the balance and the resistance it meets with from friction and the density of the air; but as there is generally an over assistant of power communicated to the balance to guard against flopping by the accession of dirt or thickening of the oil, this superfuous power has such an influence on the balance and its spring when in motion, as to produce a compound law of varying forces, somewhat different from the simple law derived solely from the elasticity of the spring, and the more this compound law varies from the simple law derived from the spring's elasticity, the greater will be the discrepancy between the theory and performance of a watch balance. The buhness of a good efeapebility of a watch or balance clock is to keep the balance in continual motion with as little interfe.ence as possible with the simple law of its natural varying forces, which it has been shown are in proportion to the distances from the point of quiescence.

After these remarks on the laws by which a pendulum and a balance together with its spring become the regulators of an horological machine, the reader will be able to form an opinion, founded on scientific principles, on the merits or demerits of the different efeapebilities that are subsequently described, not only in this article, but in the articles Chronometer and Clock, which have been already published.

Henry Sully, who was an ingenious clock and watch maker about the beginning of the 18th century, wrote a history of the efeapebilities of his time down to the year 1725, which Julien le Roy added to Sully's "Regle Artificielle du Temps," in the second edition, published at Paris, 1737, from which Berthoud has extracted his account of several efeapebilities in his "Histoire de la Melure du Temps," and which we mean to avail ourselves of in a certain degree in our subjoined descriptions.
The different ecapements of clocks and watches may be divided into four classes: viz.;

1. Those with a recoil, or which produce a backward motion of the ecapement wheel and second's hand in some parts of the vibration; (ecapement a recoil.)

2dly. Those that have the dead-beat, or that allow the ecapement wheel and hand to revolve while the whole vibration is made; (ecapement a repos.)

3dly. Detached, or free ecapements, which act on the balance or pendulum an almost indefinable time, and suffer the vibration to be performed almost without connection with the pallets; (ecapement a vibrations.)

4thly. Detached, or free ecapements with a remontoir, or auxiliary spring frequently wound up by the maintaining power, to equalize the arcs of vibration; (ecapement a vibrations with a remontoir.)

The most ancient ecapement is used at this time, and probably the first that was ever contrived, is the crown-wheel ecapement as first employed in our table-clocks and common watches; we know not who was the original inventor, but find mention made of it by Leonard de Vinci, who died in the year 1513; and Venturi thinks that the horological machines of Wallingford and Dondi, early in the fourteenth century, had the fame, as we have seen, under our article Clock, that Henry de Wyck's clock had in the year 1564. The idea of converting a rotatory into a vibratory motion, and the means adapted to effect this purpose mechanically are equally ingenious; as an effort of genius this thought is much to be admired. We have already given a general description of the connection that the ecapement-wheel has with a train of wheel work on one side of it, and with the balance on the other, under our article Clock; but as the balance has no rim, and was without the regulating springs, as it is sometimes called, the pendulum spring, we think it right to give a separate drawing and description of this ecapement, as made at present, together with some remarks on its properties.

1. Crown-wheel ecapement.—In Plate XXXI. of Horology, fig. 6, represents the crown-wheel and balance in connection, which may be in either a horizontal or vertical position, and is in fact sometimes in one position and sometimes in the other in a common watch agreeably to the different positions of the body of the wearer; and it is easy to conceive that a short pendulum might be subsituted for the balance when the crown-wheel moves horizontally in a fixed position, and the axis of the balance is placed horizontally, which is the case in most of the portable clocks. The name of crown-wheel is taken, no doubt, from the resemblance it has to an old fashioned royal diadem; but when applied to a watch it is frequently called simply the balance-wheel, from its connection with the balance: this wheel and the balance, including the pallets and regulating spring, may be considered as constituting the ecapement, the action of all which may be understood from the following short account.

Suppose the pinion a, on the arbor b of the balance-wheel or crown wheel e, to be actuated by the main-spring, or weight which forms the maintaining power, by means of the train, in the direction c f, while the pallets e and f, attached to the axis of the balance g, h, and standing at right angles to each other, or very nearly so, are long enough to all in the way of the ends of the fluted teeth of the wheel, when turned round an angle of 45°, so as to point in opposite directions, as in the figure; then a tooth of the wheel below, for instance, meets with the pallet f, supposed to be at rest, and drives it before to a certain space, till the end of the tooth e capes; in the mean time the balance attached to the axis of the pallets moves in the direction b k, and winds up the small spiral spring i, one end of which is fast to the axis and the other to a flud on the plate of the frame; in this operation the spring opposes the momentum given to the balance by this push of the pallet f, and prevents the balance from going quite round before the pallet e meets with another tooth at the opposite end of the wheel's diameter; here this pallet receives a push which carries the balance back again, having as yet but small momentum, in the direction b l, and aids the spring, which now unloads itself till it comes to its quiescent position, but beyond that point is unwound, partly by the push from the maintaining power on the pallet e, and partly by the acquired momentum of the moving balance, particularly when this pallet has escaped, at length pallet f again meets with the succeeding tooth, and is carried backward by it, in the direction the balance is now moving in, till the maintaining power and force of the spring has brought the balance to its quiescent position, and the motion is renewed. This is the action of the crown-wheel ecapement, and it may be said to be a regular law, that as the action of the maintaining power continues to press on the pallets, either with or against the balance's motion, during a large portion of each vibration, this extraneous force acting along with the elastic force of the spring makes a new law compounded of the two forces, which may or may not be a regular law, as modified by circumstances, that are to be taken into consideration; for instance, the relative forces of the maintaining power and of the regulating spring, the uniformity of each force separately considered, the ratio between the radius of the pallet-wheel and length of the pallets, the weight and diameter of the balance, the angle of action in the ecapement relatively to the whole arc of vibration, the adjustment of the length and strength of the spring for illochronism, and of its quiescent place to the position of the pallets, together with the friction and inertia of the acting parts, as well as resistance of the air to the moving balance must all enter into the account, which complex data render all calculations founded in theory very inadequate to their purpose of determining the practical results independently of experimental trials, which are necessarily adopted by the workmen in finising the adjustments. The bad effect of an almost constant force on the balance, as derived from the maintaining power, is evident by the application of the key to the fusce-arbor of a watch; and by urging the key in a direction contrary to that of winding up, for the additional force thus given to the maintaining power, will very feebly accelerate the beats of the watch, and lessen the arc of vibration, hence any inequality occasioned in the maintaining power, by the accession of dirt, or by want of perfect compensation in the fusc of the varying force of the main-spring, &c. will alter the daily rate very materially, though the mecha
ESCAPEMENT.

Mechanical adjustments at the balance may, in the first instance, have produced jointly a law of varying forces in the regulating mechanism that shall approximate near enough to the isochronous law of the balance spring, while that the motion remain invariable. It is of the utmost importance, therefore, when a crown-wheel escapement is used in any watch, that whenever a new main-spring is put in, the fusee should also be altered, so as to become as perfect a compensator as possible for that identical spring, which, we believe, is seldom, if ever, attended to in practice. This escapement usually has a pin in the rim of the balance that may catch a notch on each side of the cock beyond the extremities of the longest vibrations, called the banking, to prevent the derangement of the balance and of its regulating spring by any shock or accident.

2. Escapement a pirouette by Huygens.—About the year 1675, when Huygens was concerning the bell construction he could devise of a marine time-piece, he naturally dwelt upon the portability of the balance, as affording the likeliest plan of accomplishing his purpose, but he was aware that the balance vibrating in short arcs was not comparable in point of steadiness to a pendulum, as a regulating principle, seeing it is too much under the control of the mainspring, and therefore he executed the crown-wheel escapement, the first one at that time known. The balance under such influence, and that a variable influence, had the property of putting itself into motion when in a state of rest: Huygens, therefore, made such additions to the balance and escapement that in use, as produced much longer vibrations than it had been before witnessed, and introduced an additional wheel and pinion between the pallet-wheel and the balance to effect this object; thus, in fig. 7. of our last plate, is a side view of a small frame containing the mechanism of Huygens' escapement, consisting of two wheels, one pinion, a pair of pallets, and a balance with the spiral spring, together with the requisite cocks to bear the pivots of the arbor; a b is the crown-wheel or pallet-wheel of the usual shape and number of teeth, placed in a vertical position, like the contrate wheel of a common watch or table clock; c d is a contrate wheel placed horizontally, like the pallet-wheel of a common watch, having two pallets e f, as usual on its arbor, at right angles to each other, and acting exactly as we have explained above; the contrate wheel c d drives a pinion g on the balance or pallet-wheel h; the spiral spring i; the action is thus: when the small flar reaches far enough to fall on the pallet a and b successively, which they impel one after the other, and give motion to both, the balance and the first pallet-wheel is thus driven and the escape proceeds by means of the radii of the large flar, that rest successively against the semi-circular portions of metal not cut away, above the centres of the balances respectively. The three axes stand in the angles of an isosceles triangle, and have their upper pivots supported by three separate cocks, placed over the upper plate of the frame, the lower pivots of the balances resting on the upper plate, but the arbor of the two flars passing across the frame to take the left wheel. The action is thus; radius I of the small flar has parted with the pallet a of balance B, and the long radius d is escaping; presently radius g will fall on the pallet b of balance A, and impel it in a direction from 4 to 5, the balance B at the same time moving in a contrary direction; this impulse will continue till the radius a falls from the pallet, soon after which the long radius g will fall on the semi-circular central piece of balance A, and flop the further motion of the two flars, which move together on the same arbor, and the balances will go on in their vibrations till the spring under balance B brings them back against the pallets, and present the cut half of the central piece of balance A to the point g of the long radius, which, being impelled by the train, now escapes; the flars go on till radius 4 of the small flar meets with the pallet a of balance B, the motion of which it now opposes, and is itself brought back. To make a recoil of the hands till it has stopped the motion of the balances, which now begin each another oscillation; the radius e escapes the pallet a, and the long radius g falls on the semi-circular piece, at the centre of balance B, as it did before on that of balance A; the oscillation continues forward again till the spring brings it back, when another following radius of the small flar falls again on the pallet b of balance A, as before, and drives it; soon after which a succeeding long radius lies on the semi-circular central piece, and rests till the return of the oscillation it can escape; thus an alternation of oscillations is produced by the short radii acting alternately on the two balances, while the long radii impel the impulses by revolving on the semi-circular parts of the centres of the balances, during the latter portion of each excursion. This escapement was evidently of the first class, like its predecessors, and though it avoided the jerk usually given by one balance by the stroke of the pallet, yet was subject to the friction arising from the action of the teeth, like the precedents.

3. Escapement with two balances by Dr. Hooke, and by Du Tertre.—Dr. Hooke, says Sully, produced a balance in the year 1675, which he had invented in 1658, with two balances engaging each other by means of teeth cut in their edges, and one of them having a spiral spring on its verge or axis; but Berthoud attributes the invention of this escapement with two balances, without the spring, to a German artist on the authority of Thiout (Thiout d'Ucc.) Logerie de Thiout) where there is a drawing of the escapement in question; J. B. du Tertre afterwards made some additions, which we have given in fig. 8. of Plate XXXI., and of which the following is a description, viz.; A and B are two balances acting together, like wheels with equal numbers of teeth, and having on one of the crossets of each a pallet, at a and b respectively; at equal distances from the axes of these balances is the arbor of the left wheel of the train, bearing two flars with each five radii, one numbered 1, 2, 3, &c. which is smaller than the other, lying the lower in position, and the other marked c, d, &c. with radii long enough to reach almost to the centres of motion of the balances, which they can pass only when the semi-circular parts that are cut away are prevented to them; but at other times they rest against the central semi-circular pieces that remain intact: the radii of the small flar reach far enough to fall on the pallets a and b successively, which they impel one after the other, and give motion to both, the balances and the escapement, the escape proceeding by means of the radii of the large flar, that rest successively against the semi-circular portions of metal not cut away, above the centres of the balances respectively. The three axes stand in the angles of an isosceles triangle, and have their upper pivots supported by three separate cocks, placed over the upper plate of the frame, the lower pivots of the balances resting on the upper plate, but the arbor of the two flars passing across the frame to take the left wheel. The action is thus; radius 1 of the small flar has parted with the pallet a of balance B, and the long radius d is escaping; presently radius g will fall on the pallet b of balance A, and impel it in a direction from 4 to 5, the balance B at the same time moving in a contrary direction; this impulse will continue till the radius a falls from the pallet, soon after which the long radius g will fall on the semi-circular central piece of balance A, and flop the further motion of the two flars, which move together on the same arbor, and the balances will go on in their vibrations till the spring under balance B brings them back against the pallets, and present the cut half of the central piece of balance A to the point g of the long radius, which, being impelled by the train, now escapes; the flars go on till radius 4 of the small flar meets with the pallet a of balance B, the motion of which it now opposes, and is itself brought back. To make a recoil of the hands till it has stopped the motion of the balances, which now begin each another oscillation; the radius e escapes the pallet a, and the long radius g falls on the semi-circular piece, at the centre of balance B, as it did before on that of balance A; the oscillation continues forward again till the spring brings it back, when another following radius of the small flar falls again on the pallet b of balance A, as before, and drives it; soon after which a succeeding long radius lies on the semi-circular central piece, and rests till the return of the oscillation it can escape; thus an alternation of oscillations is produced by the short radii acting alternately on the two balances, while the long radii impel the impulses by revolving on the semi-circular parts of the centres of the balances, during the latter portion of each excursion. This escapement was evidently of the first class, like its predecessors, and though it avoided the jerk usually given by one balance by the stroke of the pallet, yet was subject to the friction arising from the action of the teeth, like the precedents.
ESCAPEMENT.

ing one; it had, however, a capability of making the angle of action and angle of the balance's motion before the escape in any ratio to each other, by altering the lengths or number of the radii respectively, as well as the distance of the pallets from the centres of motion; it had also the good property of preventing an increase in the main driving power from affecting the balances in the same proportion, by the long lever pulling against the semi-circular central part of the balances alternately, during the latter part of the excursion of the balances, so as to check any accented of momentum occasioned by an accession of maintaining power: the law of this pressure, however, might be modified by changing the shape of the escape-motion and the pallets; the friction of the pallet might bear a proportion to the angular distances of the balances from the spring's quiescent position. The friction in both cases, it must be admitted, would be detrimental to the performance. The banking, we presume, in this escapement, was the same as in an ordinary watch, as no remark is made thereon. The invention, it appears, must be attributed to three successive artists, first the German, whoever he was, invented the escapement without the balance spring, and with the small flat only, in which flat it would act under the control of the main-spring, without the regulating spring; secondly, the regulating spring was added by Dr. Hooke, and, thirdly, the large flat was introduced by Jean Baptiste Du Tertre, about the year 1724, which addition completed the escapement as given in our drawing, which in its present state will not act without a regulating spring. Of course this last addition followed Tompion's and De Bauries's escapements hereafter described, from which probably the idea of the large flat pressing on the circular part of the axis of motion was derived. Each addition was evidently an improvement on the original German escapement as described by Thibout; but the number of pivots in motion, and the increased friction occasioned by the pressure of the semi-cylindrical pieces at the centres of the balances, were obstacles too powerful to be overcome in this constriction.

4. First dead beat escapement by Tompion.—The ingenious Tompion of London was probably the first watch-maker who contrived an escapement without recoil, or escapement of the second class, called a dead-beat escapement from the circumference of the second's hand remaining motionless, or, as it were, dead, during the motion of the balance after the escape. Sully says that he succeeded in effecting this about the year 1695. In this escapement, of which fig. 7. of Plate XXXV. is a plan, the balance verge carried a cylindrical piece of metal a b c, terminating with a pallet c, with a notch cut between a and c to allow the escape of each successive tooth of the balance wheel. This wheel had its plane parallel to the planes of the plates of the frame, and its teeth bent at the end, and so distant that the cylindrical piece and pallet could revolve between and two of them. When the cylindrical part of the pallet presented its notch to a contiguous tooth of the escape wheel, it received a push therefrom, which put the balance in motion, and the next succeeding tooth falling on the circular or cylindrical portion of the pallet, now in motion in the direction e a, resisted against it without recoil till the balance spring had brought the notch back again, when it escaped in its turn by giving its push, and a third tooth fell on the cylindrical part of the pallet, and in like manner remained motionless till the notch came back again and allowed the escape; thus one escape took place at every alternate vibration, and the contrivance was admirably calculated to prevent the bad effect on the balance of any change in the impulses derived from the main-spring; but the friction on the back of the pallets when large, and at the balance pivots occasioned by the pressure of the resting teeth, constituted the same objection in practice as applied to Du Tertre's modification of the escapement with two balances. This escapement, however, was the archetype of all the succeeding dead-beat escapements, and therefore is deserving of the notice we have given it.

5. Cylinder escapement in diamond by De Baurie.—A native of Genezé of the name of Facher had applied rubies to the pivot holes of a watch about the year 1700, and went into partnership with De Baurie, a French watchmaker, established in London; the latter artist finding the advantage of applying the polished surfaces of the precious metals to the pivots of the balance, thus contrived a new escapement about 1744, of which the pallets were of diamond. Sully says that a watch of De Baurie, with the diamond pallets, was put into his hands by Sir Isaac Newton, who had found its accuracy of performance admirable. The following account will be intelligible, we presume, to any artist who understands the mechanism of a watch. The balance had two pallets on its verge confining of a semi-cylindrical diamond, and the escapement wheels, of which there were two, were vertical, with their common arbor at right angles to the verge of the balance; i.e. with their planes parallel to the verge; these wheels, which were similar, were placed one opposite the other on contrary sides of the verge in such a way, that a tooth of one fell in the middle of the space of the other, and vice versa; the pallets were 3/4 of an inch thick, and two and a half twelfths in diameter, and the distance between the ends of the teeth of the double escapement wheel about 3/5 of an inch, or twice as much as the thickness of the pallets; the pallets had their planes parallel to the plane of the balance, and had their semi-circle shaped in an angle of about 45° at the ends for the pallets to slide over, after pressing on them alternately during the respective oscillations. We will endeavour to explain the action, as we comprehend it to have been by a verbal description. Let the leading pallet be called a, and the following pallet b; and let the balance be supposed in motion with a tooth of the escapement wheel resting on the plane of the diamond; when the sloped end of pallet a arrives at the false tooth, the tooth falls off, accelerating the balance by its sliding motion, and goes on till an opposite tooth of the other wheel falls on the plane of the diamond in motion; this tooth rests without recoil, as did the former one, till the sloped end of the pallet b comes to it, when it falls off in its turn, and gives motion to the balance, which has thus its spring wound up by the momentum of the balance sufficiently far to bring the balance back again after every impulse; and thus an alternation of vibrations is continually maintained while the force of the mainspring lasts. This escapement is also of the second class, or of the dead-beat kind, but is subject to the constant friction of its immediate predecessors, though this friction is greatly diminished by the substitution of a diamond for metallic pallets, and by the polishing of the pivot holes with rubies; it possesses all the good properties of Tompion's escapement just described. (See Machines and Inventions approvées, &c. vol. vii. p. 137.) Larcum Kendal used two crown wheels in a similar manner, which W. Howell improved by adding a forked detent to make the escapement detached, which was rewarded by the Adelphi Society, in 1792. See their Transactions, vol. x. p. 216.

6. Sully's modification of De Baurie's escapement.—The præcie which Sir Isaac Newton bestowed on De Baurie's new watch induced H. Sully to bestow much attention on it, and in the year 1721 he adopted an alteration in it, which made only one wheel necessary for the escape at both oscillations;
lations, but Berthoud has expressed an opinion that his alteration constituted a real improvement, but made the adjustment of the pallets more difficult. Sully having applied his modification of the escapement in question both to a pendulum clock and a marine time-piece, presented two memoirs on its construction to the Royal Academy of Sciences in the years 1723 and 1724; which are also printed in his description of marine time-pieces, published in 1726. Fig. 1. of Plate XXXII. of Horology, represents a side view of this escapement, where A is the escapement wheel, B the contrate wheel between it and the balance C, which has a pinion only on its verge, that is actuated by the contrate wheel; the pallets 1, 2, are two circular pieces of agate, placed at the distance from one another of one space of the escapement wheel nearly; these pallets have each an inclined or flopped end, like De Bausre’s, the escape also being at the contrary ends of each; the intention of this modification is not only to make one wheel A perform the whole business of the escapement, but to produce long vibrations of the balance, even beyond a complete circle. The action was thus; on giving motion to the balance C, suppose the tooth b to rest on the plane of the pallet or agate 1, it soon meets with the end of the pallet and can be easily used without its present form, and every succeeding tooth, till the power of the main-spring is exhausted. This modification of De Bausre’s escapement is consequently of the second class also, and enables us to comprehend more clearly the action of the original one, which had its double escapement-wheel placed with respect to the balance verge, as the present one has its single one, with respect to the arbor of the contrate wheel. The effect produced must have been nearly the same on the pallets, though the vibrations of the original balance must necessarily have been shorter than of the latter, but then it had not the friction in the wheel-work between the pallets and balances.

7. Escapement with two cylindrical pallets.—In the year 1727, Julien le Roy hewed Sully some watches just brought from England into France, which had each two cylindrical pallets with notches cut in them like Tompion’s single pallet, which kind of escapement seems to have differed from his, only in having an escape at every vibration, and in having the old crown-wheel as an escapement wheel; but as we have not been able to trace the inventor of this escapement, we must consider it as a linear descendant from Mr. Tompion’s, and therefore a variety of English extraction. Its utility has been, however, evinced by the circumstance of Julien le Roy’s having adopted it as a favourite, and used it in some of his productions: it had the property of converting the recoil of the crown-wheel into a dead-beat.

8. Cylinder or horizontal escapement of Graham.—We are not informed in what particular year Mr. Geo. Graham, the celebrated watch and clock-maker, invented the escapement with a cylinder, called also the horizontal escapement, from its wheel being in an horizontal position, but it appears that Julien le Roy introduced this construction into France in the year 1728, when wonderful properties were attributed to it, but particularly the property of compensating all the inequalities of the maintaining power, which at that time was the great desideratum among watch-makers. The contrivance bears a great analogy to Tompion’s escapement, and was probably originally derived from his, which, however, does not lessen the merit of the contrivance, as it requires as much ingenuity to improve an existing instrument, frequently, as to invent a new one. Fig. 2. of Plate XXXII. is a perspective view of Graham’s horizontal escapement, in which A is the escapement-wheel, B the balance, and C the hollow cylinder fixed on the verge of the balance; each tooth of the wheel, which may have at its convenience any number of teeth, is formed of a triangular inclined plane or wedge, supported by a stem projecting perpendicularly from the plane of the wheel at its circumference; the length of the wedge of each tooth is just a diameter of the internal part of the cylinder, so that the cylinder may revolve round the wedge when the balance is in motion; in this situation the anterior point of the wedge just touches the cylinder’s interior surface, but the posterior point of the same is free, so as not to touch and stick fast in the cylinder, but to give it a push on the edge when the contact ceases; the distance between the teeth is also great enough to allow the external portion of the cylinder to come between them, when the escape has taken place, and while the balance continues its oscillation. The action is performed in the following manner; suppose the wedge to be just escaping from the hollow part of the cylinder, and to be giving its impulse to the edge of the cylinder which it quits, the balance goes on and wind the spring up, until after reaching the balance point, it meets the cylinder, and being rounded at this end, admits it easily into its concavity, at which instant the other edge of the cylinder receives a second impulse in a contrary direction; the balance now makes another oscillation, and the point of the wedge rests against the interior face of the cylinder, as it did before on the exterior, without recoil, and in both situations of rest the wedge has no other effect on the balance than that of retarding it by its pressure against the circular surface; the second tooth is now in the same situation as we found the first, and presently in its turn gives another push at leaving the cylinder altogether, and leaves the third wedge to perform the same office by first resting on the back of the cylinder, then entering it, and lately giving its parting impulse to the second edge of the said cylinder, as the two wedges that preceded had successively done before. At one time period this escapement was in high estimation in England, as well as on the continent, and even now the common watches that are constructed with this escapement will fetch greater prices than those with the ordinary crown-wheel escapement, but the detached escapements of the best chronometers are now held in much higher estimation than either. We have seen that the hollow cylinder, though constituting but one pallet, in effect performs the office of two pallets, and permits but one tooth or wedge to escape entirely at two oscillations, during one of which the point rests at the outside, and during the other at the inside of the cylinder, while the two edges of the cylinder perform the part of separate pallets on receiving separate impulses in contrary directions, it is, therefore, of importance in this, as indeed in all escapements with a regulating spring, that the quiescent position be duly adjusted to render both oscillations precisely similar in extent and duration at each side, otherwise the performance will be a species of hobbings, and the compound law of motion, derived
ESCAPEMENT.

derived from the spring's action and impulses on the pallets conjuuntly, will be far from regular; consequently not likely to be an infallible law. Berthoud has described a cylinder escapement with two balances connected by two pins, but it did not prove successful.

9. French escapement a Vingale.—The French escapement known by the appellation of a vingale, from the pallet's resemblance of a comma, is represented by fig. 6 of Plate XXXV. A, B, C, are three teeth of the balance wheel, placed very obliquely compared to a true radial line, and carry each a pin at their extreme ends, standing vertically like the supports of Graham's wedges for his cylindrical escapement; the pallet B A has its centre of motion at c, the centre of both the concave and convex portion, exactly over the verge of the balance; this centre is in the circumference of the circle that pallets through the points or pins of the teeth; the pallet, which is of hardened and polished steel, has its plane parallel to that of the wheel, and is supported between f and e by a crank piece put over the verge, which cannot be admitted as high as the pallet; this end d a, which connects the convex and concave portions, is a portion of an equi-angular spiral, and the part b d of the pallet is called the horn, probably from its resemblance of the beak of a bird; the inferior face b A may be slant like the dotted line, or curved, at the option of the maker, and the superior part f A may be of any shape; the convex part a f contains about 100°. The length of the pallet from a to d is such, that when the pin at B presses against the curved part at a, the point d of the horn will just miss the pin at A of the preceding tooth, and the height at which the pallet stands is such as to make it pass over the rim of the wheel, but not over the pins at the ends of the teeth. When the balance is at rest, and has itsspring in equilibrio, the point d of the horn is at the point i, about 30° from d; but the present position is that which the pallet has when the tooth A has just escaped from the point d of the horn. To explain the action, on a supposition that the tooth A has just escaped, the preceding pin B has just fallen on the point a, joining the fixed and convex portion of the pallet, which the balance has just received its impulse from tooth b, as it passed from b to a along the inferior face of the horn; it, therefore, proceeds in its motion in the direction d b g a of the dotted circle, while the point B slides on the convex side a f, and is detained without recoil; when the point d of the horn has arrived as far as b, more than 90° from A, the momentum of the balance is exhausted, and the balance returns; the point d comes to about the point i before the pin of tooth B comes to a, and enters the concave part of the pallet, where it slides till the point arrives about b, where the momentum of the balance spring is again exhausted; the balance returns again, and when the point d comes to i, the pin of tooth B escapes the concave part at b, and slides along the inferior face of the horn, at the same time giving it a push till it escapes entirely, and is in the situation of tooth A, where the process begins; in the same manner the following tooth C, and every succeeding tooth in its turn, will fall on the convex side of the pallet, return and enter the concave side, and then finally escape. We must observe, however, that the pallet opposes the motion of the balance as it passes along the small spiral part from a to e, which may be so proportioned as to be a counterbalance to the impulse previously given to the balance by the leading tooth, in case the friction on the back of the cylindrical part is not competent to retard the balance's impulse sufficiently. The effect produced by this escapement must be very similar to that produced by Graham's cylindrical escapement, but has this advantage, that the inclined plane formed on every wedge of Graham's construction is transferred to the pallet, and serves for all the pins to slide on in succession, thereby removing the difficulty of forming all the wedges alike in size and shape. Besides, the convex and concave sides of the pallet may be reduced to any dimensions, provided the acting teeth may not slide at once from the spiral to the horn, and allow the train to run down, which may be the case if the parts of action be small, and there be much play in the pivot holes of the wheel and balance. The contrivance is a compound of Tipton's and Graham's watch escapements, to both of which it has certain points of resemblance. In 1752, Le Paute altered this escapement, by putting pins for teeth in both planes of the wheel, as he did in Amant's escapement a cercueil, which addition gave it some advantages.

10. Escapement with one pallet and one detent by Thibaut.—Thibaut, a French clock-maker of considerable eminence, published a work in 1741, entitled "Traité de l'Horlogerie Mécanique et Pratique, approuvé par l'Académie Royale des Sciences," 2 vols. 4to, in which he has described an escapement of a watch that has been skilfully fashioned for a real detached escapement, and considered as the first that has been made of such a construction, though the inventor himself did not consider it as such, as is evident from his own description. This escapement is given in fig. 8. of Plate XXXII, and to use the author's own account, "it is an escapement of a watch in which half of the vibrations seem independent of the train of wheels, while they are performed. The detent B stops the escapement wheel, the balance bringing back the pallet A, the detent recedes, to leave the wheel free to strike the pallet; and so on. This escapement could not perform without a spiral spring." It hence appears, that the pallet A is on the verge of the balance, but that the detent B is on a separate arbor, while they are connected by the tail of the pallet entering the slit in the remote end of the detent, so that the balance is never disengaged from the detent, and therefore cannot be confided as of the detached kinds. When the balance moves in a direction from A to B the pallet gets out of the teeth, but the detent falls in, and vice versa. The curves of the claw of the detent appear to have been drawn from the centre of its motion, and therefore we are disposed to think that there would be no recoil in the escapement wheel.

11. The anchor escapement by Clement, or Dr. Hooke.—While these improvements were going on in watch escapements, an equal attention was paid to the contrivance of new clock-escapements. Huygens had placed the pallets of the crown-wheel escapement at an angle of about 60° instead of 90°, as they were made for a watch, in order that they might be accommodated to the short vibrations of a pendulum, or rather, perhaps, to the vibrations of some length performed in a cycloidal curve, by means of his cycloidal cheeks near the point of suspension; but still the arc of action on the pallets was too long to allow practice and theory to coincide, as to the performance of long and short arcs of vibration in the same time. The preference that followed to short arcs, when circular, suggested the propriety of contriving an escapement that would admit of very short arcs of vibration. This was first effected about the year 1680 according to Smith's account, by Clement, who was a clock-maker in London; but Dr. Hooke has disputed the priority of the invention, and has affirmed that he exhibited a pendulum with what is now known by the name of the anchor escapement, to the Royal Society of London, in the year 1666, soon after the great fire of that year. We will not endeavour to settle the point that relates to priority of invention, but proceed to describe the contrivance itself, which has continued, and is likely to continue, to be of permanent use.
nce in ordinary clocks. Fig. 3. of our last named plate is the representation of the anchor escape ment, as it is commonly
figured for a pendulum clock that swings seconds, which pendulum, in conjunction with the anchor escape ment, gained the appellation of the Royal pendulum. The escape ment, or flying-wheel A, has usually thirty teeth, when a vibration is performed exactly in a second, in which case a second's hand is usually inserted on its elongated pivot, to indicate seconds; but if no attention is intended to be drawn to the indication of seconds, the train may be made to allow of any other convenient number of teeth; B C is the anchor and pallets, taking its name from a resemblance to a ship's anchor, that may be observed in its shape; the distance from its centre of motion a to that of the wheel b is determined by the number of teeth that the pallets take in between them, it being essential to the freedom of action that two lines, drawn from the two centres of motion a and b, should constitute a right angle at each of the two points of action, as seen included by the dotted lines, meeting at the ends of the actuating teeth d and e in the pallets which we have made to include nine teeth, the centre of the pallet's motion falls at the point a; but if they were made to include eleven teeth the fixed point would fall above at b; and if they included fewer than nine the point for the centre of motion would fall below a: in general ten or twelve are contained between the pallets of a second's pendulum, but this must depend on the arc that the pendulum is intended to vibrate; for the more teeth are taken in, the greater is the distance of the two centres of motion, and consequently the smaller the angle or arc of action on the pallets. If a circle f g be described by a radius equal to half the distance of the centres of motion a b, round the point a, the two faces of the pallets B and C usually lie in the tangent lines e f and d g of that circle, which lines are the guides for making the flaps. The action of the escape ment before us may be explained thus: suppose the tooth d, seen resting on the slope of the pallet C, to be urged this pallet outwards from the centre of the wheel, by which a motive force is applied to the moving pendulum through the medium of the crust; presently it escapes, and pallet B is brought inwards towards b, so as just to avoid the tooth c; the wheel is now at liberty to move, and goes on, by the force of the maintaining power, till the preceding tooth f falls on the sloped face of pallet B, which is now urged outwards, and endeavours to give a contrary motion to the pendulum; but the momentum of the moving pendulum is too powerful for its impulse, and carries the tooth f back again till the momentum is expended, at which instant a recoil of the wheel and second's hand placed on its arbor take place; presently the pendulum returns, and the tooth f now pushes it on, and escapes; the pallet C is now brought back, so that the tooth following f falls on its sloped face, and in its turn experiences a recoil till the pendulum returns, when it pushes on and escapes; then another tooth next after a falls on the face of B, and experiences the same recoil and subsequent power of escaping that the others did; and thus the alternate vibrations of the pendulum are perpetuated as long as the maintaining power continues. The effect of this escape ment on the pendulum is similar to that of the crown-wheel escape ment on the balance; the pendulum is either accelerated or retarded in every part of its vibration, except during the almost ininiscible instant of the drop of the succeeding tooth, when one has escaped; but as the momentum of a heavy pendulum in motion is greatly exceeding that of a balance in motion, the bad effect is smaller in degree. When an additional weight is added to the weight constituting the maintaining power, the arc of vibration is increased, whence one might be led to ex-
ESCAPMENT.

of our description to the features that differ, and to the mode of action depending thereon. The circle B C, passing the points of the first and eleventh teeth, including the ten spaces between the pallets, forms the interior faces of the said pallets B and C, and the exterior portions B e and C d are formed by a concentric circle of larger radius. These circles are described from the point a, or centre of the anchor's motion, therefore a tooth resting at any time against any one of those circular portions remains without record; the distance between the said circles is somewhat less than one-half of the space contained between the extreme ends of any two contiguous teeth, and the nearer it is to one-half of a space, the smaller will be the drop after an escape, or, as the workmen say, the closer the pallets will be laid. The teeth are somewhat varied in shape from the inclined teeth of the recoil escapement, a portion of the slope at the bottom being cut away, that the end of the pallet may enter the space, when the pendulum vibrates beyond the arc of action, without coming in contact with the metal of the wheel, which would make the pendulum rebound, and disturb the regularity of the vibration. These observations being premised, the reader will now be prepared to comprehend the action. The tooth at e has just passed the slope of pallet B, and is escaping, after having given its stroke or impulse gradually, in sliding along the slope from e to its present situation; the pallet B is now going from the centre of the wheel's motion b, and the pallet C is come back from its excursion, in time to allow the tooth b to fall on its inner circular part, near the angular point of the slope; the pendulum goes on in its vibration till its gravity overcomes its momentum, during which time, the pallet B is no longer in contact with the wheel, but the pallet C enters the space between b and d, and the point of the tooth b rests on the inner circle of the pallet; presently the pendulum returns, the point of tooth b slides back again till the slope b d presents itself, when urged by the maintaining power, it escapes after having made its push to the pallet C, which now continues its motion outwards, and consequently pallet B falls in the way of the tooth b, which follows, but which rests on the exterior circle B e of this pallet, till the pendulum returns as before; it then meets the slope at e, and, giving its push to the pallet, escapes, as its preceding tooth had done; and thus the vibrations are alternately aided in future, while, as has been seen, one tooth only completely escapes at the interval of two vibrations: which is the reason why a wheel of 30 teeth is proper for the indication of 60 vibrations of a second's pendulum. When the wheel is made of hardened steel, and the pallets of ruby or agate, the friction is greatly diminished, and will admit a short angle of action, or diminution of power.

13. Multiplication of the dead beat by Grignon.—When we gave the "History of the succeffive Improvements in Clocks," under our article Clock, we said that the senior Thomas Grignon, of Covent Garden, London, improved the dead-beat escapement of Graham, and presented a clock to the Society of Arts in 1759, which remains in one of their rooms to this day, that has got this improved escapement, the peculiarity of which is to be, that it performed alike with four and with twelve pounds (supposing as a maintaining power: if this is a fact, the escapement must have the property, so much defined in all escapements, of rendering all the arcs of vibration isochronous. We have been favoured with a manuscript account of this escapement, and of its principle of construction. It will be doing but justice to the memory of departed genius, if we give the author's own figures, demonstration, and account of his improvement, as he has left it in his own handwriting. Fig. 5. of Plate XXXII. is the scheme, and fig. 6, the demonstration, as the author himself has intitled the figures, the latter of which has no letters of reference, but is sufficiently intelligible in conjunction with the other. "It appears from the scheme," says the author, "that the distance of the centre of the pallets from the centre of the swinging wheel in that machine (at the Adelphi) is one whole diameter of the wheel, which has this peculiar excellence, that the triangles formed at the ends of the pallets, by drawing the tangents for the flopements are equal; (nor indeed can they ever be equal, continues he, where the distance is more or less than one whole diameter of the swinging wheel,) and, on the contrary, where that distance is duly observed, all the triangles will ever be equal; for then all the interferences, made by drawing the two tangents to the circle of the pallets, will fall exactly alike, (fig. 6.) interfacing the intermediate circle, as may be seen by the figure, consequently the tangent lines, together with the chord of the swinging wheel form a rectangled triangle, the upper angle of which, by altering the flopement only, changes its place in the circumference of the circle, the same chord always continuing its base. For a farther demonstration of which, see 21st proposition of the 3d book of Euclid.

Again, when the distance is duly observed, we shall find that one of the lines for the flopement of the pallets will be the hypotenuse, and the other the perpendicular of rectangled triangles, whose bases are equal to 120', the halves of which must be 60'. That they are rectangled triangles may be easily proved; for if the base be 120', and perpendicular 60', the hypotenuse must be 180'. See 1st Prop. of the 12th book of Euclid." In another manuscript paper, Mr. Grignon says, "that the teeth of the swinging wheel have an equal effort, when they act upon the flopements or faces of the two levers or pallets, may be thus demonstrated. "Draw the lines A, A, upon the faces or flopements of the pallets or levers a, a, now these are the lines of direction; let fall the perpendiculars B, B, from the centre of motion of the pallets C; now, I say, if you measure the lengths of these perpendiculars, they give you the efforts of the arms of the levers or pallets B, B, D, D; for by the 9th prop. of Mr. De la Hire's Treatise of Mechanics, the efforts of a weight or power are not to be measured by the length of the arms of the levers, but by perpendiculars drawn from the hypomochion upon the lines of direction of the weight or power. That these levers are equal, is thus proved; for, taking C for your centre, describe the circle E E E; now if the perpendiculars B, B, are both radii of the circle E E E, they must, of course, be equal, which is what was to be proved. Again, that the faces or flopements of the pallets or levers are equal may also be thus proved: a A, a A, are the lines of direction of the action of the teeth, and being both tangents of the same circle E E E, are consequently equal." The remarks that have occurred to us on contemplating Mr. Grignon's scheme, as he has called it, are, first, that his distance between the centres of motion require ten teeth out of thirty to be taken in by his pallets, as we have shewn in our last article; secondly, the circle E E E is described with less than half the distance of the centres, and is yet made the circle to which the tangents are drawn, that form the flopices, the reason of which he has explained, the radius C B of this circle, it appears, must be determined by a line a A, drawn parallel to the line of distance, which must be a tangent to the said circle, and which affords an easy and practicable mode of drawing the flopices agreeably to this construction; thirdly, if the flopices thus formed by tangent
drawn to a diminished circle have the isochronal property, they are worthy of future imitation, under the circumstance particularly of ten teeth being included between the pallets; and lastly, we observe, that the fame circle forms the exterior curve of one pallet, and the interior one of the other, which is not the case with Graham's pallets, but which certainly makes the friction alike on both pallets, seeing the circular surfaces rubbed by the points of the wheel's teeth are at equal distances from their common centre of motion. These considerations are all in favour of Mr. Grignon's modification of the dead-beat escapement, as each excursion of the pendulum must be influenced by similar circumstances, and if moreover it poises the isochronal property attributed to it, it is somewhat remarkable, that the Aephe society have been labouring to reward inferior escapements in great variety, while one of the best dead-beat escapements is beating dead to the society, having escaped their notice, while performing its functions within their own walls.

14. Mr. Bennett's modification of the dead-beat.—Mr. J. Bennett of Norwich has published an account of what he considers an improved method of describing the curves and faces of Graham's dead-beat pallets (see Nichollies's Journ. vol. xv. 8vo.) which account we think deferves a place here in common with Grignon's method.

Draw the line A B (fig. 7. Plate XXXII. fays the author) on which describe the circle B, the size of the intended swing wheel; then, according to the number of teeth the pallets are intended to escape over far, as 60 (the double of the number of the wheel's teeth) is to $57^\circ$, so is double the number intended and one more to that proportion; thus, suppose the number intended to escape over nine, the double of which is 18, 40 which add one, and there are 19; then say,

As 60 : $360^\circ$ :: 19 : $114^\circ$; the half of $114^\circ$, which is the whole arc included, is $57^\circ$; then on the circle already drawn set off on each side of the line A B $57^\circ$, from which points draw lines to the centre of the circle; then on these points where the circle is crossed erect perpendiculars, which will intersect at the centre of the pallet's motion in the line A B, from this point as a centre draw the arc C C, to cut the points where the radial lines cut the circle; the arc thus drawn describes the receiving and leaving pads of the pallets. The inclination or inclined plane of the pallet must form an angle of $60^\circ$ with the plane of the radial lines; thus from the points of intersection, near E and G, draw the small semi-circles D and G with any radius, and set off $60^\circ$ from f to g on the semi-circle D, and from b to n on the semi-circle G, then will lines drawn from the centres of the semi-circles, through the points g and m respectively, give the proper direction of the slopes of the pallet's faces.

This construction is very similar to Grignon's, though differently projected; the centre of motion A is determined in the usual way, and the odd unit given to double the number of teeth included is an allowance for the breadth of the pallet, to have as little drop as possible; the slope of the pallet G is parallel to the line A B, in Grignon's construction, but is not quite so here, for the difference of the angles at the opposite sides of the radial line is $60^\circ - 57^\circ = 3^\circ$, which is what these lines want of being parallel, which quantity of deviation seems to constitute the principal difference between the two constructions; if the radial line of pallet G had been drawn to the lower point of the pallet, so as to have made the angle at the centre $57^\circ$, and the teeth included had been exactly ten, then the two methods would have coincided, and the point A of the pallets' motion would have been an exact diameter of the wheel from its centre.

We conceive that the effects of the two constructions may be so nearly alike, that their difference in practice may be almost imperceptible. If there is any difference, varying the maintaining power considerably in different trials will detect it, by rendering the alterations in the rates perceptible from the comparisons. Otherwise the alternate angles might each have been $57^\circ$, instead of one of them being $60^\circ$.

15. Isochronal escapement for a pendulum.—So long as about the year 1720 Saurin, Julien le Roy, and Enderlin, wrote memoirs on the nature of the curve that was necessary to give to the pallets of an anchor, instead of the concentric circles, in order that the swing wheel may have just so much recoil only, as will render all vibrations, performed in arcs of different extent, isochronal; and since their time Berthoud in France, Reid in Edinburgh, Melville and others in London, have put in practice a method of constructing pallets founded upon the same principle. We think it not improbable, however, but that the Scotch and English artists have borrowed their contrivance from the French author, who published his construction in his "Essai pour l'Ihorlogerie" in the year 1766, before which time we do not find any traces of an isochronal escapement except Grignon's just deferved, and Smeaton's, which follows. The construction of the escapement in edition of Grignon, which is, that is the circular portions of the pallets, which in the dead beat are concentric, described from the centre of the pallet's motion, in the isochronal escapement are eccentric, with respect to each other, those curves on which the ends of the teeth of the swing wheel rest being described from points out of the centre of motion. Berthoud had made several experiments with different escapements, and different maintaining powers, from which he found that the fame addition to the power which accelerated the vibrations of the pendulum, when a recoil escapement was used, retarded the fame when a dead-beat escapement was substituted; hence he concluded that there must be a medium between much recoil and no recoil, which would make the pendulum vibrate in the same time in all arcs, or, which is the same thing, with any addition or diminution of the maintaining power; he therefore fixed, after various trials, on a construction producing but a small recoil, which answered his most fanguine expectations, and which we shall be happy to defcribe here, particularly as it is to answer a better purpose than the common dead-beat, which has been long in high estimation; and as it has not, we believe, been defcribed by any English author. Fig. 1. of Plate XXXIII. is a plan of Berthoud's isochronal escapement, where A, as before, is the swing-wheel, B and C the pallets of the anchor, and a the centre of their motion; the distance of the centres a b also, as before, depending on the number of teeth taken in by the pallets; the angles $m a n$ and $o a g$, are the angles of action by which Berthoud has given his slopes of the pallets without the tangent lines $e i$, and $d g$, but we have thought it right to shew how they may be given both ways. Berthoud's method of foping to suit any angle previously given is more extensive in its application, but the quantity and direction of the impulse will vary as the angles $m a n$ and $o a g$ vary; whereas the method of foping by the tangent lines can only vary by varying the circle $f g$, as Grignon has propofed: in our plan we have taken the circle's diameter equal to the distance $a b$ of the centres for the sake of uniformity of plan, that the reader may see how the pallets are formed, differ in shape from the dead-beat pallets. The exterior portion of the circle $d C$, of pallet C, is described with the extent $a d$ from the centre a, but the interior portion $b e$ is described with the same extent from a point below.
ESCAPEMENT.

below the centre; the difficulty consists in determining the true situation of this eccentric point $P$; Berthoud's rule, founded on the result of experiments, is this: having determined the breadth of the pallets, equal to somewhat less than half a space of the wing-wheel, describe from $b$, in the line $a$, the concentric dotted circle $1, 2, 3$, &c. set the distance between the two concentric circles, or breadth of the pallet, three times over along the inner curve to $1, 2$, and $3$, then in a direction from $3$ towards $a$ set the same once to $4$; in the next place, with the extent $a b$ find the point $5$ by intersection from the points $b$ and $4$, and this point $5$ is the eccentric point defined, from which the curve $4$ is described with the extent $a b$ as before, which is the interior curve to be substituted for the concentric curve $1, 2, 3$ of the dead-beat escapement; and it is evident that while the pendulum is in motion inwards, with a tooth resting on this eccentric curve, the wheel must have a certain recoil. Again, the exterior curve of eccentricity, of pallet $B$, is thus described; the curve $1, 2, 3$, &c. is described, from the point of the tooth that is in the line $a$, and the points therein are taken as before at the distance from each other of the breadth of the pallet, or at somewhat less than half a space of the wheel; the point $a$ is here set outwards in the direction $a b$, for a pallet; then the extent of the eccentric point $5$ is determined by intersection from $a b$, $b 4$, $4 5$, which point is above the centre; lastly, with the extent $a b$, as before, draw the concentric curve $a 4$ from the point $6$, which being substituted for the concentric curve $1, 2, 3$, and $4$, will produce a similar recoil in the pallet $B$, as the curve $b 4$ produces in pallet $C$. The inner curve of pallet $B$ having no action, like the outer curve of pallet $C$, may be described from $a$, or be a straight line. The writer of this article has a half-second pendulum clock with this escapement, and Troughton's tubular pendulum, which goes admirably with any power that will keep it in motion.

16. Smeaton's escapement of the turret clock at Greenwich.—The escapement which Mr. Smeaton contrived for the turret clock at Greenwich resembles the isochronal escapement, which we have just described, in a certain degree, and was, no doubt, intended to answer the same purpose. Fig. 2. of Plate XXXIII contains the plan of this escapement, in which $A B$ is the radius of the escape wheel; $B C$ a tangent line at $3\frac{1}{2}$ teeth from the vertex, drawn from $C$, the centre of the pallet's motion; $B D E$ is a circle described from the centre $C$ through the points $B$ and $E$, $E$ being at $3\frac{1}{2}$ teeth from the vertex; $F G$ is a line drawn parallel to the vertical line $A C$ at the distance from the vertex of $3\frac{1}{2}$ teeth, and cutting the circle $B D E$ in the point $G$; then $G C B$ is half of the angle of vibration, and setting off the arc $B H = B G$, $G C H$ will be the whole angle of vibration. Draw the line $C H$ cutting $F G$ in $I$, and through the point $G$ of this pallet from the centre $A$ describe a circle that may cut the radius $A K$ in the point $K$; this will be the point of the other pallet; the line $E C$ being also a tangent to the wheel at $3\frac{1}{2}$ teeth from the vertex. Now setting off $K L$ on the circular arc $= G H$, the angle of vibration $K C L$, will be equal to the other angle of vibration $G C H$, and if through the point $L$ the line $L C$ be produced, and $L M$ be set off $= I H$, then will the wheel move equally forward, by a similar motion of each pallet. Again, with the radius $K C$, upon $K$ as a centre, describe the arc $C N$, and also with the same radius from the point $M$ describe the intersecting arc $O P$; then from $O$, the point of intersection with the line $B C$, describe the curve through the two points $K$ and $M$ to $R$, which curve will give the working face of the pallet that will produce a small recoil nearly equal to that produced by the plane $G I$; in this construction the depth of the teeth is equal to a space contained between two contiguous teeth, and the acting side of the tooth is a portion of a circle defined from the bottom of the sloped face of the fifth tooth included. The circle to which the slope of the tooth is a tangent is $\frac{1}{4}$ of the diameter of the wheel. When the wing-wheel has a greater number of teeth than $30$, $7\frac{1}{2}$ teeth are still contained between the pallets, and the centre of their motion is determined, as in the former constructions, by a tangent line drawn from the point of the acting tooth. The two ends of the anchor may be made more apparently equal in length by letting the pallet $K$ escape over $3\frac{1}{2}$ teeth and the pallet $G$ over $4\frac{1}{2}$, in which case the arc $B D$ will be of a greater radius than the arc $N D$. The false pallets or end-pieces are fixed by screws that allow an adjustment for distance or depth of the pallets, so that they may be detached, newly formed, and replaced, at any time after they have been in use.

17. Escapement with two levers by De Bethune.—Thiout says that De Bethune was the first contriver of the clock escapement with two detached levers, and that the origin of this construction was derived from the escapement of Dr. Hooke, or of a German artist, with two balances, which we have described. Thiout made the first of his in the year 1727, and says that from that time the escapement with two levers became common among clockmakers in France. Fig. 3. of our last plate is a representation of this escapement as made for a pendulum; where $A$ and $B$ are the two pallets placed individually on each a separate arbor included within the frame; to the lever $B$ is attached the crank or fork that communicates with the pendulum not seen, and the fork $C$ which is visible in the figure; the lever $A$ has a bar of metal $D$ fast to it, that carries the roller $E$, of a diameter equal to the aperture of the fork $C$; and the ends of these levers constitute the pallets placed at the distance from each other of five times thirty teeth of the wing wheel. During the action of this escapement, when one of the levers is acted upon by a tooth, the roller and fork are raised up, and the other lever becomes a detent to the wheel; then when at the next vibration the other lever is acted upon, the roller and fork are depressed, and the first lever in its turn becomes a detent; and thus the vibrations are alternately afflicted while the maintaining power continues to actuate the wing wheel. This escapement has a recoil, and Julien le Roy discovered (Memoire sur l'Horlogerie par M. le Roy, fils de Julien le Roy, 1730) that when the levers are each the same length of the radius of the wing wheel, it nullifies the isochronal property, that is, all arcs of vibration will be performed with it in the same time. We are not aware that this escapement was ever made in England.

18. Dead-beat escapement for a pendulum by Amant, (a chevalle)—Fig. 4. of the same plate shews the plan of an escapement by Amant, formerly a clock-maker at Paris, that has an escapement wheel without teeth, but with pins or pegs inserted in a concentric circle in the plane of the wheel, as appears in the figure; the pallets $A$ and $B$ are both fast to the verge or arbor of the crutch, in the usual way, and are brought together to the same pin that slides along the sloped face of one pallet $B$ immediately falls on the inner circle of the other pallet $A$, and continues without recoil till the pendulum has made its vibration; at the return of the pendulum the pin meets with the sloped face of pallet $A$ and escapes; then the next pin falls on the inner circle in the pallet $B$, and remains without recoil till the pendulum returns from its vibration, when it slides down the slope and gives a push to the pallet as the first one did before; thus the two pallets are alternately acted by the same pin before it returns.
its final escape, and fifty vibrations are made during one revolution of the plate with thirty pins. The flakes appear to stand at right angles to each other, but it is not said, in the account we have seen, how either of the flakes ought to be drawn geometrically. This is the kind of escapement at present used in the large turret clock at Harpington Court, and we have seen many other clocks in England with a similar escapement, which, we have no doubt, may perform as well as with the ordinary dead-beat escapement as originally constructed by Graham, provided the drop from the first to the second pallet, which must necessarily be equal to the thickness of the pin, do not produce a jerk that may affect the vibrating pendulum.

19. Dead-beat escapement (a cheville) by J. A. le Peute. — In the "Traité d'Horlogerie," published at Paris 1755, is an account of a dead-beat escapement as made by him for a clock, which differs from our half by Amant only in its mode of position, and which therefore requires no figure for its description; the levers of the two pallets open like a pair of dividers to any extent, but are not in the same plane, one of the levers being over the anterior plane of the pin wheel, and the other over the posterior plane; hence two sets of pins are necessary, one on each side of the action towards the holder of the pallets, which, as we have described it in Amant's escapement, which it probably excels inasmuch as the drop may here be made as little as possible, because the same pin is not required to pass between the ends of the pallets in escaping; but one pin acts only with one pallet before it escapes; there are consequently sixty pins in all, thirty on each plane of the wheel.

The same author also published an account of a watch escapement with pins (a cheville) which the reader will find described at page 198 of the same treatise.

It is easy to conceive, after what we have said about the ifochronal pallets, that both Amant's and le Peute's escapements, and indeed all the dead-beat escapements, may be made to have a little recoil, so as to become of the ifochronal kind, provided the acting concentric circles of the pallets were made in a certain degree excentric; that is, if they were deflected from points out of the centre of motion of the pallets themselves. The only difficulty is in determining the situation of those points under different circumstances, which we think is a fair object for future inquiry.

20. Harrison's clock escapement. — The escapements which we have hitherto described require oil on the pallets, to diminish the friction of the parts that rub against one another in action; but the escapement we are now going to describe as the invention of the ingenious Harrison requires no oil, on account of his construction being free from rubbing at the time of the pallets' action. Fig. 5. of Plate XXXIII. exhibits the shape of Harrison's escapement. G D O is a portion of the flying wheel, moving round M as a centre: A is the verge or arbor of the crutch that communicates with the rod of the pendulum; to this are attached the pallets, each confining of a long and a short lever with a joint at the place of union; the short lever A B is fast to the arbor or axis of motion, and carries the longer lever B C which has a claw or hook a C, and a slender spring is so applied as to keep these two levers nearly at right angles to each other; at right angles to A B is also the shorter lever A E fast likewise to the axis of motion, and bearing the longer lever E F, as A B acts on the lever B C; the joints are at B and E, and a similar small spring holds the levers AE and EF in like manner at right angles to each other, when not otherwise acted on. The lever E F has not only a claw, like the other long lever, but a heel to it, or projecting part f. The action of this contrivance may be thus explained; suppose the tooth D urging the pallet or claw C, while the pendulum is moving towards the right hand in its excursion; this preface of the tooth produces a tendency in the lever B C to move round, but the joint at B yields, and opens the angle A B C a little; during this motion round A, the short lever A E is lowered a little; and, with it the long lever E F, which we will call the detent; its claw F therefore falls in the way of the tooth G, which now drops on the back part of the claw, and is inserted into a notch under the projecting heel f; the further motion of the pendulum, and consequent depression of the short lever A E, carry the end of the tooth G back again till the vibration is finished, and produce a recoil. At the moment when the tooth begins to have a recoil, the tooth D at the pallet or claw C is withdrawn and escapes; the slender spring of the lever B C, which had been bent from its quiescent state, now resumes its original situation, and throws out the lever B C, till its angle formed at B is again nearly a right angle; in the mean time the wheel is detained by the heel of the detent E F, in which situation it opposes the vibration through the medium of the two levers E F and E A, which are attached to the crutch of the pendulum. The tooth F, therefore, being just in contact with the right, the left, and the wheel is at liberty to advance again; the preface of the tooth G on the claw of the detent now affords the vibration through the arc of escapement or arc of action, and causes the pallet C to approach the wheel, till the tooth following D falls on it and experiences a recoil in its turn. This recoil fets the detent F at liberty from the preface of the tooth G, which now flies back by means of its slender spring to its rectangular situation, as it regards the small lever A E; presently this vibration terminates and the pendulum returns, while the tooth following D aids its vibration by pulling forwards the pallet C, when the process of making two successive vibrations is gone through; and the same operation is repeated. The reader will have observed in this account that the tooth and pallet, or tooth and detent, do not slide on one another, but give each other a direct push, or pull, the business of the small springs being to remove them from contact by one sudden leap, where rubbing is altogether avoided, which contrivance supercedes the need of having oil applied to the pallets, and is certainly a great improvement of the practice. It must be observed, however, that the recoil, such as it is, takes place at the extremities of the vibration, when the momentum of the pendulum is almost exhausted, and is therefore the most unfavourable part of the vibration to occur in; notwithstanding which disadvantage the escapement has performed as well as any other that had preceded it, perhaps as well as any that has followed it, as the regulator to which it was applied has seldom if ever been excelled in steadiness and accuracy of performance for fourteen years of uninterrupted service. The imperfection arising from the recoil taking place at the extremities of the vibrations seem to have been compensated by the immense momentum of the pendulum that this escapement admitted of with a comparatively small maintaining power, while the absence of friction and of oil gave it the advantage of permanently uniform action. Of course the pendulum was of the grid-iron form, that compensated the effects of varying temperature, and allowed the escapement to have its merit appreciated. The report of the performance of Harrison's regulator with the escapement in question was, that it did not vary one second per day from any preceding or following day for the space of fourteen years, and that the aggregate of the variations from true mean time did not amount to half a minute.

Haley also constructed clock pallets that required no oil, but
but as none of them have fallen under our notice, we pretend not to say how they differed from Harrison's.

21. Escape by Alex. Cumming for a clock.—Mr. Cumming published his elements of clock and watch-making in the year 1766, in which, among other matters, he describes a construction of an escapement of his contrivance, that removes the friction and influence of oil not only during the time of rest of the pallets, but also during the motion of the swinging wheel, so far as they can influence the vibrations of the pendulum; and also obviates all the irregularities that can possibly arise from the maintaining power as transmitted through the train. Fig. 6. of Plate XXXIII. exhibits as much of this escapement as is necessary for explaining its general action, but those readers who wish to see all the minutiae of the construction, as represented by different plates of sections, must have recourse to the book itself, as the complexity of the parts represented in various points of view demands more minute representation than our plan admits of. Our figure is a copy of plate 5 of the author, in which A B C is the escapement or swinging-wheel; D E the pallets that are merely movable on the axis of motion, and having each a little ball or weight H and I respectively supported by horizontal arms; each pallet with its attached weight is separately moveable from the other round its respective axis of motion, so that when one is raised by the wheel the other remains at rest; F and G are two detents firmly attached together, like the ordinary pallets of a common dead-beat or recoil escapement, and are fixed to a cylinder of brass P P, that surrounds the two axes of motion of the pallets, which are in the same straight line but separated from each other at the middle of the cylinder, where is a partition that bears the interior pivot of one axis and the exterior one of the other; the crutch of the pendulum is also fast to the cylinder; so that the two detents and crutch move together always with the cylinder, without the motion of either pallet; and each pallet can move separately without the detents and crutch. M is a load to counterpoise the detents and crutch in any position given them; and n o are two pins carried by the pendulum that project far enough to fall alternately in the way of the arms that carry the balls H, I; as the pendulum vibrates.

To explain the action of this escapement, let us suppose the pallets D and E, the detents G and F, the crutch L, and pins n and o, together with the balls H and I to be exactly as represented in the figure, where the lever of the detent G is hid behind the lever of the pallet E, but may be conceived to be parallel to it, the pallet D having been previously lifted from its quiescent position, where its point rested on the rim near the foot of tooth A; then if we conceive the pendulum moving from right to left with the ball I urging the pin o attached to an arc fixed to the pendulum, or crutch of the pendulum, the vibration is aided by the gravity alone of this ball. The arc, that bears the pins n and o, has a contrivance not seen in the figure for unlocking the detents at the moment when either of the pins bears against its ball, which contrivance it will be sufficient for our purpose to call Z. Conceive now the pin n brought into contact with the arm of ball D by the moving pendulum; the detent F is unlocked, and the tooth A of the wheel quits the end of pallet D; the ball H now acts by its gravity on pin n, and defends, at the same time aiding the returning vibration, while the pallet D, united to the arm of ball H, defends also towards the wheel; but as soon as the pendulum has begun its original vibration, the pin o was withdrawn from the pressure of the ball I, by means of the attached pallet E falling on the tooth C of the wheel, so that all the latter part of the vibration was free; this preface of pallet E on the tooth C diminished the pressure of tooth A on the detent F at the instant of the unlocking, which we have mentioned; the wheel now in motion by the action of the maintaining power, (through the medium of the train,) goes on till the tooth C, acting on the pallet E, raises it outwards, together with its attached ball I, till the detent G stops the wheel's motion, when all the parts are at rest till the pendulum nearly finishes its returning vibration, and then its pin o, meeting with the elevated arm of ball I, presses against it and concludes the vibration; at the moment this preface is felt the contrivance Z unlocks the detent G, and allows the tooth C to escape; in the mean time the ball I by its gravity urges the pendulum for a short time, while the tooth following A, meeting with pallet D, raises it and the ball H a second time, the tooth following C comes in the way of pallet E, and stops the further action of the ball I on the pendulum, which now vibrates, as before, free, till its pin o again meets with the arm of ball H, when the same process is repeated; and thus the weights H and I are alternately raised by the wheel, and then alternately act for a short time on the pendulum, at the beginning of each vibration, so that gravity alone is properly speaking the maintaining power of the pendulum, and whatever may be the maintaining power of the train, it never affects the motion of the pendulum; but only raises the balls, that afterwards act on the pendulum by their gravity alternately exerted from a state of rest. Thus, whatever may be the effects of oil, dust, friction, wear, &c. on the action of the train of wheel-work, as it has no immediate connection with the pendulum, except during the small instant of unlocking the detents, these effects are almost entirely avoided, as they regard the pendulum or regulating part of the motions.

The greatest objection in theory to this construction is, that the additional gravity commences instantaneously, and also ceases instantaneously, and at a part of the vibration where the instantaneous exertion of extraneous force of any kind is the least favourable for aiding the simple gravity of the pendulum's ball, which consideration is analogous to the observation we had occasion to make on Harrison's escapement, but, like his, the escapement before us has fixed the extent of practical experience, notwithstanding its complexity, in his majesty's private observatory. If, however, this escapement is not better than any of the other escapements, the number of its adjustments, and variety of its parts, constitute a practical objection to its general adoption; and we believe no proof has been given of its being preferable to Harrison's, or even to the common dead-beat or illeochronal escapements, except that the works of the clock that has this escapement may not require to be so often cleaned. This escapement leaving the pendulum free or detached from the wheel-work during the greatest part of each vibration, is of the third class of escapements.

22. Escape by Mudge for a clock. — The clock escapement contrived by Mr. Mudge to detach the pendulum from the train, so as to allow it to have nearly a free vibration maintained by gravity alone, may be considered as a simplification of Cumming's escapement just described, from which its principal difference is, that each of his two separate pallets act also as detents; the mode of action and effect produced are very similar in both. Mr. Mudge's escapement is represented by fig. 7. of our last plate, in which L M is a portion of the swinging wheel; G A and G B are two levers separately moveable round one common axis of motion, and have each a pallet at the lower extremities; these pallets are formed like the common recoil pallets, except that each has a claw at the lowest point, that prevents the escape of the sliding tooth when acting thereon; the pallet G A has a lever, which
which may be called its tail-piece G O, attached to it, and also a small metallic ball v surmounted on a pin over the pallet, which may be easily changed for one of a different weight; the pallet G B has a similar tail-piece I O, with a similar ball v over its pallet B; and the dark circular spot at N is the end of a stiff pin projecting from the pendulum, or its crutch, far enough to fall in the way of the tail-pieces alternately, as the pendulum vibrates. After having perused our account of the action of the preceding escapement, the reader will anticipate the explanation we have to offer of this mechanism. Suppose the wheel to be urged by the train in its proper direction from P towards M, and an impulse given to the pendulum, to produce a motion in it in a contrary direction; the pin N keeps pace with the pendulum towards L, while the tooth at L is locked in the claw of pallet A, (which it is supposed to have raised so as to bring the tail-piece G O out of its vertical direction,) and at length meets with this tail-piece, to which it gives a push, at the extremity of the vibration, sufficiently strong to drive the pallet A from its locked tooth L, when the wheel is at liberty to proceed, till the tooth near pallet B raises it and its surmounted ball v until the claw detains the further motion; in the mean time the returning vibration commences, and the ball v urges the pendulum, by means of its tail-piece G O being in contact with the pin N; when, however, the tail-piece has gained its vertical situation, the pallet A meeting with the rim of the wheel drops; the pendulum now finishes its vibration in a detached state, having gained an accession of force by the impulse from the ball v downwards, which has been greater than the resistance it met with in moving upwards at the instant of unlocking; the tail-piece I O is now in the situation of I P, by reason of the ball v being elevated by the wheel, therefore when the pin N of the pendulum arrives at I P, which is at the other extremity near the returning vibration, its stroke drives the pallet B in its turn from the locked tooth near M, which now escapes; the wheel is again at liberty to proceed till the tooth behind L has raised the pallet A a second time, while it is again locked by the pendulum begins another vibration, aided by the ball v till its tail-piece resumes its vertical position, and then the pendulum is again detached, after being a second time urged down a longer arc than it was opposed up; and thus the vibrations are maintained by the excess of the downward push over the resistance upwards at every new vibration, which excess, derived from gravity alone, is in fact the maintaining power of the pendulum. This escapement is also of the third class, and being more simple in its construction than its predecessor and parent, perhaps we may add, is better adapted for practice. The external force derived from the gravity of the balls in aid of the pendulum’s gravity is here also both applied and withdrawn suddenly, as well as at the most unfavourable parts of the vibration, as was the case with Cumming’s escapement; but it possesses the same advantages of detachment from the train.

23. Detached escapement by Peter le Roy in 1748.—We have deviated a little from the regular order of time, in having noticed the detached clock-escapements before those that were previously applied to the balance, in order that the succession of improvements made in clock-escapements might not be interrupted by an intermixture with watch-escapements. We now go back again to the year 1748, when Peter, the eldest son of Julien le Roy, invented an escapement for a balance that vibrated a considerable portion of its total arc without any connection whatever with the escapement wheel, and which therefore may be considered as the father of the third class of escapements, and the origin of the subsequent more recent improvements in the escapement of chronometers. Fig. 3 of Plate XXXIII. will afford us the means of explaining this escapement, a model of which was presented to the Academy of Sciences at Paris in the year 1748, previously to which year, no detached escapement had been made public; though Du Tertre is said to have invented one, and even to have made it at the time; but as the invention, or at least the construction, was kept a secret, it did not derogate from the merit of Peter le Roy’s contrivance, which must be considered as original. G H is the escapement wheel of the contrivance kind, actuated by a pinion on its arbor, receiving the force of the maintaining power; its profile is seen contiguous to it, at g h; T V is the balance, the verge of which has a spiral spring attached to it at the interior end in the usual way; a curved pallet A E is fast to the verge under the balance, and the semi-circular piece C I is affixed to the same above the balance, but under the spiral spring; the end C of this piece is now perfectly free from all contact with the centre of the balance would form with the curve A E an angle of about 80°. An angular lever Q P X, turning on pivots under a little cock on the plate at C, is so proportioned, that the branch P Q will reach the pallet, while the other branch P X with a concave end will reach to a tooth G in the balance wheel, when not relying on a pin K, to which in its quiescent state it is kept by the spring R M, made fast to the plate on the other side at R. Suppose now, the regulating spring moved from its state of natural rest, and the balance to move with it through a certain arc of vibration, more or less, till the rounded end C of the semi-circular piece falls on the branch P Q of the angular lever near Q, and pushes it from its situation, at the same time bringing the concave end of branch P X into the way of a tooth G of the wheel; when the acting tooth, which we will call D, escapes the pallet A E; the wheel is then at liberty till its tooth G falls on the concave end of the branch P X, which may be called the detent, because it now detains the wheel from moving further under exciting circumstances. This balance is now perfectly free from all contact of the acting part of the branch P Q, and continues its vibration, after having received a push from tooth D on its pallet; presently its velocity is destroyed by the tenion of the regulating spring, the re-action of which now makes it return with an accelerated motion, when the pallet comes into contact with the escapement wheel at the tooth following D, which now experiences a recoil for about half a space in the wheel: the branch P X, or detent, is relieved by this partial recoil, and obeys its spring R M, which takes it back again to its state of rest at the pin K; when the wheel, having stopped the balance, sends it off again with a new impulse, by striking the pallet in a contrary direction, when the same operation of the angular lever is repeated, and the vibrations are maintained as in other escapements. It must be remarked of this escapement, that it does not allow the balance to be detached for an entire vibration, but opposes the balance back from the point where it gave its forward push, thereby producing a certain recoil, which, so far as this is a leading consideration, would entitle us to rank the escapement among those of the first class, but is much as the balance vibrates in a detached or free state in the remaining portion of its vibration, we may place this escapement with propriety at the head, in point of time of the third class.

24. Peter le Roy’s second or improved detached escapement. Some time after Peter le Roy had completed his first detached escapement, and had considered its principal defects, he set about contriving another, less liable to objections, in which he succeeded in a very considerable degree; when in
the year 1766 he presented a time-piece to the Academy of Sciences, which was afterwards tried at sea by the French government, with his improved escapement, which we shall now describe. Figs. 1, 2, and 3, of Plate XXXIV. exhibit sufficient of Peter le Roy's improved escapement to enable our readers to form a complete idea of its construction; the leading feature of which is to give the balance one temporary push that shall maintain its motion for two successive vibrations, one forwards and the other back, and that this push may be given at a moment of the balance's vibration that is most favourable for avoiding a derangement of the law of the spring's forces. Fig. 1, is a view of the balance-wheel, which has fixed radial levers for teeth, but no nails, that it may be as light as possible, the ends of which levers are bent downwards, that is, in an opposite direction to those on the horizontal wheel with Graham's cylinder escapement; the connection of this horizontal balance-wheel with the train is by means of the pinion on the opposite end of its arbor; fig. 2, is the arbor of the detents, on which there are three levers, one double one for locking, and two single ones for unlocking, all clearly shown in the figure; fig. 3, shows the wheel, detents, unlocking levers, and balance in their relative situations, and in one of the actuating positions: A is a portion of the balance, on the plane of which is screwed a pallet $p$, so as to fall in the way of one of the levers of the balance-wheel. The same letters denote the same parts in fig. 3, as in figs. 1 and 2, which therefore explain themselves. The action may be explained thus: suppose one of the levers of the balance-wheel to be detained by the claw of the detent $D$, while the balance puts in motion is vibrating in the direction from $i$ to $A$; when the force of the balance spring, not seen, overcomes the momentum of the balance, it returns by means of the spring's forces, which is now at its greatest tension, or dilation from the point of quiescence; the direction of the balance, we have said, is now from $A$ towards $i$; in this return a pin at $i$, situated in the superior plane of the balance, strikes the end of the lever $H$ of the detent arbor, unlocks by this stroke the detent $D$ from the claw of the wheel's radial bar or tooth, and at the same instant directs the other end $H_e$ of the double detent into the way of a succeeding radial bar of the wheel $K$, which now re-sets on this end of the detent; this part of the action is called by the inventor the preparation, the vibration goes on to $s$ and, the spring brings the balance back; at a certain part of this vibration the balance receives its Stroke from the radial bar $K$, which impels the pallet $p$, screwed on the balance itself, in this manner; a pin, situated like the former pin at $i$, but placed on the inferior plane of the balance, out of sight, and a little farther from the balance's centre than the former pin, strikes the end of the short lever $H_2$, and unlocks the radial bar of the wheel, that has been retarding against the opposite end of the detent $D$, and that now runs on to $D$, which is in the way to catch it; during this short period the wheel is free, the pallet having already got into the way, the motion $F$, the point $K$ of the radial bar $K$, of the wheel pursues the pallet and makes its stroke on, about the time when the balance-spring, as we suppose, is at its quiescent point, and therefore when the balance is moving with its most accelerated velocity; the stroke is of short duration on that account, as well as on account of the short distance the wheel has to run before it is again detained by the detent $D$: the backward vibration is made as before, and the same process is repeated of two lockings and unlocking at each stroke of the wheel on the balance. The stroke, however, which the balance receives, has more force than both the strokes that its pins give in the acts of unlocking, and therefore the difference of these contrary strokes constitutes the real maintaining power of the balance, which was of the thermometrical kind, with alcohol and quicksilver, as described under our article Compensation-balance. The stop made towards perfection, when this escapement was devised, was very long, and the principal objection to it in practice is, that it has too many pivots that require oil, as well other parts that come successively in contact during the action, which therefore are not sufficiently free from friction and consequent wear. It may be necessary to add, that to prevent the detent's being displaced by any jerk, a long tail-piece behind it is contiguous to a circular appendage of the balance, seen from $i$ to $F$, against which it falls, but only when any derangement of the detent accidentally takes place, and this reinforces it. The stroke is given to the balance not only when its velocity is greatest and least liable to be deranged, but the pallet that receives it, being removed from the centre of the balance, requires but a comparatively small impulse in this situation; besides, the spring, which the inventor considered as not desirable, for holding the angular lever to its place of locking, is here entirely dispensed with. This was considered as an improvement at the time, but subsequent experience has proved the utility of spring detents, which are now in universal use in the best English chronometers.

25. Detached escapement by F. Berthoud.—Ferdinand Berthoud, one of the members of the National Institute of France, and the author of various works on horology, has contrived different escapements for clocks and watches at different times, and has written more on the subject than any other author, but it will not come within our plan to detail here all the alterations that have presented themselves to him; we shall satisfy ourselves with describing a few of those which he has himself selected as most worthy of public attention in his last publication; "Histoire de la Méthode du Temps." Others may be seen in his "Traité des Horloges Marines," or in the "Supplement" to that work. The first that we mean to describe is contained in fig. 5, of Plate XXXIV., which is a perspective view of all the parts necessary to be seen: A represents the verge of the balance, to which is affixed by two screws the circle of escapement $B$ as a pallet; $C$ is the escapement wheel, $a b c$ the detent, which has at $b$ a claw to catch a tooth of the wheel, when it fulfills its motion, during the period of the balance's free vibration; the portion $a b$ of the detent is a flexible spring, that yields first at the point $a$; this, therefore, is the spring of the detent; the other part $b c$ properly forms the detent, which has a claw rounded at the end $c$; another tender spring $b e$ lies cross-wise near the said end, and is held fast to the circle $B$ by a screw and fixing-piece $f$; this second spring carries a pin $d$ near its extreme end, which acting on the end of the detent, dilates the locked tooth of the wheel, when the balance vibrates in a direction from $B$ towards $A$; at that instant the succeeding tooth of the wheel acts on the notch or pallet point of the circular piece $B$, at $d$, and transmits an accession of force to the balance, which now vibrates in free space; at the balance's return, the pin $d$ of the small spring $d$, borne by the balance's circular piece $B$, applies itself to the end of the detent, so as to slide past it without disturbing its position with regard to the claw, against which the next tooth is now retting; when the balance has finished this second vibration it returns, the pin $d$ again pushes aside the detent, and unlocks the wheel, which now gives another push at $b$, and the same operation is resumed that we have just been describing. Thus two vibrations are performed at once unlocking, and at one stroke of the wheel on the notch of the circular pallet piece. The small spring $b e$ may be
be called the lifting spring, in opposition to the detent spring, or spring detent; and to give a clear idea how it detaches the claw of the detent in passing forwards, but not in passing back again, it may be necessary to observe, that this lifting-spring has a pin in the circular piece $B$, against which it rests, to prevent its lying too much hold on the back or spring part of the detent's extremity; but it is at liberty to yield in the contrary direction to the verge of the balance; and as the spring is very slender, and has its yielding point or centre of motion at the remote end, it gives way to the detent in the direction that pushes the detent against the tooth of the wheel, which becomes a prop to steady it; but when the impulse is in a contrary direction, the detent, having no such prop, and its end being at that side denied to receive the blow of the pin without its sliding, itself yields and withdraws its claw from the wheel, which is then unlocked. The spring of the detent is also confined from rebounding too far by a pin $g$ fixed in the plate. Here we have an instance of a retrograde step in the improvement of escapements, the spring which Peter le Roy laboured to reject in his second construction is here resumed with an additional spring, and the adoption of the spring-detent has become general in the subsequent constructions. Berthoud began his detached escapements in the year 1754. 26. Another modification of a detached escapement by Berthoud.—The escapement which Berthoud employed in some of his watches, particularly No. 25, was considered by him to be more sure in its action than the preceding ones, as well as more easy of construction; $f_2$, 5. of the fame plate represents the plan of one of these escapements, where $L$ is the escapement wheel; $m$ the circle of escapement carried on the verge of the balance; $p$ $r$ the detent, the claw of which at $r$ suspends the motion of the wheel; the verge carries above the circle $m$ a small tube made fast by friction, and to this tube is made fast a projecting forked claw, in which a pin is adjusted to act on the detent and raise it. The pin, which we will call $r$, in turning in one direction, acts on the part of the detent, and withdraws the claw $r$ from the wheel; this is now at liberty to impel the circle $m$ by its notch and with it the balance; the slender spring $u$, brings back the claw of the detent, and the vibration goes on; at its return the pin meets with the end of the detent-spring fixed on an arm at $t$, this spring yields to the retrograde motion of the balance. The balance at its return makes its pin (of the fork) urge the spring $p$ against a pin $s$ in the arm $n$ of the detent; this arm turning on its centre of motion, withdraws the claw of the detent from the wheel, which now acts again on the notch of the circle $m$, as before. The pin $q$ serves as a stop to the detent, and the arm $k$ of precaution is to lock the wheel when the balance is dismounted.

27. Another escapement without a spring by Berthoud.—Fig. 6. of the last plate is a view of an escapement by Berthoud, in which he has dispensed with springs altogether. The action of the wheel $A$ is transmitted to the balance, as before, by means of the detent wheel $B$ where the present position of the parts is for the moment when the detent allows the wheel to begin its action on the notch of $B$. The detent $C$ has two arms, with each a claw $a$ and $b$, the faces of which are circular; the claw $a$ serves to suspend the action of the wheel after its stroke is made; but the claw $b$ receives the tooth of the wheel when the balance in its return makes the tooth at $a$ to escape. These effects are produced by two levers $C, d$, $e$, forming the fork that moves the detent $C$: this fork is fixed on the centre $C$ of the detent, and its levers lie one above the other. The lever $C$, which is contiguous to the detent, corresponds to the small semi-circular piece $d$, placed on the circle of escapement $B$: this semi-circle is notched by lines, one of which tends to the centre; this side of the notch unlocks the wheel by its action on the arm $C d$ whenever the balance retrogrades from the first vibration of the pair; during this effect the wheel advances but a short way, just sufficient to unlock the claw $a$, and to suffer the balance to proceed in its retrogradation. The balance, having finished in a detached state this second vibration, returns, when the semi-circle $f g$, placed over the other semi-circle, and notched in like manner, presents its acting side to the upper arm $f C$ of the fork, and unlocks the tooth at claw $b$; at this moment another tooth, catching the notch at $c$ of the circular piece $B$, gives it another impulse, and consequently puts the balance in a state of renewed force, and the process already described is renewed, while the semi-circular pieces $d e$ and $f g$ on the verge alternately serve to keep the arms $C d$ and $C e$ of the fork in a firm position to ensure the desired effects of the escapement. It is easy to perceive that there must be much friction in this escapement, and that the semi-circular pieces on the verge of the balance, if not somehow counterpoised, must affect the rate of going in different positions of the time-piece.

28. Detached escapement with a detent and spring by Berthoud.—Fig. 7. of the same plate is the plan of another of Berthoud's escapements with a detent and spring, and that which we understand has been most copied by others. It was used in the author's marine time-piece N° 9. $A$ is the circle of escapement; $C$ the wheel; $a b d$ the detent with three arms; the arm $a$ suspends the motion of the wheel while the balance oscillates in a free state; the spring $d$ serves to bring the detent $a b d$ back again as soon as the pallet $c$ has ceased to act on the arm $b$; at that moment one of the teeth of the wheel impels the circle of the verge by acting on the roller $b$, and communicates its force to the balance; this having finished its oscillation returns, and in the return the pallet $a$ meets with the end $b$ of the detent, which turns the pallet back towards $B$, the centre of the circle, till it has passed without unlocking the wheel; its spring $b$ brings the pallet back again to its original state of rest on the pin at $c$, the oscillation ceases, and in the return of the balance the pallet $a$ again meets with the arm $b$ of the detent, which it turns aside, the tooth being no prop to it in this direction; the unlocking therefore takes place; the wheel's motion is resumed, and a new impulse is given to the moving balance. Here the detents are arms or levers acted on by a separate spring, as is also the pallet, consequently there still remain pivots that require oil, though we are disposed to consider this as the best of Berthoud's watch escapements; perhaps equal to any of the English constructions.

29. Isochronal escapement of a watch by F. Berthoud.—Among the other contrivances of Berthoud is an escapement for a watch with isochronal pallets, similar to those applied to a pendulum which we have described above, but the mode of applying them is different. In fig. 8. of our last plate, $A$ is the escapement wheel; $B$ the anchor with the isochronal pallets producing a small recoil, and formed in the manner before described, (see fig. 1. of Plate XXXIII.) $C D$ the balance; $a$ a pinion on the verge above the wheel, that is actuated by a sectorial toothed piece $b$, attached to the anchor of the pallets, and moving with it round the common centre of motion of it and the pallets at $E$; the intention of this construction is to produce a long oscillation of the balance compared to the motion of the wheel and toothed sectoral piece, and to render all the oscillations, however long or short, of equal duration, the area of action being large in proportion to the whole oscillations. This construction may
may have given rise to that which is now known by the name of the Liverpool escapement, which so greatly resembles it, that they may be considered as the same thing. We obtained a watch by Litherland of Liverpool, with a view of giving a separate description and drawing, but we found that the only difference is, that the pallets are placed a little on one side of the wheel, instead of the three points being in one straight line, and that the centre of the pallet's motion is between the verge and pallets requiring a counterpoise behind; a further description is therefore unnecessary.

32. Modern escapements of English chronometers. — If we had not already anticipated our descriptions of the modern escapements for chronometers, as they are now made in England, we should have given them a place here; but as we have been very minute in our account of the escapements of Meffes. Mudge, Arnold, the Brookhasks, and Earnshaw, under our article CHRONOMETER, and have given drawings of them in our Plates XIII. XIV. and XV., it would be superfluous to enter into a second detail of the same here, and therefore we pass over them by a simple reference to the article already named.

It may not be improper to mention here, that Mr. John Watkin, of Welthmithed, has proposed an alteration in the situation of the pallets in the modern spring detent escapement, for which he received thirty guineas as a premium from the Adelphi Society, in the year 1804. His alteration consists in bringing the pallets into a situation between the centre and circumference of the wheel, and making the wheel a contrate one with the teeth upwards. (See the Transactions of the Society, vol. xxiii. p. 375.)

31. Mudge's forked escapement. — Mr. Mudge contrived another detached escapement besides the one we have referred to as already described, which we shall now notice, though he did not seem to place so much value on it as Emery, Margetts, and others have done after him; we shall not be able to make the reader comprehend the construction without two figures: Fig. 1. of Plate XXXV. is the plan of this escapement, and Fig. 2. a profile or side view of the frame that contains the mechanism: A is the escapement wheel, B the anchor of the pallets, which are of Graham's dead-bolt kind adapted to a watch, and which give the necessary force to the balance for maintaining its motion; a is the centre of motion of the anchor, nearer to the wheel than to the balance; B is the forked part of the anchor, the two prongs of which appear in Fig. 1. to be close together in the same plane, but in Fig. 2. flames that they are one above the other. The pallets are on the verge of the balance, and are of the cylindrical form, one above the other, so as to fall in the way of the two prongs alternately, pallet 1 is urged by a, and pallet 2 by the other prong in its turn; the time of action of the prongs on the two pallets is very short, and the blows are made alternately one in each vibration; the remainder of the vibration is perfectly free, the wheel being in the intervals rolling on the circular portions or pads of the anchor's pallets, which may in this case be considered as detents and pallets alternately. A timepiece by Emery with this escapement performed with wonderful accuracy, though the detachment continues only for a portion of one vibration before the balance has its force renewed, which constitutionally might be supposed to have its motion more disturbed than if the impulse had been given at each alternate vibration. The wheel's watch by Mudge with this escapement had a slight recoil, which kept one of the prongs pressing gently against the cylinder of the verge to steady the fork. The performance was excellent.

32. Margetts' modification of Mudge's forked escapement. — The late ingenious Margetts adopted Mr. Mudge's escapement, which we have just described, for his chronometers that indicated both solar and sidereal time, but made some alterations with the fork. Fig. 3. of the same plate shows the plan and profile of Margetts' modification, where A is the wheel; a b the anchor movable at a; b the fork where the prongs are in the same plane; c a piece of steel carrying a pin e under its extreme end that strikes the prongs of the fork b alternately, one at each oscillation of the balance g, which unlocks the wheel: b and d are two banking fingers, the points of which act as stops to the anchor at opposite sides of the centre of motion, and keep the fork in its place to be caught by the pin e, either, or one of them at each vibration; d is a circular piece of metal, under the pallet piece e, which has a notch in it, bounded by straight lines going towards its center; and f is a pin carried under the anchor, as seen in the figure, the end of which gives the circular piece d a push, by acting on its notched face at each unlocking of the wheel, thereby aiding the vibration: the pin f is always at the notch when the pin e is in the fork, therefore the notch in d and the pin e are always placed in the same vertical line over one another, and as they move together on the verge will always remain so, while the pin f and fork b are also together on the anchor. The writer of the present article has a chronometer by Margetts with this escapement, which acts very well when stationary, but when carried in the pocket the pin is apt to catch the outside of the prong, when any jerk has sent the anchor back during the balance's excursion.

33. Modification of Mudge's forked escapement by R. Robin of Paris. — R. Robin, a watch-maker of Paris, published a memoir in 1794, containing an account of a free escapement, which he considered as new, but which we consider as another modification of Mr. Mudge's forked escapement, though we allow that in theory it appears to be an improvement. Fig. 4. of the same plate is a plan of this escapement, in which the wheel returns the exhausted force of the balance once only in two vibrations, which circumstance confutes the impulsion: to effect this, pallets G, H, and G', acting as detents, are made of unequal length from G, the centre of their motion, and the fork, which is seen separately at e, as well as the tooth or pallet d and lever f, are concealed under G, the circular piece carried by the balance; the fork e is fast to the end of one of the pallets a, instead of forming an anchor with the pallets, but this shape makes no difference in the action; the lever f is also fast to the same underneath the fork; but the tooth d', which acts with the fork, is fast to the verge under B, as we have already said. We have given three positions of the circular part B and pallets, to shew more clearly the nature of the action, as some of the acting parts are concealed. One of the claws a of the pallets being removed, the wheel A escapes, and acts on the notch of the piece B, thereby aiding the balance; the claw b receives another tooth and holds it as a detent, and the balance supplies its oscillation; at its return it unlocks the tooth at a, which is the longer pallet, and the wheel runs on a very short way till a leading tooth falls on the pallet a, and the balance vibrates without a new push; at its return the tooth at a is unlocked, and its cleaving tooth gives the notch of B another push, which serves for other two vibrations: but if the two ends of the pallets G b, and G a, had been of equal lengths, the escapement would have acted in the usual way, and would have given its push at each oscillation. The manner in which this effect is produced, however, does not yet appear evident: the lever f', which is fast to the end a of the pallet or detent G a, rolls in a groove made in a circular collet on the verge, and holds the fork e from going on one side, like as the banking screws.
ESCAPEMENT.

The escape of Margetts' escapement, then the tooth $d$, falls to the balance, strikes the two prongs of the fork alternately, one at each vibration, which strokes make two unlookings during the time that one path is made to the balance by a tooth; because the said tooth previously made two leaps forward, one long and one short, before it escaped to make its path. We have not been informed how this modification performed, but we see no reason to doubt its competency, while we much reason to admire the ingenuity of the application of two detents of unequal length, formed like the pallets of the anchor escapement, which detents we have named pallets on that account.

34. Prior's modification of Mudge's forked escapement.—In the year 1798 Mr. John Prior received 30 guineas as a premium from the Society for the Encouragement of Arts at the Adelphi, for his invention of what he considered a new detached escapement; but its fork differs from Mudge's principally in its having a roller for a pallet borne by an arbor carried by the balance itself; the wheel of escapement, together with its acting pallets, were similar to Le Pouate's improvement on Amant's wheel, and therefore had nothing original in it. The reader who wishes to see the account and drawings of this escapement, composed as it is of Mudge's and Le Pouate's contrivances, which notwithstanding the author might not have seen or known, may find it in the 16th vol. of the Transactions of the Society just named, and also in the 2d vol. of Nicholston's Journal, 410. ed. p. 363 and 364, where the editor has remarked that Mr. Crollwhaite of Dublin had made a pendulum clock with similar pallets in 1758, which was described in the Memoirs of the Trin. Acad. vol. II.

Prior's junior has very recently been rewarded by the same society for another escapement contrived by him for a clock, but the account of it is not yet published in their Transactions, and therefore cannot with propriety be given here.

35. Duplex escapement.—We are not informed who was the original contriver of the escapement known by the name of Duplex escapement, a name probably taken from the circumstance of its having a wheel with two sets of teeth necessary for the escaping; neither are we aware of its date; but the idea in which it is held by those who have tried it, entitle it to a place in our collection. Fig. 5. of Plate XXXV. exhibits on a large scale enough of the acting parts to enable us to convey an idea of its action. A B is a part of the escapement wheel, having teeth $a, b, c, &c.$ at the periphery, intended for detaining the wheel while it oscillates beyond the angle of action. An agate cylinder $d e f$, placed on the verge of the balance, acts with these teeth to produce the desired effect. This cylindrical agate has a notch $g$, which passes by the tooth at D, that is supposed to rest on the cylindrical surface, when the motion is in the direction $d e f$; but when the motion of the cylinder is in the contrary direction $f e d$, the tooth at D falls into the notch and accompanies it, pressing on one of its sides till the notch comes into the situation $d$; the tooth, then at the situation of $b$, escapes from the notch, and a succeeding tooth falls on the convex surface of the cylinder at D. The other set of teeth are erect on the plane of the wheel's rim, and are strong and squared at the sides; they stand a little short of the middle of the spaces between the pointed teeth on the edge of the wheel, but conflict of the same number; they are to be seen at $b, i, &c.$ denoted by darkened parallelograms; above the small cylinder we have named as being made of agate, is a larger one $E F G$ without a notch, and placed high enough on the verge to go over the edge of the wheel's rim; this bears a pallet of ruby or sapphire G, long enough to fall in the way of the square vertical teeth, when they happen to be near the line joining the centres of motion of the balance and wheel, but short enough to avoid touching the teeth when not near that line. The larger cylinder is so placed with respect to the small one, that when the tooth $h$ has just escaped from the notch, the pallet G has just pulled the square tooth $b$, which was at $A$, while D rested on the small cylinder, but is moved from A to $b$, while D moves to $b$. The wheel is now free, and the tooth B exerts its force, derived from the main-spring, in the most direct way on the pallet G, and urges it forward till another tooth on the edge falls on the convex part of the small cylinder $d e f$, and the same action that has been described is repeated. The angle of action in this escapement depends partly on the length of the pallet G, and partly on the diameter of the small agate cylinder, and advance of tooth D into the notch; for when a horizontal tooth on the edge falls on the said small cylinder, the motion of the wheel is arrested, and the vertical square tooth ceases to impel the pallet G so far as it otherwise would have done. This escapement requires very little oil on the small agate cylinder, and none at all on the pallet G, which receives a direct push without friction, and its excellence is considered as at least equal to that of Graham's horizontal or cylindrical escapement.

36. Free escape under the pendulum.—The clock escapements which we have before described suppose a connection with the upper end of the pendulum, which is the most common connection, but there are escapements that give their impulse at the inferior end, one of which is represented by fig. 6. of Plate XXXV, which we shall now describe, though we know not who was its original contriver. The part A B C D E F G H I is a made fast to the rod of the pendulum, and vibrates therewith; at B is a joint on which the lever B C is moveable; so that when the end C meets with any resistance the lever mounts upwards at this end, but cannot fall below a horizontal line; it terminates in a claw with both an interior and exterior slope or inclined plane; D is a pallet of agate or other polished stone, with a flat face next the end C of the lever, and made fast into the vertical part A D; F G H I is a two-armed detent, moveable round H as a centre, but kept in its present position against the stop or pin K, by means of the weight G, when not otherwise acted on. In the present position the arm H I, which forms the detent, detains the tooth I of a vertical wheel of escapement, while the pendulum is supposed to be vibrating clear of all the teeth. Let us suppose the end C of the horizontal lever, moving with the pendulum, to be approaching the end F of the second arm of the detent; presently it gives the end F a blow, the lever C flies up, rides over the inclined face of F, and returns into its horizontal position; when the vibration terminates, the pendulum returns by virtue of its gravity, and the interior face of the claw C catches the exterior one of the arm F, and gives it a pull sufficient to draw the end of H I from the tooth I; the wheel is then at liberty to run on till the tooth E, moving faster than the pendulum, overtakes the pallet D, and gives it a direct push forwards; this push aids the claw C to get over the claw of F, and the weight G replaces the arm H I to catch the following tooth M, which prevents the further impulse of the wheel on the pallet D, and suffers the pendulum to finish its vibration in free space; at the return of the pendulum the same operation is repeated, and the pendulum continues to receive one push at every two vibrations, and that when the pendulum is in its vertical position, or moving with its greatest velocity, which we have said is the most favourable point of the arc. The arc of action, before the pallet is quitted, depends greatly on the
ESCAPMENT.

the radius of the wheel compared to the length of the pendulum, when the number of teeth is limited. The pendulum, however, ought to be of the compensating kind, otherwise an increase in the length of the rod will derange the action of the claw C, with the claw F, as well as of the tooth on the pallet D, in all the extremes of atmospheric temperature. The maintaining power of the train that actuates the wheel E M may be either a spring or weight, as the mechanism may think proper. Berthoud has proposed this construction of a free escapement for a half-second's pendulum in his "Histoire de la Mesure du Temps," tome i. p. 214; but he does not clearly say that it was of his own contrivance; on examining his drawings, since our observations were written on this escapement, we find that this author proposed a compensation pendulum to be used with it, and he proposes such a combination of parts as a proper model for an astronomical clock to vibrate half-seconds. Mr. Nicholson, who has also described the same escapement as one he has noticed in England, does not venture to ascribe its invention to any particular artist.

37. Detached escapement of a clock by Berthoud.—Among the numerous contrivances of F. Berthoud in clock-work, we frequently find this author applying the same contrivance to answer different purposes; for instance, when he had hit upon an isochronal escapement for a clock, he adapted it soon after, as we have seen, to a watch; and in the instance before us, he has converted a free or detached escapement of a watch into a clock escapement, which we shall here describe, not knowing the exact date of the application. Fig. 1. of Plate XXXVI. is a representation of an escapement of the third class adapted to a half-second's pendulum, as described by Berthoud himself. F is the escapement wheel, and a b, the detents of escapement, (formed like the pallets of the dead-beat escapement of Graham,) the action of the wheel F is transmitted to the pendulum by means of the notch made in the circular portion of the escapement piece A B, thus; the detent has two claws, a and b, formed by portions of a circle, at the holding parts. The claw a serves to suspend the action of the wheel, when it has communicated its motion to the notch of the escapement piece, which this does again to the pendulum, by means of the lever C, which it carries, and of the roller D, corresponding to the pendulum. The claw b serves to receive, and to detain the wheel, when the pendulum returns. These effects are produced by two levers d e c, fixed on the centre c of the detent; but one of them more distant from the plane than the other. These two levers form a fork that corresponds to the circle of escapement b g. The lever d e, which is nearest to the detent, answers to one portion of the circle g, carried by the circle of the escapement D. This part g presents a straight line to the fork d, which being acted on, detaches the claw a of the detent, and, consequently, sets the wheel at liberty. The notch f presents itself, and the tooth of the wheel acts on the notch, and restores to the pendulum the force that it had lost. The wheel having finished its action on the notch f, a tooth presents itself to the claw b, and the pendulum finishes its vibration in a free manner, at its return, the portion of the circle g, which is most elevated, meets with the arm e of the fork, and disengages the claw d; the tooth that was last detained in the escapement a is short finished before another tooth drops on the claw a, and the process is repeated. We have not seen this escapement in England.

38. Escapement by Mr. Nicholson.—Some time in the year 1793, Mr. Nicholson says (Phil. Journ. vol. ii. 410. p. 59.) that he contrived a clock escapement to go without oil, and which is of the dead-beat kind; it was constructed in the year 1798, and when the account was written had been going freely for a year or more. His account is this, fig. 2. of Plate XXXVI. "is a sketch, in which G H represents a steel wheel; D and E are pallets of agate, with flat polished faces. The pallet D is fixed to the lever D C, which is confined to its present situation by the loaded branch or arm C B resting on the stop f. The lever E C is also kept in its situation by the loaded arm C A resting upon I. A pin N proceeds from the pendulum rod to its situation between the levers. The centre of motion of the pendulum is in the continuation of the axis of the pallets. Suppose the vibrations to be begun; the pin N in its progress will lift the pallet D towards L, while part of the weight B is supported by the tooth of the wheel which will follow, and at half escape and fuller the opposite tooth F to fall on the pallet E. But in its return, or descent, the pendulum will be acted on by the whole weight B, and, consequently, its vibration will be kept up. When the pin N raises the pallet E, a similar effect will take place on the side of the perpendicular towards M, and thus the process will go on as long as the wheel G H retains any force." In this escapement, the two weights are not raised entirely by the action of the wheel, but are chiefly lifted by the pendulum itself; therefore though the vibration is made during the repose of the wheel, in a state detached from the train, yet the pendulum is not detached from the weights, and, consequently, the compound law of forces by which the pendulum is maintained conforms to the action of the pendulum's gravity, of the action of the ball's gravity, which acts in concert with the other, and of a short action of the wheel on the agate pallet; this compound action differs from Mudge's and Cumming's in this respect, that their weights are raised by the wheel entirely without opposing the pendulum, otherwise than by the short stroke made at unlocking.

39. Crank escapement by Simon Goodrich.—In the year 1799 the Adelphi Society rewarded Mr. Goodrich for his contrivance of a crank escapement, which is exhibited in figs. 3. and 4. of Plate XXXVI. of which fig. 3. is a front view, and fig. 4. a side view of the same, where the figure letters of reference apply to both. A A A is the back plate of a clock frame; B the crank fixed to the end of C the arbor of the lathe pintion of the train; D D, are two small wire chains, composed of two links only attached to the crank B, by means of two coils, with great liberty of play. These chains are fastened to E E, two small springs twere to F F, a bar that goes across, and is fastened in the middle to G G, the crutch of the pendulum. I I, are two screws going through the bar F; the ends of which are made to act against the springs E E, serve to adjust them to a proper distance and degree of strength, and by that means easily to put the pendulum into proper beat. In fig. 3. the pendulum is partly represented by dotted lines, in order to shew the crank, &c. The advantages attributed to this construction are, simplicity of construction and consequent cheapness; total silence during the escape; uniformity of action on the pendulum; durability and certainty of continuance; and the power of acting without oil. These properties may recommend the escapement before us, but as its influence on the pendulum is confiant, it is but ill calculated to counteract any irregularities in the maintaining of it as transmitted and varied by the train under different circumstances of wear, dirt, and friction. The originality of the contrivance is that of a rotatory motion converted into a vibratory one, which Souville had done very nearly in the same way in the year 1746. (See Machines et Inventions approprées par l'Academie Royal des Sciences; tome xiii. p. 325.) As there is no escapement wheel, a further
further explanation is unnecessary to every one who has seen a trellis in action; but it may be necessary to remark that an additional wheel and pinion must be requisite in the train where the last pinion revolves more frequently than in other escapements.

40. - Mr. Maffey's escapement without a verge was one of two escapements which together gained him twenty guineas from the Adelphi Society in 1800; the other, being the 4th class, will be described in another place. Fig. 5 of Plate XXXVI is a plan of this escapement, which is of a novel construction, borrowed probably from the spring detent escapement of the modern chronometers, and adapted to a clock for use in a pendulum fusee, during a large portion of its vibration. The pendulum rod is seen at $a$, suspended by a piece of watch spring in the usual way, but without a crutch and verge; $b$ is the fixing wheel with its teeth shaped like the dead-best kind, except that they are rounded at the end; this wheel is not within the frame as usual, but on the outside of the back plate; $c$ and $d$ are the arms of the pallets $f$ and $g$ respectively; these arms are attached to the frame, and are adjustable for the included angle by the keys $e$ and $i$, which press against the upper ends of the arms, that open like a pair of tongs, and are kept open by a slender spring $e$ forced into notches at the ends. A crofs bar $k$, carried by the pendulum, gives alternate strokes to the two pins fixed in the pallets $f$ and $g$, at the time of unlocking. In the figure the pendulum is supposed to be in motion with the pin of pallet $g$ reeling against the crofs bar $k$, which bar it imparts on the returning vibration, and aids the pendulum, while the inclined plane of pallet $f$ is raised by the wheel to give its stroke, when unlocked, in a contrary direction. Thus the pallets are raised partly by the wheel and partly by the pendulum, as is the case with Mr. Norallon's pallets for the spring in this case performs the same office that the weight does in that; but in this easement the inclined planes must require oil, which is not necessary in the other, where the wheel acts by a direct push without any sliding motion. The inventor tells us, that a more than usually large maintaining power is necessary when this easement is adopted, which indeed must be the case with all detached escapements, where the duration of the impulse is short.

The reader may have observed that we have not yet noticed in this article the fourth class of escapements which act by the aid of remontoires; this omission has been intentional, not only for the purpose of avoiding the further enlargement of the article, but that we may give the history of the invention of the remontoire, and of its modifications by the different ingenious men, who have preferred its use to that of a detached escapement without such additional aid. We have already had occasion to speak of Harrison's and Mudge's auxiliary springs, or remontoires, under our article Chronometer, and it will suffice, for our present purpose, to name here that Huygens, Leibnitz, Galvani, Haly, Breguet de La Fons, Maffey, and others, have taken a part in bringing the remontoire into notice, as we shall have occasion to relate more particularly under the article Remontoire.

ESCARAY, in Geography, a town of Spair, in Old Castile; 5 miles S. of Calzada.

ESCARIGO, a town of Portugal, in the province of Beira; 12 miles N.W. of Penna Macor.

ESCARPE, or SCARP, in Military Affairs, relates to the exterior slope of every defence, while on the other hand the interior slope of every excavation beyond or facing the escarpe is designated the counter-scarp. It may be necessary to remark, that, in skirmish, the term is not applica-
ESC

ESC

ESCATARI, a small island about 5 leagues N. of Louisbourg, in the island of Cape Breton.

ESCATRON, a small town of Spain, in the province of Aragon, above the confluence of the Martin and Ebro, nearly opposite to Rueda, between Saragossa and Mequinenza.

ESCOUT, the, more generally known in England by its Flemish or Dutch appellation of the Schelde, or Schelte, was formerly a river of Austrian Flanders, and is now a river of France, which gives its name to one of the northern departments. It has its source in the department of the Somme, near Beaurevoir, a few miles to the north of Saint Quentin, a town of the department of the Aisne; runs by Beauvois, Cateau, Homécourt, Créveceur, Cambray, Houdain, Bouchain, Nœuville, Denain, Valenciennes, Fraine, and Condé, where it becomes navigable, after having received the Aisne; it then flows to Mortagne, where it receives the Scarpe; from thence it goes on to Tournay, Gand, and Antwerp, where it is 701 miles, or 360 fathoms wide, and 10 metres, or 33 feet deep at low water; the tide at high water rises 15 feet. After having passed Antwerp, the Eifaut branches out into two channels; the easterly one passes by Bergen op Zoom, the west channel, called the Upper Eicaut, loses itself between the islands of Zeeland into the North sea, near Flémalle or Flushing. From Antwerp to this place its course is 74 miles; it widens gradually, and has petty nearly the same depth every where; but its bed is obstructed by sand-banks, which render its navigation difficult and dangerous.

The Eicaut has a communication with the river Somme by means of a canal, part of which is under ground.

ESCOUT, the department of the, is the ninth department of the first region or United Countries (pays réunis) of France, and derives its name from the river Eicaut (Schelde) which traverses it from north to south. It is composed of part of Austrian Flanders; its chief place is Gand. The limits of the department of the Eicaut are to the north, the kingdom of Holland; to the east, the departments of the Dyle and of the two Nethes, from which it is separated by the Eicaut; to the south, the department of Jemmapes, and to the west, that of the Lys. Its principal rivers are the Eicaut, the Lys, the Duréne, the Lévere, the Dender, &c.

There are several canals in this department; that which goes from Gand to Bruges, and from Bruges to Ollent is the most important. Another towards the north opens a communication between Rodenherpen and Sao-de-Gand; a third one, near Merbeek, communicates by one of its branches with Axel, and by the other with Hull. There are also several keller canals for the purposes of irrigation, or of draining low marshy grounds.

The soil is in general fertile, and produces all sorts of corn and vegetables, chiefly hemp, flax, and hops. It abounds in game. Domestic fowls and sweet water fish are plentiful. The chief manufactures are those of hene yarn, linen cloth, coalbt, Prussian blue, ribbands, woollen cloth, earthenware, glass, writing paper. There are also several paper mills, sugar-houses, salt-works, and bleaching grounds.

The territorial extent of the department of the Eicaut is 2884½ square kilometers, or 1592 square leagues; its population 595,278, or 3750 inhabitants to the square league. The whole department is divided into four districts, Gand, Audenarde, Termonde, and L'Escaut; 41 cantons, and 328 communes. The average contribution of every individual to the expenses of the state is about 97. 25. 1 1/2. Reaping annually. Hébrin Statistique de la France.

ESCUT and MEUSE, the department of the, in Dutch the department of the Schelde and Maas, is one of the new divisions of the kingdom of Holland, and is reported to comprise the western part of the ancient Dutch Embratt, Zeeland, and the islands of the Maas or Meuse. Middleburg is its chief place.

ESCH, a town of the duchy of Luxembourg, on the Sour; 7 miles W. of Dirich.

Eseh, in botany, a name given by Hildegard, and others to the fish we call this Grayling, or amber, and the generality of authors, the thymallus. It is of the coregonid family, and is distinguished by Artedi by the upper jaw being longer, and the back fin containing twenty-three bones. The Germans call it ofsh, and the Italians temello. See Salmo Thymallus.

ESCHALLOT, Cepa apiolanesia, in Botany, a species of onion, cultivated in gardens for its use in cookery, and nearly resembling the Welsh onion. See CEP.

ESCHAR. This term, in surgery, implies a portion of flesh, deadened by the application either of actual fire or caudic substances. In cases of violent burns we often use echars produced; and whenever we wish to make a common urine, for the relief of any such disease as a white-swelling, a caries of the vertebrae, &c. we cannot accomplish our object better, than by forming an echar with the kali purum cum calce vivi. The separation of an echar, or its detachment from the living parts, is a work of nature, being chiefly effected by the action of the absorbent vessels, which remove the particles of matter, connecting the dead and living parts together, so as to loosen the echar, and allow it to be taken away, without pain, bleeding, &c.

ESCHARA, in Natural History, the name of a species of coraline, &c. the characters of which are these: they are of a lrony or coral-like hardnes, and resemble a woven cloth in their texture; and the microscope shews us that they consist of arrangements of very small cells, whose surfaces appear much in that form. (See Millepola.) For other species, see Plaster and Madrepora.

ESخار, a word used by the old writers in Medicina, to express a coarse kind of barley-meal, which had been torrid over the fire.

ESCHAROTICS, in Surgery, are certain substances and applications which, when put on any part of the body, occasion an echar, or slough. Although the strict meaning of the word echarotic is the same as that of cautic, yet, modern practitioners usually understand by the first term some application that is milder in its action, than such substances as are denominated caudicis. By the latter, a fur-on generally means the kali purum, with or without quicklime, or the argentum nitratum, ammonium muriaticum, &c. But by echarotics he commonly implies applications like the cuprum viridolatum, hydrargyrus pereptitatus ruber, &c.

The chief use of echarotics, in the practice of surgery, is to destroy excrecences, fungusses, and high exuberant granulations. When mixed with ointment, so as to have their action weakened, they are also sometimes employed for stimulating fowes, which are of an indolent nature.

ESCHARATON, in Medicine, the difference between the diesis eunharmonica and the hyperboles; that is, what remains, after taking the difference between the semi-tone minor and diesis eunharmonica, from the latter. Hendlings, in Med. Persoln, vol. 1, p. 279, 280.

Thus the difference between the semi-tone minor and the eunharmonic diesis is

\[
25 \div 125 = \frac{3125}{5072}
\]

from.
from the disaster, is 128 \[ \frac{3125}{125} = 393216 \] 0.64 \[ \frac{390625}{393216} \] and is the major residual; which fee. This interval is about the ratio of a comma, as will easily appear by logarithms. Mr. 100

Henning has taken notice of this interval. He calls it

echellon, from its being the leaf and the last interval that occurs in his fyltem.

The word is Greek, ἔσχατος. See Interval.

Echéaton of Dr. Callot's MSS., is an interval whose ratio is \[ \frac{16677181.1}{5 \pm 2} \] and is the greater residual, which fee.

ESCHE, in Geography, a town of Switzerland, in the canton of Uri; eight miles S.E. of Altorf.

Echéation, Echéat, or Echelon, formed from the French esclair, or éclair, to happen. In Law, denotes an omission of the course of defendant, and a consequent determination of the tenure, by some unforeseen contingency; in which case the land naturally refits back, by a kind of reversion, to the original grantor or lord of the fee. (1 Feud. 86. Co. Litt. 13.) This was one of the fruits and consequences of feudal tenure: and is incident to tenure in socage, as well as tenure in knight-service; except only in gavel kind lands, which are subject to no echelons for fealty, though they are to echelons for want of heirs.

The civilians call such echelons, or forfeitures, bona caduta; and in the same sense, as we say the fee is echelated, they say secadum operatur.

The word echelata sometimes also signifies a lawful inheritance depending on the heir. But then it is usually distinguished by the addition of rettæ; as retta echelata.

Echéat is also used for the place or circuit within which the king, or other lord, hath echelons of his tenants.

Echéat is also sometimes used for a writ, by which the tenant having elate of fee-simple, in any lands or tenements holden of a superior lord, dies feised without heir, general or special; in which case the lord brings this writ against him that poiffes the lands, after the death of his tenant; and thereby recovers the same in lieu of his services.

Echéator, an officer who anciently took care of the king's echelons in the county, and certified them into the exchequer, or chambery.

He was appointed by the lord treasurer; held his office only for one year; nor could any person be echetour above once in three years. But this office, having its chief dependence on the court of wards, is now out of date.

Echéfeld, in Geography, a small town of Saxony, near Woflitz, in the circle of Leipzigz, remarkable for its quarries of beautiful jasper, known by the name of Bandstein von Gnandstein.

Echéel, in Mineralogy, a term used by the small-workers, to express a sort of grey sublinate resembling ashes, which is usually mixed with the smalt when in fusion. This is carefully separated from it before it is powdered for use, otherwise it would debase the colour. Phil. Trans. N° 396.

Echéallon, or Echéllon, in the military acceptance, is a term borrowed from the French language, in which it signifies a ladder; alluding to the regular and parallel gradations of any series of lines, more or less inclined on any given base line. Thus if we suppose in fig. 1. Plate 1. Taxis, the line A B to be divided into any given number of equal parts, as 1, 2, 3, 4, 5, 6, and suppose the left end of each division to be moveable on a pivot, the other end swinging round at pleasure, we shall find that those several divisions are capable of being moved forward, at the assumed angles from the base line A B.

Now it is necessary to be well understand, that, according to the military flep, the number of files from any given pivot will determine the number of places to be taken to make a wheel, corresponding with a right angle; thus, when the 8th file from the pivot makes eight places in wheeling, the whole of the division performing such evolution will make a wheel equal to the quarter of a circle, because all distances from the centre will invariably corespond with the quarter of a circle, of which such distances are respectively radius.

But the echelon movements are never understood to amount to the quarter of a circle; that being considered a full wheel, changing from line into column; yet the echelon is itself a species of column, disposfable with equal promptitude either to flank or front; thus affording peculiar advantage, while it gives a at the same time a parallel movement of a line, broken for the moment, into small portions, towards any object obliquely situated towards either flank; in front or rear. These important advantages have not been overlooked by modern tacticians, who have amply availed themselves of the mutability thus afforded; consequently we find the echelon adopted in the existing code of evolutions, on an unlimited scale.

It being ascertained that the eighth file, by moving forwards eight places in a regular curve on the given pivot, makes a wheel of one quarter of a circle; it is obvious, that any intermediate part, of which one pace is the multiple, may be wheeled, by taking the specified number of places; thus, four places will make an octave, or the eighth part of a circle, which is the most frequent declination from the base line; two places will give the sixteenth of a circle, or the fourth part of a quadrant; and thus of any number.

Let us suppose it requisite to change the front of a battalion to a new position, forming, as nearly as the eye could estimate, an angle of 75° from the base line A B. Now, as each flep of the eighth file gives a change of front equal to about eleven degrees, it is obvious, that seven ordinary paces will rather exceed the given angle; therefore, if very great precision should be indispensable, the eighth file should make six long, and one short pace, which would throw the whole battalion into echelon at such an angle as would allow the several divisions to march with a full front to their positions in the new line. This is a most important object; because it admits the utmost freedom of individual movement, and avoids that oblique tendency which must be reported to whenever such full frontage cannot be preferred.

Echéallon may be formed towards either flank; whether to the rear or to the front; the open column may be readily formed by wheeling so as to complete the quarter of a circle, including the original portion, and adding it to the supplement; both wheels being in the same direction. Thus if only the eighth of a circle was wheeled into echelon, another wheel, of another eighth, will be needful to bring the corps into open column.

To form the line from echelon; either a back wheel may be made equal to the wheel forward; thus, if a battalion has broken into echelon by wheeling an octave to the right, it will, by wheeling back an octave on the right of divisions, be instantly formed into line. In this instance the right flank gives the point d'appui. But if the left is to give it, there the whole of the divisons must wheel forward on their left pivots, as many degrees as were included in the original wheel to the right. If the first wheel was only the 10th
16th part of a circle to the right, the complementary wheel to the left must be equal to only one sixteenth. In saying this, it is necessary to understand, that all the divisions are supposed to be of equal strength; otherwise it will be indispensably necessary that the respective pivots, which are to guide: the alignment, be properly drest; that is, cover, currently, before any wheel is made under their guidance.

Echelon divisions do not always move with a full front towards that point on which the wheel is made; on the contrary, it is often expedient to wheel to the right, when the new front is towards the left. This is done for the purpose of giving the flanks of the divisions a proper direction, that they may respectively march by files, towards their flations in the new line; and is particularly necessary in broken ground, as well as in countries covered with wood. The several leaders of files must, in this case, be extremely correct in maintaining their original direction; attending to their several pivot-men, if such be in fight: where that guide cannot be afforded, the greatest care must be taken to observe any two distant objects that may be in the given direction; so as to proceed, as nearly as possible, to the appointed spot.

From the foregoing it will be collected, that, while direct changes of front are made by full wheels (i.e. the quarter of a circle,) to either right or left, oblique changes are effected by means of a due degree of parallelism, produced in conformance of wheeling in any proportion less than the quarter of a circle. Therefore, as the code of regulations now in use for the movements of battalions properly inculcates, the echelon position and movements are not only necessary and applicable to the immediate attacks and retreats of great bodies; but also to the previous oblique or direct changes of situation, which a battalion, or a more considerable corps, already formed in line, may be compelled to make, to the front or the rear, or on a particular fixed division of the line.

When a battalion marches in echelon its route must be on the reverse principles of Marey's parallel rule, which consists of a scale, having a triangular piece sliding at liberty along its edge, as shown in Fig. 2. In that the inclined plane A B even follows a line not perpendicular to its front, and this is the main distinction between the echelon movement and the oblique-step; the former may continue for any distance, rather giving cay, than proving unsually fatiguing, to the men; whereas the oblique-step is peculiarly disagreeing, if kept up for a length of time; while it besides lessens the great disadvantage of gaining but little ground. In the above figure the line A B may proceed the whole length of C D, without gaining ground towards its opposite, or exterior flank B; because it is, in a manner, fixed by the inner flank A, which may be said to run in a groove on the line B C; whereas if we applied the echelon movement to the line A B, that is perpendicular to its own front, its course would be according to A E B F, and ground would be gained to its right, as well as to its front, in exact proportion to the angle D A B; if that be small, there will be a greater tendency to the front of the line C D, than towards its left flank, and vice versa; ever carrying in mind, that so soon as the wheel amounts to a quarter of a circle, the term echelon is annulled.

We shall here exhibit the use of an echelon movement as applicable to the reinforcing of a line advancing at the debouchure of a detroit; where, in consequence of the regular expansion, it becomes necessary to keep adding to either, or perhaps to both flanks, in order to prevent the enemy from penetrating; so as to attack the rear. It may be expedient to observe that not only companies, but whole battalions, may form in echelon; and that it is an evolution suited equally to cavalry and to infantry. When a park of artillery has to flank an enemy, in a position where the proper line cannot be assumed, so as to bring the several guns to a line perpendicular to the direction of their fire, they must then, properly speaking, be individually in echelon. Thus when guns are mounted in barbet, (i.e. where there are no embrasures, the muzzles traversing over the parapet,) whenever the object does not bear at right angles with the face of the battery, each gun is obliqued, and the shots fired from the whole would represent the movements of divisons thrown into echelon. Fig. 3. shews a line forming as the army issues from a detroit, the several battalions confining it being allowed to reinforce the centre until due space be gained for the whole to wheel into echelon. Now it will be seen, that each battalion formed in column, in by files, successively assumes a position perpendicular to that line; but, that when space admits, the wheel is made, whereby each division is directed towards the pot it will occupy on the flank, as the expansion takes place. Here S S is the line, and O P the battalion directed to cover the right flank; its several divisions, being thrown into echelon, must in their progress fall into its respective polls, at the new position a a one after the other, filling up the augmenting space with celerity and exactness. It is, however, to be understood, that each, as it approaches its station in line, must accelerate or retard its pace according to circumstances; since it cannot be expected that the ground will expand with perfect regularity.

In case of an attack, in which the enemy may succeed in getting round the flank, those divisions close to that flank must wheel back into line; leaving to two or three of the rear divisions to join on their flank in the direction of the echelon front; thus forming a re-entering angle, effectually cutting off the enemy's progress, and subjecling him to a concentrated fire; as shewn by the dotted positions at E. The dotted lines emanating from the several echelons shew their direction when marching; their prolongation would shew how they would fall in on the flank, so as gradually to extend the front; completing the new line a a. When necessary, the same operation is performed towards the left.

It has been observed that the eighth file gives a determinate measurement, in regard to the wheel of divisions into echelon; it is therefore expedient, when the ground is hilly, to cause the eighth file to step out the required distance, (say four paces for the eighth of a circle,) observing, that his advance must be on a wheeling principle: that is to say, curved; the pivot being considered as the centre, and the distance between that and the eighth file being radius. Each division thus sending forth its eighth file, the whole are ordered to wheel until those files are reduced to their places in their divisions: during the wheel of the divisions, each must necessarily remain motionless; that all may drefs by them, so as to give a true parallel throughout the line of echelon.

ESCHENAU, in Geography, a town of Germany, in the archduchy of Austria; eight miles S. of St. Poilten.

ESCHENBACH, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles N. E. of Nuernberg.

ESCHENBERGA, a small town of Germany, in the duchy of Saxe Gotha, with a population of 504 inhabitants, remarkable for its trade in madder. It was anciently of more importance.

ESCHERSHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg; 10 miles.
It is chiefly used in a figurative sense, for explanation of an obscurity or difficulty. The eclaircissement of difficult passages in the Bible, is to be sought for from similar passages, or in the like kind occurring in other places.

ESCAME, in the Mange, an obsolete French word, formerly used to signify a light-bellied horse.

ESCLATTE, in heraldry, is applied to a thing violently broken. Thus a bend or rather partition, escatat, is represented torn, or broken off, like a shield shattered with the stroke of a battle-axe.

ESCOBAR, Anthony, surnamed De Mendiza, in Biography, a Spanish Judkin, who flourished in the beginning and middle of the fourteenth century. The opinions which he maintained have been censured by modern writers; and the principles of his morality have been exposed by Pascal in his "Lettres Provinciales," and by other authors of less note. He left behind him many works, among which are "Theologin Moralis," "Commentaria in Vetus et Novum Testamentum," and "Examen y Pratica de Confessores," of Merori.

ESCOL, in Ancient Geography, a valley or torrent of Palestine, in the southern part of the tribe of Judah; mentioned in the book of Numbers.

ESCORT, in Military Affairs, signifies that guard granted, either under military authority, or of military persons, for the safe conveyance of persons, property, &c. from one place to another. This may be said to distinguish an escort from a convey; the latter being generally applicable to land extensive affairs as relate rather to the guarding of supplies, &c. on their way to an army, or to a fortress. The extent of an escort is usually proportioned either to the dignity of the person attended, if it be meant as a compliment; or, if of treasure, according to the sum, and the dangers lying in the way. In some cases, escorts are taken only from particular corps; as, for instance, those which attend upon his majesty, which are selected from certain regiments only, unless on extraordinary occasions. When an escort is employed on such an occasion, its commander is usually placed under the orders of the person to be guarded; but when treasure, prisoners, &c. are in question, the commander is in every respect paramount; he being responsible for the safety of the guards, and the delivery, of whatever is under his charge. Such is the custom with which the responsibility of an escort is upheld, that a few years back, when a defterer who was under charge of a guard made an attempt to abscond, one of the party fired at him, but unhappily missed the fugitive, killed an unfortunate passenger in the same street; the man who fired was considered to have done no more than his duty. We naturally view such an occurrence with much concern, and commiserate the sufferer; but when we consider what might have been the situation of the defterer, had he omitted to do his best towards preventing the escape, though we cannot exactly applaud his conduct, we must sufficiently see much in extenuation of the manslaughter.

When travelling any distance, and that speed is essential, it is usual to relieve the escort, when convenient, at certain stages. In such case, it behoves the commander of each party to be very careful in examining every matter previous to taking charge. If there be treasure, or other values, &c. under seal, the impressions should be minutely inspected; and if the articles, or packages, be numerous, but more especially if subject to damage, he should cause the whole to be counted, and alculated, in the presence of the persons from whom he receives them, the exact state and appearance, noting every point worthy of observation in the way.
bill, and exclusively giving a receipt, in which all casualties or deficiencies should be fully described. This inspection should always be made in the presence of others of his own party, and it would not be amiss were he to cause them to attend the condition in which the articles should be, at the time of his receiving charge. Should any accident take place while under his own protection, the hour, the place, and the cause, ought to be in like manner noted, so long as possible, until he certifies of credible persons the fact; or at least some of his own party. By such precautions much imputation will be avoided; while at the same time a character for correctness, and for fidelity, will be gained.

ESCFI, in Geography, a small town of France, in the department of the Lower Pyrenees; 6 miles S. of Oloron, remarkable for a cooling mineral spring.

ESCUADE, or SCUAN, is usually the third or fourth part of a company of foot; so divided for mounting guards, and for the more convenient relieving of one another. It is equivalent to a brigade of a troop of horse. See Brigade.

ESCROL, or SCROLL, in Heraldry, a long slip, as it were, of parchment, or paper, wherein a motto is placed.

Leigh observes, that no person, under the degree of a knight, might, long after King Henry V. place his credit on a wreath, as is now usually done, but only on an eperon.

ESCROW, in Law, a deed delivered to a third person, to be the deed of the party making it upon a future condition when such thing is performed; and then it is to be delivered to the party to whom made. It is to be delivered to a stranger, mentioning the condition; and has relation to the first delivery. 2 Roll. Abr. 25, 26. 1 Inst. 31. See Deed.

ESCU, or EUÇU, the French crown, of fifty sols, or three livres. The escu was called, because the escutcheon, or arms of France, which they call escu, is struck thereon. See Coin.

ESCU, Emans de P. See Emaux.

ESCUAGE, or Scutage, an ancient kind of knight's service, called also "service of the shield," the tenant holding by which was obliged to follow his lord to the Scotch or Welsh wars, at his own expense. But personal attendance being inconvenient, the tenants compounced for it by a pecuniary satisfaction, which was levied by assessments at a certain rate for every knight's fee; and thus it became a pecuniary lien in lieu of a military service. The first instance that occurs was in 5 Hen. II. on account of his expedition to Toulouse; it afterwards became more general and oppressive; so that King John was obliged to content, by his Magna Charta, that no scutage should be imposed without consent of parliament; but the clause was omitted in the charter of Hen. III., which directs, that it should be taken as it is used to be in the time of Henry II. or in a reasonable and moderate manner. However, it was afterwards enacted by 25 Edw. I. cap. 5 and 6, and many subsequent statutes, that the king should take no aids or tasks but by the common assay of the realm; and it appears that scutages were the ground work of all succeeding subsidies, and of the land-tax of later times. Blackl. Com. vol. ii. p. 74.

ESCUAGE was also a reasonable aid, demanded by the lord of his tenants, who held of him by knight's service. See Aid.

ESCUAPIUS. See ESCULAPIUS.

ESCUENT, in Gardening, is a term frequently applied to such roots or plants as are replete with nutritious matter, and consequently proper for being eaten as a food. Carrots, parsnips, turnips, raddishes, and various others of a similar nature, are of this kind.

ESCLUS, in Botany, a name given by many authors to the plagues, or sweet oak, called also the eculent oak.

ESCLUS, or ESCULUS. See ESCULUS.

ESCURA, in Geography, a province of the empire of Morocco, called by Leo Africanus Algor, which, together with that of Ramma, formerly composed only one government. It has been divided to keep the people of these countries, so near to the mountains, more easily in subjection. Ramma and Escura have the province of Morocco to the south, that of Dacquella to the west, the river Morobe to the north, and Mount Atlas to the east.

ESCURIAL, by the Spaniards written Escorial, a term that denotes the place of residence of the kings of Spain. Escorial originally signifies a little village in Spain, situated in the kingdom of New Castile, 22 miles to the N.W. of Madrid, on the side of a chain of mountains, called by some the Carpenate, or Carpathian mountains, and by others the Pyrenees, as being the branch of the Pyrenean ridge, and enibosed by woodlands and green fields. Here King Philip II. built a lofty monastery of the order of St. Jeron, held by the Spaniards for one of the wonders of the world, and called the Escorial. It was begun in 1563, and finished in about twenty-two years, at the expense of six millions of pittests.

Fa. Francisco de los Padres, in a description thereof, intitled "Description breve del Monasterio de S. Lorenzo el real del Escorial, &c." assures us it was built by that prince in memory of the battle of St. Quintin, gained on the day of St. Laurence, Lorenzo, a famous Spanish saint, and at his intercession; accordingly the plan of the work resembles a gridiron, the instrument of the saint's martyrdom.

The king and queen have their apartments there; the refit being polished by the monks. Whence many of the grand transactions of that court are dated from the Escorial.

This superb palace is a long square, 740 by 580 Spanish feet, behind 460 for what may be termed the handle of the gridiron. The height of the roof is 60 feet; and at every angle is a square tower, 200 feet high. In the west front there are 200 windows, and 356 in the east.

The Escorial has a very fine church, the dome of which is 330 feet, supported by four rows of pillars, and paved with black marble, containing 40 chapels, and 48 altars. To this church Philip IV. annexed a beautiful mausoleum, called the Pantheon, or Rotonde, built on the plan of that temple at Rome, 36 feet in diameter, and incrusted with marble; in which the kings and queens of Spain, who leave any politeness, are interred; the refit being laid in another vault of the same church, together with the infants, and other princes.

The palace possesses every convenience and ornament that can render a place agreeable in so hot a climate; such as an extensive park, groves, fountains, cascades, grottos, &c. The adjacent country contains specimens of all the mineral substances, flowers, earths and vegetables, which are found in other parts of the kingdom. The library belonging to this palace is said to consist of 30,000 volumes, contained in two magnificent apartments, each 19 Spanish, or somewhat more than 82 English feet in length. In the lower room are chiefly printed books; and in this is deposited the
famous MS. of the four gospels, written in gold letters, said to be a work of the 11th century. Over these are collected 4500 MSS., of which 567 are Greek, 67 Hebrew, 1800 Arabic, the latter of which are well described in a catalogue published by Caiiri. In the middle of the lower room is a temple, with a great variety of figures, containing 1443 ounces of silver, and 43 of gold, besides rich gems. In every part of the convent of the Escorial, are seen the works of the best masters, and of them most capital performances. The bell of the pictures are collected in five principal apartments; the great saloon is beautiful, adorned with fresco-paintings of the battle of St. Quintin, by Luca Jordan. The situation of the Escorial, as a residence, is not pleasant; exposed, as it is, to the full broke of the meridian sun, and raised up near to regions covered with eternal snow; without shelter and delinitte of shade, it has no local charms at any season of the year. (Townsend's Travels, vol. 2.) Part of this superb palace was burnt in 1671.

Escrolles, in Geography, a small town of France, in the department of the Alber, chief-place of a canton, in the district of Gannat, with a population of 1042 individuals. It is 6 miles N. of Gannat. The canton contains 15 communes, and 11,468 inhabitants, on a territorial extent of 2372 Kilometres.

Escutcheon, or Scutcheon, in Heraldry, the field or coat, wherein the bearing, or arms, of any person are represented.

The word escutcheon is formed of the French escuison, and that from the Latin scutum, shield; which was the plain arms were originally borne on, before they came on banners; and still, wherever they are placed, it is on something representing the form of a shield. The Latin scutum, no doubt, came originally from the Greek, savy, lather, wherewith the shields were usually covered. See Shield.

The escutcheon is a square figure, excepting the bottom part, which is usually a little rounded, ending in a point in the middle.

Till within a few hundred years, the escutcheons of the French and English were triangular; those of the Spaniards are still quite round at bottom, without any point; those of the Italians are oval; and those of the Germans in form of a catoosse.

The ancient escutcheons were generally crouched, or inclined; and they only began to place them upright, when crowns, &c. were put over them by way of crest.

In France escuison, escutcheon, was formerly confined to a shield, or coat, pointed at bottom; by which it was distinguished from the escu, which was quite square, and was only allowed to be borne by the counts and viscounts. Tho' of the inferior quality were confined to the escuison or pointed escu.

The several parts or points of the escutcheon have their proper names: A, the point of the escutcheon, or the dexter chief point; B, the middle chief; and C, the sinister chief point; D, the honour point; E, the fesse point; F, the bend point; G, the dexter base; H, the middle; J, the sinister base point. See Plate of Heraldry.

The dexter side of the escutcheon answers to the left hand, and the sinister side to the right hand of the person that looks on it.

The escutcheon is differently denominated, according to its divisions. It is called dexter, when the perpendicular line that divides it is to the right of a third part of the escutcheon; sinister, when on the left; tierced in pale, when this line is double, and divides the whole escutcheon into three equal parts; paled, when increased to the number of six, eight, or ten. A horizontal line makes the chief, when at one third part from the top; the plain, when at a third from the bottom; and when double, in the middle at an equal distance from both extremities, it makes the fesse, and the pierced in fesse; when it is multiplied, it denominates it felled; when there are eight or ten equal spaces barbrel. A diagonal from the dexter point of the chief to the sinister point of the base, makes it tranchée; the contrary double; if it be double at equal distances the chief makes bendé, and the pierced in bendé; the other barre, or tierce in barre; increasing the number of the bars makes bendée, and cöttée; and increasing that of the second barre, and traverse.

Escutcheon of pretences, is an inescutcheon, or little escutcheon, which a man who has married an heiress, and has issue by her, may bear over his own coat of arms, and in it the arms of his wife; and, in this case, the surviving issue will bear both coats quarterly.

Escutcheon, in Sea Language, a name sometimes given to the compartment for the names or arms of the owners, or of the person whole title the vessel affirms. It is usually fixed on the middle of the ship's stern; and is more peculiar to the French, and other foreigners, than to English-built vessels. Falconer.

Escutcheon, Secret, is a contrivance to be placed before a lock, which closes up, and conceals the key-hole, and renders it inaccessible for any person except the owner, who is acquainted with the secret.

The marquis of Wexfber appears to have invented some secret escutcheons, for in his "Century of Inventions," published in 1663, at N° 72, after having spoken of three kinds of locks invented by him, says, an escutcheon to be placed before any of these locks with these properties: "The owner, though a woman, may with her delicate hand vary the ways of coming to open the lock ten million times beyond the knowledge of the Smith that made it, or of me who invented it." Many attempts have been made to form a machine equal in its properties to the description here given; and from thence, it is probable, arose the kind of padlocks which have been long made in this country, in great numbers, which having several letters on different rings, can only be opened when a certain set of those letters is arranged in one order; but this was in no degree equal to the end proposed; for besides the workman who made it, being at all times informed of the position the letters must be in, and consequently enabled to open it, the letters and rings admitting of no variation of place, at the will of the owner; reverting, at the same time, a power of opening the locks whenever the proper arrangement became known, the secret was divulged, and all security at an end; but by the improvement lately made by Mr. Marsham (for which the Society of Arts rewarded him with ten guineas,) the letters or figures allowing an almost infinite variety of changes, the owner may, in one minute, alter the secret in such a manner, that even the maker would be as unlikely to open it, as he would be of gaining the highest prize in a lottery, by the chance of a single ticket. Thus this kind of escutcheon is infinitely more secure than any hitherto in use, especially as the alteration of the letters may be made every day for years, without recurring to their first state; and as the owner may at one time chuse to trust a friend, or a domestic with the secret, so that they might have recourse to his valuables, &c. he may also at another time with to exclude them from that privilege, which this contrivance renders very easy to be done. As this improvement relates only
to the escutcheon, it is obvious that every attempt to pick
the lock it covers, or to open it by means of false keys, is
prevented; a circumstance of no small importance, when
locks of a curious construction, and when a number of fine
wheels are made use of.

The escutcheon for which the bounty was given is re-
served in the repository of the society for the inspection of
the public.

Figs. 3, 8, 9, Plate XII. *Miscellany,* represent this contrivance: Fig. 3, is a view from behind the
machine, supposing it to be first removed from the door.
Fig. 2, is an elevation of the machine, as it appears upon the
door; A B C D is a brass box, fastened over the key hole;
it has a square hole through it, covered by a small door E;
this door is kept shut by a pin fixed into a small lever a,
fixed in the axis of the machine, which enters a projection from
the side of the door, and thus prevents it being open, unless
the lever is first drawn back; a spring b is applied behind the lever to force
it outward, and another at E always presses against the door,
and acts to throw it open as soon as the lever a is drawn
back, which is accomplished by means of a pin, which
comes through a groove in the plate; this pin is fastened in a
square bar F, figs. 2 and 5, (shown separately in fig. 4.)
on the front of the plate. The small perspective, fig. 8,
represents two brass cocks d, d, which support the ends of a
cylindrical wire g, in which is a groove for the bar F
to slide backwards and forwards; these cocks are screwed to the
plate within, as shown at d d, figs. 2, 3, and 5, and
come through an opening in the plate; so that the bar F
is in front of the plate; the wire g is the common axis for
five small rollers a, a, s, m, o, the structure of one of these is explained by figs. 5, 6, 7, and 9; b is a circular piece
of brass which fits upon the centric wire g; this, as is known
in the feelings, figs. 5 and 9, is thicker at the outside than the
middle; and the front view, figs. 6, 7, shew how a recess
is cut in the roller, making with the centric hole; now when the five
rollers are turned round upon the central wire g, so that
the recesses are all brought into the front, the projecting
teeth x, s, of the roller F will meet with no obstruction, and
may be drawn back so as to open the escutcheon; but when
any of the rollers are turned round, so that the thin
parts pass: the centre are brought between the teeth of the
roller, then the roller cannot be withdrawn. The position
of the roller, when the roller is at liberty, is known by
bearing five of the letters which are engraved on the out-
side of the rollers uppermost, and it is in these letters that
the secret confists. But to render the combination of let-
ters variable, the letters are not engraved upon the outside
of the rollers themselves, but upon a thin brass hoop e,
which is fitted on round the roller; a spring n is fastened to
the roller, and pressing upon the inside of the hoop caulis such a friction, that they go together in general; but when
the secret is to be changed, the roller F must be drawn
partly back, so that its teeth x come in the way of the thin
parts of the rollers, and they cannot, therefore, be turned
round; the roller must then be forced round upon the
inside one, and a fresh letter brought opposite the recess ;
by this operation the secret is altered, and the escutcheon
cannot be opened till the same combination is produced.
Each roller has four letters upon it, in all twenty letters, and
the combinations which they are capable of are so numer-
ous, that the chance is strongly against any person not ac-
quainted with the secret opening it.

**ESCUTCHEON-grafting. See GRAFTING.**

**ESDEN,** in Geography, a town of Germany, in the king-

**ESDRAS,** or ESDRELA, in Ancient Geography, a village of Palestine, in the tribe of Issachar, the same as
Jezreel, 10 miles from Selinthus, according to the old
Itinerary. (John xix. 18.) It gave name to a plain, which
extended east and west from Selinthus to Mount Carmel;
like likewise the "Great Plain," the "Valley of Jezreel,"
and the "Plain of Esdreles."

**ESDRAS,** See Ezra. We have four books of scripture
under the name of Esdra; of which, only the two
first are acknowledged as canonical; and they were formerly
reckoned by the Hebrews as one, according to St. Jerome.
The first of these is allowed to be the work of Ezra; for
he relates events of which he was witness, and often speaks
in the first person. Some, however, have supposed that
the first chapters were composed by a more ancient writer;
and they allege, that the author of these chapters was
at Jerusalem in the time of Darius the son of Hytafes.
(Ch. v. 4.) From this passage it is inferred that the writer
was then at Jerusalem; but Ezra did not come thither till
the reign of Artaxerxes, as appears by the beginning of the
7th chapter. To this argument it is replied, that Ezra
speaks in the name of the Jews, and that it is usual for his-
torians of a country to speak in the first person in the name
of their own nation, although the historians themselves had
no participation in the events which they record. Another
difficulty occurs in explaining the genealogy and number of
those who returned from Babylon to Jerusalem under Ne-
emiah, mentioned in the second chapter, and related in the
same manner, though with some additions and alterations in
the 9th chapter of Nehemiah. Some suppose that Ne-
emiah transferred this out of the book of Ezra, adding the
names of those persons who came to Jerusalem in the se-
cond return from the captivity. Others, on the contrary,
advocate that Ezra copied the passage from Nehemiah, since
mention is made in it of Nehemiah. Others pretend that
the genealogy of Ezra was afterwards corrected from that
of Nehemiah. However, none of these conjectures are re-
concilable with the differences that occur in the two gene-
alogies. But after all, there is no necessity for supposing
that one of these authors transcribed from the other, for
they might both of them have written these genealogies:
Ezra having survived the second transmigration made un-
der Nehemiah, and not having written his book till the lat-
er end of his life. The second book under the name of
Ezra, is attributed to Nehemiah; though some incompre-
ensible particulars have been added to it, which cannot belong
to Nehemiah; such as the mention of the high-priest Jau-
dua, and king Darius. (Neh. xii. 22.) This Jadnea is Jad-
dus, in whose time Alexander the Great came to Jerusalem;
and Darius is Darius Codomannus, over one hundred years
after Nehemiah. The first of these two books contains the
history of the deliverance of the Jews from the
captivity of Babylon, and of their re-settlement in Judea,
from the first year of Cyrus to the 20th of Artaxerxes
Longimannus; and the second begins at the 20th year of the
former, to the reign of Darius Nothus. The chrono-
logy of this space of time depends on the duration of the
reigns of the kings of Persia.

The third book, under the name of Edras, is thought by
the Greeks to be canonical. Its author is not known,
but he is supposed to have been a Hellenist Jew. The book is
the same as the former of Edras, but interpolated;
and in different parts of it we have a summary repetition of
the two last chapters of the second book of Chronicles, as
well as of the books of Ezra and Nehemiah. Against its au-
thority there are several material objections, for which we refer
to Arnold's excellent commentary in the Apocrypha, p. 122.
The fourth book of Estdas is written with sufficient art, as if Estdas himself had composed it; but the marks of falsehood are discernible in it. Neither the Synagogues, nor the Greek or Latin church ever unanimously received it as canonical; though some of the fathers have cited it, and the Latin church has borrowed some words out of it. It is not now extant in Greek; and it never was in Hebrew. It seems most probable that the author was a Jew, converted to Christianity, who, in hopes of converting others, composed this work under the name of a writer, for whom the Jews had the highest esteem. And there seems good reason for concluding that the author lived in the times of the first heathen perfections, from many passages encouraging faith, and a spirit of constancy under perfections.

ESEBON, a name given, by some of the chemical writers, to common sea salt.

ESENS, in Geography, a town of Germany, in the kingdom of Westphalia, and county of East Friseland; 24 miles N.N.E. of Emden.

ESFARAIN, a town of Perlia, in the province of Chorasan; 80 miles E. of Herat.

ESGUEDA, a river of Spain, which runs into the Duero, at Valladolid.

ESGREIRA, or ESQUERIA, a town of Portugal, in the province of Beira, containing about 1600 inhabitants; 8 miles S. of Aveiro.

L.KH, in Rural Economy, a term provincially used to denote the ash-tree.

ESHANESS, in Geography, a cape on the west coast of Mainland, the largest of the Shetland islands. N. lat. 60° 38'. Long. 1° 7'. E. of Edinburgh.

ESCHOL. See Escol.

ESHTAOL, in Ancient Geography, a town of Palestine, in the tribe of Dan, which belonged first to Judah. According to Eusebius it was 10 miles distant from Eleutheropolis, towards Nicopolis.

ESHTEMOTH, a city in the south of Judah, which, according to Eusebius, was a large town in the district of Eleutheropolis, north of that city. It was ceded to the Franks. 1 Chron. vi. 57.

EST, in Geography, a town of Italy, in the state of the church, and marquisate of Ancona; 11 miles S.S. W. of Ancona.

ESK, South and North, rivers of Scotland, which descend from the Benakinian mountains on the north border of Angus. The former runs S.E. and E. by Corthachie, Tamadys, Brechin, and falls into the German ocean below Montrose, to which town it is navigable from the tide-way in the German ocean. (See Canal.) The direction of the latter is E. and S.E. through a narrow valley, till it reaches the strath lying between the Grampians and the sea. In the lower part of its course it forms the common boundary of Angus and Kinardie.

ESK, a river in Cumberland, which is navigable from the Solway forth up to the town of Longton.

ESKARAKRUN, a town of Perlia, in the province of Chorasan; 90 miles S. of Sufa.

ESKE, a river in the East Riding of Yorkshire, which is navigable only from the sea up to Whitby-bridge. See Canal.

ESKE, a river in Cumberland, which is navigable from the sea near Ravenglass to Mulefater. Near to Ravenglass it is joined by the Ir river.

ESKER, a river of European Turkey, which runs into the Danube; 20 miles W. of Nicopoli.

ESKI-BABA, a town of European Turkey, in Romania; 30 miles S.E. of Adrianople.

ESKIER, a town of Arabia, in the country of Yemen; 60 miles N. of Aden.

ESKIJALFA, a town of Persian Armenia, in the country of Erivan; 120 miles S. E. of Erivan.

ESKI-HISAR, a town of Asiatic Turkey, in the province of Natolia; 16 miles W. of Mogla.

ESKI-HISSAR, a town of Asiatic Turkey, in the province of Natolia, formerly Leadica, now almost a heap of ruins; 8 miles N. of Dezgizlu.

ESKIMAUX, or ESKIMAUX. See Eskimaux of Labrador.

ESKIMAUX BAY, a bay on the south-coast of Labrador. N. lat. 51° 30'. W. long. 57° 53'.

ESKIMAUX ISLANDS, a cluster of small islands in the gulf of St. Lawrence, near the south-coast of Labrador. N. lat. 52° 15'. W. long. 63°.

ESKISADRA, a town of European Turkey, in the province of Romania; 48 miles E. of Filippopolis.

ESKISHEHR, a town of Asiatic Turkey, in the province of Natolia, on the river Sakhrania; 116 miles S.E. of Constantinople. N. lat. 39° 48'. E. long. 32° 58'.

ESLA, a river of Spain, which runs into the Duero, between Zamora and Miranda de Duero.

ESLINGEN, a town of Germany, in the circle of Suabia, which, till the peace of Luneville, was a free imperial city. It now belongs to the king of Wurttemberg, and is situated on the Neckar, 30 miles N.E. of Tubingen, and 6 miles S. E. of Stuttgart.

ESMONA, or AZEMONA, in Ancient Geography, a town of Arabia Petra, which was one of the stations of the Israelites in the Desert. The book of Joshua ascribes it to the tribe of Juda, so that it is probably the same with Ezem.

ESMOUTIER, in Geography, a small town of France, in the department of the Upper Vienne; 21 miles E. of Limoges.

ESNA, in Ancient Geography, a town of Palestine, in the tribe of Juda. Josh. ch. 15.

ESNECY, Ezechias, dignitas primogenita, in Latau, a private prerogative, allowed to the eldest coparriene, where an estate has descended to daughters for want of heirs male, to chuse first after the inheritance is divided. Peta, lib. v. cap. 10. "Jus ezechiae est jus primogenitum," in which sense it may be extended to the eldest son, and his issue, holding first. In the state of Marlbidge, cap. 9, it is called "initia pars hereditatis."

ESN, ESNI, or ASNIA, in Geography, one of the most important towns in Upper Egypt, seated on the left of the Nile, in N. lat. 27°. E. long. 49° 15'. This town is governed by an Arabian prince and by a Cachef, dependent on the Bey of Girgeh. The Mahometans have several mosques here, and the Copts a church, that is served by two priests. According to the description of Abulfeda, which corresponds in a great degree to its present state, Esn is remarkable for its public baths and its commerce; it is built on the westward of the Nile, between Aflouan and Cous, but nearer to the latter. The Copts are said to be its founders. The well-cultivated territory abounds in grain and palm-trees. Situated on the edge of a rich country it is shaded by groves of orange-trees loaded with fruits and flowers, and immediately surrounded with gardens amply stocked with fruit-trees. It presents to view several ancient monuments conspicuous from the Copts, and supereruics. This town, formerly called Lato- polis, revered Minerva and the fuit Latus. (Strabo, l. 17.) It contains within its boundary an antique temple, inclosed on three sides by thick walls. Six large fluted columns, crowned by a capital, ornamented with the palm leaf, form the façade of it; eighteen others support the roof; which is composed
emposed of large squares of marble; the building is surrounded by a frieze, and innumerable hieroglyphics cover its exterior aspects. Tho' of the minds, executed with greater care, mark the progress made by the Egyptians in sculpture. These hieroglyphics contain, among other subjects, a zodiac and large figures of men with crocodiles' heads; the capitals, though all different, have a very fine effect; and as an additional proof that the Egyptians borrowed nothing from other people, it is remarked, that they have taken all the ornaments, of which these capitals are composed, from the palaces of their own country, such as the lotus, the palm-tree, the vulture, the uff, &c. The portico of this temple is represented by M. Denon, (Travels in Egypt, vol. 2. and 3,) as the most perfect monument of ancient architecture. Denon has given a plan and elevation of this portico, and delineated the varieties of its capitals, and part of the sculptures on the cippus; but he was surprised that, after all his research, he could find no representation of the fish *latus,* from whose name the town was called *Lato-polis.* At present this temple is foiled by the ordure of the cattle kept there by the Turks, who convert the most beautiful monuments of ancient Egypt into stables. About a league to the west of Efnc is another temple, on the walls of which is carved in several places a woman seated, representing an Egyptian deity called "Neith," to whom the ancient Greeks gave the name of Minerva. The columns of this temple, as some have conjectured, gave to the Greeks the idea of the Corinthian order; the capitals being ornamented with a foliage very much resembling the Acanthus. Several animals painted on the cippus have prefered their colours. To the south of Efnc are seen the ruins of a monitory founded by St. Helena, and near it the burying place of the martyrs, adorned with tombs crowned by cupolas, supported by arcades. The inhabitants of Efnc having revolted against the persecution of Diocletian, this emperor destroyed the town, and put them to the sword. This place, consecrated by religion, is become a celebrated piligrimage among the Copts, who repair hither from the most distant provinces of the kingdom. In the chain of mountains, which stretches to the eastward of the Nile, and nearly opposite to Efnc, are quarries of a soft stone, called "Barim," which hardens in the fire, and is used in the manufacture of kitchen utensils. Savary's Letters, &c. vol. ii.

**Cochen, a turbecle within the auras.**

**Eopus. See Kingston.**

**Exoteric. See Exoteric.**

**Esoc in Ichthyolog, a genus of the abdominal kind, distinguished by the following essential particulars. The head flattened above; mouth and throat large; jaws toothed, unequal, the upper one flat, lower punctated; tongue broad, loose; palate smooth; eyes large, moderate size, and lateral; nostrils double, near the eyes; gill-covers large, aperture ample, with from seven to twelve rays; body elongated, covered with hard scales; above convex, and compressed at the sides; lateral line straight, near the back, and scarcely visible; dorsal and anal fin very short, and generally placed opposite.**

**Species.**

The pike is an inhabitant of most of the lakes of Europe, and the north of Asia, and also of many of the larger rivers in Lapland, Siberia, and countries adjacent. It grows to a considerable size, those of four or five feet in length not being uncommon in the northern regions, and sometimes even they attain to the length of eight feet or more. The pike is highly prolific, and from its extreme voracity as well as cunning, is called the wolf, or the fox of fishes; it subsists on fishes, on frogs, serpents, and other reptiles, and on the young of swans and other aquatic fowl, and is reputed fo undaunted in its attacks that it will even contend with the otter for its prey. This fish spawns in spring between the months of February and May. The colours vary in brightness; at different seasons; in general the upper part is olive green, the back nearly black, and the whole spotted with yellow, whitish, or orange, according to the health of the fish. The belly white, and the fins beautifully variegated with vivid colours and spots of blackish purple. The jaws contain a formidable armament of teeth disposed in longitudinal rows. The longevity of the pike is well known to be a great; but what credit ought to be repose in the afferances of some writers, that it lives to the age of two or three hundred years, must remain for others to determine. Their multiplication is immense; in the northern parts of Russia, and in Siberia, where they are taken in the greatest plenty, they constitute an article of commercial importance, being prepared by means of salting and drying, for exportation.

**Viridis.** Green; lower jaw longer, scales thin. Gmel.

This is regarded by Bosc as a variety only of the common pike, (Eox lucius,) the accuracy of which opinion appears rather uncertain, as we may perhaps be unacquainted with the species or fish intended by Gmelin; the reference of the latter author to the Acus maxima Iquamofa viridis for the same fish is suspect to be incorrect.

**Sphyrana.** Dorfai fins two, the first spinous. Linn. Arted. Sea pike or Spitschly, Charli.

There is some remote resemblance between this fish and the common pike, from which among other particulars it is distinguished by having the gill arches advanced, the body more slender, the tail furred, and the back furnished with two dorfal fins instead of one. The rays of the first dorfal fin are spinous, and are described both by Linnanua and Arvedi as five in number, but according to Bloch these amount to only four. The fish is bluish above, beneath white; the pectoral, ventral, and anal fins red. It grows to the length of two feet, and inhabits the Atlantic and American seas. The fish is in essem.

The Barrexaundu pike of Shaw's Gen. Zool. described after Catenby, appears very closely allied to the preceding, if it be not the same; the character "brown, elongated, whitish beneath, with two dorfal fins and forked tail," differs from that fish only in having the upper part brown instead of bluish. It is found in the West Indies, and grows to the length of eight or ten feet.

This agrees so nearly with the EOX sphyrana that we cannot suppress our suspicions of its being the same. The only authority on which it is described is a drawing by Plummer; this, indeed, represents a fish of somewhat more elongated form, in which the sides are marked with a series of blue spots not observable in the former. If it prove distinct it is certainly very analogous. It is described as a native of the American seas.

**Auroie-viridis.** Body golden-green, with two dorfal fins, a spine before the first; lower jaw longer. Sphyrana auroe-viridis, Cepede. Gold-green pike.

Described and figured by Cepede from the drawings, Plummer; the body is deep, as in the pike, the head sharp pointed,
pointed; scales middle sized; tail forked and lunate. The species inhabits the American seas.

**Vulpes.** Doral fin in the middle of the back; gill membrane three-rayed. Gmel. Vulpes bahamensis, Catesby. *Foe pike.*

Resembles the common pike, but is more slender in proportion towards the tail, the colour brown above, beneath paler. Native of Carolina and the West Indies.

**Symodus.** Doral fin in the middle of the back; gill membrane five-rayed. Gmel. Symodus, Catesby. Closely allied to the former, and inhabits the same seas, and according to Cepede the Mediterranean sea. The body is marked with dusky bands; abdomen silver; fins striped with black.

**Margineus.** Doral and anal fins opposite; lateral line silverly; lower jaw six times as long as the upper. Forsh. Fr. Arab.

This and the preceding are supposed to be the same. The latter is described by Forshkal as an inhabitant of the Red sea; its length about a span and a half; the body linear, tapering each side, and covered with broad spots; entire scales, the colour brown above, beneath white; the anal fin small, triangular, glaucous, and yellow without; dorsal yellow externally; tail bilobate, the upper lobe pale yellow, the posterior edge brown.

**Chilenis.** Head slender, lower jaw longer; eyes large and protuberant. Sphyraena chinesis, Cepede. Slightly described by Cepede from the manuscript of Commerson as a native of the Indian seas. The general colour is said to be green with a silver hue, and the scales of the middle size.

**Chilenis.** Jaws equal; lateral line blue. Molina. *Chili pike.*

Native of the Chilean seas. Length from two to three feet; body round, covered with bony angular deciduous scales, above golden, beneath silver; flesh white, and excellent.

It inhabits fresh waters of New Zealand and other islands of the southern ocean.

**Brasilium.** Lower jaw very long; body serpentine. Linnaeus. *Brazil pike.*

These are several figures of this fish in different authors, most of which are defective in one particular or other. Nieuhoff omits the anal and ventral fins, Valenty and Renard constitute two species of the same fish; and in other representations the dorsal fin is omitted. Linnaeus erroneously refers to the Timucu of the Brazilians as being synonomous; the fish so named by these people has both the jaws elongated, and ending in a point, and is supposed to be the species Belone. Gmelin adopts the same mistake. The length of this fish is from twelve to fifteen inches; the upper part of the body green, beneath yellow, and the back marked with about six broad and equidistant bands of fuscoce. The species inhabits the Brazil, and is esteemed a delicacy for the table.

**Gymnocephalus.** Jaws equal; gill-covers very oblique; head naked. Linnaeus. *Naked-headed pike.*

Native of India, according to Linnaeus, who speaks of it as being the size of the sand lance.

**Malabaricus.** Two canine teeth in each jaw; gill-membrane with five rays. Bloch.

Found in the rivers of Malabar. The length is about twelve inches; its form somewhat resembling that of the common pike. The colour above greenish-blue, beneath yellow; fins yellow; at the base purplish, and marked with several distinct bands of brown. The lower jaw is rather longer than the upper, and the tail is rounded.

**Chirocentrus.** Breast armed on each side by a spine over the ventral fin; lower jaw longer. Cepede.

Described from the manuscripts of Commerson. Its form resembles in some respects that of the common pike. The spine is said to be strong, and tightly curved; its length about two-thirds of that of the fin, of which it appears to be the first ray.

Length from eighteen inches to three or four feet, of a very slender and like form, with long projecting front, the back line green; belly silverly. It is a common species in all the European seas; migrating annually in large schools from the depths of the ocean to the shore. They appear on our coasts in the spring, commonly announcing the arrival of the mackerel, but remain with us for a much shorter period than that fish. They deposit their spawn close to the shore among the rocks and sea weeds, where the young are hatched, and after a certain time retire. We have seen the fry of this fish on our coasts during the summer months. As an article of food the garfish is held in far less estimation than the mackerel, to which it owes the same food, having many people the fish is considered unwholesome, and even poisons; arising, no doubt, from the flagellate circumstance of the bone becoming of a fine grafs green colour in boiling. This species grows to the length of eight feet. Domin. Brit. Fishes.

The obscurity that prevailed respecting this curious fish till within a very recent period, induced us to enter on the details of its general description with rather more than ordinary minuteness; the writer of this article has already treated at some length on the Efox saurus in his work on British fishes lately published, and conceives a repetition of the following observations submitted on that occasion may not prove altogether unacceptable.

Our countryman Ray appears to be the first writer who describes this rare and curious species of efox as native of Britain; he speaks of it as a Cornish fish, under the provincial name of skipper. Rondelius and Gefner previously mention it as a scarce kind among the fishes of the Mediterranean. In 1769 the same fish was again introduced to notice by Mr. Pennant in his tour of Scotland, and afterwards in his British Zoology, wherein we are informed, that vast numbers of them were thrown ashore on the sands of Leith near Edinburgh, after a great storm in November 1778. In the summer of 1800 a single specimen was taken near the isle of Portland, in Dorsetshire, after a hard storm; an account of which, accompanied with a figure of the fish in its natural size, is given by the Rev. Mr. Rackett, in the third volume of the Linncean Transactions. "This fish (Mr. Rackett observes) appears to be rare on the Dorset coast. Of the fishermen in this part, only one was acquainted with it, and called it a skipper, the name under which, according to Ray, it was known in his time on the coast of Cornwall. This writer adds that the species has not been noticed by Linnaeus, Gmelin, nor Bloch; and that Penn
nunt has given a very indifferent figure of it in his Tour in Scotland, and has made use of the same plate in his British Zoology." See Linn. Trans. 2, p. 92.

It is altogether singular that this fish has no place in either edition of the Linnean Systema, nor even that by Cuvier, it is imported by Dr. Turton in his translation on the authority of Pennant. The length of this species is about eighteen inches: the body of a long and slender form; not like that of an eel, as writers describe, but agreeing precisely with that of the common garfish (Efox belone). The fin is subulate, fine, toothed, and curving upwards. The jaws are of unequal length, the lower being longest, and bending upwards at the tip, in which respect it differs from the figures of Mr. Pennant and Mr. Rackett, in both which the jaws appear straight and of equal length. Neither do the jaws, when closed, exhibit that remarkable hiatus or gap seen in those two representations; there is a kind of flexuosity in the shape of the mouth, when open, which might excite such an idea, but upon closely closing it the curvature in the form of one jaw will be found to correspond with the future of the other; so that the character "maxillis medio labiatis," alluded to it, is by no means applicable. Dr. Shaw mentions the Gar, to prove that "in a specimen figured in the work of Cepede, the jaws are represented upwards, contrary to what has hitherto been observed; the specimens figured in the work of Mr. Pennant, as well as that of Rood-Letius, and the drawing by Mr. Rackett, have the jaws straight." This is certainly true, and it is therefore to be presumed that the examples from whence the figures of the latter mentioned writers have been taken must have sustained injury, or been misrepresented; for it is clear Cepede is right in representing the jaws curving upwards: it is indeed evident, from the comparative shortness of the jaws in the figure by Pennant and others, they could not be perfect, the back in the fish itself being nearly twice the length represented by either. Dr. Shaw has also been apparently misled to the perversion that the fin of this fish is reticulated by fine fins decussating each other at equal distances, which is not by any means the natural appearance of the fin, and the figure in the British Zoology is still more erroneous, as it appears entirely smooth, and deficient of scales.

Some misunderstanding seems to prevail likewise as to the colour of the fish. Mr. Pennant describes it as having the back dusky and the belly bright and silvery, in which particulars he is followed by Dr. Shaw, who remarks that the colour of the whole animal is dusky above, and silver beneath, with dusky or blueish brown back. This is not, however, correct, the true colour of the back of the fish is a most lovely azure blue, changeable to green, and glossed with purple and yellow, and the lower parts silvery.

The body has a smooth appearance, the scales with which it is covered being thin and glabrous: the lower part of the body from the gills to the tail is marked with a longitudinal carina or keel, which terminates at the latter part in a somewhat protuberant manner.

The species may be readily distinguished by the pinnules or spiny fins on the body near the tail, in which particular it agrees with the scoller or mackerel genus; these have been variously misrepresented; in the fin itself they amount altogether to twelve in number, five of which are disposed above and seven beneath; and it is also necessary to add that they are perfectly detached from each other. The fleck, in point of flavour, resembles that of the mackerel.

OCEANUS. Upper jaw longer; scales bony. Linn. Efox maxilla superiore cauda quadrata, Arted.

Native of North America and Asia, and has been found in Europe. (Donov. Brit. Fishes.) The species is from two to three feet in length, and is covered with thornlike scales.

CEPDEDIANUS. Sansot long, jaws spatulate; scales bony. Le pêseur long, spatulate, Cepeude. Efox cepedianus, Shaw.

The principal difference between the two last mentioned fishes seems to consist in the mouth being shorter in proportion in E. cepedianus than the other. There is likewise another pike of the same bony scale kind, which has the jaws rather shorter than either, and bears the name of Lowrians. We are not entirely satisfied that the three last mentioned differ specifically from each other.

No small degree of uncertainty seems to prevail throughout this tribe of fishes independently of those last adverted to; the species synodus, hepeterus, vulpes, and marginatus, appear to be imperfectly understood; barracuda, viridis, and becauna, are perhaps more doubtful, as are also chironurus, and chincus; and it will have been observed that the true characters of the species fansus were not till lately ascertained.

The viper-mouthed pike (Efox flavissimus), and vipers marina of Catheby, is distinguished by having four of the teeth much larger than the rest: this is a very extraordinary fish, and ought, in our opinion, to constitute a new genus.

ESPADACINTA, in Geography, a town of Portugal, in the province of Tras-os-Montes, situated on the Duero, and borders of Spain; 34 miles S.W. of Miranda de Duero, and 28 N. of Almeida.

ESPAGNAC, JOHN-BAPTIST-JOSEPH DE SAHUQUET-DAMARZIL, BARON D', in Biography, a military writer, was born in the year 1713 at Brive la-Gaillarde. At the age of nineteen he entered the army, and became celebrated for great skill and prowess. In 1742 he was aide-de-camp in the war of Bavaria, and was afterwards employed by marshall Saxe as aide-major general and colonel of a regiment of grenadiers. In 1780 he was raised to the rank of lieutenant-general, and died at Paris in 1783. As an author he attained a good share of celebrity by his "Campaigns of the King in 1745—48," which were published in four octavo volumes. He published also "Essays on the Science of War," 3 vols. 8vo. "An Essay on the great Operations in War," in 4 vols. 8vo; "A Supplement to the Revers of Marlborough," in 2 vols. 8vo. 1773. He likewise drew up "The History of Marlborough," in 3 vols. 4to, in which are detailed plans of his battles and marches, together with those particulars of the life of that general, as render it a work of considerable interest to literary as well as to military men." Nouv. Dict. Hist.

ESPAGNAC, in Geography, a small town of France, in the department of the Lozere; 12 miles S. of Mende.

ESPAGNE, JOHN D', in Biography, a French protestant divine in the seventeenth century, was born at Dampierre, and became minister of the French church in London, an office which he sustained during the reigns of James I. and Charles I. He published several small tracts, which were afterwards collected and published at Geneva and the Hague, in three and in two volumes 12mo. about the year 1670. He also published a work, which he dedicated to Charles I., entitled "Errours Populaires en points Generaux qui concernent l'Intelligence de la Religion." Of this and of some other of his pieces Bayle speaks in terms of commendation. Moreri. Bayle.

ESPAGNE, in Geography. See ESPAGNAC.

ESPAGNET, JOHN D', in Biography, a species which flourished in the 15th century, was president of the parliament of Bourdeaux. As a literary character he published a work entitled "Enchiridion Phyllicis Reclititona," which was afterwards
wards translated into French under the title of "La Philosophie des Anciens rétablir en France," This may be regarded as the first book that appeared in France, in which there is a complete system of physics contrary to that of Aristotle; though the author pretended that he had merely re-established the ancient philosophy. He published also a work concerning the philosopher's stone, entitled "Arzenum Hermeticum Philosophiae Opus." Also an old MS. entitled "Le Roi des Guerres," found at Nercq in the king's closet, and attributed, though erroneously, to the pen of Lewis XI. To this work he added a treatise of his own, upon the education of a prince. In publishing the "Roi des Guerres," he followed the original with the utmost exactness, because, says he, "this little tract seemed to me so good, that I would not embellish or disguise it, but have left it in its native simplicity; and though the language of it is not in use in this age, yet it may be understood, being so full of good sense and meaning, that with all its jargon it may influence the affected language of the court and bar. I have also carefully preserved the spelling, because in adding or diminishing a letter, a word is often changed, and of old made new." Bayle.

France, 10, Saint, in Geography, a small town of France, in the department of Indre and Loire; 15 miles S.E. of Chinon.

Espalier Trees, in Gardening, are such fruit trees of low growth as are trained to trellises or framed woods made for the purpose, in ranges, so as to constitute a sort of hedge. They are usually planted in single rows along the borders, on the sides of the principal walks, in the main divisions of the garden, affording shelter to other plants as well as ornament to such parts.

The trees of fruit trees most employed in this way are those of the apple, pear, and plum kinds; but many others may be managed in this method where variety is wanted; as the quince, cherry, almond, apricot, mulberry, and filbert. And it is necessary, with a view to beauty and uniformity, to manage them in such a manner as to have them that are nearly of the same growth in the same range or line of planting.

The trees of apples most adapted to this use are those of the golden and other pippin kinds, the nonpareil, rennet, and variety of pears and quinces. In the pear kind, the jargoule, blanquette, bergamot, burre du Roy, &c.: the melting pears being always better in this way than those of the breaking kind. On strong moist soils those grafted on quince stocks are the best, but on dry ones those on free stocks.

Trees intended for this use should be grafted or budded within a few inches of the surface of the ground, that branches may be thrown out regularly from the bottom upwards, to furnish and fill the trellis; and the more effectually to accomplish the purpose, the first shoots from the grafts, &c. should be cut off, or headed down within a few inches of the grafts, in the spring season, when they have had one year's growth. The branches or shoots thus produced, whether the trees are in the nursery, or planted out as espaliers, should, in the latter part of the summer, or beginning of autumn, be trained both ways laterally in their advancing growth, to flakes put down for the purpose, or the espalier frames. In this way the trees acquire a proper form, those in the nursery being thus trained and kept for sale. A second heading down in the upper branches may likewise be practiced when necessary, in order to fill up the middle, and completely cover the frames.

When these trees have been thus trained for three or four years in the nursery-ground, they are generally in a proper situation for being planted out as espaliers in the borders or other parts along the fences of the walks, in the garden or pleasure ground, a sufficient breadth being allowed for the borders according to the face or extent of such grounds, as fix, eight, ten, or more feet.

Besides this, there is another method sometimes practiced in forming espalier trees, which is that of, after heading the first shoots down as above, training the side-shoots horizontally in the direction of the frames, and the middle one upright, forming the lateral shoots, which it throws out horizontally on each side; and, if they are not thrown off sufficiently low, heading the upright one down, by which lateral branches will be sent off, so as to range with regularity at the distance of six or seven inches, one above another, on each side, from the bottom to the top. In this way the trees have a very neat appearance.

In planting the trees out, when they are of the apple or pear kind, on dwarf walks, the distance in the rows should be fifteen, eighteen, or twenty feet; and when on free walks, not less than twenty or thirty; and for free growing trees considerably more. For plums, the distance should be eighteen feet or more; and for cherries, apricots, almonds, and walnuts, it should be more than fifteen. Considerably less distance will, however, be sufficient for filberts, especially in the poorer sorts of soil.

When these trees have been planted, it is the usual practice to put flocks down in a line to train them to for the two or three first years; but it has a much neater appearance to have the trellises fixed down to train them to at once.

Frames for this use are made in different ways, according to the taste of the person who has them; but the most usual sorts are those constructed of three or four inch square pieces of oak timber for the poits, with rails of deal carried from poit to poit, at the distance of every ten or twelve inches from the bottom to the top. Between these rails thin upright pieces are again sometimes fixed at the same distances, for particular purposes. The whole should be well painted over in oil some time before the trees are to be trained to it. This is performed either by tying the branches to the trellis by offer twigs, woollen-yarn, or other similar fleshy trees, or by railing them in the manner of wall-trees. In which manner it should be well waxed in this way, and the whole should be always covered, and the branches or shoots that may have a neat regular appearance. The manner of performing the future pruning and managing of these trees will be explained when we come to speak of the nature of pruning in general. See Pruning of Fruit Trees.

These sorts of trees are chiefly advantageous in admitting the branches to produce fruit spurs on both sides, which is not the case with wall-trees; in taking up but little room in the garden; in not being so injurious to the crops that are near them; in affording fruit of a finer flavour, from the more free admission of air and sun, and in the fruit not being liable to be blown down and injured as in other cases.

Espalier, in Geography, a small town of France, in the department of the Aveyron, chief place of a district of the same name, with a population of 262 inhabitants. It is situated on the river Lot, 18 miles N.E. of Rhone, and has some manufactures of coarse woollen cloths. The canton has a territorial extent of 1814 square kilometres, 12 communes, and a population of 6170 individuals.

As chief place of a district, Espalier has a sub-prefecture, a court of justice, and a register office. It has a wine, and madders, grow in its neighbourhood; and the whole district contains 8 cantons, 106 communes, and 58,855 inhabitants, on a territorial extent of 1650 square kilometres.
ESPER, John Frederic, was born at Droffenfild, in Bayreuth, in 1732. He studied very diligently at Erlangen, where he applied himself chiefly to theological pursuits, but at the same time made himself well acquainted with natural history and botany, of which he afterwards became a teacher. He died of a fever in July 1781, leaving behind him a considerable reputation as a naturalist, particularly in that department which relates to the zoetikes in the principality of Bayreuth. In this place are a number of large subterranean caverns, partly inundated, and partly connected with each other, which contain immense numbers of homes of various animals, thrown together in heaps to a considerable height, and covered with the earth arising from decomposed animal bodies. The entrance to these caverns is highly picturesque, but almost as soon as a person enters them he is surrounded by darkness, and the passage becomes still more difficult and narrow, till the eye at last is struck by the immense extent of an awful arch, which on every side presents fissures and crevices, strewed with the fragments of once living bodies, which excite the idea of a repotory of the dead. With the aid of an ingenious apparatus of Erlangen, Esper undertook an examination and description of these curiosities, and published the result of his labours under the following title: "An accurate Description of the Zoetikes of Untkeren animals. &c." This was published at Nuremberg, in the year 1774, in folio, with different colleges in Latin, to the principal of which he was chosen rector at a very early age. When he was about thirty years old, he took his doctor's degree, soon after which he was invited by the cardinal of Lorraine to reside in his house, "to manage the ecclesiastical concerns of which he had the care. In the year 1544 he accompanied the cardinal on an embassy to Flanders, to negotiate a treaty of peace between Francis I. and the emperor Charles V. He was afterwards selected by the king to assist at the ecclesiastical conference, to consider the questions proper to be proposed for discussion at the council of Trent; and in 1547 he was appointed by Henry II. to attend the council of Trent, which was then transferred to Bologna. Some years afterwards he was employed in negotiating at Rome in favour of the French court, where his talents, as a diplomatic minister, produced such an impression in his favour, that the pope, Paul IV. wished to attach him to his interests by making him cardinal. He declined the intended honour, and having finished the business on which he was sent to Rome, he returned to his native country, where he appeared with a high reputation at a meeting of the Estates of Orleans in the year 1562. In the following year he was appointed a member of the conference at Poissy, where he attached himself to the Calvinists, which was highly disagreeable to the Catholic divines, by whom he was likewise suspected of being the author of a treatise on Image Worship, which occasioned him some trouble with the faculty. After this, he passed his life in retirement, devoted to his studies, till he died at Paris in the year 1571. His works are chiefly theological; the most important are his "Commentaries on the Epistles of St. Paul to Timothy and Titus;" in these, several questions relative to hierarchy and ecclesiastical discipline are discussed. Most of his treatises were written in the Latin language, in the knowledge of which he was suppos'd to excel his contemporaries. He was one of the most learned, judicious, and moderate ecclesiastics of his time. He was very conversant in the canon and discipline of the church; and not least celebrated for his knowledge of profane literature. He was attached to the Catholic religion, but was a decided enemy to every species of persecution and intolerance. Moreni.

ESPER, Claude de, was born at Chalons sur Marne in the year 1511. He received his education at Vol. XIII. of the Lower Canada; 74 leagues N.E. of Quebec. N. lat 57°, W. long. 63°.

ESPAGNE, a town of Persia, in the province of Segefan; 54 miles S.W. of Kina.

ESPARRON, in Agriculture, a name sometimes given to Sainpoin.

ESPARRAGOSA, in Geography, a town of Spain, in the province of Aemudura; 35 miles E.S.E. of Meridia.

ESPARZAS, a town of Spain, in the province of Catalonia; 15 miles N.N.W. of Barcelona.

ESPAZA, a town of Spain, in Navarra; 22 miles E. of Pamplona.—Alfo, a town of North America, in Mexico, and province of Cufla-Rica.

ESPEJAS, a town of Spain, in the province of Cordova; 17 miles N.N.E. of Montilla.

ESPELETTE, a small town of France, in the department of the Lower Pyrenees, chief place of a canton in the district of Bayonne, with a population of 1200 individuals. Its canton has a territorial extent of 3754 kilometres, 7 communes, and 7861 inhabitants.

ESPELEN, Zeger Bernard van, in Biography, was born at Lom, in the year 1646. After going through the usual course of studies at the university, with much credit to his talents and diligence, he was admitted to priest's orders in the year 1675, and, had, within two years of this time, the degree of doctor of laws conferred upon him. From this period till the year 1702, he lived in the college of pope Adrian VI., where he performed the duties of professor, and applied himself to the study of those works which have rendered his name illustrious. He obtained so much respect by his various writings that he was consulted from every quarter: by the tribunals of justice, by the bishops, and by several sovereign princes. His principal work was entitled "Jus Ecclesiasticum universalium." Besides this, he is well known for other treatises, "De peculiaritate et Simonia;" "De Officis Canonicorum;" "Tractatus Historicoco-Canonicus in Canones;" "De promulgatione Legum Ecclesiasticarum;" and many others, all of which were collected and published in 4 vols. folio, in 1753, at Paris. When he was in his 65th year, he gave up the fight by a cancer, which was not removed for two years; during this time, however, he neither lost his cheerfulness, nor remitted his application. His manner of living was at all times frugal, and very simple, his temper was benevolent, modest, and humble. He was eminent for piety towards God, and for his candour and good-will towards men. He nevertheles had made himself enemies, by the integrity and independence of his mind; some of whom, to render EspeLEN obnoxious to the ruling powers, had forged a treatise, containing some things very offensive, in a religious and political point of view, which they attributed to him; but he luckily detected the imposture, and punished the agents. On other accounts, he met with severe and unmannerly persecution, and in one instance, after a variety of procefses, sentence was pronounced against him, without any declaration respecting the definitive judgment of the court. Under these circumstances, believing that it was intended to put him under an arrest, he withdrew to Maerich, and afterwards to Amersfort, in the province of Utrecht, where he died in 1728, in the 83rd year of his age. He left behind him, which was afterwards published, a learned treatise, entitled "Commentarius in Canones Juris Veteris ac Novi," and other dissertations, which are said to contain discourses on some of the most important points in moral philosophy, as well as the canon and civil laws. Moreni.
fourteen illuminated plates. Elpher was author likewise of various papers in the Translations of the Friendly Society of the Searchers into Nature: and he wrote an account of

“A Method of determining the Orbits of Comets, and other Celestial Bodies without Instruments, or Mathematical Calculations.” Gen. Diog.

ESPERAŻA, in Geography, a town of France, in the department of the Aude, and district of Quillan; 25 leagues S. of Limoux.

ESPERNAY. See Espernay.

ESPERNON, a small town of France, in the department of Eure and Loiré, on the river Gonne; 15 miles N.E. of Chartres, and 6 miles E. of Maintenon.

ESPESEL, a town of France, in the department of the Aude, and district of Quillan; 24 leagues S.W. of Quillan.

ESPHLASIS, (from ἐσφλασός, to recline inwardly,) in Surgery, a recession of a part of the body inwardly, in consequence of some violent outward force.

ESPIERRE, a town of Savoy, in the county of Maurienne, on the river Arc; 3½ miles S. of Argentina.

ESPIERS, in Geography, a town of Flâlandes; 8 miles N. of Tournay.

ESPINAL, See Espinal.

ESPINTER, a town of Spain, in Old Castile; 18 miles S.S.W. of Segovia.

ESPINAL, a town of Portugal, in the province of Beira; 18 miles S.E. of Coimbra.

ESPINOSA DE LOS MONTENES, a small town of Spain, in Old Castile; situated in a pleasant valley, watered by the river Truera, among the mountains of Burgos, about 15 leagues N.W. of Miranda, in the north corner of the province.

ESPINOSA, a town of Spain, in New Castile; 44 miles S.W. of Toledo.

ESPIRITU SANTO, the largest and most westerly of the New Hebrides islands, in the South Pacific ocean; about 57 miles in length, and 35 in breadth.—Also, a province of Brazil, which is chiefly productive of sugar.—Also, a town of Brazil, seated in a fertile country on the sea-coast, with a small castle and harbour. S. lat. 20° 15'. W. long. 41°.

Also, a river of Brazil, which runs into the Atlantic.—Also, a town on the south coast of the island of Cuba; 55 miles S.W. of Bayamo.—Also, a bay on the west coast of East Florida. N. lat. 25° 36'. W. long. 82° 54'. It has a good harbour and safe anchorage; but the land about the sea-coast is very low. Several low, sandy islands and marshes, covered with Mangrove bushes, lie before the main land. This bay abounds in the summer with fish, which may be taken with a seine, in quantity sufficient to load a ship, if the climate would admit of curing them, in a few days.—Also, a lake towards the extremity of the peninsula of East Florida, south from the chain of lakes which communicate with St. John's river.

ESPIRITU SANTO, Islas del, islands situated on the S.W. of Providence in the West Indies. See Andros Islands.

ESPLANADE, in Fortification, called also the glacis; a part which serves the counterfeet, or covert way, for a parapet; being a declivity, or slope of earth, commencing from the top of the counterfeet, and losting itself, insensibly, in the level of the champagne.

ESPLANADE also signifies the ground which has been levelled from the glaciers of the counterfeet to the first houses; or the vacant space between the walls and the houses of the town.

The term is also applied, in the general, to any piece of ground which is rendered flat, or level, and which before had some eminence that obstructed the place.

ESPLEES, Espitile, from splatis, in Laos, the products which ground or land, &c. yield; as the hay of the meadows, the barmage of the pastures, corn of the arable, rents, services, &c. and of an adowson, the taking of tithe in groves by the parson; or wood, the felling of wood; or of an orchard, the fruit growing there; or of a mill, the taking of toll, &c. These and such like illuses are termed espiles. And it is observed, that in a writ of right of land, adowson, &c. the demandant ought to allege in his count, that he or his ancestors took the feples of the thing in demand; otherwise the pleading will not be good.

Sometimes this word hath been applied to the farm, or land, &c. themselves. "Domineus L. Labi hit omnes extetitas & proficiones de corona emergentia." Plac. Parl. 33 Ed. I.

ESPOSENDA, in Geography, a town of Spain, in the province of Galicia; 12 miles S.W. of Orense.

ESPOSENDE, a small port town of Portugal, in the province of Entre Minho, at the mouth of the Cavado, three leagues S. of Viana. Its shallow harbour is slightly protected by a fort, 22 miles W. of Oporto.

ESPRIT, James, in Biography, was born at Lezzer in the year 1611. Having passed through his initiatory studies, to which he had applied himself with great diligence, he was introduced to the duke de la Rochefoucault, who brought him acquainted with the chancellor Seguier, who not only allowed him a pension from his own private purse, but procured for him a pension of two thousand livres, on an abbey and a brevet of counsellor of state. Through some secret enemies he incurred the displeasure of the chancellor, and withdrew to the vicinity of St. Magloire, where he became acquainted with the prince of Conti, and at that time had serious thoughts of entering the church. This prince was so charmed with the conversation of M. Esprit, that he gave him handsome apartments in his own hotel, and a pension of a thousand crowns. In a short time afterwards Esprit gave up all thoughts of the ecclesiastical life, and determined to marry. On this occasion he received some handsome presents from the prince, to whom he became so much attached that he followed him, in 1664, to his government of Languedoc, and became his most confidential friend and adviser. After the death of his patron, he devoted the whole of his time to the education of that prince's children. He himself died at the place where he was born in 1678. As a literary man he left behind him "Paraphrases on some of the Psalms," and a treatise entitled "La Faustite de Vertus Humains," which was published the same year in which he died, and which was intended as a commentary on the maxims of his first patron the duke de la Rochefoucault, to show the fallacy of the virtues that are merely human, and the reality of Christian virtues. By the Abbé d'Oliva and others he is supposed to have been the translator of Pigni's paraphrase on Trajan. Esprit was a member of the French academy, and in its infancy was considered as one of its hinting ornaments. Moreri.

ESPRIT, Saint, in Geography, a small town of France, in the department of the Lands. chief place of a canton in the district of Dax, with only 593 inhabitants. Its canton has a population of 10,161 individuals, dispersed in eight communes, on a territorial extent of 147 square kilometres.

ESPOUSALS, Sponsalia, in Law, a contract or mutual promise between a man and a woman to marry each other. Marriage or matrimony is said to be an espousal de prefent.
ESPRONCEDA, in Geography, a town of Spain, in Navarre; 14 miles W.S.W. of Elasilla.

ESQUADRILLE. See Quadrille.

ESQUADRÓN. See Squadron.

ESQUERDES, in Geography, a town of France, in the department of the Drats of Calais, and district of St. Omer; one league S. of St. Omer.

ESQUIAVINE, in the Manager, an old French word signifying a long and heavy charioteer of a horse in training.

ESQUILE or ESQUILINS MORS, in Ancient Geography, one of the seven mountains on which Rome was seated, where was annually one of the gates of the city, now the gate of St. Lawrence, to the whole magnificent church it leads. This gate seems to have been annually called "Libitinae," on account of the dead bodies that were carried through it, in order to being interred in the Campus Equilinus, which was the general burying-place of the common people. The name of Equilinus was varied, for facility of pronunciation, from Equilinus, a corruption of Excubius, <espus> Excubius, from the watch that Romanus kept in this place. It was taken in by Servius Tullius, who had his royal seat upon this hill. Varro will have the Equilii to be two hills. To the east, it has the city walls; to the south, the via Labicana; to the west, the valley lying between Mons Cuchus and Mons Palatini; to the north, Mons Viminatii; and is in compas between three and four miles. It is now called "Il Monte de Santa Maria Maggiore." One of the 14 regions or wards, instituted by Augustus, was denominated "Equilina." It contained 15 streets, eight luce, six temples, five ades, 75 public baths, 13 granaries, 22 mills, and 180 great houses; and its circuit was 15,050 feet.

ESQUIMAUX, the inhabitants of the coasts of Labrador and Hudson's Bay, who differ, in several characteristic marks, from the inland inhabitants of North America. That the Greenlanders and the Esquimaux agree in every circumstance of customs, manners, and language, which are demonstrations of an original identity of nation, was discovered near half a century ago. Gravitz, in his "History of Greenland," (vol. i. p. 262.) informs us, that the Mo- ravian brethren, with, the consent and furtherance of Sir Hugh Palliser, then governor of Newfoundland, visited the Esquimaux, or the Labrador coast, found that their language, and that of the Greenlanders, do not differ so much as that of the high and low Dutch. Mr. Hearne, in 1772, traced this unhappy race farther back, through that part of the globe, from whence they had originally coasted along in their skin-boats, having met with some of them at the mouth of the Coppermine river, in the latitude of 72°, and near 1500 leagues farther west than Packer's the rose weatherly fiction in Davin's slant. Their being the same tribe, who now actually inhabit the islands and coasts on the west side of North America, opposite to Kam- felhats, is a discovery, the completion of which was referred for captain Cook. The reader of his third voyage will find them at Norton sound, and at Oonalefsha, and Prince William's found; that is, near 1500 leagues distant from their stations in Greenland, and on the Labrador coast. And left amplitude of manners should be thought to deceive us, a table exhibiting proofs of affinity of language, drawn up by captain Cook and inserted in the appendix to the work just cited, will remove every doubt from the mind of the most scrupulous inquirer after truth. See New Britain and Labrador.

ESQUIMAUX BAY. See Ensigns.

ESQUINANCY, in Medicine, from the French esquire; whence our more common term Quinic. See Cancris.

ESQUIRE, a title of distinction, next below that of knight, and above that of a simple gentleman.

The origin, both of the name, and the thing, esquire, is very obscure. The English denomination is confessedly borrowed from the French, esquieu; and that from the Latin fstatus, shield, as some will have it; or, as others, from sticatori, or stiger, shield-bearer; or from fteuris, stable; or from equus, horse. So many different opinions of the formation of the word have given rise to as many about the primitive office of esquires; unless, perhaps, the latter hath given occasion to the former. Palquier, in his Recherches, liv. 1. chap. 15, maintains the title of esquire, efquiere, sticatori, to be very ancient. From the time of the declension of the Roman empire, he observes, there were two extraordinary kinds of soldiers in the Roman army: the one called equites, and the other sticatori.

Amman, Marcellin, lib. xiv. cap. 7. and lib. xvi. cap. 4. speaks of thes sticatori as men of redoubted prowess, and even deemed invincible: it is added, that Titus the Apollite set a mighty value on those troops, when he was among the Gauls; and hence, probably, it was, that the Gauls, or perhaps only the Franks, finding the braved among the Roman forces were called equites, and sticatori, gave the like names to the boldest and bravest among themselves: such, according to that curious antiquary, is the original of esquires.

Esquire, however, afterwards came to be used in a somewhat different sense; viz. for a gentleman who attended a knight in the wars, and on other military occasions; bearing his shield, status, before him (whence he was called fstatus, stiger, or stifier), as also his lance, and other weapons; whence his other Latin appellation, usual among us, armiger, q. d. armour-bearer. And hence likewise it is, that, in all our ancient romances, the hero is constantly attended by a gentle and trusty fquire.

After all, the most probable derivation of the word is not from esquius, status, as is the common opinion; but from equus, horse; the primitive esquires being no other than what the Latins call equi/s, who had the care and attendance of the esquiers, or staries, only.

Be this as it will, the title esquire, armiger, as now established among us, is not below that of knight, eques. They who bear this title are all younger sons of noblemen and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons successively; both which species of esquires for Henry Spencaer entitles armiger natitii; the four esquires of the king's body, now diffused, and esquires created by the king, by putting about their necks a collar of S8's, and belowing on them a pair of silver spurs, letters patent, or other investiture, and their eldest sons. Lastly, divers others, in the superior public offices, are reputed esquires, or equal to esquire; as sheriffs of counties, serjeants at law, justices of peace, mayors of towns, colonels at law, lieutenant-colonels, majors, captains, &c. during the time of their commission.

Lastly, the heads of some ancient families are likewise esquires by prescription. To these may be added the esquires of knights of the Bath, each of whom constitutes three at his installation; and all foreign, say Irish peers; for not only these, but the eldest sons of peers of Great Britain, though frequently titular lords, are only esquires by the law, and must be so styled in all legal proceedings. See Gentleman.

ESQUISE, in the French Painting, a term signifying the full eight sketch or draught of a picture; the first thought

3 x 2
thought of a design drawn halfly with a crayon; or in
colours, on paper, canvas, or the like, in order to be
minned, and painted, or engraved afterwards.

He had not the trouble of making a finished and correct
design, but went to work upon the effige.
The word is formed of the Italian *effige*, a splat; be-
cause an effige of a painting only represents, as it were,
plafhes, or tabs, of colours.

**ESQUERO.** See ESQUERO.

**ESRSTO.** See ESRSTO.

**ESS, in *Agriculture*, a term made use of in some places to
signify after.**

**ESSA, in *Ancient Geography*, a town of Palestine, on the
other side of Jordan, according to Josephus, who says
that it was taken by Alexander, king of the Jews.**

**ESSCHORD, See HESCHORD.

**ESSIANS, See ESSI.

**ESSORE, in *Geography*, a town of Egypt; three
miles S.S.E. of Achmin.**

**ESSARS, Les, a town of France, in the department of
La Vendée, and district of La Roche-sur-Yon; 3 leagues
N.E. of La Roche.**

**ESSART, or ASART. See ASART.**

Du-Cange derives the word from some of the barbarous
Latin words, *exartum*, *exartum*, *exartum*, *exartum*, *exartum*, *exartum*, *exartum*, *exartum*, *exartum*; which all signify a forest cut down, or dug up;
though Snelman chooses to deduce it from the Latin *exartum*, *exartum*, or unrooted. Others from *ferfino*, to weed;
and others, lastly, from *exaro*, I plow; whence *exarare*;
and, by opposition, *exartum*. In our ancient law-books,
*exartum facere in fylva*, is to effect a place in a forest.
To effect, is to grub up, or extirpate bulbles, trees, old
roots, thumps, or the like; in order to fit the ground for
tillage.

**ESSARTS, Les, in *Geography*, a small town of France,
in the department of La Vendée, chief place of a canton in
the district of Montaigne, with a population of 2089 indi-
viduals, 24 miles W. of Mauléon. Its canton contains 9
communes, and 5043 inhabitants, on a territorial extent of
2441 kilometres.**

**ESSARTUM, a word used by some of the chemical
writers to express the medicinal power or sunny property
reuding in simple medicines.**

**ESSAY, a trial, or experiment, to prove whether a
thing be of the requisite quality or goodness.**

The word is French, *effai*; which some authors derive
farther from the Latin *examin*.

**ESSAY is also used for an attempt, or tentative, to learn
whether or not a thing will succeed.**

**Effays of machines should be made in large; it is not
eough that they succeed in little.**

**ESSAY, in *Monasteries*, is particularly used for a trial
which a person makes of the monastic life, in a peculiar
habit.**

This essay is of one, two, and, in some monasteries, of
three months. The essay is not reckoned in the noviciate.

See **PROBATION.**

**ESSAY, or *Assay*, or simply *Say*, in *Coinage*. See As-
say.**

**ESSAY, in matters of learning, is a peculiar kind of com-
pition; whose character is to be free, easy, and natural;
not tied to strict order, or method, nor worked up, and
finished like a formal fyllem.**

The matter of an essay is supposed to consist principally of
fudden and occasional reflections, which are to be wrote
much at the rate, and in the manner, a man thinks; some-
times leaving the subject, and then returning again, as the
thoughts happen to strike in the mind.

At last, this has hitherto been the practice; and Mon-
tagne, who has acquired no small reputation by this way
of writing, felom keeps many lines to the subject he pro-
poes; though it is his opinion, that lord Bacon, in many of
his works, is a better pattern in the essay kind. Mr. Locke,
however, and a few other physicians, use essay in a
stricter sense; the Essay of Human Understanding, every
body knows, is a regular, artful, and laboured work; though
perhaps so called to guard against too severe criticisms,
by pleading the title.

**ESSAY-MAKER.** See MINT, and ASSAY.

**ESSE, in the *School Philosophy*, is used in the same
sense with efficacy, principally for that which is actual, or
actually existing.**

The word is pure Latin; being the infinitive of the verb
*essum*, I am; whence *effe*, to be.

From *esse* arises *essum*, a barbarous term, now almost
obsolete, signifying that which is ended with efficacy, or
nature; or which is connected with the virtue, or efficace, of
another. Some distinguish *esse* into *real* and *intentional*; and, again,
into *esse* and *vollsum*.

**ESSEDARIUS, among the Romans, a gladiator,
who fought in a car or chariot. See Hill, Acad. Infercip.
vol. ii. p. 376, seq.**

**ESSEN, or ESSEL, in *Geography*, a town of Ger-
many, in the circle of Westphalia, and county of Verden;
2 miles N. of Verden.**

**ESSEN, a small town of Germany, in the circle of West-
phalia, remarkable for its manufactures, chiefly of swords
and fire arms; but more particularly for a rich abbey, which,
until the peace of Luneville in 1801, was a free imperial
abbey. It was secularized, and its possessions, together with
the town and its territory, were given to Prussia as an
indemnity for her losses on the right shore of the Rhine.
After the peace of Tilsit in 1807, when Prussia lost all her
dominions beyond the Elbe, Essen was added to the grand
duchy of Berg and Cleves, which now belongs to the eldeft
son of the king of Holland. There are other towns of this
name in the circle of Westphalia.**

**ESSENBACK, a town of Denmark, in Jutland; 4
miles from Randers.**

**ESSENBERG, a town of Germany, in the circle of West-
phalia, and county of Meurs, near the Rhine; 3 miles E.
of Meurs.**

**ESSENCE, a term much used among the schoolmen;
and denoting what the Platonists called the idea of a species.
The word *essentia* is said to have been made by Cicero;
but his authority could not give it currency, until long
after his time. It came at last to be used, and the school-
men fell into much the same errors concerning essences,
as the Platonists held concerning ideas. The essences of
things were held by many to be uncreated, eternal, and
immutable. Mr. Locke distinguishes two kinds of essence,
the real and the nominal. By the former he means the con-
futation of an individual, which makes it to be what it is.
This essence must begin and end with the individual to
which it belongs. It is not therefore a Platonick idea. But
the latter or nominal essence, so called by Mr. Locke, is
the constitution of a species, or that which makes an
individual to be of such a species; and this is nothing
but that combination of attributes which is signified by
the name of the species, and which we conceive without re-
gard to existence. The essence of a species is, therefore,
what
what the Platonists called the idea of the species. The nominal essence depends on the real essence; thus, the nominal essence of gold, is that complex idea which the word gold represents: *e. gr.* a body, yellow, heavy, malleable, fusible, and fixed; but its real essence is the constitution of its insensible parts, on which those qualities, and all its other properties depend; which is wholly unknown to us.

In philosophy, the essence of a thing is defined to be, that whereby a thing is distinguished from every other thing. The Cartesians hold the essence of matter to consist in extension; and, on that principle, deny that there is any such thing as mere space, or vacancy; but the hypothesis is false, as will be shown under the articles Matter, Space, Vacuity, Plenum, &c.

Gallendus, and most of the corpuscular philosophers, hold the essence of matter to consist in solidity, or impenetrability, refiiniment, or, more accurately, in a solid impenetrability refilling the touch; which it must be allowed, of all the properties of matter, seems to have the fairest title to it.

The school philosophers give us two significations of the word essence; the first denies the whole essential perfection of a being, and, consequently, its entity, with all its intrinsic, or essential, and necessary attributes, taken together; in which sense essence may be defined to be, all that whereby a thing is, and what it is. In which case the essence of a thing is to the thing itself, what humanity, *e. gr.* is to man.

The second signification of essence is, that whereby it denotes the principal, and most intimate, of all the attributes of a thing; or that which agrees to every such thing, and such alone, and that always, and in such manner, as that the mind, with all its attention, cannot perceive any thing prior thereto; by which essence is distinguished from the essential attributes, *i. e.* from such as flow from its essence, or first attribute. Thus, the essence of the human mind is commonly supposed to consist in the power of thinking; because all its other perfections seem to pre-approach this; but this pre-approaches none. And thus the powers of understanding, doubting, assenting, willing, &c. do all flow from the power of thinking; and cannot exist without it, though this may exist without any of them.

It must be allowed, however, that the essential properties of a thing do go closely together, to, and inhere, in the essence itself, that it is scarcely possible to distinguish the one from the other. Hence, what some urge, that, letting aside all the attributes and properties of a thing, and what remains is its essence, is a mere chimera. For let aside, *e. gr.* from the mind, the powers of understanding and willing, with the rest of its attributes, and what will there remain to call its essence?

It is greatly disputed in the schools, whether the essences of created things be eternal? or whether the essences, as well as their existence, had their origin in time? The Cartesians hold, that the essences of things depend absolutely on the free concurring will of God.

**Essence.** Essential oil, Essential fat. The essence of a vegetable, according to the old chemists, was, that one of its proximate elements, in which refined the quality of taste or odour, which peculiarly distinguished it from other vegetables, and rendered it especially applicable to pharmaceutical purposes. Thus the fragrance of orange peel, of pepper-mint, of cinnamon, was found by experience to be separable from the other parts of the vegetable, by means of distillation, &c.; the result of this process was a small portion of highly fragrant oil, in which was contained the entire odour that had been naturally diffused through the whole mass; hence the oil thus procured obtained the name of essential oil. Again, four vegetables, as forhel, lemons, &c. owe this quality to the presence of an acid, which, when separated from the other vegetable principles, assumes a crystalline appearance, and was known by the name of its essential fat. The name appellation was also given to all those vegetable principles which, when pure, are capable of crystallizing, whether they were acid to the taste or not. Thus sugar was ranked among the essential fats. The term, however, is at present obsolete. Essential oil still retains its place in chemical nomenclature, and we refer the reader to the article Oils, essential, for a particular account of their species and properties.

**Essence of Fire.** See Roses.

**Essence of Wine.** A term used by Paracelus, and some of the German chemists since his time, to express what is called sometimes the philosophical spirit of wine, or the spirit of wine of the ancients. It is not a distilled spirit like what we call spirit of wine, but approaches more to what Stahl has greatly recommended to the world, under the name of concentrated wine, or wine whose strength has been reduced to a smaller compass, by separating its aqueous parts only by freezing. Stahl recommends the immediately expelling of wine to the frothy air on this occasion; but the prospects ordered by Paracelus for the preparation of this liquor is more tedious. He orders that the finest and best flavoured wine be chosen; that it be put into a glass, filling it up three parts in four; and the neck being then sealed hermetically, it is to be put into horse-dung for three months, and then exposed to the frothy air for a month, after which the ice is to be thrown away, and the liquid part, which is the essence, preferred. Shaw's Chemical Essays.

**Essendo Quietum de Tolleinis, in Laws.** A writ to be quit of toll, and fines for citizens and burghers of any city or town that by charter or prescription ought to be exempted from toll, where the same is exempted of them. Reg. Orig., 248.

**Esseneux, in Geography, a town of the Netherlands, in the duchy of Limburg, situated on the Ourt; 9 miles S. E. of Liege.**

**Esseni, Essenes, or Essent, an ancient sect among the Jews.**

As to the origin of this sect, Pliny affirms, without mentioning his authority, that it had subsisted for several thousand years. The most probable opinion is, that this sect was formed by Jewish exiles, a little before the time of the Macedeans, who were forced to fly from the persecution of their enemies into caves and deserts. The first Essene we read of are mentioned in the fourth book of Maccabees, under the name
name of Haidanim, and by Josephus; both which accounts agree that they were already settled in Judaea, at the time of Jonathan, the brother and successor of Judas Maccabaeus, about a hundred and fifty years before Christ. Josephus states that their number in Judaea was about four thousand, meaning, as Dr. Lardner (Works, v. i. p. 120.) suggests, tho’ of them, that entirely rejected marriage. Philo says, that in Syria and Palæstine there were about 4000 of them, but he makes the number in Egypt much greater. Philo says, that they sacrificed no living creatures, and that they shunned cities. Josephus says that they fept presents to the temple, but offered no sacrifice there. They seem therefore not to have exposed themselves much to public view, nor would they admit a man of another sect into the apartments in which they lived. Some have expressed their surprize, that no mention should be made of this sect in the New Testament. This proceeded, as some imagine, from their retired mode of living, by reason of which they never came under our Saviour’s observation, as the Pharisees and Sadducees often did. Others suppose, that, being very honest and sincere, without guile or hypocrisy, they gave no reason for that reproach and cenfire, which the others very justly merited. It should be considered, that it was the design of the evangelists to write the history of our Saviour’s ministry, and not that of the Jewish sects. Pridain observes, that almost all that is peculiar in this sect is condemned by Christ and his apostles. Prid. Conn, vol. iii. p. 354. However, it has been supposed, that they are referred to by the apostle Paul in his epistle to the Colossians, ch. ii. 18.

Josephus, making mention of the several sects among his countrymen, distinguishes three; viz. the Pharisees, Sadducees, and Esseni; which last he prefers to the two former, as to their manner of life. He affirms us, farther, that they were Jews, by original; from which it should appear, that St. Epiphanius was mistaken in ranking them among the Samaritans.

In effect, the Esseni appear to have been true Pythagorean philosophers, in every thing that related to their manner of living; for they greatly affected solitude and retirement; and avoided all conversation with women, to devote themselves more entirely to the contemplative life. Grotius will have the Esseni the same with the ancient Ἱοδάν, Ἰοδάνιος, or Haidanii; thus called, according to Philo, from their singular piety, humility, and devotion. Among these, Gale observes, it was, that the Hebrew philosophers chiefly flourished. Porphyry is very profic in his prates of the Esseni:

*Extr. 6. 34. Extr. 3. de Abh. 1 Ed. 15. 33. 35. 124. &c.* He represents them as despisers of pleasures, riches, glory, and delicacy; and firenecval retainers to tranquility, assenity, flulty, &c. He adds, they decline marriages, and adopt and educate other people’s children in the principles of religion and Philosophy; they are all on a level, hold every thing in common, neither buy nor sell, &c. By long habit, they arrived at such a degree of patience, that Porphyry affirms us, flames and tortures had not the least effect on them. They scorned to intret their tormentors; nor ever cried a tear; but would smile under all their agonies, &c. As to their learning, Philo Judæus, in his treatise, That every good Man is free, tells us, that they despised logic, as uields to the acquiring of virtue; physics they left to the sophists and disputants, as judging it to transcend the human faculties; and applied themselves wholly to morality. Porph. de Abh. lib. iv. § 11. leq. Gale Philo. Gener. lib. i. cap. 4. § 11.

Both Josephus and Philo give a surprizing account of their austere way of life, which the curious reader may fee at large in Prideaux’s Conn. ubi supra. Their houses were neat; their clothes made of wool, without any dye; they never changed their clothes or shoes till they were quite worn out; their food was plain and coarse, and their drink water; they neglected all bodily ornaments, and would by no means anoint themselves with oil, according to the fashion of those times. They lived in faddism, and had all their good in common; their morals were very exact and pure, and they kept the Sabbath much stricter than any of the Jews. Before any of them were admitted to the common table, they bound themselves by a solemn oath to observe the rules of the society, which were very strict and exemplary.

Some have said that the Esseni, as well as the Pythagoreans, prohibited oaths; that they used only immaculate sacrifices, and that they not only worshipped towards the rising sun, but worhipped the sun itself. But it has been urged, that neither of these charges seem to be well founded; or at least, that it is difficult to reconcile them with their known veneration for the writings of Moses, and other instances of their conduct. Pliny, and others on his authority, have ascertained, that they wholly declined marriage; and Philo (lib. ii. cap. 17.) with more wit than justice, says, that for several thousand of years, this people is perpetually propagated without any being born among them, to fruitful and prolific unto them, as the repentance of others. But Josephus informs us (De Bell. Jud. lib. ii. cap. 1.), that there is one fort of Esseni, who agreed with the others, except in the article of marriage. For they reckoned, that those that do not marry cut off a great part from the number of the living, and that thus the whole race of mankind would soon be extinguished. Accordingly they made choice of those women, who, after three years trial, were found fit to bear children, and never cohabited with them after they were known to be with child; consulting the propagation of their species, and not their own gratification in this business.

With respect to the religious opinions of the Esseni, they believed the existence of angels, the immortality of the soul, and a future state of rewards and punishments, but denied the resurrection of the body. They maintained, that fate governs all things, and that nothing happens to man but by its appointment.

The Esseni seem to have been, among the Jews, what the most retired and austere monks are, or were, among the Christians: which was what gave them their denomination of Ἱοδάνιος ἱερεῖς, Jewish sacerdotes.

Many Catholic writers have even deduced the origin of monks from them; building, principally, on what Philo relates of them, who divides them into two branches, or sects; the one who married, and the other who lived in celibacy.

Josephus seems likewise to have had an eye to these two forts of Esseni. Serrarius, who has wrote very amply on the subject, follows Philo in making two classes of Esseni. The first are those whom he calls Ἰεραπετας, who lived in community; the second, those called Therapeutai, who lived in solitude, and led a life of pure contemplation. He adds, that Josephus only makes mention of the first; omitting the contemplative kind, whom Philo calls Therapeces, and who were principally found in Egypt. See THERAPEUTAI.

It is true, that the Esseni, called Therapeutai, were real Christians, or Jews converted by St. Mark, who had embraced this kind of life. Scaliger, on the contrary, maintains, that these Therapeutai were no Christians, but real Esseni, who made profession of Judaism; however, he
he allows of the two kinds of Effeni above-mentioned. But Velchius, in his notes on Lefcisius, absolutely rejects any such distinction: he denies that the Therapeutæ were any real Effeni; and that chiefly on the authority of Philo himself, who never calls them Effeni, and who places the Effeni in Judæa and Palestine; whereas the Therapeutæ were spread throughout Greece, Egypt, and other countries.

Some traces of the Effeni are found under the emperor Trajan, and under Justinian; but they were much degenerated from their primitive purity both of doctrine and manners; and the fact about that time became extinct. Though the Therapeutæ, as well as the Effeniæ, were chiefly Jews, and not Christians, it is not impossible, that some of them, becoming Christians, might still affect their former reducible way of living; and being imitated by others, laid the foundation of monkery among Christians.

ESSENIAE, ANDREW, in Biography, a learned Dutch divine, was born at Bommel in the year 1611. He was educated chiefly at Utrecht, was admitted to the exercise of the ministry in the year 1639, and in the following year took the degree of M. A. He obtained some preferment, and took his doctor's degree in the year 1645. Soon after this, he was chosen pastor of the principal church at Utrecht, and in 1653 was appointed professor of theology at that university. He died in 1677; leaving behind him many works, that were very highly esteemed by his contemporaries. He was what the world has usually denominated an orthodox divinity, and wrote again Crellius, and others among the Unitarians. One of his largest publications was "A System of Divinity" in 2 vol. His most popular piece was entitled "A short View of Theological Controversies, with an Index to Scripture Passages." This has gone through many editions. More is.

ESSENTIA DULCIS, in Chemistry, a name given by Kunkel, and some others of the German authors, to a menítrhum, of which they relate wonderful effects; but the preparation of which seems hitherto a secret. They say this menítrhum has nothing acid or corrosive in it; but that it approaches to the nature of spirit of wine, yet that it is capable of dissolving the molten metals, and of converting any of them into a pure white felt, which has all their virtues, but nothing of that vitriolic acrimony, which they have when prepared in the common way. The salts of mercury and of gold thus prepared have great praisès bestowed on them, and are said to cure epilepsies, the real disease, and many other diseases, without any violence or danger. Kunkel, De Sols Metal. See Metal.

ESSENTIAL, something that is necessary to constitute a thing, or that has such a connection with the nature and reason of a thing, that it is found, or supponed, wherever the thing itself is.

Thus, it is essential to God to be just. Mr. Locke has laboured to overturn that great principle of the Cartesians, that thinking is essential to the soul.

The heart, brain, and spinal marrow, are parts ordinarily supponed essential to life, or without which life cannot be; yet we have instances, in history, of children being found, and alive, without almost any of those parts. See Brain, &c.

ESSENTIAL characters, in Natural History, or Diagnost., are such particulars, as mark or distinguish a plant or animal from all others in the same genus or order. Mr. William Martin, in his "Outlines of the Knowledge of Excruciating Foibles," p. 189, states the principles under five heads, which should direct the choice of parts of a fossil animal or plant, to be considered as its diagnostic or essential characters. See Reliquia.

ESSENTIAL oils. See Oils.

ESSENTIAL properties, are such as necessarily depend on and are connected with, the nature and essence of any thing; so as to be inseparable from it; in distinction from accidental.

ESSENTIAL faults, are those prepared from deceptions, or those which are found crystallized in the juices and infusions of plants; in contradistinction to those made by incineration. See Salt.

ESSENTIAL Fever, Form, Mode, Part, Perfection. See the substantives.

ESSEQUEBO, or GUAYB. in Geography, one of the four provinces into which the Dutch possessions in Guiana are divided; the other three being Surinam, which is the chief settlement, Berbice or Berbys, and Demerara. This settlement derives its name from that of the large river on which it is situated, and which at its discharge into the Atlantic is 3 leagues wide. The productions of this country are sugar, coffee, and cotton. See Guiana, Surinam, Berbice, and Demerara.

ESSEWA, a river of Spain, which runs into the Cinca, in Aragon.

ESSEWA, ESSE, or E., in Medicine, a generic denomination, used by the Arabian physicians, and comprising several popular eruptions, and rashes, which appear on the skin: especially the eruption of the summer fesión, in warm climates, which has been termed the Petecaly-beat, the Nettle-rush, the Prurigo of Dr. Willan's classification; &c. See these articles. See also Willan on Cutaneous Diseases, genus Lichen.

ESSERM, in Geography, a small town of Denmark, in the island of Zealand, in the diocese of Cramburg, and the herred of Holboe. Before the Reformation it was remarkable for a rich monastery of Bernardines, founded in 1540, in an extremely pleasant country, watered by lakes abounding in fish. But Efferum is now much more interesting for a royal seat of horses, and for having constantly flocks of the most renowned foreign sheep, Spanish and others, which are distributed among the farmers to improve the Danish breed. In the beginning of the year 1800, there were at Efferum 672 choice sheep, of which 223 ewes, and 33 rams, were Spanish of the best Merino breed. Cæteau Tableau des Etats Danais, vol. ii. p. 147.

ESSES, in Military Language, are fixed to draught chains, made in the form of an S; one end of which is fastened to the chain, and the other to hook to the horse's harness, or to a staple; they serve likewise to lengthen and piece chains together.

ESSEX, in Geography, the name of one of the English counties, which has for its boundaries the German ocean and river Thames to the sea and south; the counties of Suffolk and Cambridge to the north; and those of Middlesex and Hertfordshire to the west. The area of land thus enclosed measures about sixty miles in length from east to west, by fifty from north to south; its circumference being about 25 miles. It is divided into 20 parts, of which fourteen are hundreds, five half hundreds, and one a royal liberty. These are subdivided into about 400 parishes and townships, and twenty-five towns; containing, according to the late official report, 39,398 houses, and 22,645 inhabitants. When the Romans invaded Britain, this district, with that now denominated Middlesex, were inhabited by a tribe or tribe of the Britons, called Trinovantes, or Trinovants, who policed, according to Cæsar, and some other ancient writ-
ERS.

ners, two considerable cities or fortified towns; one, the site of modern Loundon; and the other, that of Colchester in this county. This tribe was the first to submit to and become vassals to the Romans, who, to keep them in subordination, established five military stations within this district. These were Durotrigem, Caer aromagus; Caerwicker, Bignor, and Ad Anfum. These stations were all seated on the road which formed the fifth tier from Londonium to Venta Icenorum, Callor in Norfolk. Colchester was unquestionably the principal station in Essex, and through its site has been much contested by different writers, an attentive examination of the several places assigned, combined with a knowledge of the antiquities discovered in the vicinity of each, will admit little doubt of Colchester being the real situation. Essex formed a separate and distinct kingdom during a certain period of the Saxon Heptarchy, and was called East Saxan; but the times of its establishment and termination are not precisely authenticated. Turner states that this district, and East Anglia, were originally occupied by the Saxons at nearly the same period; and that Erken- 

By the Domesday-book it appears, that ninety land-owners of this county were deprived of their lands by the Con- 

queror, during whose reign the whole civil and ecclesiasti- 

cal establishment of the kingdom, and of each county, under- 

went very considerable changes. Essex was now govern- 
ed and tyrannized over by Norman barons, who constructed castles on their estates to secure themselves, and to awe their dependant vassals. In the civil wars between the houses of York and Lancaster, and in those of Charles's time, this county suffered greatly from the interference of the De Vere's in the former, and during the long siege of Colchester in the latter. Formerly there were twelve castles, or forti- 
sed buildings in this county; two of which, Landguard 

fort, and Tilbury fort, were denominated royal castles, as 
built for national security; the others were baronial resi- 
dences, viz. Colchester, Hadleigh, Canfield, Hedingham, 

Clavering, Raleigh, Ongar, Plehly, Staunfield-Monthelet, 

and Walden. These formidable fortresses, though once 
the pride of the nobility, and the terror of the peasantry, 
are mostly reduced to the ground; the only parts remaining 
being their high keeps and wide fosse. At Colchester, 

Hadleigh, Hedingham, and Walden, some parts of the 

walls still remain. Essex composes part of that tract of 
country on the easterly side of England which forms the 
largest connected space of level ground in the whole island; not one lofty eminence or rocky ridge being found in sev- 
eral contiguous counties. The surface of Essex is not, how- 
ever, totally flat, having many gentle hills and dales; and 
towards the north-west, where most of the rivers proceed, the country rises, and presents a continued inequality of sur- 
face. The most level tracts are those of the southern and easterly hundreds. The sea-coast is broken into a series of 

Iflets and peninsulas, deeply cut in by arms of the sea, and 

exhibiting evident tokens of the force and effects of that 

refract element. Extensive salt marshes border most of the 

coast, the greater part of which is protected by embank- 

ments. The banks of the Thames, and the lower part near the sea, are likewise low and marshy. This county 

dies under a proverbial imputation of being particularly unhealthy; but this character can only apply to a small part 
of it; as the middle and northern districts are justly noted 

for a dry soil, and a wholesome clear air. That part known 

by the name of the hundreds of Essex, bordering on the 

soth coast, from its low and marshy situation, and exposure 

to the easterly winds and sea fogs, is certainly inimical to 

health, and many intermitting fevers proceed from these 
causes. The principal productions of this county are wheat, bar- 

ley, oats, beans, peas, turnips, tares, rape, mullahard, 

ryegrass, and trefoil. Many districts on the east side are 

extremely productive; wheat is not unfrequently found 
rife to a load an acre; oats, (particularly the Poland,) to 
eleven or twelve quarters; beans and other corn in propor-

tion. Among the more rare plants cultivated in Essex, are 

those of coriander, taceil, and carroway; many acres are 

also appropriated to the produce of hops, and various horti-
cultural plants and roots. The latter are confined to the 

vicinity of large towns, and to the lands adjoining to the 

metropolis. Almost every species of soil is to be found 

within the limits of Essex, from the most rubbly to the 

mildest loam. The north-west side is characterized by a 

chalky sub-fratum; but the east and south sides abound 

with marshy and boggy land, having abundance of gravel 

intermixed. Of waste lands and forests, Meffs. Grigg in 

their "General View of the Agriculture of Essex," 

computed the county to contain fifteen thousand acres; the 
greater part of which, they observe, is capable of producing 
corn. Since their report, however, many districts have been 
icolosed and cultivated. Though Essex is not highly 

celebrated for its dairy, yet that in the parish of Epping 

and its vicinity are famous for the richness of their cream and 

butter. The butter is mostly sent to London, where it 

bears a high character and price. Few counties have less 

minerals than Essex; which is also nearly exempt from 
quarries, or any mals of rocks. In consequence, the houses 

are almost wholly built with brick; and many of them are 

angular and curious specimens of brick-architecture. In 

constructing the castles, the monastic buildings, and many 
of the old manor-houses, the builders have endeavoured to 

render them not only durable monuments of their skill, but 
also examples of their taste, displayed by a variety of orna-

ments in the cornices, doors, pilasters, and particularly in 
the chimneys. Some mineral waters rise in the county, but 

few have obtained much repute; that of Tilbury is occa-

sionally reorted to, and found to be impregnated with some 
earthly and muriatic salts.

The principal rivers, properly belonging to this county, 
are the Colne, the Blackwater or Punt, the Clelmer, the 
Crouch, the Ingerbourn, the Roding, and the Cam. Befides 
these, Essex partakes of other rivers, which serve as natural 
boundaries, and irrigate and fertilize its land; these are the 
Thames, the Lee, or Lea, the Stort, and the Stour. In the 
early periods of our history, it is reasonably pre-

fumed, that the whole, or the greater part of Essex, was one 

extensive forest. During the Briti and Roman govern-
ments, many parts must have been cleared for stations, 
roads, and cultivation, yet in the time of king Stephen it 
appears that the principal portion of the county was either 

forest, or subject to forest laws. In his reign, however, a 

large tract in the north-east part of the county was disaffo-

refied, and cultivated; and this tract, the greater part of north of 

Romford, was disafforested by king John, Henry the 

Third, in the twelfth year of his reign, directed perambula-

tions to be taken of Waltham forest, in order to ascertain 
its extent and value; and about the same time had large tracts 
cleared for the plough. This judicious plan was pursued by 

Edward the First, in the twenty-sixth and twenty-eighth 

years of his reign: yet much forest land still remained; 

and Paul, vicount Bayning, with many other gentlemen 

of the county, purchased of the crown, and disafforested 

several
fif a parts of it. These proceedings, combined with the
two equitable decisions of subsequent monarchs, occasioned
the forests to contract their boundaries, and be left injurious
to the public. While the forests continued in the crown,
and were under the local government of arbitrary foresters
and stewards, the subject, whose estate was contiguous,
suffered repeated oppressions. The grievance was partly
reddened in the perilous reign of king John, when the barons
compulsively procured from that monarch the "Charter of
Forests," by which many of these royal districts were dis-
afforested, and stripped of their oppressive privileges; while
more lenient regulations were adopted in the government of
those that remained. The forests of Epping and Hain-
mault still retain the name, and support a few deer, &c. The
office of chief forester for Essex was deemed highly honorary,
and was generally belittled on some illusory person.
The stewardship was also an office of great consequence,
and was usually enjoyed by some of the nobility. It con-
tinued in the De Veres, earls of Oxford, for many genera-
tions, but was taken from them by Edward the Fourth, on
account of their adherence to the Lancastrian party. On
the accession of Henry the Seventh, it was restored by grant
to John, earl of Oxford. The steward had power to sub-
stitute a lieutenant, one riding forester, and three yeomen-
foresters, in the three bailiwicks of the forest. He also had
many lucrative privileges, and was keeper of Haverhill At
Bower, and of the house and park there.

Previous to the dissolution, Essex contained forty-seven
religious houses; of these, two were mitred abbeys; six
common abbeys; twenty-two priories; three nunneries;
three colleges; two preceptories of tempars; and nine
hospitals.

Essex, one of the most populous and best cultivated
counties in Maffachusettts, in the United States of America;
bounded N. by North Hamphire, E. and S. by the ocean,
and the town of Chelsea in the county of Suffolk, and W.
by Middlesex county; 38 miles long and 25 broad; of a
triangle shape, Chelsea being the acute point. It is sub-
divided into 22 townships, containing 7644 houses, and
61,156 inhabitants, about 135 to each square mile. The
first settlement in Massachusetts proper was made in Salem,
the capital of this county, in 1628, and it was made a
shire in 1643, being one of the three into which the colony
was divided. Essex county pays about 5th part of the
rate-tax, elects six senators for the government of the
commonwealth, and two representatives in the legislature of
the United States. The principal towns are Salem, New-
bury-port, Gloucester, Marblehead, Beverly, Newbury,
and Ipswich; and in it are two academies, one by Baysfield,
and another at Andover. The face of the county is agreeably
variegated with hills, vales, plains, and woods; the land
is generally fruitful, but more suited to the culture of
barley than most other parts of the state; it has quarries
of marble and limetone, and the coast is indented with a
number of good harbours. The north part of Essex county
is intersected by Merrimack river; and between it and the
North Hampshire line is a strip of land three miles wide,
divided into the towns of Methuen, Haverhill, Aln bury,
and Salisbury, containing 1429 inhabitants. The chief
island on the coast of this county is Plum island.

Essex, a county in Upper Canada, bounded on the E.

EST

he is detained by nicknacks in such a village, that he cannot come pro lucrari et pro perdere; and this will be admitted; for it is a proof of the plaintiff to prove, whether the effigy is true or not.

ESSOIGNES, Clerk of the. See Clerk.

ESSOMMES, in Geography, a small town of France, in the department of the Aisne, on the river Marne; 3 miles S. of Château-Thierry.

ESSONE, a river of France, in the department of Seine and Oise, which has its source near Pithiviers in the forest of Orleans, flows by Ferté-Alais, receives the Juine near Saint-Vrain, 3 miles above Villeroi, and falls into the Seine near Corbeil. It has lately been rendered navigable.

ESSONNE, a small town of France, in the department of Seine and Oise, near the river Essone, 24 miles S. of Paris, and 25 miles N. of Fontainebleau. Remarkable for its manufactures of gunpowder and of writing paper.

ESSORANT, from the French essor, to air, in order to dry, in Heraldry, a term used to express a bird standing on the ground with the wings expanded, as if it had been wet, and were drying itself.

ESSOYES, in Geography, a small town of France, in the department of the Aube, chief place of a canton in the district of Bar-sur-Seine, with a population of 1,955 individuals; 7 miles S.W. of Bar-sur-Aube. Its canton contains 21 communes, and 11,655 inhabitants, on a territorial extent of 375 kilometres.

ESTABLISHMENT of Dower, in Law, is the assurance or settlement of dower made to the wife by the husband on marriage; and assignment of dower signifies the setting it out by the heir afterwards, according to the establishment. See Dower.

ESTABLISHMENT of Religion. See Religion.

ESTACHE, is used in our Old Writers, for a bridge or flint of stone and timber.

ESTAFFLEISCHEN, in Geography, a town of Poland, in the palatinate of Kalisz; 14 miles N.E. of Kalisz.

ESTAFORT, a town of France, in the department of the Lot and Garonne, and district of Agen; 3 leagues S. of Agen.

ESTAGEL, a town of France, in the department of the Eastern Pyrenees; 3 1/2 leagues N.W. of Perpignan.

ESTAGNAC, a small town of France, in the department of the Charente; 33 miles E. of Angoulême.

ESTAIN, See Estain.

ESTAIN, a small town of France, in the department of the Aveyron, chief place of a canton in the district of Espalion, with a population of 1,375 individuals. It is situated 18 miles N. of Rhôdés. Its canton contains 12 communes and 6,700 inhabitants on a territorial extent of 195 kilometres.

ESTAINE, a small town of France, in the department of the North, on the river Lys, between Merville and Armentières; 15 miles W. of Lille.

ESTAMBOL, or Istanbul-Antir, a town of Arabia, in the island of Mecca, near the coast of the Red sea; 160 miles N.W. of Medina.

ESTAMPES. See Estampes.

ESTANDARD. See Standard.

ESTANFORDE, in Geography, a town of Flanders; 13 miles S.W. of Ypres.

ESTAPA, or Estapo, a town of North America, in Mexico, and province of Tabasco, situated on a river of the same name; 10 miles S.W. of Villa Hermosa.

ESTAPLES. See Estaples.

ESTAPO, a strong town of America, in New Spain, inhabited by Spaniards and native Americans, situated at the mouth of the river Tlahim. N. lat. 17° 30'. W. long. 105° 5'.

ESTARREJA, a town of Portugal, in the province of Beira; 18 miles S. of Oporto.

ESTATE, in Law, the title or interest which a man hath in lands or tenements, &c. An estate in lands, tenements, and hereditaments, signifies (says judge Blackstone) such interest as the tenant hath therein; so that if a man grants all his estate in Dale to A. and his heirs, every thing that he can possibly grant shall pass thereby. (Co. Litt. 345.) It is called in Latin status, signifying the condition or circumstance in which the owner stands with regard to his property. For ascertaining this with accuracy, estates may be considered in a three-fold view: first, with regard to the quantity of interest which the tenant has in the tenement; secondly, with regard to the time at which that quantity of interest is to be enjoyed; and, thirdly, with regard to the number and connexion of the tenants.

1. The quantity of interest which the tenant has in the tenement is measured by its extent and duration. Thus, either his right of possession is to subsist for an uncertain period, during his own life, or the life of another man; to determine at his own demise, or to remain to his descendants after him; or, it is circumscribed within a certain number of years, months, or days; or, lastly, it is infinite and unlimited, being vested in him and his representatives for ever. This occasions the primary division of estates, into such as are freehold, and such as are less than freehold. See Freehold.

Estates of freehold, understood as they are defined under that article, are either estates of inheritance, or estates not of inheritance. The former are again divided into inheritances abso-fute or fee-simple, and inheritances limited, one species of which is usually denominated fee-tail. See Fee, Fee-simple, and Fee-tail.

Of estates of freehold, not of inheritance, but for life only, some are conventional, or expressly created by the acts of the parties; others are merely legal, or created by construction and operation of law. As estates for life, expressly created by deed or grant; see Life-estate. As to the estate of tenant in tail after possibility of issue extinct; see Tail and Fee-tail. As to tenant by courtesy, and tenant in dower; see Tenant and Dower.

Of estates that are less than freehold, there are three sorts; viz. 1. Estates for years; 2. Estates at will; 3. Estates by sufferance. For the two former, see Lease; and for the latter, see Sufferance.

Besides the several divisions of estates above enumerated, in point of interest, there is another species which is called an estate upon condition; being such whose existence depends upon the happening or not happening of some uncertain event, whereby the estate may be either originally created, or enlarged, or finally defeated. (Co. Litt. 211.) Estates upon condition are of two kinds: 1. Estates upon condition implied; 2. Estates upon condition express; under which last may be included, 3. Estates held in àvenu, gage, or pledge; 4. Estates by Œd另一方面-merchant or Œd另一方面-specie; 5. Estates held by lieu. See the several articles.

II. Estates, with regard to the time of their enjoyment, when the actual receipt of the rents and profits commences, may be considered either in possession or in expectancy; as to estates in possession, sometimes called estates executed, whereby a present interest passes to and resides in the tenant, not depending on any subsequent circumstance or contingency, as in the case of estates executory; all those above-mentioned are of this kind; but the doctrine of estates in expectancy contains, says Blackstone, some of the nicest and most
most abstruse learning in the English law. Of experiences there are two sorts: one created by the act of the parties, called a remainder; the other by act of law, and called a reversion. See Remainder and Reversion. See also Executory devise and Limitation.

III. Estates considered with respect to the number and connexions of their owners, or the tenants who occupy them, whatever be their quantity or length of duration, and whether they be in actual possession, or expectancy, may be held in four different ways: viz. in fee simple, in joint-tenancy, in appurtenancy, and in common. See Fee Simple, Joint Tenancy, Coparcenary and Parceners, and Tenants in Common.

With regard to the title to estates and the different modes of tenure; see Title and Tenure.

Estates are acquired divers ways, viz. by descent from a father to the son, &c., conveyance or grant from one man to another; by gift or purchase, deed, or will; and a fee simple is the largest estate that can be in law. 1 Litt. 541.

Estates are real, of lands, &c. or personal, of goods and chattels; otherwise distinguished into freeholds, that descend to the heir, and chattels, which go to the executors. The word estate, generally, in deeds, grants, and conveyances, comprehends the whole, in which the party hath an interest or property, and will pass the same. 3 Mod. 46.

Estate, additions of. See Addition.

Estate, base. See Base.

Estate, grace. See Que estate.

Estate, or simple State, denotes also the empire, kingdom, provinces, or extent of lands under the government of any sovereign.

The estates of the grand seigneur, of the king of Spain, &c. are very extensive; those of the king of France were before the revolution compact, and well peopled. Italy was formerly cantonized out into a great number of petty states. We fry, ministers of estate, secretaries of state, &c.

Estate, or State, is also generally applied in the same sense with chiefs or order; thus, the lay part of his majesty's subjects, or such of the people as are not comprehended under the denomination of clergy, may be divided into three distinct estates or states, the civil, the maritime, and the military. See each term.

Estate is more particularly applied to the several ranks or classes of people assembled together, for concerting measures, reforming public abuses, or composing the disturbances of a state. In England, the three estates, viz. king, lords, and commons, meet ordinarily in parliament. See Parliament.

Estates General. See States General, &c.

Estavayer, in Geography, a small town of Switzerland, in the canton of Fribourg, pleasantly situated on the eastern shore of the lake of Neufchatel, N. lat. 46° 49'.

Este, a town of Italy, in the Paduan; 1 miles S.S.W. of Padua.

Estella, a handsome manufacturing town of Spain, in Navarie, with an university in its neighbourhood, founded A.D. 1555. It contains several churches and convents, and 4500 inhabitants, defended by a wall, situated in a plain, watered by the rivers Ega and Ubeda; 6 leagues S.W. of Pampeluna. The environs of this place are agreeable and fertile.

Estellmuir, a town of Asiatic Turkey, in the province of Crimania; 120 miles S. of Cogni.

Estenhede. See Ensenide.

Estepa, a town of Spain, in the province of Seville, or, according to some geographers, in that of Granada, celebrated for its olives and oil; 15 miles S. of Ejea.

Estepona, a small fishing town of Spain, situated near the coast in the province of Granada, between Gibraltar and Marbella. Its territory furnishes abundance of wine.

Estering, or Easterling. See Sterling.

Esternay, in Geography, a small town of France, in the department of the Marne, chief place of a canton in the district of Epernay, with a population of 837 individuals. Its canton has 23 communes and 6398 inhabitants, upon a territorial extent of 325 square miles.

Estete, in Heraldry, is used by the French to signify a head whose head has been, as it were, torn off by force, and, consequently, the neck left rough and rugged; in contradistinction to deft, or decapit, where the neck is left smooth, as if the head had been cut off.

Estevé, M. in Biography, a writer on the theory of music, or rather on sound or harmonics. He has attacked the demonstration of the principles of harmony by Rameau, in which M. Laborde allows him to have reason on his side; however, as he does not build his scale by the triple progression of Pythagoras, in the way which the abbe Rouffier prefers it, and without which series of perfect fifth he thinks there never was nor ever can be any music fit to be heard, M. Estevé has not been honoured with the feal of Melli. Laborde and Rouffier's approbation. He has, however, explained the cause of more and less perfection in concords, from the coincidences of vibration, which has been known ever since the time of Galileo, (see Bassé fundamento), but never so clearly explained in France.

Esther, a canonical book of the Old Testament, denominated from a celebrated Jewish captive of that name, in Persia, whose beauty preferred her to the bed of Ahasuerus (supposed by some to have been Darius Hytaipis, by others Xerxes, but probably Artaxerxes Longimanus, though Jacob Capellus makes him to be Ochus, called in Herod Achaæchus-Vereby), and the throne of Persia; and who, in that quality, saved her countrymen, the Jews, from the death to which Ahasuerus had doomed them, by the counsel of his favourite Haman; who wished that he be revealed on Mordecai for withholding from him that respect to which he conceived himself entitled. Mordecai informed the queen of the danger to which her nation was exposed; and induced her to set out upon the king, and invite him and Haman to a sumptuous banquet which she had prepared. Haman was puffed up with this high honour, and thought himself secure of accomplishing his amble scheme of vengeance. During the interval, the king chanced to read the public records, which reminded him of Mordecai's having discovered a conspiracy that had been formed against him. Determined to distinguish him by some signal token of favour, he ordered Haman to conduct Mordecai in triumph through the city. The queen having discovered to Ahasuerus, that she belonged to the Jewish nation, interceded for justice against Haman on behalf of her people, for the destruction of whom he had obtained the king's decree. Ahasuerus ordered Haman to be hanged on the gallows which he had erected for the execution of Mordecai: revoked the decree inflicted against the Jews, and granted another, by which he permitted them to avenge themselves on their enemies on the day appointed. After the death of Haman, the king bestowed his estates upon Mordecai, and admitting him into his confidence, as the acknowledged uncle of the queen, advanced him to a station of high office and trust in his court. The history of this transaction makes the subject of the book of Esther. Editor was of the tribe of
of Benjamin, and a descendant from one of those families, which had been carried into captivity by Nebuchadnezzar, king of Babylon, and afterwards settled in the city of Shushan. She was the niece of Mordecai, and her Jewish name was “Haddassah.”

The critics are divided about the author of this book: St. Epiphanius, St. Augustine, and Isidore, attribute it to Ezra; but Eusebius will have it to be of a later date. Some ascribe it to Joschim, high priest of the Jews, and grandson of Jofedek; others will have it composed by an assembly, or synagogue, of the Jews, to whom Mordecai wrote letters, informing them of what happened. Either. ix. 29.

But the generality of interpreters, Hebrew, Greek, Latin, &c. ascribe the book to Mordecai himself; Elias Levita, in his Maff. Hamum. pref. 3. mentions this opinion as unquestionable.

It is chiefly founded on that passage, chap. ix. ver. 29, where it is said, that “Mordecai wrote these things, and sent letters unto all the Jews, that were in all the provinces, &c.” It is also supposed that queen Esther herself might have some share therein: it being expressed in the same chapter, ver. 29, that Esther and Mordecai wrote a secret letter, by the king’s authority, to ordain the feautaining a yearly feast, called purim, that is, day of lots, in commemoration of the Jews being delivered from the lots, or fortes, whereby they had been condemned.

Some will have this book to be deuterocanonical, or apocryphal; others contend for its being canonical, as far as chap. x. ver. 3. inclusive; and all the rest deuterocanonical. Of this sentiment are, St. Jerome, De Lyra, Dionysius the Carthusian, Cajetan, and others. The council of Trent turned the scale for its being canonical throughout; so that the matter is determined for the Catholic countries.

But the Protestants retain the old opinion, and assert it as far as the third verse of the tenth chapter; the rest, to the end of the sixteenth chapter, is thrown among the apocryphal books. See Canon and Apocrypha.

Esthioménos, in Geography, a town of America, in the county of Lancaster, and state of Pennsylvania, situated on the east bank of the Susquehannah river, a little N. of Harriuffburg.

Esthioménos, (from &oslash;os, to eat,) in Surgery, the disease called herps excedens. Also any obdurate ulcer, which continues to eat away the parts.

Esthonia, in Geography, is the ancient name of the Russian government of Reval, on the southern coast of the gulf of Finland, over-against Finland Proper. In the year 1386 Esthonia was fold to the Teutonic order, and formed a part of Livonia; with which, after a separation of a hundred years, when it was under the dominion of Sweden, it was united to the Ruffian territory.

Not only the government of Reval, but also the greater part of Livonia, or five circles of the government of Riga, are inhabited by Esthonians. In the former they probably amount to 180,000, in the latter to 257,000 individuals. The language, manners, complexion, dwellings, and husbandry of the Esthonians prove their relationship to the Finns, who are one of the most far spread nations of the globe, extending from the shores of the Baltic to the remotest confines of Asia. In the Russian annals, where they act a considerable part, as they, in common with the Novgorodian Slav, founded the Russian state, the Esthonians are called Tzchades. Tooke’s View of the Russian Empire, vol. i.

Estoile, in Antiquity, solemn sacrifices to Vesta, called in Greek τεμενος, of which it was unlawful to carry any way, or communicate any part to any beside the worthiappers. Potter, Archæol. Græc. lib. iii. cap. 29. tom i. p. 396.

Estiatores, in Geography, among the Athenians, persons appointed by lot to provide an entertainment for the whole tribe. Besides those appointed by lot to this office, others voluntarily undertook it to ingratiate themselves. Potter, Archæol. Græc. lib. i. cap. 15. tom. i. p. 86.

Estimione, in Natural History, a name by which fome call the barremou.

Estissac, in Geography, a small town of France, in the department of the Aube, chief place of a canton in the district of Troyes, with a population of 1255 individuals. Its canton has 869 inhabitants, dispered in 10 communes, on a territorial extent of 200 kilometres.—Also, a small town of France, in the department of the Dordogne, 18 miles N.E. of Bourdeaux.

Estival, a town of France, in the department of the Vosges, and district of St. Diey; 2 leagues N. of St. Diey.

Estival occident. See Occident.

Estival orient. See Orient.

Estival foliace. See Estival, and Solstice.

Estivarailles, in Geography, a town of France, in the department of the Allier, and district of Montluçon; 5 miles N. of Montluçon.

Estius, William, in Biography, a learned Dutch divine, was born at Gurecum in Holland in the year 1542. He received the early part of his education at Utrecht, and finished his studies in philosophy and theology at Louvain, where he afterwards became an instructor. In 1580 he was admitted to the degree of doctor in divinity, and was successively chosen professor of theology, in the university of Douay; superior of that seminary, and afterwards its chancellor. He died in 1613 at the age of 71, while he was in the discharge of the various duties of his laborious office at Douay, highly esteemed on account of his modesty, piety, and active virtues. He had ever been indefatigable in his studies, and zealous in promoting the interests of those committed to his care. As an author his principal works are, “Commentarii in omnes S. Pauli et V.I. Catholicae Apostolorum Epistolas,” in two volumes folio. “Annotatiores in prosapia ac difficiliae S. Scripturae Loca.” Another work is mentioned with much applause, it is a discourse “Contra Avarizitatem Scientiae,” intended to expel those who lock up their learning in their closets, and refuse to communicate it to the public by useful writings, or to individuals by well-timed and seasonable advice. The writings of Estius are recommended by Du Pin as exceedingly useful to young theologians in their enquiries after truth. Moreri.

Estoile. A crofs citolle is a star with only four long rays, in manner of a crofs; and accordingly broad in the centre, and terminating in sharp points.

Estolle. Peter de l’, in Biography, who flourished towards the close of the sixteenth century, was educated to the profession of the law, and became grand advocate of the chancery of Paris. He died in 1611, and after his death was published from his manuscripts “A Journal of the reign of Henry III,” which has passed through many editions; of these the last was edited by the Abbé Lenglet du Fresnoy in 5 vols. 8vo. The fame learned editor gave to the public “L’Estolle’s Journal of the reign of Henry IV,” in four volumes, 8vo. This, as well as the other work, is enriched by some curious pieces not to be found in the preceding editions. The style and manner of these journals possefs much simplicity, exhibiting the air of truth,
truth, and affording a lively and accurate picture of the times. Moreri.

ESTOLLE, Claude de l', son of the preceding, was a poet, and admitted a member of the French academy in the year 1632. He was patronized as a dramatic writer by Richelieu, but his pieces were not well received by the public, though he is allowed to have had a talent at verication, and a thorough knowledge of the rules of the stage. He was a rigid censor of his own performances, and of those of others, and is said to have occasioned the death of a young author by the severity of his criticism on a comedy put into his hands. He died in 1632 about 50 years of age. He had obtained, and richly deferved, the character of an honourable and truly independent man. In the earlier part of life, though ill provided for with respect to fortune, he chose to quit the capital with a wife whom he loved, rather than submit to the meannesses which men of letters are too much inclined to practise in courting the opulent. Moreri.

ESTOPPEL, formed, of the French effpurer, oppilare, elfsparre, to stop, or block up, in Law, an impediment, or bar of action, arising from a man's own act, or deed; against which a man is forbidden, by law, to speak, though it be to say the truth. See Bar.

Goddard defines an estoppel to be any bar, or hindrance, to one to plead the truth; and extends it not only to the impediment given by his own act, but by another's also. There are three kinds of estoppel; viz. by matter of record, by matter in writing, and by matter in pais.

ESTOVERS, is used by Bracton, (I. iii. tr. 2. c. 18.) for that fullenance which a man, committed for felony, is to have out of his lands, or goods, for himself and his family, during imprisonment.

In Rat. 6 Edw. 1. it is used for an allowance in meat, or clothes. In some manors the tenants have common of effovers; that is, necessary botes, or allowances, out of the lord's wood; in which last sense, effovers comprehends house-bote, hay-bote, and plow-bote; so that if a man have in his grants these general words, "de rationabili effoverio in bovis, &c." he may thereby claim all three.

Estovers is also used for alimony, which if the husband refuses to pay, there is, besides the ordinary process of excommunication, a writ at common law, "de effoveris habendis," in order to recover it.

ESTOURMELLES, in Geography, a town of France, in the department of the North, and district of Cambrai; 14 league E. of Cambrai.

ESTOUTEVILLE, a small town of France, in the department of the Lower Seine, 12 miles N. of Caudebec. Also, a small town of France, in the same department, 15 miles N. of Rouen.

ESTRAC, in the Mange, signifies a horse that is light bodied, lank-belted, thin-flanked, and narrow-chested. See Belly.

ESTRADE, a French term, literally signifying a public road, or highway. Hence the military phrase, bailli de estrade, to beat the estrade, that is, to lead scouts, or horsemen to get intelligence, to learn the dispositions of the enemy, and inform the general of every thing likely to fall in their way. An army never marches without finding bar- teurs d'estraade on every side.

The word is formed of the Italian estrada, street, or road; which is derived from the Latin strata, a paved street. Some derive it from estradiato, who were cavaliers anciently employed in beating the estrade.

Estrade is also used for a little elevation of the floor of a room, frequently encompassed with an alcove, or rail, for placing a bed in; and sometimes, as in Turkey, only covered with fine carpets, for receiving visitors of distinction.

ESTRADES, Godfrey Count of, in Biography, was at an early age desigined for the profession of arms, and served under prince Maurice in Holland, with whom he acted as agent of the French court, and afterwards attained the high honour of marshal of France. He was highly esteemed as a diplomatic character, and in the year 1661 went to England as ambassador extraordinary, where he maintained with spirit the precedence of the crown of France to that of Spain. In the following year he went to Holland in the same character, and concluded the peace of Breda. He was intrusted with the important negociation for a general peace at Nimogue, and acquitted himself to the satisfaction of all concerned. He fulfilled with high reputation various other diplomatic characters, and in 1685 was nominated governor to the duke de Chartres, but died within a few months, at the age of seventy-nine. The count left behind him an abundance of MSS. concerning the different negociations in which he had been engaged; from these, which consisted of twenty-two volumes folio, a collection was published in 1709, entitled 'Letters, Memoirs, and Negotiations of the Count d'Estrades.' An improved edition was published in 1743 at the Hague, in 9 vols. 12mo.

ESTRANGE, Estrangis, in the Syriac Grammar. Estrangis character, is a particular species, or form, of Syriac letters; serving as the majuscule letters in that language.

Abraham Ecchellenius takes the estrangis character for the true ancient Chaldean characters, and it is certain the Abyssinians, who call themselves Chaldeans, still occasionally use the estrangis character, if we may credit Hottinger, in his Thesaur. Philol. p. 286. Bishop Walton, in his Prolegomena, gives us an estrangis alphabet.

ESTRAPADE, in the Mange, is the defence of a horse that will not obey, but to get rid of his rider, rides much before, and while his forehead is yet in the air, yeers furiously with his hind legs, striking higher than his head was before; and during his countermay goes back rather than advances.

ESTRAY, or Stray, signifies any tame beast, or sheep, oxen, swine, and horses, found within a lordship, and not owned by any man; in which case being cried, according to law, in the church, and two market-towns adjoining, if it be not claimed by the owner, within a year and a day, it becomes the lord's of the soil where found. If the owner claims it within the year and day, he must pay the charges of finding, keeping, and proclaiming; and he may seize it, without telling the marks, or proving his property, which may be done at the trial if contested. If the beast stray within the year to another lordship, the first lord cannot retake it. An estray must be fed and kept, uninjured, and without labour, till it is claimed, or the limited time expires.

ESTREAT, Extractum, in Law, is used for the true copy, or duplicate, of some original writing, especially of amercements, or penalties, set down in the rolls of a court, to be levied by the bailiff, or other officer, on every offender. Justices, commissioners, &c. are to deliver their estrats into the exchequer yearly, after Michaelmas; and fines to have writs, which shall be entered in the estrat, in order as they are entered in the chancery rolls, &c. fl. 51 Hen. III. fl. 5. 16 Edw. II. All forfeited recognizances are to be first estrated in the exchequer by sheriffs of counties; on which process issues to levy the same to the use of the king. Stat. 22 and 33 Car. II. cap. 22. Sheriff's
E S T

Sheriff's edicts must be in two parts, indented and sealed by the sheriff, and two justices of peace; who are to view them, and one of them is to remain with the sheriff, and the other with the justices. Stat. 11 Hen. VII. c. 15. The edicts of fines, at the quarter-seions, are to be made by the justices; and to be double, one of which is to be delivered to the sheriff by indenture. Stat. 14 R. II. c. 2. Fines, poll-fines, forfeitures, &c. must be treated into the exchequer twice a year, on pain of 50l. And officers are to deliver in their returns of edicts upon oath. Stat. 22 & 23 Car. II. c. 22. 4 and 5 W. & M. c. 24. It is the courie of the court of B. R. to send the edicts into the Exchequer twice a year, viz. on the last day of the two infulable terms; but in extraordinary cases there may be a rule to treat them sooner. 1 Salk. 45.

ESTRETS, Clerk of the. See Clerk.

ESTREES, Francis-Anneal D', in Biography, was born in 1575, and educated for the church, in which he had the bishopric of Noyon conferred upon him by Henry IV. at a very early age. When he was only twenty-one he resigned his ecclesiastical preferment, on account of the death of his elder brother, and assumed the profession of arms, in which he became distinguished under the title of the marquis De Coevres. He was embaassador extraordinary to Switzerland and the princes of Italy, in 1614. He was created marshal of France in 1626, and in 1632 succoured the duke of Mantua, who was besieged in his capital. In 1636 he was deputed embaassador extraordinary to Rome, a character in which he well supported the honour and interests of his crown in opposition to pope Urban VIII., with whom, and the nephews of the haughty pontiff, he was continually involved in quarrels. He was recalled by his own sovereign, who considered him as an affront, and refused to appear at court, to give an account of his conduct. He died at Paris in 1670, at the great age of ninety-eight years, highly respected by his countrymen. At the decease of cardinal Richelieu, he drew up "Memoirs of the Regency of Mary de Medecis," which was published at Paris in 12mo. in the year 1660. "A relation of the Siege of Mantua, in 1630," and "An Account of the Conclave, in which Pope Gregory XV. was chosen in 1621," have also been given to the public from his papers. Moretti.

ESTRES, Caesar D', son of the preceding, was born in 1628, and being brought up to the church, he was raised to the bishopric of Laon in 1655. He was created cardinal by Clement X. in 1671; and at the death of that pontiff entered the conclave, and managed so as to put off the election five weeks, till the arrival of the other French cardinals. He was sent into Bavaria to negotiate the marriage of the dauphin in 1677, and afterwards went to Rome, on other important and difficult business. He supported the rights of the crown, and of the Gallican church in opposition to pope Innocent XI., whom he prevented from publishing any act infringing on both. He refrained many years at Rome, the sole resident on the part of France, and exerted much influence at the election of succeeding popes. On his return to France he was rewarded with the rich abbey of St. Germain des Pres, where he died in 1714, in his eighty-seventh year, greatly regretted, &c. leaving behind him a high character as a politician. Moretti.

Estres-Saint-Denis, in Geography, a small town of France, in the department of the Oise, chief place of a canton, in the district of Compiegne, with a population of 1642 individuals. The canton has a territorial extent of 150 kilometres, with 22 communes, and 10,325 inhabitants.

ESTREMADURA, i.e., Extrema Dutii, a province of Portugal, bounded on the north by Beira, on the east by Beira and Alentejo, on the west by the ocean, lying between 38° and 40° N. lat., and obliquely between 6° 10' and 9° 30' W. long.; being 140 miles from north to south, and 50 in breadth; containing 5,440 square miles, 8 jurisdictions, 400 parishes, and 5,500 inhabitants. Several districts of this province are abundantly fertile, yielding grain, wine, oil, and fruits. The whole country is covered with flowers, and the bees produce a great quantity of honey. The manufacture of salt affords one of the chief articles of commerce. The principal towns are Lisbon, Leiria, Abrantes, Pombal, Alcobaca, Setubal, Thomar, Santarem, Alcanquer, Torres Vedras, Cinta, and Calcaes; and the chief rivers are the Tagus, or Tajo, and the Sador or Sado, sometimes called Cadizn and Caldas.

ESTREMADURA, a province of Spain, bounded on the N. by Leon; on the E. by New Castile; on the W. by Andalusia; and on the E. by Portugal; lying between 38° and 40° N. lat.; and between 7° 10' and 4° 40' W. long.; being 140 miles from north to south, and 50 — r. 0. from west to east. This province was formerly a part of Portugal, but being separated from that country, it is sometimes called Estremadura of Castile. It is traversed by the rivers Guadiana and Tajo, which divide it into three equal parts. Intersected by ridges of hills, it abounds in grain, fruits, and excellent meadows, but good water is scarce, and the air in summer is excessively hot, insupportable to strangers, but to the natives not infallibrable. The principal commerce consists of cattle and fine wool; and the hills are covered with oaks, the acorns of which feed large herds of swine, that are black. The inhabitants are in general inclined to corpulence; and are considered as humane, affable, sincere, fluid, and brave. The principal towns are Badajoz, Placentia, Coria, Albuquerque, Caceres, Truxillo, Merida, Montejio, Xeres de los Cavalleros, Elierena, and Zafra; and the chief rivers are the Guadiana, the Tajo, and the Alagon.

ESTREMEIRA, a town of Spain, in New Castile; 27 miles S.E. of Madrid.

ESTREMOZ, a fortified ill-built town of Portugal, in the province of Alentejo, containing three churches, six convents, two hospitalls, and 6,500 inhabitants; pleasantly situated on a rising ground in a fertile country; 7 leagues N.E. of the capital; and famous on account of a victory gained by the Portuguese over the Castilians, in the year 1663. In its vicinity there is excellent marble. The country on the west side of the town is pleasant and well cultivated, abounding in orange gardens and laurels; but at some distance no traces of cultivation appear. This town has a manufacture of beautiful earthenware.

ESTREPAGNI. See ESTREPAGNY.

ESTREPEMENT, in Law, an impoverishing or making of land barren, by continual plowing and sowing, without due manuring, rest, and other husbandry. The word is derived from the French escrepier, to make; or the Latin exterpares, to extirpate, root up.

ESTREPEMENT is also used for any wale, or spoil, made by the tenant for life, upon lands or woods, to the prejudice of him in reversion; as the cutting down of trees, or lopping them further than the law allows, &c.

ESTREPEMENT is also a writ which lies in two cases: the one, by the flat of Glenclocher, 6 E. 1. c. 13, when a man having an action depending, as a foremon, writ of right, or the like, fails to inhibit the tenant from making wale during the suit.

The other is for the demandant, who is adjudged to recover fein of the land in question; and before execution, for
ETA

for fear of walske to be made till he can get possession, fues out his writ.

ESTRICH, or OESTRICH, in Geography, a town of Germany, in the circle of the Lower Rhine, and electorate of Mentz on the Rhine; 14 miles W. of Mentz.

ESTUCUA, a town of Mexico, in the province of Mechocan; 58 miles W. of Mechocan.

ESULA, or ESULUM, in Ancient Geography, a town of Italy, situated on a mountain, near the Tiber.

ESULE, or ESULUM, in the Materia Medica, the name of a root of the plant of the spurge kind, sometimes used in medicine. The root, most confiding of a cortical part, and an inner flinky one, the bark only is used; and such should be chosen as is new dried, and of a reddish colour without and within, with such as, when held in the mouth, assarts a very disagreeable taffe, with great acrimony. It is a very violent purgative, and has been said to have performed cures in drophical cases, when more gentle medicines have proved ineffectual. It is a good medicine to maccate it a day or two in vinegar before it is used.

ESURIS, in Ancient Geography, a town of Spain, supposed to be Xerex.

ESUS, or HESUS, in Mythology, a deity among the Gauls, to which they sacrificed after victory whatsoever came alive into their possession. They sometimes sprinkled the altars of this deity with the blood of their women and children.

ESZER, in Geography, a town of Selavonia, with a wooden bridge, built by the Turks over the D rave; 48 miles W.N.W. of Peter-Waradin, and 50 N.W. of Belgrade.

ETABLES, a town of France, in the department of the North Coasts, and district of St. Brieuc; 29 leagues N. of St. Brieuc.

ETAIN, or ESTAIN, a small town of France, in the department of the Meuse, chief place of a canton in the district of Verdun, 13 miles N.E. of Verdun. It has a population of 2,000 individuals, and its canton comprises 30 communes, with 12,550 inhabitants, on a territorial extent of 247.28 kilometres.

ETAILLE, a small town of France, in the department of the Yonne, chief place of a canton in the district of Neufchâtel, with a population of 1,000 individuals. Its canton has a territorial extent of 280 kilometres, and 13 communes, with 9,013 inhabitants.

ETAMPS, a small town of France, in the department of the Seine and Oise, chief place of a district of the same name, with a population of 7,786 individuals. It is situated on the left bank of the river Joinville, at the confluence of two other rivulets, 36 miles E. of Chartres; 45 miles N. by E. of Orleans; and 40 miles S. of Paris. Lat. 48° 25'. The canton contains 14,857 inhabitants, dispersed in 15 communes, on a territorial extent of 192.56 kilometres.

As chief place of a district, Etampes has a sub-prefet, a court of justice, and a registrar office. There are some manufactories of hosiery, woollen, and cotton yarn, and leather. The rockings, in particular, are known in the French trade by the name of rockings of Beauvoir, or Bas de Beauvoir, from the village where the bell are made.

The soil of the district of Etampes is Juda: it produces, however, some wheat, rye, barley, oats, and hemp. There are a few vineyards and some artificial meadows. The district contains 6 cantons, 111 communes, 1372.36 kilometres, and 58,380 inhabitants.

ETANGS, i.e., a town of France, in the department of the Moflede, and district of Boulay; 34 leagues N.E. of Metz.

ETAPLES, or ESTAPLES, a small town of France, in the department of the Pas de Calais, chief place of a canton in the district of Montreuil, with a population of 1,506 individuals. It is situated at the mouth of the river Canche, which forms a small harbour, 12 miles N.E. of Boulogne, 168 miles N. of Paris. Lat. 50° 30' 44'. The canton contains 15 communes, and 7,807 inhabitants, on a territorial extent of 232.4 kilometres.

ETAPPE, in War, an allowance of provisions and forage made to the soldiers upon march through a kingdom, or province, to or from winter quarters.

Hence, he that contracts with the country, or territory, for furnishing the troops in their march, is called etapper.

ETARKY, in Geography, a town of Hindostan, in the country of Bahar; 34 miles S.W. of Arrah.

ETAULIERS, a town of France, in the department of the Gironde, and district of Bourg; seven miles N. of Blaye.

ETASAGGAH, a town of Hindostan, in the Carnatic; 10 miles S.E. of Bahar.

ETAVERAM, a town of Hindostan, in the Carnatic; 10 miles E. of Colipetta.

ETAYA, a circuit of Hindostan, in the Soubah of Agra, bounded on the N. by Rohilla; on the E. by the circuit of Pattan, Canope an Corah, and on the S.W. by Jumna. Etaya is the capital.

ETAYA, a town of Hindostan, in the country of Agra, on the N.E. side of the Jumna, 52 miles S.E. of Agra. Lat. 26° 45' E. long. 79° 17'.

ETCH, in Agriculture, a term signifying the same thing as erth. See ESUX.

ETCHAUK, in Geography, a town of Bengal, 22 miles N. of Ramgur.

ETCHING, in the Polite Arts, an important branch of that species of engraving which is performed with the view of delivering impressions on paper, by means of the rolling-press, is the superaddition of the chemical process of corrosion, to the art of drawing through etching-varnish, or etching-ground, as it is more frequently termed, on plates of metal; though it has sometimes been successfully performed on other substances, and particularly on glass.

Etching is most frequently performed on plates of copper; and (though aqua-tinta be a species of etching, for which see AQUA-TINTA) the means commonly employed, are lines drawn with a litylum, or steel-point, termed an etching-needle, which are afterwards corroded by aqua-fortis.

The etching-needle resembles the dry point (see the article DRY-POINT) in all respects, excepting the superior sharpness of the latter, and that it need not be quite so long as dry-points are at the first. Of these needles, the artist should provide himself with three or four, for etching linear or coarser lines, of various dimensions and different degrees of bluntness; for the finest and most delicate lines being little lefs sharp than the dry-point. That he may with certainty etch lines of similar strength and depth, where such are required, as in covering a surface of an even tint, the extreme point of his needle should be very delicately and gradually rounded off on a leathern frop supplied with crocus-martix, or putty-powder.

The practicioner in etching should, moreover, provide himself with a soft and large camel's-hair brush, wherewith occasionally to sweep the dust, and etched etching ground, from the surface of his work; and an etching-board of from three to six inches in breadth, bevelled to an edge on one side, supported at the ends by small bars of wood about one-third of an inch in thickness, and of sufficient span to stand as a bridge over the varnished plate, and prevent the engraver's hand from touching and marling his work, should also be provided,
pro provided, and the copper-plate, being previously prepared, as see Copper-Plate, he may proceed to lay his etching-ground in the following manner.

The plate is put upon a German flanne, or chafing-dish, and heated over the fire; or, if small, held with a hand-

vice, the polished side being upwards, and heated with the flame of paper burning under it; when hot, it is rubbed over with etching varnish (such as is described in the sequel of this article) wrapped up in taffety, which should be gently

pasted from one side to the other in a right line, so as to form several rows, till the plate is every where moderately cov-

ered; then with a dabber, formed of cotton, tied up in Per-

fian silk, let every part of the plate be beat gently, while the varnish is in a fluid state; and in order to give it a fine grain, and that the varnish may be equally spread over the surface of the plate, continue to beat it with the dabber, after the plate is taken from the fire, till it attains a somewhat harder confidence in cooling; but the use of the dabber should be discontinued long before the varnish is cold, left it should be

made to rife from the plate.

When the plate is thus uniformly and thinly covered with the varnish, it must be blackened whilst it is yet warm by a piece of flambeau, or of a large wax-candle, or taper, twisled together, till fix or more flames unite in one, which affords a copious smoke; dispatch is of importance, that the varnish may not grow cold during the operation, which should be performed, if possible, at one heating of the plate, for repeated melting of the varnish does it much damage. Large plates may be suspended from the ceiling of a room by four cords and iron rings, with the varnished side downwards, for the greater convenience of being blackened. Care should be taken that the flambeau or candles be kept at a proper distance from the plate, that the wick may not touch and burn, or otherwise impair the varnish. The var-

nish may be made white, if that colour is preferred to black, by grinding white lead in water, and putting it into a glazed earthen dish, with a little good glue dissolved, and melting the whole together. This mixture is spread with a brush or pencil of hog's hairs thinly and evenly on the varnish laid on the plate and smoothed. The colour is then left to dry; if it fixes with difficulty on the varnish, the composition should be mixed with a drop or two of ox-

gall.

When the copper-plate is thus varnished, and is quite cold, it remains to transfer from paper to the varnished plate, the tracing, or outline of the design. If the outline be reduced from an oil or water-colour picture or other original of larger dimensions than the intended etching, and be executed with lead pencil or red chalk upon drawing or writing paper, the method most in use among English engravers, is, to take the varnished plate and outline to the rolling-preis printers, and (suffering the latter to lie between wetted paper for a quarter of an hour or so, that it may become sufficiently damp for the lead or chalk to be in a certain degree liquified, while the paper is sufficiently soft-

ened to do no injury to the etching ground,) to pass it through the press, the upper plate of the same quantity, and the press continued to the same degree of pressure, as for printing. If this be carefully performed, the outline will appear at once transferred, and reversed on to, the surface of the etching-ground, and the artist has nothing to do but to pro-
ceed with his etching. By these means the trouble both of retouching and reversing (i. e. of changing the right hand view of his picture round to the left, and vice versâ, the left to the right, as it would appear if reflected in a looking-
glass,) is saved to the engraver. The method formerly used, which must ever be used where no rolling press is at hand, and which is still believed to be generally practised in the other countries of Europe—is, either to trace the outline of the design on transparent paper, that by simply turning the paper it may be seen in reverse, or using thin drawing paper for the purpose, to render it transparent afterwards by means of oil or varnish. When this is thoroughly dry, a piece of fan, or other very thin, paper, of the size of the out-

line to be traced, must be evenly rubbed over on one side with powdered red chalk or black lead, and interposed between the outline and varnished plate, with the chalked or leaded side downward, and both outline and tracing paper being stretched tight over the varnished plate, and fastened by means of small bits of wax placed along the margin, a blunt etching-needle must be carefully palled over the sev-

eral outlines with a moderate degree of pressure, which will occasion so much of the powdered lead or chalk to adhere to the smoked etching ground, as, when the papers are removed, will exhibit the outline or tracing of the whole design in all its correctness.

Having proceeded through these introductory mechanical preparations, which require care and some knowledge of drawing, the engraver's task as an artist, or man of taste or genius, properly begins. Who shall prescribe laws to genius?—He may now execute the knowledge he has previously stored, and call forth his inventive powers. The forms of his objects must now be severally drawn, with such taste and feeling as he may possess; and his shadows, demi-
tints, and lights, excepting such as he may prefer to leave to be executed by the graver or dry point, be hatched, by employing lines more close or more open, and prefiguring on his needles more lightly or more strongly, as a skilful musician preludes on the keys of his harpsichord, and as the several parts of his work may demand, varying his line with the nature of his object.

The characteristic, or local advantage of etching, for certain purposes, over lines cut with the graver, consists in the unlimited freedom of which this mode of art is suscepti-

ble. The etching-needle meeting little resistance from the varnish, glides along the surface of the plate, and easily takes any turn that the taste of the artist may direct, or his hand accomplishes: and hence its peculiar adaptation to the expression of that class of objects which artists term picturesque, such as trees, rocks, ruins, cottages, the shaggy hair of animals, broken ground, or other rough and irregular sur-

faces.

It has formerly been much disputed among the curious, whether Germany or Italy had the honour of giving birth to the invention of etching, and with the view of ascertaining this point, the dates of the impressions from the earliest etchings by Albert Durer and Parmeggiano have been affidavishly fought for and compared. The writer of the present article conceives that some portion, at least, of this discussion and research, might have been spared, had the disputants reflected that etching, originally Eisen, is not an Italian but a German word, and how very unlikely it is that an Italian invention should have been denominated by a German word.

Although this art afforded means analogous to the ob-

jects themselves, of drawing and characterizing all those objects, of which wildness and freedom, communicated by spontaneous perception and feeling, is the soul, yet engraving with the graver had been previously invented, and in the beginning of the sixteenth century impressions from such engravings had called forth the admiration of the tasteful. For these reasons, and from the prevalence of those habits, and prejudices of taste and education, which hang like dark veils about the faculties of man, the extent and variety of energy of which etching was capable were not perceived, and
and probably are not even yet perceived; the means of engraving, or manual operation of the graver, was mistaken for the end; and hence a false criterion of merit obtained considerable influence; connoisseurs gravely put on their critical spectacles in order to see in what degree, and how conveniently, the etcher had imitated the clear and clean-cut lines of the graver; just as the early printers with the letter press, merely endeavored to imitate M.S. initials and bisides, without perceiving the superior degree of perfection of which printing was susceptible. The Sadeler, Le Boffe, and others run into this egregious mistake, and the latter, who wrote a treatise on the art of engraving, lays it down as a principle, that the perfection of this mode of engraving consists in the close facility of etching to the work done by the graving-tool.

That the efforts of the most tasteful, bold, and inventive among the engravers of our own country, have largely contributed to dispel these prejudices, will be seen towards the close of this article. At present we proceed with our account of the process of etching.

The forms of the several objects of which any given etching may consist, being drawn with requisite knowledge and care, and the chiaroscuro, and expression of the textures of the several substances introduced into the composition, hatched with the degrees of tape and truth, which the ability of the artist may enable him to discover, the founded of corrections, which is technically called Biting-in, begins. For this purpose a border of such wax as is of a moderate degree of hardness when cold, and of a moderate degree of tenacity whilst warm, must be applied round the margin of the plate, in the form of a little wall or rampart, about an inch, or three quarters of an inch in height. This wax may be composed of beef wax, either tempered with common pitch, or with Venice turpentine and tallow, and at one of the corners a gutter, or spout, should be formed for pouring the aquafortis conveniently off the plate. The plate being thus bordered, it is usual further to fortify or secure the work against the egrets of the aquafortis whilst biting, by turpentine-varnish thickened with lamp-black, and applied with a hair pencil on the margin of the plate, and under the inside edge of the rampart of wax. This varnish or composition (which is called flip-ground) being sufficiently dry, the aquafortis may be poured on the plate.

We are now arrived at a part of the process where experience, combined with chemical knowledge, is the only practical guide on which anything like found reliance may be placed. Yet a few general rules may not be dispensed with. The aquafortis may either be pure nitrous acid, diluted with pure water in the proportions of four or five parts water to one of nitrous acid for the more delicate parts of the etching, or it may be the double aquafortis of the flops diluted with pure water in the proportions of two to one, or sometimes of equal parts, according to the degree of strength or delicacy of the faintest parts of the work. Of aquafortis thus diluted, but which must be gradually strengthened as the work proceeds, let a sufficient quantity be employed to rive, when poured on the plate, about half an inch above its surface. If all things have been rightly conducted, it will now be seen that the meatus will soon exert its action in those lines or hatches where the artist has pressed hard on his etching-needle, and will gradually begin to corrode the more delicate lines. It may here be proper to observe that a feather, or camel's hair brush, should be used during the biting, to burth the small bubbles of fixed air which are liberated from the copper, and cleanse away from the lines the verdigrise which is generated during the operation of the aquafortis: by thus moving the aquafortis to and fro on the plate, it will exert its action uniformly over the whole etching.

In about a quarter of an hour, or when the effects of the aquafortis have become visible in the more tender parts, it may be poured off, the plate washed with clean water, and dried by exposure to the air, finifhine, or (which is now more common, because more expeditious) by the operation of a pair of bellows. After trial made by taking off a small portion of the etching-ground with the feraper, or a small piece of pointed charcoal, such parts of the etching as are believed to be sufficiently corroded, must be painted over carefully, or stopped-out, with the composition of lamp-black and turpentine varnish which is mentioned above; and when this is dry, the aquafortis must be re-applied, and the biting proceeded with in the same manner, till the strongest parts are judged to be sufficiently corroded, the aquafortis being strengthened from time to time according to the judgment of the operator.

To bite-in a large plate will sometimes occupy several days, for great judgment and nicety of observation are required in grading the chiaroscuro, and considerable care must be exerted in the stopping-out. It need scarcely be mentioned, that the operator should be as cautious as the necessity degree of attention to his work will allow, not to proceed to the etching, and in some cases the plate is miffed; though in most cases it happens that the engraver's taste and judgment direct him purposely to leave certain parts to be finished with the dry point and graver.

For an account of the early progress of the art of etching, the reader is referred to our account of the German and Italian schools of engraving. Its more recent improvements have taken place in England. In etching trees, which no other mode of engraving can adequately express, Vivares and Pouceney have displayed an art of characterizing the species of tree which it was their object to represent, and at the same time of suggesting in the varying ylbes of their foliage, those masses or countefe numbers of leaves which are seen in nature itself. Their etchings of trees are decidedly superior to those which have been produced on the continent, unless we might except the trees of Waterlow and Kobell, and have rarely been equalled by those of the engravers of our own island.

He who would see the most perfect specimens which have been produced of this species of art, should look at aquafortis proofs (not the finished engravings) which Vivares has produced after Claude, Patel, and Gainborough; and those which Pouceney has etched after Wilson, Hearne, and Farington. In looking at the former, he will see with surprise how much Vivares has attained of the peculiar beauty, feeling, and delicacy of Claude's pencil, although he could only have been acquainted with certain pictures—the larger Colonna Claude for example, from which he has produced a most exquisite etching—through the medium of chalk drawings, and those not very good. It is not less worthy of admiration, at least of high approbation, to observe how truly Pouceney has characterized the painting of Wilson in...
his etchings of "Athens in Prosperity," and "Athens in Ruin," which are also executed from chalk drawings copied from the originals of Wilton in the library of the late Mr. Willett.

In rocks and cottage subjects Browne has scarcely been less successful, as may be seen in the aquafortis proofs of the belt of his large plates after Both, Salvator Rosa, and Du Sart. In the rocks of his "St. John preaching," after Salvator Rosa, he is perhaps somewhat extravagant, and out of harmony with his own figures and foliage, though vigorous and characteristically rugged; but in "the Cottagers," and "the Fount of Fulani," after Du Sart, he is unrivalled; the several textures of the old plaster walls, old planks, thatch, broken ground, rough coated animals, (though these are probably etched by Woollett,) and even the dust which trickles down the hog-trough, are etched with the truest feeling of nature and Du Sart.

In etching ruins, as well as more perfect architectural subjects, Piranesi the Roman led the way, and Rooke the elder successfully followed. These artists more than perhaps any other, except Mr. Lowry, showed the affinity, or susceptibility of picturque union, which subsists in fine art, between freedom of handling and geometrical precision; as may be seen with pleasure in the antiquities of Rome and Paestum, which Piranesi etched from his own drawings; (the original and very matterly drawings of the temples at Paestum being preferred in the collection of Mr. C. Lambert of the Temple F. A. S.) in the six large views of London, which Rooke etched after the drawings of P. Sandby and himself; and among numerous other works from the hand of Mr. Lowry, in the plate of the west door of the cathedral of Carrara from the drawing of Flaxman, as well as in various other plates of architectural and mechanical subjects, by which this work is illustrated and adorned, and which contain almost entirely of etching.

With the view of etching subjects of this kind with superior accuracy and facility, Mr. Lowry, about twenty years since, invented and began to construct several instruments or machines, which is it within the knowledge of the writer of this article have been much employed on the engravings which are spoken of above. The first was for etching successive lines either equidistant, or in just graduation from being wide apart to the nearest approximation, ad infinitum; the compass of the instrument being commensurate with the possible demands of the art. The second, which is more recently contrived, is for etching elliptical, parabolical, and hyperbolical curves, and, in general, all those lines which geometerians call mechanical curves, from the dimensions of the point of a needle, to an extent of five feet.'

Within the last seven years he has constructed other machinery for facilitating particular operations in etching, and enforcing precision in delineating arches of circles of every possible radius, lines converging to points at all distances; various kinds of spiral lines, and the cogs and smaller teeth of wheel work; of the several uses and superior powers of which machinery, numerous examples may be seen in what has already appeared of this Cyclopaedia.

Of these inventions it may be truly said that they combine elegance with utility, and are of high value if only considered as auxiliaries of the imitative part of this branch of engraving; but as the auxiliaries of chemical, agricultural, and mechanical science, they are of incalculable advantage. The accuracy of their operation, as far as human sense, aided by the magnifying powers of glases, enables us to fay fo, is perfect; and it is not necessary here to inlill on the advantages that must result to the whole cycle of science, from mathematical accuracy. A hope may be indulged that before the completion of these volumes, Mr. Lowry may be induced to favour the public with plates, and particular descriptions of his various apparatus.

It now remains to describe the composition of the several kinds of etching-ground, which have been used by different engravers from time to time.

Of etching grounds there are three principal kinds, viz. common etching ground, hard ground, and soft ground.

The hard ground was formerly much used, being better accommodated to the intention of imitating the engraving with the tool; but the former has now wholly superceded the use of the other, as it gives a power of expression incompatible with the great inflexibility of the hard varnish, which confines the lines and hatches to such a narrowness and regularity as give a stiffness of manner, and coldness of effect to the work.

There are various directions for preparing the common etching-varnish, which is by far the most in use and the most worthy of being fo. Le Boffe recommends the following: take of virgin wax, very white and clean, and of grains of malleable very clear and pure, each one ounce; and of calcined asphaltum, half an ounce: grind the malleable and asphaltum separately, very small, and melt the wax over the fire in an earthen pot well glazed. When the wax is thoroughly melted, and very hot, sprinkle the malleable into it gradually that it may melt, and stir the mixture that the ingredients may incorporate. Then sprinkle the asphaltum into the mixture, furring the whole composition over the fire till the asphaltum be entirely melted: take the pot from the fire, and let the mixture cool; and pour the varnish into clean warm water, and by working it with the hand, form it into a roll of about an inch in diameter, or into small balls, which may be wrought into the form of the hard varnish. The quantity of wax should be increased in winter, in order to temper the varnish to the existing state of the atmosphere.

The following varnish is used by many of the engravers at Paris: take of virgin wax, and asphaltum, of each one ounce; half an ounce of black pitch; and a quarter of an ounce of Burgundy pitch: the asphaltum must be pounded in a mortar, and the wax melted over a slow fire in a pot of glazed earthenware, and the rest of the ingredients added by little and little, furring the mixture till the whole be well melted and incorporated. Then throw the whole mass into a vessel of clean warm water, and proceed as before.

Mr. Lowry's recipe for common etching ground is as follows:—To two ounces of asphaltum add one of Burgundy-pitch, and an ounce and a half of white virgin wax. The asphaltum must first be finely powdered, and then melted in the glazed earthen vessel over a moderate fire, before the Burgundy pitch is put in: the wax must be added last, when the whole composition must be well thried, and then poured into warm water, to be further incorporated by means of the hands, and made up into balls for use. The hard varnish, which was used by Calloitt and other engravers of the continent, and which was commonly called the Florence varnish, was prepared in the following manner. Take four ounces of fat oil, very clear, and made of good linseed oil, like that used by painters. Heat it in a new pot of glazed earthenware, and afterward put to it four ounces of grains of malleable well powdered, and stir the mixture briskly till the whole be well melted together, then filter the whole through a piece of fine linen into a glass bottle with a long neck, that can be flopped very fecurly, and keep it for use.

In laying this varnish on the plate, it may be spread evenly with the dabbér and flopped, as before directed, but after
ETCHING.

After it is so spread, there remains to dry or harden it over the fire, for which purpose it will be proper to prepare a charcoal fire which shall emit no sparks; it should be containing in a coal-pan or charguing-dish, somewhat larger than the plate, which should be placed over it for the space of an hour or two, twenty minutes, every precaution being used to prevent dust from approaching the plate. Whilist in this situation the varnish will soon begin to smoke, and when this smoking is observed to decrease, the plate must be removed from the fire, and touched at the side or on the margin with a little piece of hard wood. If the varnish be easily raised by the touch, it is yet too soft, and the plate must be again placed over the fire. After a short time it must be ready to be tried with the flick, and if the flick adhere to the varnish so as to require some slight effort to draw it away, the plate must from that instant be left to cool. If on the first trial the flick adhere strongly to the varnish, water must be immediately thrown on the back of the plate, to cool it as quickly as possible, lest a longer continuance of the heat render it too hard, or burn the varnish. When the plate is cold, the artist may proceed with the tracing and etching, as before directed.

The soft ground or varnish is prepared simply by mixing common etching ground with animal oil, in proportion of more or less according to the exigent state of the atmosphere; a much smaller portion of the oleaginous ingredient being admissible in summer than in winter. If common tallow be used for the purpose, the fat which it may contain should first be precipitated, by dropping the melted tallow into water, and afterward skimming it from the top; but Mr. Gilpin recommends real fats, and it is probably to be preferred.

The method of using soft ground is as follows. Over a plate thinly covered with this sort of varnish, and smoked in the case of the common etching ground, the artist cautiously spreads a sheet of very thin paper, which it is best to spread in a damp plate, and to taken with strong paste by the edges, which should be folded over for the purpose on the back of the plate: the paper will thus, when dry, be stretched tight and flat over the surface of the varnish.

All is now ready for the reception of the etching, which is performed simply by making a hatched drawing of the intended subject with a black lead pencil on this paper. Great care must be taken during the etching that nothing but the pencil touch the paper, and for this purpose such a bridge must be employed on which to rest the hand of the artist, as is before recommended. When the drawing is complete, the paper must be carefully removed from the surface of the plate, which must be surrounded with a rampart of wax, and the aquafortis applied as before directed. This is the whole of the process of etching in soft ground.

As much of the varnish as it was necessary to remove, in order to admit the aquafortis to the copper, will be found to have adhered to the back of the paper on which the artist has been drawing, which, preceding the plate to be judiciously bit-in, will exhibit the exact archetype of the impression which the etching will produce.

It remains to be said of etching in soft ground, that the flapping with the graver, which it is sometimes found necessary to add in certain parts, after the plate is bit-in, does not incorporate thoroughly with the sketchy自贸区 and chalky texture of the etching, but that a judicious eye will always discover the junction, and a delicate touch will dwell on it with the same kind of dissatisfaction that we regard a modern repair of a fine old picture that has been damaged; and further, that though it be a mode of art extremely well calculated to imitate a painter's sketch or drawing in black lead or chalk, it is by no means capable of producing a complete abract of a finished picture.

There are certain local energies peculiar to every branch of engraving. He who should endeavor in mezzotinto or the chalk manner to rival the playful freedom and characteristic taste which is displayed by Vivares in his etchings of trees, would find himself as much mistaken in his aims as he who by etching through soft ground, or on stone for which see Etching on Stone, should attempt to render the delicate blandishments, so as to produce a complete abract of the full harmony, of the finished works of Correggio & Claude. On the other hand, either of these modes of etching is far more capable of producing a faithful transcript of a drawing hatched with chalk or lead-pencil, than the power of the graver and aquafortis united on copper, and of multiplying such drawings, certainly affords the most efficient means.

It may not be superfluous to add that it is not the painter's sketches that it is most desirable to multiply, but his finished performances; we with most to fee the merory of his active imagination amalgamated with the flering gold of his cultivated understanding; and we july value an art of engraving as it is capable of rendering or reproducing the pure forms into which this rich mass may be moulded.

Etching on Stone. A method of etching on calcareous substances, which may be termed a chemical art of multiplying hatched drawings, has also been recently discovered in England, or recently imported from Germany; and some very spirited sketchy etchings have been executed in this way by the president Weft, and Meffrs. Fedeli, Colway, Barry, and some other members of the Royal Academy. Meffrs. Corbould, Stubbs, and C. Heath are also among those who have successfully practised this new art.

The materials were supplied by a gentleman not now in England; the knowledge of the exact proportions of the ingredients of which they consisted, was not imparted to those who made use of them, either is it believed to have been imparted to any one else; but the materials themselves being known, the proportions may presumpitively be ascertained by a little experience.

The stone was of a species resembling that fine-grained stone of a yellowish colour, which is found in large quantities in the neighbourhood of Bath, and is called Bath stone. The etchings were of two kinds; those performed with a crayon, and those performed with pen and ink. The crayons was a mixture of white wax and lamp-black, with a small quantity of shell-lac. The ink consisted of shell-lac, borax, and water, and the stones which received the crayons were ground to a surface somewhat less smooth than those which were prepared for the reception of the ink.

The method of etching is merely drawing on the stone with these materials. The mystery, or secret—which any chemist would easily develop—refides in the manner of printing these drawings, and is simply as follows.

The ink is to be prepared as printer's ink is commonly prepared, namely, ground up with oil, and the paper to which it is to receive the impression must be dipped in the usual manner. The etched stone is then to be wetter by immersion in water; when it is taken out, and while it is still wet, the ink being carefully applied on its surface, without violent friction, by means of a printer's ball (such as is used in letter-press printing) will be found to adhere only where the stone has been hatched by the artist, with the crayon or ink, the antipathy of oil to water effectually preventing it from sticking anywhere else. The paper is now to be placed as in letter-press printing, and a pressure, which need not be very violent,
ETE

violent, applied either by means of a roller passed over the back of the paper or otherwise: a blanket or finer woolen cloth, being interposed between the roller and paper.

Etching or Glass, is performed in the following manner: Lay a thin coat of white wax (as etching ground is laid) on the plate of glass. On this the drawing must be traced in the usual way. When the subject is etched, a border or wall of wax of a very even height must be put around; take then some flour & powder to about the fineness of oatmeal, and strew it evenly over the etching, and on this pour a mixture of equal quantities of sulphuric acid and water, till the whole is the consistence of thick cream: cover of metal or wood must then be laid over, and fitted close to the border of wax, to keep in the fumes of the acid, the escape of which would so weaken the liquor that it would not act on the glass, and would besides be very hurtful to the lungs.

If the subject be to be etched with care, and high finishing be required, the acid mixture must be taken off occasionally, and the plate, after being well washed and dried, must have the parts that are bit-in enough, floated-out, as in common etchings, when the mixture must be again put on, and closed down as before; and this must be repeated till the several gradations of shade be believed to be sufficiently corroded.

Etchings on glasses are printed by means of the rolling press, and it need scarcely be added that much care is requisite on the part of the printer, let the plates of glasses should split in passing through the press.

ETEA, or Eta, in Ancient Geography, a small town of the isle of Crete.

ETELENT, in Geography, a town of Asiac Turkey, in the Arabian Iraq, situated on the Tigris; 66 miles N.N.W. of Bajlora.

ETENDUE, Fr. in Music. See Compass.

ETEON, in Ancient Geography, a town of Greece, in Boeotia.

ETEONOS, a town of Greece, in Euboa.

ETERNAL Flower, in Botany. See Xeranthemum.

ETERNITY, duration which is conceived incommensurable with time, and exclusive of beginning, prefigured, ending, &c. See God.

Authors are much at a loss for a proper and just definition of eternity: that of Boethius, De Consol. Philos. lib. v. part 6. win. "Interminabilis vitae tota simul et perfecta posseillo, i.e. a perfect possession of a whole endless existence altogether," though retained by S. Thomas and others, is faulty in divers respects.

Celerinuss, De Die Natalis, defines eternity by infinite duration, that is, duration which has always been, and always will be. Others more fully describe it by a duration that exists altogether without any flux or succession of parts prior or posterior to each other: where the word duration, taken abstracly, imports no more than the perseverance of a thing in its existence, the a durare being here opposed to the se effondere, in exisltendo.

But the word duration how you will, it is scarcely conceivable but by conceiving a quantity thereof, nor a quantity without conceiving a succession. Others, therefore, define eternity by a perpetuum nunc, a perpetual now, or a nunc sempem flatus, an everlasting now; but neither are these unexceptionable, the word perpetuum and sempem flatus importing an obsolete sort of duration. See Duration.

ETERNITY, in Mythology, a divinity among the Romans, who had neither temples nor altars. They represented it under the figure of a woman, who held the sun in one hand and the moon in the other: her symbols were a phoenix, globe, and elephant.

ETERNOZ, in Geography, a town of France, in the department of Doubs, and district of Quingey; 2 leagues S.E. of Quingey.

ETESIA, or ETESIAN Winds, are such as blow at stated times of the year, from what part former of the compass they come. They are so called from the Greek word etesia, year, being yearly or anniversary winds, such as our seamen call monsoons and trade-winds, which, in some parts of the world, continue constantly blowing for certain stated seasons of the year. Thus the north winds, which, during the dog-days, constantly blow upon the coasts of Egypt, and hinder all ships from sailing out of Alexandria for that season, are called etesia in Cesar's Commentaries. In other authors, the west and west-south winds are called etesia, when they continue blowing for certain seasons of the year. Vide Schim. Exercit. in Solin. p. 421.

Cellarius endeavours to prove that these winds are properly etesian which blow from that part of the horizon which is between the north and west about the time of the solstice. Geog. Antiq. lib. i. cap. 8. See Monsun and Wind.

ETETA, in Ancient Geography, a town of Upper Myias, according to Ptolemy; called Ægöta in the Itinerary of Antonine.

ETFU, or ENFOU, in Geography, a village of Upper Egypt, situated near the Nile, above Efinch, built on the ruins of the great city of Apollo, or Apollonopolis Magnus, and now governed by an Arab sheikh. It possesses an ancient temple, covered with hieroglyphics, among which, says Savary, we distinguish with falcons' heads. Its inhabitants were enemies of the crocodile. The extent, majesty, and preservation of this edifice, says Dion, who has given a view of it, "surpassed all that I had been in Egypt, or elsewhere; it made an impression on me as vast as its own gigantic dimensions. This building is a long suite of pyramidal gates, of courts decorated with galleries, of porticoes, and of covered naves, constructed, not with common stones, but entire rocks." "The excellent preservation of this ancient edifice forms a wonderful contrast" with the grey ruins of modern habitations built within its vaft inclosure; a part of the population of this village is contained in huts built in the courts, and around the fragments of the temple; which, like swalows' nests in our houses, defy them without concealing or injuring their general appearance." Below Etfu, the cultivated country becomes very narrow, so that there is only a quarter of a league in breadth between the desert and the river.

ETHAM, in Ancient Geography, a town of Egypt, situated in the defect, which gave name to the lower part of the Red sea, opposite to Magdala. It was the third station of the Israelites in their escape from Egypt.

ETHELBERT, in Biography, king of Kent, succeeded to the throne about the year 590. He began his reign with a revolution to revive the reputation of his family, which had been sinking in the scale of monarchy; with this view he made war upon the king of Wessex, by whom he was twice defeated, though he was afterwards triumphant, and acquired the complete ascendancy over Wessex and the other states, except Northumberland, and reduced them to the condition of his tributaries or dependants. In the reign of Ethelbert, Christianity was introduced into England. The king had married Bertha, daughter of the king of Paris, who being a Christian, had stipulated for the free exerice
exercised of her religion, and had carried over in her train a French bishop. So exemplary in every respect were her life and conduct, that she inspired the king and his court with a high respect for her person, and for the religion by which she was influenced. The pope, taking advantage of this circumstance, sent a mission of forty monks, at the head of whom was Augustine, to preach the gospel in the island. They landed in Kent in 597, and were well and hospitably received by Ethelbert, who altered their inhabitants in the isle of Thanet. A conference was held, and the king took time to consider of the new doctrines propounded to him; and in the mean while gave them full liberty to preach to his subjects. Numbers were converted, and at length the king submitted to a public baptism. Christianitv proved the means of promoting knowledge and civilization in this isle; and the king, with the consent of his flates, enacted a body of laws, which was the first written code promulgated by the northern conquerors. Ethelbert died in the year 616, and left his crown, after a reign of 50 years, to his son Eadbald. Hume's Hist. of Eng.

ETHELWALF, king of England, was son of Ethelwulf, and succeeded to the government of the eastern part of the kingdom in 857, and in three years afterwards he became sole king. He was wise, learned, and kind, in the course of his reign, several important events were carried on against his dominions from the inroads of the Danes, who at that period were cruel enemies to this country, and continued to ravage one part as they were repulsed from another. Hume.

ETHEL, in Geography, a river of Asia, which separated between the Troade and Mytila. ETHELIEB, or AETHELIEB. See AETHLING.

ETHELRED I., in Biography, king of England, son of Ethelred, succeeded his brother in the year 866. The reign of this monarch was short but full of troubles. The Danes had already gained an ascendency over the kingdom, and seemed now to threaten it with entire conquest. The enterprising Alfred united his skill to the power which his brother the king was able to call forth; they purified the invaders from place to place, and drove them from the centre of Mercia. The Mercians, careless of their liberties, or jealous of the superiority which victory was likely to give to the monarch, refused to co-operate with him; and Ethelred was under the necessity of opposing the Danes with his own forces. With these he was generally successful, till large reinforcements were sent for the invaders, which enabled them to make a stand against the natives. The actions fought were frequently very bloody, and in one of them Ethelred was wounded. He died in 871, leaving his crown to the immortal Alfred; of whom we have already spoken. Hume's Hist.

ETHELRED II., king of England, was son of Edgar, and brother to Edward the Martyr, whom he succeeded to the crown in the year 978. He was at this period a minor, and from his want of capacity and vigour in the affairs of government he was, in his riper years, characterized by the epithet of "The Unready." No man, however, stood more in need of exertion and enterprise, for the Danes, who had for several years refreshed all rebellions, renewed their attacks with the utmost fury; and meeting with little opposition, they became more bold, till, at length, in the year 993, under Sweyn king of Denmark, and Olave king of Norway, they made a general invasion of the country. At first nothing seemed to oppose the rapidity of their progress; and they laid siege to London, which was gallantly and successfully defended by the citizens. A mistaken policy in behalf of the English induced them to purchase the departure of the invaders, who, in 997 and 999, returned in large bodies, laid waste the southern parts of the kingdom, and demanded a still larger bribe than they had before received. To strengthen himself by a foreign connection, Ethelred married, in 1001, Emma, sister to Richard II., duke of Normandy. In the following year a dreadful massacre took place, on the same day throughout England, of all the Danes settled in the kingdom. The English in this instance were the willing instruments in the hands of the king to execute his bloody orders. They spared neither age nor sex; even a filter of the Danish sovereign, who had married an earl, and had conformed to the Christian profession, was barbarously murdered, having already witnessed the death of his husband and infant children. Such revenge, says the historian, added nothing to the strength of the nation, but rendered its enemies more implacable. In 1003, Sweyn again invaded the island, and carried devastation all along the Western coast. On a subsequent occasion the bold invader obliged the nobles to swear allegiance to him as king of England, while Ethelred, in 1013, fled into Normandy with his family. Sweyn maintained his power only a year, when death put an end to his reign, and Ethelred was recalled by his loyal subjects. He returned the government, but had not learned that wisdom which his misfortunes had failed to teach; he submitted to Canute the son of Sweyn, whose valor and activity he was unable to resist. Ethelred died in 1016, after an inglorious reign of thirty-five years. Hume.

ETHELWOLF, king of England, succeeded his father Egbert in the year 898. Little ambitious of government, one of his first acts was to give his eldest son, Athelstan, the sovereignty over Essex, Kent, and Suffe. His whole reign was molested by the incursions of the Danes, and about the year 857 they became so formidable as to threaten the total subversion of the government. The natives were not inactive, but opposed the enemy with the utmost vigour; nevertheless they took up their winter-quarters in England, and before they returned, burned Canterbury and London. In the midst of these dangers the king, excited by a spirit of devotion, made a pilgrimage to Rome, where he remained about a year, being accompanied by Alfred, who was afterwards king. During his absence he left his eldest son Athelstan as regent, who soon after died, and thus afforded an opportunity to his ambitious brother of seizing the reins of government with an intention of dethroning his father. To avoid the evil consequences of civil war the king, without hesitation, ceded the western part of his dominions to his son. After this, influenced, in all probability, by the intriguing monks, he summoned the bishops of the whole kingdom, and solemnly conferred upon the clergy the tithes of all the produce of the lands. This act of piety, as it was denounced, was considered as the most effectual measure for refuting the Danes. Ethelwolf died in 897. Hume.

ETHER, in Chemistry, is a light, odorous, inflammable liquid, produced by the action of certain of the acids upon alcohol. The acids that have actually been employed for this purpose are the sulphuric, the nitric, the muriatic, the acetic, and the florid; whence originate as many species, or perhaps varieties of ether, all of which we shall describe in due order.

§ 1. Sulphuric ether. — The method of preparing this sub-

Stoff is first mentioned in the Difpenatory of Valerius Cordus published about the year 1540; it was also known to Bafl Valentine, Paracelsus, and Boyle: it had, however, attracted the notice of chemists only in a very imperfect degree, before it was described by Tróben, a German, in the
ETHER.

Philosophical Transactions for 1732. Since that period the preparation and properties of sulphuric ether have been carefully investigated by many able chemists, especially Scheele, Dallius, Macquer, Pelletier, Vauquelain and Tournay.

The mode of obtaining ether in the small way is as follows. Take a tubulated glass retort, of the capacity of about six quarts, lengthen its neck by an adaptor, and pass the other end of the adaptor into a two necked quilled balloon receiver; fix another adaptor into the opposite neck of the balloon, and join this common quilled balloon receiver, by having, in such a position that the quill, instead of pointing directly downwards, as in the first receiver, shall point gently upwards; then lute all the junctures with linseed meal or common paste, except that of the retort to the first adaptor; fix also a 24 ounce vial to the quill of the first receiver, and loosely close the quill of the second with a cork or plug of muff paper. The lute being moderately dry and hard, withdraw the retort, and pour in through the tubulure 40 ounces by weight of rectified alcohol, and 32 ounces of the strongest sulphuric acid. Replace the retort with its contents, being careful to shake it as little as possible, and let it remain for 12 hours or more, during which the acid and alcohol will gradually act on each other, producing a considerable degree of heat. Afterwards withdraw the retort, and mix together its contents as accurately as possible, by communicating to them a gentle circular motion; this being finished, replace the retort, and carefully close by lute its junction with the adaptor, and leave the whole in this state till the contents of the retort have acquired a reddish-brown colour, which will take place in a day or two. Now proceed to distillation, by placing a pot of lighted charcoal beneath the retort, observing to heat it very gradually. The first impressions of the fire drives off a little highly dephlegmated alcohol, but as soon as the mixture begins to boil, the ether itself passes over and condenses on the sides of the receiver in large streaks. It is now essentially requisite to keep the receiver as cool as possible, by the application of ice or of wet cloths wrung out in cold water and frequently renewed; and if this is properly attended to, by far the greater part of the ether will be condensed in the first receiver, whence it will flow into the vial beneath; a little, however, will pass through the second adaptor into the second receiver, where it must be condensed by the same means as have already been recommended. The contents of the retort are to be kept moderately boiling, till sulphuric acid gas begins to pass through the quill of the second receiver, which may be known at once by its strong suffocating odour. As soon as this is perceived, the fire is to be withdrawn, and the vial is to be detached from the receiver, and its contents poured into a ground-stoppered bottle; being then replaced as before, the process of distillation is to be re-commenced till about six or seven ounces of a coloured liquid are produced, after which the operation is to be stopped. The original mixture of sulphuric acid and alcohol is thus divided into three separate parts; namely, the residue in the retort, and the products of the second and first distillations. In the retort is a black thickish matter, smelling strongly of sulphurous and acetous acids, and intensely four to the taste. If diluted with an equal bulk of warm water and filtered through pounded glass or clean white sand, it will be separated from the carbonaceous matter with which it was loaded, and by subsequent boiling the sulphurous and acetous acids will be driven off, leaving behind sulphuric acid in a considerable degree of concentration, and applicable to a variety of useful purposes. The product of the second distillation consists of two distinct liquids, the heaviest of which is acidulous water, and the lighter an impure ether, called oil of wine, which may be separated from the water by inverting the vial that contains them in warm water; a little of the ether is in consequence converted into volatile vapour, which forces out of the vial the lower and heavier fluid. The product of the first distillation is impure ether, in quantity about 17½ ounces. Thus from 32 ounces of sulphuric acid and 40 ounces of alcohol there are procured about 17½ ounces of impure ether, and three ounces of oil of wine; and the sulphuric acid that may be recovered, taking into consideration its quantity and density, amounts to about 46 per cent. of that originally employed. A little of the impure ether, if distilled, is contaminated by sulphurous and acetous acids and a little coloured oil, in conjunction of which it is necessary to purify it by rectification. This is generally done by adding to the ether successive portions of caustic potash or soda dissolved in water, and shaking together the two fluids in a well closed bottle, after each addition of alkali, till the sulphurous odour is totally destroyed; the contents of the bottle are then to be poured into a retort, and by the application of a gentle heat, without amounting to ebullition, the ether will pass into the receiver in a state of great purity, leaving behind a watery saline liquid covered by a thin film of brownish-yellow oil. Scheele recommends that the alkali employed in rectification should be dissolved in alcohol instead of water; the advantage of which is that no spontaneous separation of the liquids takes place, and therefore the sulphurous and acetous acids are neutralized and separated with greater certainty. Distillation at a gentle heat will readily separate the ether from the other ingredients. A still cheaper and very effectual method of rectifying ether is the following, first employed by Mr. W. Bye. Fill three-fourths of a bottle with the impure ether, add a little water and a portion of stilled lime; agitate the bottle with violence, and keep it for some time in cold water, before taking out the cork; if the smell of the sulphuric acid be not removed, add a little more lime and agitate a second time. Decant off the ether into a receiver, and distil it off." Another very cheap and ingenious process was invented by Pelletier. It consists in adding to the impure ether a little finely pulverized black oxyz of manganese. The mixture being corked up in a bottle, is to be well shaken four or five times a day for the space of a week, at the end of which time the sulphuric acid will have been converted into sulphur and will have combined with the manganese, from which the ether may be poured off without the necessity of distillation.

By any of the above methods ether is rectified sufficiently for any purposes to which it is usually applied; but if the greatest possible degree of purity is required, there should be added to the rectified ether successive portions of dry powdered nitrate of lime, till it ceases to be dissolved; from this mixture, by distillation with a very gentle heat, and keeping at the same time the receiver quite cold by the application of ice, an ether may be procured, probably entirely free from alcohol and water, and of the specific gravity of 0.67.

Rectified ether exhibits the following properties. It is a transparent colourless liquor, of a peculiar and to most persons an agreeably fragrant odour, and a hot penetrating, and somewhat suffocating taste. Its usual specific gravity, according to Lavoisier, is = 0.758. It is volatile at a lower temperature, and more rapidly than any other liquid, a considerable proportion being lost, especially in hot weather, by merely pouring it from one vial into another; hence the vessels in which it is kept ought to be very exactly closed, and for further security are often kept inverted in cold water.
ETHER.

Ether. It boils at 68° Fahr. under the usual atmospheric pressure, and at 20° in vacuo.

Owing to the extraordinary rapidity with which ether evaporates, it possesses a very great power of refrigeration. This is made obvious to the feeling by pouring a little into the palm of the hand; it is almost instantly volatilized, and the hand becomes painfully cold. So also if some fine tow is wrapped about the bulb of a small thermometer, and the bulb from a pair of double bellows is let upon it, after it has been well soaked in ether, the mercury in the thermometer will, in the face of a minute or two, be lowered to 0° Fahr. Ether, by its volatile, its ready volatility, is capable of being congealed at a low temperature. If a small matras filled with this fluid is cooled down to -25° Fahr. by a mixture of snow and muriat of lime, the liquor becomes gradually filled with brilliant transparent crystalline lamina, resembling benzoic acid or oxyoxymuric of potash; and presently, especially at a somewhat lower temperature, the whole is congealed into a white almost inodorous mass. Ether is remarkably inflammable, taking fire instantly on the near approach of an ignited body; it burns with a large white flame and a little smoke, and is resolved into water, carbonic acid, and a minute quantity of charcoal. When puffed through a red-hot earthenware tube, it is entirely decomposed, and a large production of carbonated hydrogen takes place. Ether remarkably increases the bulk of any of the permanent gasses to which it was added, as was first observed by Dr. Priestley. A small quantity of this fluid being mixed with oxygen confined over mercury, exactly doubled its bulk, nor could any additional quantity occasion a further dilatation. Nearly the same effect took place with atmospheric air, azot, hydrogen, nitrous gas, and carbonic acid; but by a slight agitation in water the ether was absorbed, and the gas resumed its former dimensions without any alteration of its original properties. If oxygen gas thus diluted by ether is set fire to, it burns rapidly, but does not explode; but if one part of this mixture is added to three parts of oxygen, the application of an ignited body, or of the electric spark, causes a violent explosion, the products of which are water and 21 parts of carbonic acid. Hence it appears that one part of ether requires 6.8 of oxygen for its saturation, and that the proportion of carbon to hydrogen in sulphuric ether is nearly as 5 to 1.

Water and ether appear to combine with each other in two different proportions. If equal parts of these fluids are shaken together in a graduated tube, the ether will be found to have diminished in bulk about 1/8, and the water to have enlarged in nearly the same proportion; the lower fluid confits of water saturated with ether, and the upper fluid is ether combined with a little water. Ether in this state is said to be 'flushed,' and acquires in consequence some properties which pure ether does not possess; in particular, it is now capable of diffusing caustic and with great ease, whereas this substance is acted upon by pure ether only in a very imperfect manner. Phosphorus is soluble in ether, but the solution is not luminous. When ether is boiled with phosphorus, it often deposits crystals by cooling; agitation with water produces no change in this liquid, but the addition of a little alcohol causes an immediate turbidity, whence the sophistication of ether by alcohol may be detected by the addition of a few drops of phosphorized ether. The fixed alkalies seem incapable of uniting with ether, but ammouniacal gas is absorbed by it very copiously. The same may be observed of nitrous gas; but neither of these combinations has hitherto been submitted to an accurate examination. Sulphuric acid acts on ether with considerable energy, especially if assisted by a gentle heat; it is converted into a brownish oily fluid, much heavier than ether, called oil of wine, and at a higher temperature is changed into olefiant gas. With regard to the action of oxymuriatic acid on ether, a curious experiment is related by Mr. Crobick-fank. "If we fill a bottle of the capacity of three or four pints with the pure oxymuriatic acid gas, taking care to expel the water as completely as possible, and then throw into it about a dram of half a dram of good ether, covering its mouth immediately with a piece of light wood or paper, in a few seconds white vapour will be perceived, moving circulrly in the bottle; this will soon be followed by an explosion, accompanied by flame, at the same time a very considerable quantity of carbon will be deposited, and the bottle will be found to contain carbonic acid gas." Nitric acid excites a considerable effervescence in ether, and seems to convert it into oil of wine. The essentiai oils are soluble in ether, and it combines with alcohol in almost all proportions.

Concerning the theory of etherification, much has been written, and many experiments have been made by able chemists, without, however, obtaining the satisfaction that could be wished. According to Macquer, ether is a substance intermediate between alcohol and oil, and alcohol approaches to the flate of oil precisely in proportion as it parts with its water of composition. But though it is true that the production of water accompanies the conversion of alcohol into ether, and of ether into oil of wine, yet this is by no means the only phenomenon, so that the theory of Macquer is, at best, imperfect, since the deposition of charcoal, and the generation of acetic acid, are not at all accounted for. According to Pelletier, Chaptal, and others, the whole proceeds of etherification consists in a transfer of oxygen from the sulphuric acid to the alcohol: the engagement of sulfulphuric acid accompanies the production of ether, and therefore shews that the sulphuric acid is oxygenated; the oxygen, thus separated, does not come over in the state of gas, and therefore must be combined with the alcohol forming ether. But in reply, it may be observed, that this mode of explanation accounts for only a few of the phenomena, and that the preparation of ether, if carefully managed, may be carried on without the difengagement of any sulphuric acid. The most elaborate enquiry into this intricate subject was undertaken by Vaquelin and Fourcroy, which we shall now proceed to detail, though it is by no means so complete and satisfactory as to preclude the necessity of further researches. The facts and observations by which this theory is supported are the following.

If one part of alcohol and two of sulphuric acid are mixed together, the temperature rises to about 200° Fahr.; the mass immediately acquires a deep brownish-red colour, which deepens into black in a few days after, and at the same time exahes a vapour manifestly etherous.

Equal parts of concentrated sulphuric acid and rectified alcohol acquire on mixture a temperature of 195° Fahr.; bubbles of gas are extricated, the liquor becomes turbid and opaque, and at the end of a few days acquires a deep red colour. The whole being then transferred to a distilatory pneumatic apparatus, and being heated to 107° Fahr., ebullition takes place, and ether passes over into the recipient; if the operation is carefully conducted no clastic fluid is diffigenged, and the vapour, when condensed, is found to be only water and ether. When the liquor thus obtained amounts to about half of the alcohol employed, sulphuric acid begins to be manifest, and, in a short time, the production of ether ceases, and is succeeded by oil of wine, accompanied by acetic acid. The contents of the retort being kept boiling, and becoming more and more concentrated as
the distillation proceeds, are constantly acquiring a higher temperature; when this amount to about 234° Fahr., dis- 
fluent gas begins to come over, and continues till the oil of 
ephan to flow. At this period carbonic acid gas first 
makes its appearance, and water and sulphuric acid still 
continue to be produced, the residue in the retort being in 
the mean time reduced to little else than sulphuric acid 
thickened by charcoal.

From these facts the able chemists who observed them 
have concluded,  
1. That the spontaneous action of alcohol and sulphuric 
acid, with which this latter is considerably in excess, is sufficient 
for the formation of ether without the assistance of any ex- 
traneous heat, and that by duly proportioning the two sub-
stances, the alcohol might be wholly decomposed and made to 
yield all the ether of which it is capable when treated in 
the usual manner.

2. That the formation of ether is not owing to the affi-
mit of the oxygen of the sulphuric acid, for the hydrogen 
and carbon of the alcohol, because in the preparation of 
ether no sulphurous acid gas is evolved till the production of 
ether has almost ceased. It must therefore be the entire at-
traction of the acid for one or more of the elements of the alcohol that determines its decomposition; now since water 
is formed during the whole process, and, since the attraction 
of sulphuric acid for this substance is very powerful, it appears 
likely that this is the cause that destroys the equilib- 
rium of the affinities by which the elementary particles of 
alcohol are retained in combination, and induces the oxygen 
and hydrogen to unite and form water. Hence it might at 
first sight be supposed that ether differs from alcohol in con-
taining a smaller proportion of oxygen and hydrogen. This 
however will not be found to be the case, when we advert 
to the deposition of charcoal, which, equally with the pro-
duction of water, accompanies the formation of ether: 
now the amount of charcoal deposited is greater in propor-
tion to that which is left, than the hydrogen of the water 
compared to what remains in the ether; therefore this latter 
fluid, though composed of the same elements as alcohol, 
differs from it in containing a smaller proportion of carbon 
compared with the hydrogen. During the progress of dif-
tillation the heat to which the materials in the retort are ex-
posed is constantly increasing, and (the affinity of the acid 
and alcohol also augmenting) the acid itself is at length 
decomposed, sulphuric acid is generated, and the excess of 
oxygen deprives the alcohol of part of its hydrogen 
whence results the oil of wine, differing from ether in con-
taining a larger proportion of carbon; and in confirmation 
of this, it may be observed, that the charcoal deposited 
during the production of oil of wine is not so abundant as 
during the generation of ether.

Hence as (according to the authors of the above hypo-
theses) no decomposition of the sulphuric acid takes place 
during the formation of ether, the agency of the acid is 
partly that of detaining the alcohol in a temperature more 
than sufficient for the volatilization of this fluid when uncom-
bined, and partly that of afflicting the caloric to decompose 
the alcohol in consequence of its own powerful affinity for 
water.

A circumstance, however, first remarked by Scheele, but 
which has hitherto failed to obtain the notice to which it is 
so well entitled, sufficiently proves that in the formation of 
ether the acid employed acts a much more important part 
than is assigned to it in the theory of Vaquelin and Four-
æroy. The admirable chemist above-mentioned states that 
if sulphuric ether be duly rectified by agitation with caustic 
alkali and subsequent distillation, it occasions no precipitate 
with barytic falls; but if to the ether thus purified there be 

added nitric acid, a copious precipitate is then produced by 
any of the soluble salts of barytes, indicating the presence 
of sulphuric acid. This fact strikingly points out that a 
portion of the base of the acid in a more or less deoxygerenated 
state actually combines with the alcohol to compose ether. 
A like fact respecting muriatic ether is also mentioned by 
Scheele, namely, that though this ether, when rectified, oc-
casions no decomposition of nitrate silver, yet the watery 
residue, after combustion of the ether, occasions a copious pre-
cipitate of muriated silver when mixed with the nitrat of 
this metal.

§ 2. Nitrous ether.—Although nitrous ether appears to 
have been known to Bafi Valentine and Kunkel, yet the 
mode of its preparation being kept a secret, it soon ceased 
to be attended to by chemists, till in the year 1740 it was 
rediscovered by Duhamel, and afterwards was more parti-
cularly described by Navier, Sebastiani and others. It 
was prepared by Navier in the following manner. Put 
12 ounces of rectified alcohol into a strong bottle, and add 
it to gradually and at intervals 8 ounces of strong nitric acid; 
after each portion of acid the liquors are to be well mixed 
by agitation, and the bottle is to be kept close corked and 
immerged up to its neck in ice and water; when the whole 
of the acid has been added, the bottle is to be well corked 
and further secured by a leather cap. A frustum of ether 
rises by degrees to the surface of the liquor, and after five 
or six days the cork is to be pierced by a needle in order to 
let out the nitrous gas formed during the process; this gas 
being thus expelled, the whole contents of the bottle being poured into a separatory funnel, the ether is thus procured unmixed with the heavier fluid on which it floats. This is, however, a very rude way of pro-
ceeding, and is attended with the utmost risk to the appa-
ratus, the ether obtained also is in small quantity, and very 
impure. In order to prevent the violent and rapid action of 
the concentrated acid on the alcohol, which is the chief 
difficulty in the preparation of nitrous ether, Dr. Black 
proposed to interpose a thin stratum of pure water, and 
Fisher on the same principle made use of a little weak 
spirit of nitre for the same purpose. M. Dolfus, from a 
careful repetition of the latter process, obtained the following 
result. Upon two ounces of very strong nitric acid he 
poured gently six drachms of the same very much diluted, 
and upon this three ounces of rectified alcohol. The bottle 
was loosely corked and suffered to stand undisturbed for 
three days; at this time the lower liquor appeared perfectly 
homogeneous with a frustum of ether floating above it. The 
whole being put into a retort and subjected to a gentle heat, 
the ether was obtained thereupon had a drachm of very pure 
ether unmixed with any acid, and the residue in the retort 
consisted of weak acetous acid mixed with oxalic acid, 
nearly the whole of the nitrous acid having been decom-
pored.

The last mode by which nitrous ether may be prepared, 
that we shall mention, and which on the whole appears to be 
the best, consists in mixing together alcohol and sulphuric 
acid, and pouring the liquor upon pulverized nitre; the sul-
phuric acid divengages the nitre, which immediately re-acts 
on the alcohol, and ether is the result. The able chemist 
whom we have already mentioned has shewn the excellence 
of this method by the following experiment. Having put 
into a retort four ounces of perfectly dry and pulverized 
nitre, he added to it a mixture consisting of two ounces of 
concentrated sulphuric acid, and four ounces of alcohol. 
The whole being submitted to distillation, there came over 
first five drachms of dulcedispire of nitre, and then three 
ounces of a liquor from which by subsequent rectification 
were procured two ounces of pure ether.
Ether.

Nitrous ether, when recently made, contains in loose combination a considerable quantity of nitrous gas, which in some degree modifies its properties, and renders it peculiarly liable to burst the bottles in which it is kept, especially in warm weather. This loss and trouble, however, may be avoided by rectifying the ether, which is best done in the following way. Pour into a strong vessel so as to fill it two thirds, one part of ether and four parts of pump-water, and agitate it cautiously at first, frequently removing the thumb from the mouth of the vessel in order to afford a free passage to the dilengaged nitrous gas; when no more of this gas is given out add a quantity of dry pyrazal equal in weight to the ether, and make the whole well together; then put the mixture into a tubulated retort and proceed to distillation, taking care that the temperature does not exceed 120° Fahr.; the ether will pass into the receiver quite pure, and may be kept for any length of time in strong well closed bottles, with no more risk of accidents than sulphuric ether is subject to.

Nitrous ether resembles sulphuric ether in most of its properties; it has, however, a dilute yellow colour, and a somewhat different odour and flavour; this appears to be owing to the presence of a little refrinous matter, from which it can never be entirely freed; by repeated distillations from fresh parcels of dry white sugar, as Deyceux has observed, this impurity may, in great part, be separated, and in proportion as this takes place the ether becomes more and more analogous to that prepared by sulphuric acid.

Nitrous ether appears capable of uniting with nitrous gas in two proportions; when the ether is in excess it forms nitrous ether in the flake which in it appears previous to rectification; when the nitrous gas exceeds the ether it forms a permanently effusive fluid that has obtained the name of etherized nitrous gas. The preparation of this differs only in the rapidity with which the nitrous acid and alcohol are made to act on each other: when the combination takes place very slowly much ether and little etherized gas are the result, but when the contrary is the case these two products are formed in an inverse proportion. If equal parts of alcohol and strong nitrous acid are mixed together at the common atmospheric temperature, or at a higher heat in proportion as the acid is diluted, a very rapid and copious effervescence takes place, a little ether is condensed in the receiver, and a large quantity of gas passes through the conducting tube, the first portions of which are etherized nitrous gas, and the latter common nitrous gas. What remains in the retort is acetic acid with a little oxalic acid. The properties of etherized nitrous gas (according to Van Diemen and his associates, to whom we are indebted for its discovery) are the following. It has a disagreeable ethereal odour, exactly resembling that of olefiant gas when treated with oxymuriaitic acid. By the application of fume it takes fire and burns with a yellowish lambent flame like alcohol; after the combustion has ceased, the vessel in which it was carried on contains a vapour of singular pungency. Water absorbs this gas, but requires a considerable time to effect this, except agitation is had recourse to, enfeebling in this respect, carbonic acid. Alcohol prevents the absorption of the gas, and takes up the gas not only more rapidly, but also in larger proportion. A solution of caustic potash also dissolves it, but with considerable difficulty, and on the addition of sulphuric or muriatic acids the etherized gas is again set at liberty unaltered in any of its properties. Ammonia, whether liquid or in the gaseous state, is incapable of contracting any union with it; the same is the case with oxygen gas at the common temperature, but a mixture of the two, when inflamed, produces a most violent explosion; sulphuric acid immediately decomposes this gas, by absorbing the ether, the nitrous gas retaining its elastic state. Sulphurous acid produces the same effect, only it requires some days for this purpose. If sulphuric acid, previously diluted with an equal weight of water, is placed in contact with this gas over mercury, its action is greatly retarded, the diminution of volume in the inclosed air takes place much more slowly, and even after some days a portion of ether is retained by the nitrous gas, which in consequence acquires the property of elongating the flame of a taper that is immersed in it, in the same manner as nitrous oxyd does. Nitrous acid, according to the degree of its concentration, absorbs either wholly or in part, the etherous portions of the gas, and the same may be observed of muriatic acid.

Etherized nitrous gas, when passed through a red-hot tube, deposits a little oil, and by sublimate walking in lime-water is freed from some carbonic acid; the residue is nitrous gas, mixed or combined with common carburetted hydrogen, and is not acted on by the sulphuric, nitric, or muriatic acids, by caustic potash or alcohol. The addition of oxygen gas produces red vapours, the nitrous gas is converted into acid, and the gaseous residue is carburetted hydrogen.

§ 3. Muriatic ether.—After chemists had shown the production of ether by means of the sulphuric and nitric acids, it was natural to attempt its preparation by the muriatic acid. But this latter, in its usual state of dilution with water, has no action on alcohol, and therefore the various modes that were first practised to obtain muriatic ether entirely failed. A few chemists were said to have succeeded by employing simple muriatic acid, but in a more concentrated and dry state than the common liquid acid; the procés, however, was both difficult and doubtful, and muriatic ether can hardly be said to have been known till Rouelle discovered that it might be prepared by diffusing together alcohol and the smoking liquor of Libavius, which is a concentrated muriac of tin in its highest state of oxydation. The marquis de Courtaulx, having repeated the procés of Rouelle with great care, proposes the following as the best method of making the substance in question. Mix together in a retort three parts of the fuming muriat of tin and one of alcohol; a considerable degree of heat is immediately excited, and a white suffocating vapour arises, which, however, soon disappears on agitating the mixture. As soon as an ethereal odour is perceived, let two balloon receivers be fitted on, and kept as cool as possible; then by the application of a gentle heat to the retort there comes over first a little dephelegmated alcohol, which is succeeded by the ether; by an increase of temperature a few drops of coloured oil are produced, and there arises, partly in the form of a foat butter and partly in that of a dense brown liquid, a quantity of smoking muriat of tin, part of the metallic oxyd remaining in the retort as a grey powder. When the ether thus procured is mixed with pearls, a copious effervescence and precipitation take place, owing to the decomposition of some muriat of tin contained in the ether; after which, by distillation at a gentle heat, the ether mixed in a state of great purity, amounting to half the impure product of the first distillation.

Several others of the metallic muriats have been found to be equally efficacious with the liquor of Libavius; the corrosive muriats of antimony and of arsenic, the muriats of bismuth and zinc, and the red muriat of iron, have in particular been used with success in the preparation of muriatic ether. Scheele.

Scheele, the discoverer of oxymuriac acid, was induced to try the effect of this in the preparation of muriatic ether. For this purpose he put three ounces of alcohol into a receiver,
ether, with which was connected a retort holding two ounces of common salt, upon which was poured an equal weight of muriatic acid; the muriatic acid thus diffused passed into the receiver, where it combined with the alcohol; and this, when saturated with acid, was transferred to another retort, containing three ounces of black oxide of manganese in fine powder; the mixture instantly assumed a green colour, and presently after became so hot as to boil. When the ebullition had ceased, there was found in the receiver a liquor, from which, on mixture with water, a quantity of ether immediately separated. The same method is recommended by Van Mons, except that he employs only one fourth of the manganese used by Scheele, and performs the second distillation in a Woulfe's apparatus, the bottles of which contain a solution of caustic potash, by which the acid is prevented from reacting on the ether.

Another mode of applying oxymuriatic acid to the preparation of ether, first practised by Scheele, is mentioned by Pelletier, and deferves to be repeated, as being perhaps the most expeditious and economical of any. He introduced into a large tubulated retort a mixture of eight ounces of manganese, and 16 ounces of dissected common mordant, into which he poured a mixture of 12 ounces of fulphuric acid, and eight ounces of alcohol. From this mass ten ounces were drawn off by distillation at a gentle heat, which, by subsequent rectification, yielded four ounces of ether.

It deferves to be remarked, that the ether prepared by oxymuriatic acid generally deposits, during its rectification with potash, a considerable quantity of a clear aromatic and bitter oil, which sinks in drops to the bottom of the vessel; the ether also, according to Dolfius, at least before rectification, is completely miscible with water when shaken with it for some time. The preparation of ether, by means of simple muriatic acid, is not easy, and was readily suppos'd to be impossible by some of the leaders of the modern school of French chemists, because it contradicted one of their early theories, that the process of etherification; yet Beaumé, a chemist of great experience and unqualified veracity, had affirmed, that he had obtained a small quantity of ether, by mixing together alcohol and muriatic acid, both of them in the state of vapour. The practicability of this method appears to be established beyond doubt by the following formula of M. Boffe. Keep a quantity of common salt in fusion for about an hour, in order to drive off all the water of crystallization, then pulverize it, and put 40 parts into a tubulated retort, connected with a Woulfe's apparatus, in the first of which are to be poured 20 parts of most highly rectified alcohol; then add to the salt in the retort 20 parts of the strongest sulphuric acid, and proceed to distillation by a gentle heat, keeping the bottle holding the alcohol as cool as possible. When the alcohol is saturated with acid, transfer it to a retort, and distill over about one half of it; agitate this portion with an alkaline ley, and the ether will presently separate and float on the surface, whence it may be obtained by decantation or distillation. The quantity of ether from the above materials amounts to about five parts.

Muriatic ether has a striking resemblance to that prepared by sulphuric acid; its specific gravity, however, is greater, amounting, according to Hermbold, to 0.94; its taste also has a peculiar alluringly like alum, and when burning it exalts a strong acid odour, somewhat resembling that of sulphuric acid.

§ 4. Fluid ether.—All that we know of this subsance is derived from the discoveries of Scheele. He first impregnated rectified alcohol with fluoric acid gas, by distilling pulverized fluor spar with sulphuric acid, and placing alcohol in the receiver; the first spirit thus obtained was distilled with a gentle heat, but no sign of ether made its appearance. Another portion of the acidulated spirit was then mixed with black oxide of manganese, and by subsequent distillation an etherous fluid came over, from which, by subsequant rectification, a little ether was obtained of a very agreeable odour, resembling nitrous ether.

§ 5. Acetic ether.—Acetic ether was first discovered by the Count de LaRauquais; the method of its preparation was by distilling together equal parts of alcohol and acetic acid. Scheele, Porre, Bergman, and other chemists, repeated this process ineffectually, and hence were induced to suspect some error. In consequence of these doubts, Pelletier entered into a careful examination of the subject, and has both shown the reason of the failure of Scheele, and has given the proper method by which to succeed. He distilled together equal parts of alcohol and acetic acid, and drew off a little more than half; this liquor was acidulous, and had an etheral odour, but no true ether could be made to separate. He then mixed together 12 ounces of strong muriatic acid, and the same quantity of alcohol, and distilled over half of it at a boiling temperature. He then re-acted the mixture, poured it back into the retort, and recommenced the distillation; the produce of this and of a third distillation were in like manner recollected, and having distilled the whole again for the fourth time, he finally obtained 12 ounces of an etherous fluid; with this he mixed a quantity of carbonated potash, sufficient to saturate the acid which it contained, and then submitted it to gentle distillation. The first six ounces that came over were pure acetic ether, the next four ounces also contained ether, but not so pure as the former. It is remarkable that during the coagulations a considerable absorption of air took place.

Scheele obtained acetic ether in a much more copious manner, by mixing together acetat of potash, or of lead, or of copper, with alcohol, and then adding as much sulphuric acid as was requisite to decompose the acetic acid, and distilling the mixture at a low heat. The produce being shaken with water, the ether rises to the surface and may be poured off. From 16 parts acetat of lead, six parts strong sulphuric acid, and nine parts of water, Bucholz obtained six parts rectified ether.

Acetic ether always retains the odour of the acid by which it is formed; it is not so volatile as the ethers procured by the mineral acids; it burns with a lambent blue flame, like alcohol; it is soluble in a little more than twice its bulk of water, and is decomposable into acetic acid by repeated distillations at a very gentle heat.

Various other acids have been distilled with alcohol for the purpose of procuring ether, but with little or no success. Oxalic acid, with an equal weight of alcohol, yielded Bergman a watery somewhat etherized alcohol. Benzoic acid and alcohol, according to Scheele, afford no ether, but when a little common muriatic acid is added to the mixture, an etherous liquor comes over, of which part floats on water and part sinks in the same fluid. The ether, or the lighter portion, has the odour of benzoic acid, burns with a clear flame and smoke, and is about equal in volatility to acetic ether. The phosphoric, boracic, tartaric, citric and fucicic acids, were found by the same able chemist to be incapable of producing ether, either by their own action on alcohol, or when mixed with oxide of manganese or muriatic acid.

Ether, in Ancient Geography, a town of Palestine, in the tribe of Juda, which afterwards was assigned to the tribe of Simeon.
Biography. 

FRENCHITY. 

FRENCH, GEORGE, in Biography, chiefly known as a writer of comedy, was born in the vicinity of London about the year 1636. Little is known of his early years, but it is supposed he was educated at Cambridge; spent some time in foreign travel, and afterwards entered himself at one of the inns of court. His talents were but ill adapted to the laborious profession of the law; he was fond of gay and polite company, and became a writer for the stage. In 1663, his first comedy, entitled "The Comical Revenge, or Love in a Tub," was presented to the town, and well received. The author was immediately enrolled among the wits of the age. His next piece is thought to have been entitled more to praise for wit than for morality. It is entitled "She would if she could!" its licentious tendency was justly represented by the "Spectator," who says he knew of but one author who had professedly written a play upon the desire of multiplying our species, and that is the polite Sir George Etheridge in the play of "She would if she could!" Other poets, he adds, "have here and there given an intimation, that there is this design under all the drollaries and affectations which a lady may put on, but no author except this has made sure work of it, and put the imaginations of his audience upon this one purpose, from the beginning to the end of the comedy." His next piece was not produced till the year 1676; it was entitled "The man of the mode, or Sir Peeping Flatter," and dedicated to the second duchess of York, Mary of Modena. It was very popular, and regarded as a true model of polite comedy; one of its principal characters was said to be a representative of the earl of Rochester, the finished fine gentleman and man of pleasure. Etheridge lived a dissipated life, and in a few years incurred his fortune and constiuution. With a view of maintaining his rank in society, he paid his addresses to a lady of considerable fortune, who refused to marry him, unless he could procure the honour of knighthood. This he readily obtained, and upon the accession of James II. he was sent out envoy to Ratisbon, where he resided some time, and from whence he wrote letters which are favourable specimens of his talent for easy pleasantry. He died soon after the revolution, but the account of the time and manner of his death has been differently related. By some he is supposed to have died in his native country soon after his return from France, whither he had been on public business, and by others it is said, that it happened at Ratisbon by a fall down stairs. Besides the comedies already mentioned, Etheridge was author of many smaller poems. His letters to the duke of Buckingham are in the Bibliography Britannica, to which the reader is referred.

ETHERINGTON'S BAY, in Geography, a bay on the north-west coast of the island of St. Vincent; a little to the north of Chateau Belbar bay.

ETHESIUS LAPIS, a name given by some authors to the chrysolite.

ETHICAL GOOD, ETHICAL POSSIBLE. See the respective articles.

ETHICS, Eθικα, the doctrine of manners, or the science of moral philosophy. See PHILOSOPHY and MORALITY.

The word is formed of εθικος, morer, manners, because the scope or object thereof is to form the manners.

Greek makes ethics only the first part or branch of moral philosophy, εθικον, that which regards private persons, or in a private capacity.

By manners or morals is here meant a way, or manner, of living confirmed by custom or habit, or certain habits of doing, or actions which are often repeated, which, if they be according to right reason, the morals or manners are said to be good, otherwise, evil and vicious.

Hence the object of ethics is the exercise of right-reason in all our affairs, actions, and relations; or it is a man himself considered as dirigible, and to be conducted according to reason; and the end of ethics is to make him good and happy: so that if a man conducted himself according to right reason in all the circumstances of his actions, affairs, and relations, he would arrive at the highest pitch of moral perfection and beatitude.

Whence ethics may be defined a right manner of thinking in order to attain to human felicity, or a science whereby man is directed to conduct his will, and the actions thereof, so as to live well and happily. See Will.

The principal, say, the only topics thereof, are happiness and manners, whenever arise two parts or branches of ethics: the first on moral happiness, considered as the end; and the second on moral virtues or good manners, as the means to arrive at that end.

ETHICOPROSCOPIA, formed of εθiki, manners, and προσαπt, to look on, in Antiquity, the name of a sect. Dandeciussus, in his Treatise of Herefore, tells us, that the denomination of Ethicoprocopate was given to such as revered in matters of morality and things relating to practice that were to be done or to be avoided, &c. who blamed things laudable and good in themselves, or recommended or practised things evil. On this footing the Ethicoprocopate, though a numerous body, were no particular sect.

ETHIOPIA, in Ancient Geography, was a name given to several countries, both of Asia and Africa, whose inhabitants were either perfectly black or of a swarthy complexion; but Ethiopia, in a more restricted application of the term, or Ethiopia propria, was limited on the north by Egypt, extending to the eastern part of the island of Elephanta; on the west by Libya interior; on the south by the Red sea, and on the north by a part of Africa unknown to the ancients, but probably comprehending that space which includes the modern kingdoms of Girgir, Abba, Makua, and part of Adel or Zeila. Proper Ethiopia, however, seems to have varied in extent at different periods; but for several ages it seems to have been the tract which at this day comprehends the kingdoms of Dongola, Sennaar, and Abassia, with part of Adel or Zeila; and consequently to have taken up 17 degrees of longitude, and to have reached from the tropic of Cancer to within fix degrees of the line. Some geographers have restricted it to the tract of country that lies between Egypt and Abyssinia, about 600 miles in length, and 500 in breadth, which was called by the Arabian geographers Nuba.

The proper Ethiopia was anciently distinguished by a variety of appellations. Sometimes it was called India; sometimes Cepheus; and most usually of the ancients, in India and Ethiopia. We also find Chaldea, Asia, and Persian denominated Ethiopia by some authors according to their reputation; and it must be allowed, that the ancients called all those countries, extending themselves beyond each side of the Red sea, indiscriminately India or Ethiopia.

According to the Jews, the LXX, the Vulgate, and other versions, Cufi, when applied to scripture to a country, is always to be understood of the proper Ethiopia. This opinion is supported by Philo, Josephus, Euphemius in Euthus, Euthadius, the author of the Alexandrian Chronicon, and the concurrent testimony of the Greek and Latin fathers. See CUSI.

Ethiopia did not abound in cities and towns of any considerable
fiderable note. Axumae, Axumis, or Axume, reckened
the metropolis of Ethiopia, was undoubtedly the same city as
the modern Axuma, or Axum. This country was extremely
mountainous, and therefore the climate in different parts of
it was very various. (See Abyssinia.) The days and
nights, as Ethiopia lay between the tropic of Cancer and the
line, were for the most part nearly equal. The winds that
blew on the mountains were, generally speaking, salubrious
and pleasant; but the atmosphere over the plainsflagitated
and became unwholesome. The soil in those parts that
admitted of cultivation was extremely fertile, and produced
valt quantities of grain, pulse, and fruit. It abounded with
metals, particularly gold, minerals, vegetables, and a great
variety of animals. (See Abyssinia.) The moft famous
river that waters this country is the Nile. (See Nile.)
The chief ports and emporia of ancient Ethiopia were those
of Adulis, Mononds, Opopa, Mosfollon, and the principal
city of the Axumite, seated upon the Red Sea. The Arabs
imported from their country into these ports fruit, corn,
wine, and cloths; and exported from thence to Oeclis and
Muff, opposite harbours, in which they sold their
merchandise, and several other commodities. The most
noted realms pertaining to Ethiopia were Meroe, the spo-
states of Agatharchides, Aflate, Ara Palallis, Cythitis,
Myronis, Diaphine, Magi, Acanthine, Isis, Mondus, and
Menuthis.

According to Pliny, Ethiopia was anciently divided into
45 kingdoms, of which the most powerful and flourishing
was Meroe; but he does not inform us, whether they were
independent of each other, or under one supreme head.
There is reason to believe, however, that the kings of
Ethiopia always ruled with an uncontrollable sway. If we
admit the Ethiopian tradition, that a long succession of
princes, descended from Solomon, reigned in this country,
and that their authority was unlimited, as that of the Hebrew
monarch knew no bounds. It appears from Strabo and Pliny,
that some Ethiopian nations were governed always by
kings, whose common name was Candace, as that of the
Egyptian kings was Pharaoh, and Ptolemy. From Diodorus
Siculus we learn, that a great part of Ethiopia was
inhabited by Cushites, the heads of which were chosen out of
their priests,
and that all these princes made the laws of their respective
kingdoms the basis of their government. According to
Diodorus Siculus the laws of Ethiopia agreed in substance
with those of Egypt; which the Ethiopians accounted for
by the assertion, that Egypt was first peopled by colonies
that migrated out of their country. Herodotus, however,
represents the Ethiopians as having been civilized by the
Egyptians, and as having learned the customs and manners
of that people at so late a period as the reign of Pharnathi-
chus I. Jupiter Ammon, according to the Greek and
Latin authors, appears to have been the principal object
of religious worship in Ethiopia; though the natives paid
likewise divine honours to Isis, Pan, Hercules, Aëcu-
pius, and others, whom they considered as the greatest
benefactors to mankind; and if these authors may be
credited, their religion differed not much from that of the
Egyptians. Diodorus Siculus tells us, that the Ethiopians
valued themselves upon their being the first nation that had
a religious establishment; and for this reason they believed,
that their sacrifices were more acceptable to the gods than
those offered by any other people. He affirms, however,
that some of them were atheists, who looked upon the sun,
on account of his scourging rays, as their implacable enemy.
If a tradition of the modern Abaffines could be relied on,
the Ethiopians, or at least a considerable part of them,
adered zealously to the law of Moses from the time of
Solomon till their conversion to Christianity. According to
this tradition, the queen of Sheba, whom our Saviour calls
the queen of the south, and who ruled over a powerful
nation of Ethiopians, had a son by Solomon named Menilek,
who was educated at that prince's court, and instructed,
under the care of his father, in the law of God. Being
afterwards appointed king of Ethiopia, and sent home to take
possession of his kingdom, at the desire of several eminent
Israelites and doctors of the law that attended him, he
introduced his father's religion, which continued among his
subjects and their posterity till the time of St. Athanasius.

(See Abyssinia.) Ethiopia, in ancient times, was a country of vast extent, in-
habited by different nations; and, therefore, it is natural to sup-
pose, that a considerable variety of languages, or at least of
dialects, must have prevailed in it. The most ancient of these
was that called the Ethiopic, into which the scripture was
formerly translated, and in which all the books of the Abaf-
finies, both sacred and profane, are printed. This language
more or less resembles the Chaldean, but, according to Ludolfus,
who spent 62 years in the study of it, it bears as great an affinity to the Hebrew and
Syriac, and approaches nearer still to the Arabic, from
which it appears to be immediately derived. Ludolfus affirms,
that a competent knowledge of the Hebrew, or any other of
the oriental tongues, will enable a student soon to make
a very rapid progress in the Ethiopic. The purest dialect
of this tongue was that used in the kingdom of Tigré,
where Axuma and the old Ethiopian kings reigned. Upon
the failure of the Zagana line, a Sasanian prince ascended
the throne, upon which Amharic dialect was introdu-
ced at court, and gradually diffused over the whole empire.
(See Abyssinia.) From comparing the ancient Ethiopic
alphabet, as given by the learned Job Ludolfus, in his "Histo-
ry of Ethiopia," with the old oriental alphabets, it seems
not improbable, that some of them were derived from the
old Assyrian, Phoenician, Samaritan, and Syriac characters.
The number of letters likewise in this alphabet, and the
names of several of them, indicate, that though Ludolfus
believes these characters to have been invented by Axumites or Ethiopians themselves,
and to be much older than even the Cufic character of the
Arabs. The Ethiopians both write and read from the left
hand to the right, contrary to the custom of the orientals:
a circumstance which indicates that their alphabet was
totally different from the same extraction with that of the
Arabs.

The Ethiopians agreed in several points with the Egyp-
tians, though they had many customs peculiar to themselves,
some of which were very singular and uncommon. From
this mutual agreement in most of their laws, their splendid
funerals, the deification of their princes, the several colleges
of priests, circumcision, and most of their sacred and civil
institutions, it is highly probable that the same arts, sciences,
and learning, as well as religion, prevailed in both nations.

The Ethiopians were naturally bold and intrepid, but
violent in their temper. They likewise frequented the
people of most other nations in beauty and size, to which
a sufficient degree of strength was generally annexed.
According to various authors, the proper ancient Ethiopians
were, in general, perfectly black, as we find their posterity
at this day, though those of some particular cantons were
white, called by Pliny white Ethiopians. Their women
were strong and lufly, and brought forth their children
with little pain. From the testimony of Herodotus, com-
pared with the relations of some modern authors, it is not
unlike,
ETHIOPIA, in Modern Geography, is a denomination including the countries of Nubia, Abyssinia, Abess or Abyss, and Anian, which are bounded by Egypt and the desert of Barca on the north; by the Red Sea and the eastern ocean on the east; by Zanguebar and Caffraria on the south; and by Guinea, Nigritia, and Zaara, on the west. Nevertheless, all the countries still, according to the ancient division, that lie almost in a straight line from Egypt to the Cape of Good Hope, may be comprehended under the general name of Ethiopia. Ethiopia is divided into Upper and Lower, the former including Nubia and Abyssinia; and the latter comprehending all the kingdoms south of the equinoctial line, as Congo, Lower Guinea, Caffraria, Monomotapa, &c., which see respectively.

ETHIOPIAN. See BIBLE, Ethiopic.

ETHIOPIC Year. See Year.

ETHAES, in Ancient Geography, a town of Upper Media, according to Antione de's itinerary.

ETHMOID, or Ethmoidal, in Anatomy, a name given to one of the bones of the head. See CRANIUM.

ETHNARCHA, ETHNARCH, formed of ethn, nation, and arch, command, a governor and ruler of a nation.

There are some medals of Herod I. surmounted the Great, on one side whereof is found Hæreos, and on the other Etnarch, q. d. Herod the Ethnarch. After the battle of Philippi, we read that Antony, passing over into Syria, constituted Herod and Phseael his brother tetrarchs, and in that quality committed to them the administration of the affairs of Judea. (Jof. Ant. lib. xiv. cap. 23.) Herod therefore had the government of the province before ever the Parthians entered Syria, or before Antigonus's invasion, which did not happen till fix or seven years after Herod was commanded in Galilee. (Jof. lib. xiv. cap. 24, 25.) Consequently Herod was then truly ethnarch, for he can be no otherwise denominated; so that it must have been in that space of time that the medals were struck, which only gave him this title; which medals are a confirmation of what we read in history of the government that this prince was intrusted with before he was raised to the royalty.

Josphus gives Herod the appellation of tetrarch in lieu of that of ethnarch; but the two terms come so near to each other, that it is easy to confound them together.

Though Herod the Great left by will to Archelaus all Judea, Samaria, and Idumea, yet Josphus tells us he was then only called ethnarch.

ETHNOPHONES, in Antiquity, a sort of heretics in the seven century, who made a profession of Christilanty, but joined thereto all the ceremonies and follies of paganism, as judicial astrology, fortileges, auguries, and other divinations.

They derive their denomination from ἐθνός, nation, and φωνή, sound, speech of paganizers, or persons whose thoughts or sentiments were still heathen or gentle.

They practised all the expiations of the gentiles, celebrated all their feasts, and observed all their days, months, times, and seasons. See Damascenus, Hære. N. 94.

ETHOLOGUS, among the Antients, a mimic, or actor, who could represent all the various habits and dispositions of the mind.

ETHOPHIA, or ETHOPEA, in Rhetoric, called also Ethologie, a draught or description, expressing the manners, passions, genius, tempers, aims, &c. of another person.

The word is of Greek original, being formed of ἑθος, behaviour, disposition, and τοια, so, such, as, by Quintilian, lib. ix. cap. 2, calls this figure imitatio morum alienorum; and in Greek, μιμησις, imitation. In English we denominate it a picture or character.

Such is that beautiful passage in Sallust, in his Bellum Catilinarum, wherein he gives us a picture of Catilina: "He had an uncommon strength both of body and mind, but an ill-turned and wicked disposition. When very young, his great pleasure was in trifling broils, rapine, laughter, and civil discord. His body was formed to undergo falling, cold, and watching, beyond all belief. His mind was daring, deceitful, and various, and could imitate or accommodate itself to every body; he was extremely covetous of other people's goods, and profuse of his own. His lufts and desires were very high; his stock of eloquence considerable, but he had little or no discretion."

The ethopoeia is divided into profopoeia and ethopoeia, properly so called; the former of which is a picture of the body, countenance, make, drefs, gait, &c. and the latter of the mind.

ETHULLA, in Batany, a name concerning whole origin or meaning we have met with no conjecture. Linnaeus its author rarely explained names of his own contrivance, nor is any thing upon this occasion mentioned in his son's Decas Prima Plantarum, where Ethulia first appeared. Could he possibly allude to the remote country whence it came, as extra, (beyond) Thule, suppos'd by the ancients the uttermost part of the earth? If the plant had been of American origin, such an appellation would, not inelegantly, have alluded to the famous prophecy in Seneca's Medea, so expressive of the discovery of the western world, and ending—

—" nec fit terris
Ultima Thule."—

Gen. Ch. Common Calyx rounded, simple, of many linear, equal, spreading-pointed scales. Curr. compound, diencephalic. Florots all fertile, numerous, uniform, tubular, funnel-shaped, with some space between them; their limbs five-cleft, creet. Stam. Filaments five, very short, capillary; anthers united into a cylindrical tube. Phyl. German angular; nyle thread-shaped, the length of the flamin; filaas two, recurved. Pet. five, none, except the permanent one. Seeds solitary, truncated, top-shaped, five-angled, five-furrowed; crown none, except a prominent margin. Recept. naked, convex, dotted with minute excavations.

Eff. Ch. Receptacle naked. Seed-down none. Florots tubular, five-cleft, numerous. Scales of the calyx pointed. This is but a vague and confused genus, depending properly on the three following species only.

fend by Professors David Van Royen to Linnaeus, who raised them in his rove at Upsal, and the plant proving new, was described and figured by his son, in a work of which only two fasciculi ever appeared. Linnaeus supposed it a native of Ceylon, which may possibly be correct. No new information appeared concerning it, till it was mentioned in the Hortus Kewensis as sent by Thoem, and from afterwards Vahl discovered it to be the Kabiria of Forfalki, so that we hence learn it to be certainly a native of the muddy banks of the Nile, where it flowers early in November. The root is annual, fibrous. Stem four feet high, alternately branched, hollow, downy, leafy. Leaves alternate, on short stalks, lanceolate, pointed, equally serrated, fragrant, downy beneath, three inches long; without stipulas. Flowers pale blue, in compound corymbose panicles about the tops of the branches, remarkable for the slender and divergent tubes of their florets. The seeds form an almost globose head; each of them is crowned with a pale univalved angular border.

2. E. Sparganophora. Linn. Sp. Pl. 1171. (Sparganophorus Vaillantii; Garm. v. 2. 395. t. 165.) "Flowers in little axillary clusters. Calyx-folios recurved."—This we know only from the work of Vaillant, (from whom Linnaeus adopted it,) and that of Gartner; nor is its native country ascertained. The leaves are said to be like those of Golden Rod. Seeds exactly like the half in general structure, less than any doibt of their belonging to the same genus.

3. E. Struchium. Swartz. Prod. 111. (Struchium; Browne Jam. 312. t. 34. f. 2.) Flowers axillary, sessile, moily foliate. Calyx with straight spinous points.—Gathered by Browne in Jamaica. Stem herbeaceous, two or three feet high, leafy, smoothish. Leaves elliptic-lanceolate, four or five inches long, pointed, firmly serrated, thin, very slightly pubescent, on stalks an inch in length. Flowers small, axillary, sessile, either solitary or in pairs, or if more together, they have smaller leaves between them. We premise the straight spinous points of the calyx-scales will afford a certain specific difference between this and the laft, whether their foliage be different or not.

In his first Mantissa, p. 110, Linnaeus added three species to his genus Eibula. Of these E. tenuifolia must be entirely flruck out of the sytemm, being no other than his own Artemisia cibemna, and not having either the habit or characters of an Eibula. The second is E. divaricata, Bumr. Ind. 1756. t. 58. f. 1. (Clyrhannthemum angustifolium, Prem. Phys. f. 31. t. 4.) Leaves linear, toothed, decurrent. Flowers solitary, flarkled, terminal. Stem divaricated.—Native of rice-fields in Malabar. Koenig. Root annual. Stem three or four inches high, erect, much branched in a corymbose manner; branches leafy, quadrangular, winged, somewhat cottony. Leaves alternate, linear-lanceolate, toothed, running down into the wings of the branches. Flowers on short, simple, solitary, terminal stalks; Calyx of numerous, imbricated, sharp and somewhat spinous, spreading, purplish scales. Seeds without any crown.—We have, as Willdenow has already done, preferred to correct the description of Linnaeus, and his quotation of Burmann. Linnaeus moreover quotes his own Artemisia minima, Sp. Pl. ed. 1. n. 19, with the original specim before him, for this Eischial, but very erroneously, and his citation of Burmann is so placed as to imply that he had committed the same fault, which is not true. We cannot but observe here that Burmann in his Floras Indiae has copied E. kooksiis and E. Sparganophora from Linnaeus, without any real knowledge of them, so that his authority is of no avail respecting those species. Gauter, v. 2. 389. t. 164, retains this E. divaricata as the only real Eibula, adding a good synonym from Plukenet (who states the plant twice), Crysanthemum parum ramosum, Linnaeus, membranaceae caulibus ad mentis. Pech. Phys. 156. l. 5. Gartner therefore prefers the name and genus of Valentin's Sparganophora, which he considers a well-different genus from this plant. In the last part he appears to be right, but the above three species unquestionably confirme what Linnaeus meant by Eibula, and they only agree with his generic description, so that the divaricata ought perhaps to be referred, not with his want of a fold-crown, to the Genus of Adanson and Jussieu, as the latter suspect, or rather to make a genus by itself. (See Grangola.) Jussieu indeed prefers Browne's Struchium as a genus, but, as we premise, improperly.

One more suppofed Eibula remains to be noticed, named bidonis, Mant. 810, from its resemblance to Bidens triparti. This has nothing to do with the genus under consideration, being the very identical Flexuosus caputis of Jussieu, of which we shall speak under that name hereafter. It is native of Chili.

With the Eibula uniflora of Walter and Willdenow we are not at all acquainted. 

ETIENNE, in Liguorphy, the name of a family who have been celebrated as learned printers, and are more celebrated for their new and different works than for their English. The founder of the family was Henry, a printer at Paris. He is chiefly distinguished as the editor of a Psalter, in which the compositions were divided into verses, and distinguished by figures, being the first book of Scripture in which this practice was observed. He died at Lyons, leaving behind him three sons, all eminent printers, of whom the second was

ETIENNE, ROBERT. This young man worked at first under Simon de Colines, who had married his mother, and then set up in business for himself at Paris. He had received a very liberal education, and was well acquainted with the ancient languages, and was deeply skilled in principles of sound criticism. He carried the art of typography to a very high pitch of excellence, as a number of his books well known at present will testify. His office is said to have resembhed a learned seminary, in which the Latin language was the only one allowed to be spoken by all the persons employed by him. He established an early reputation by the editions of the bible in different languages. He by the first person who introduced the division of the whole into verses; of which we are informed, he made the necessary preparations, as he was on a journey on horseback from Paris to Lyons. These divisions have been useful as marks for reference, but in other respects they have been injurious to the work, on account of the faultiness of the divisions which not unfrequently give a wrong sense to important passages of the sacred writings. In the year 1532 he published his excellent "Theaurus Lingue Latinae" in two volumes folio. This work obtained a very high reputation, and has passed through many editions: the best are said to be that printed in London in 1734, and the one printed at Basle in 1740. Both editions consist of four volumes folio. In the year 1539 the reputation of Robert attracted the attention of Francis I. who reimbursed him sums of his exences in procuring manuscripts and founding new types, and gave him the honour of king's printer for Greek and Latin books. At the reformation this worthy printer, in common with many biblical critics, fell under the suspicion of heresy, and endured a long persecution excited by the doctors of the Sorbonne, who, in the year 1548 unanimously decreed that
that his bible with a version by Leo Judae, and notes, ought to be suppressed, and placed in the list of prohibited books. By many liberal and respectable persons Etienne was supported against the fanaticism of bigots and priests, but, at length, he thought it advisable to withdraw to Geneva, where he more openly avowed himself a friend to the reformed religion. He felt himself called on to vindicate his conduct, and published an apology, in which he retaliated upon his persecutors, and the church, by whom he had been driven into a kind of exile. At Geneva he continued to follow his profession, and published many books in favour of the Protestant cause. He was elected burgger of Geneva, and lived in habits of friendship with Beza and Calvin. He died in the year 1559, at the age of fifty-six. He has been, since his death, to the present day, the theme of admiration with the learned, and by the illustrious De Thou he was considered as better entitled to the gratitude of his country, by the perfection which he gave to the art of printing, than those warriors who had extended the boundaries of the French empire. Moreni.

Etienne, Charles, a physician of the faculty of Paris, who is considered by his biographers as an honour to the age in which he lived, in consequence of the extent and variety of his attainments. He was born about the year 1503. His father, Henry Etienne, and his brother, Francis and Robert, were all celebrated for the ingenuity with which they cultivated the art of printing. But this family was not less unfortunate than ingenious; for, being attached to the cause of the Protestant reformation, some of them were banished from France, and others died in prison. Charles, however, during these troubles, lived and flourished at Paris, where he had for many years practised his profession, when his brother Robert became the object of persecution, and fled to Geneva. He immediately undertook the superintendence of his printing-office, which he continued to manage for several years, in the hope of effecting the restoration of his brother, practising medicine at the same time with his former profession and success. Robert died at Geneva, however, in 1559; and Charles terminated his life unfortunately, a few years afterwards, being killed in a dungeon in 1564, at the age of above sixty.

Dr. Etienne, the subject of this article, made several discoveries of minor importance in anatomy, which had escaped his predecessors, especially Galen, of whom he was a great admirer; he published some anatomical figures, the execution of which, however, was claimed by a surgeon of the name of Riviere, and generally allowed to be his; but the explanations were admitted to be Etienne's. He published a great number of works, some of which have no connection with his profession, especially the histories of Lorraine, of Flanders, and of the duke of Milan. The works relative to medicine, besides the anatomical book just mentioned, were principally on botanical subjects. He also wrote a volume, consisting of three books, "De Nutrimentia," Paris, 1550. Eloy.

Etienne, Henry, the son of Robert, was born at Paris in 1528, and became distinguished as one of the most learned men of his time. His father spared neither pains nor expense in his education, and the youth had a great facility in acquiring the Greek language. At the age of eighteen he assisted his father in compiling the MSS. of Dionysius Halicarnassensis. After he had performed this business he set out on his travels; passed some time in Italy, where he became well acquainted with the learned men of that country, and obtained much valuable information from the Italian libraries. From Italy he came to England, and from thence he passed through the Low Countries in his way to Paris, whither he returned at the moment his father was driven from that city. Here he followed the united professions of printer and editor. In 1554 he published the Odes of Anacreon from the MSS. which he found in Italy. He accompanied this edition with fragments of Sappho and other lyric poets, and with an elegant metrical version. To him the learned are likewise indebted for various other Greek authors, published from MSS. which he had collected in his travels, all of which he corrected and enriched with valuable annotations. In 1572 he published his "Theaurus Linguarum Graecarum," in four volumes folio, a capital companion to the Latin Theaurus by his father. Scapula made an abridgement of this vast work, which greatly hindered the sale of the original, and thus defrauded the learned author of the recompense to which he had the most just claim. This valuable man was protected by Henry IV. of France, who was so far attached to him, that he employed him in a work entitled Sur la prelucence de la Langue Francoische. He was, however, too deeply imbued with the liberal principles which real literature always infuses in the minds of her votaries, to escape the malice of the monks. They brought a profession against him for his "Preparation à l'Apologie pour Herodote" Approved of his great danger, and well knowing the nature of his enemies, he fled from the city and took refuge in the mountains of Auvergne. Scarcely had he left the city, when finding that he had escaped their cruel fangs, they burnt the excellent man in effigy, regretting, no doubt, that they had not his person on which to wreak their vengeance. After this Etienne refixed chiefly at Geneva, though he made occasional visits to his literary friends in Germany and France. He was subject to many difficulties, and doomed to other and more severe persecutions, which at length did break his spirits as to cause derangement, and in this state, as well as in poverty, he died at an almshouse at Lyon in 1598. Besides editing the Poëta Gracci Principes; Maximus Tyrius; Diodorus Siculus; Medicius artius Principes; Porphyr. and Galen; and the Nov. Tell. Graco; to which he prefixed an admirable preface; he was author of some excellent works, besides what have been already mentioned; viz. Dialogue De bono in fideribus logus Graeco fluidis; De aequalis et perpetuis Graecis et Latinis, and other pieces in the French language, as well as in verse as in prose. He was a man of many singularities, but truly respectable and highly respected. He left several children, of whom his son Paul succeeded him in his Genevan printing-office, and inherited a share of his reputation. Moreni.

Etienne, Saint, in Latin Faurna Santiti Stephani, or Faurnis, in Geography, a considerable town of France, in the department of the Loire, chief place of a district of the same name, with a population of 16,259 individuals. It is situated on the river Furon, 36 miles S.W. of Lyons, and 348 miles S. by E. of Paris, N. lat. 45° 22'. The town is divided into two cantons, East and West, the former with three communes and 12,735 inhabitants, the latter with three communes and 14,569 inhabitants; the whole canton has a territorial extent of 923 kilometres. There are at Saint Etienne and in the neighbourhood several manufactories of fustians and fire arms, cutlery, and hardware of all sorts, ribbons, forks, and good bleaching grounds. The district abounds with coal mines, and the proximity of two large rivers, the Rhone and Loire, affords great facility for the transport of the produce of the manufactures.

As chief place of a district, Saint Etienne has a sub prefecture, two courts of justice, and a register office. The district contains 9 cantons, 76 communes, and 99,761 inhabitants.
The choristers, See "17A small How to an 1509 population the 36" he an 1509 population the 36" He 1509 population the 36" in the canton—fatal—of the canton with 6,877 inhabitants. The canton contains 10 communes and 64,966 inhabitants.

Etienne de Boissey, Saint, a town of France, in the department of the Lower Pyrénées, chief place of a canton in the district of Mauléon, with a population of 6,877 inhabitants. The canton contains 10 communes and 64,966 inhabitants, on a territorial extent of 210 kilometres.

Etienne de Cauens, Saint, a small town of France, in the department of Montbéliard, chief place of a canton in the district of St. Jean de Maurienne, with a population of 830 individuals. The canton has a territorial extent of 1,733 kilometres and 6 communes, with 6,496 inhabitants.

Etienne de Lagarde, Saint, a small town of France, in the department of the Ardèche, chief place of a canton in the district of l’Argentière, with a population of 1,529 individuals. The canton has seven communes and 3,493 inhabitants, on a territorial extent of 1,835 kilometres.

Etienne de Montbel, Saint, a town of France, in the department of the Lower Loire, chief place of a canton in the district of Savenay, with a population of 4,118 individuals. The number of the inhabitants of the canton amounts to 12,453; they are dispersed in five communes, on a territorial extent of 2,723 kilometres.

Etienne de Sainte Geoire, Saint, a small town of France, in the department of the Isère, chief place of a canton in the district of St. Marcellin. It has 1,456 inhabitants, and its canton comprises, on a territorial extent of 1,621 kilometres, 13 communes, with a population of 9,381 individuals.

Etienne en Dépôt, Saint, a small town of France, in the department of the Upper Alsace, chief place of a canton in the district of Cap, with only 766 inhabitants: but the canton has four communes, and a population of 2,184 individuals, on a territorial extent of 2,624 kilometres.

Etienne les Orgues, Saint, a small town of France, in the department of the Lower Alps, chief place of a canton in the district of Forcalquier, with a population of 984 individuals. The canton has a territorial extent of 2,714 kilometres, 12 communes, and 12,650 inhabitants.

ETOLATION of Plants, in Gardening, the rendering them white, crisp, and tender, by excluding the action of light from them. See Blanching.

ETIQUETTE, a French term, primarily denoting a ticket or title affixed to a bag or bundle of papers, expressing its contents. It is also used when applied to the Spanish and some other courts, to signify a particular account of what is to be done daily in the king’s household, and in the chief ceremonies relating to it. It likewise denotes those forms that regulate the decorum of conduct towards persons of various ranks and stations.

ETIVA, in Geography, a small town of Switzerland, in that part of the canton of Berne which is called the Upper Land, or Upper Country, being at the foot of the highest Alps, and extending to the glaciers, or ice mountains. It is situated in the district of Gellenay, and is remarkable for its mineral springs, the water of which has a sulfurous taste.

ETLINGEN, or Ettlingen, a small town of Germany, in the grand duchy of Baden, situated on the river Alb, between Pforzheim and Rastadt, at the distance of 12 miles from each. N. lat. 48° 55’.

ETMARSHAUSEN, or Etmarshausen, a small town of Germany, in the duchy of Saxe Coburg, in the district of Saltzungen, remarkable only for the following inscription, which is engraved on an old garden gate of stone, in Latin characters: "ver weisz obs wahr ist," (who knows whether it be true.) It has become a proverbial saying in that part of Saxony, and frequently used as a polite intimation that a person is suspected of having rather deviated from or embellished the truth; people then observe that what has been related is engraved at the garden gate at Etmarshausen. The origin, occasion, or motive of the inscription itself, has never yet been explained, and has puzzled several antiquaries of the neighbourhood.

ETMASER, a town of Arabia, in the province of Yemen; 36 miles N. of Chamir.

ETMULLER, Michael, in Biography, an eminent physician, was born at Leipzic on the 26th of May, 1614. Possessing a taste for the sciences which his native city afforded him the most ample means of cultivating, he diligently studied under the celebrated professors of that period. He afterwards spent a considerable time in travelling through France, England, Holland, Italy, and Germany, with a view to the farther acquisition of knowledge; and on his return took the degree of doctor of medicine at Leipzic in August 1668. In 1676, he was appointed professor of botany in that university, and extraordinary professor of surgery and anatomy. He fulfilled those offices with great applause; and his death, which happened on the 6th of March, 1683, when he was but 39 years of age, was generally regretted by the faculty of Leipzic. The disorder, which occasioned it, was contracted while he was employed in some chemical experiments. He was a very voluminous writer, and his works were deemed sufficiently interesting at the time of their publication to be translated into molt of the European languages. His medical practice and opinions were built upon the theory of Sylvius de la Boë, and the chemical facts.

ETMULLER, Michael Ernest, son of the preceding, was born at Leipzic on the 26th of August, 1673; and, after having studied at Zittau, Altenberg, and other schools of Germany, he took the degree of doctor of medicine at his native place, in 1697. He afterwards travelled to the most eminent universities of Europe, and became successively professor of anatomy, of philosophy, and of pathology at Leipzic. He had like wise been two years director of the Academia Naturae Curioforum, when his death occurred, on the 25th of September, 1732. He has left some disquisitions of his own, but is chiefly known as the editor of the works of his father.

ETNA. See Ätna.

ETOBESA, or ETOBEMA, in Ancient Geography, a town of Spain, in Edetania, mentioned by Livy under the name of Etovisilla, and situated at some distance W. of Valencia.

ETOCETUM, a place in the Isle of Albion, according to the Itinerary of Antonine, which Gale fixes at Wall, near Litchfield.

ETOILE, in Geography, a town of France, in the department of Drôme, and district of Valence; 3 leagues N.W. of Crest.

ETOLIA. See Ätolia.

ETOON, in Geography, a large village in the hundred of Stoke, and county of Buckingham, England, is noted for its grammar school, or college, in which many eminent gentlemen, authors, military heroes, &c. have received their scholastic education. This college was originally founded by king Henry the Sixth, in the year 1440, for a provost, ten prebends, four clerks, six choristers, twenty-five poor grammar-schoolers, and twenty-five poor men. The first provost was Henry Sever, who was succeeded by William Waynfleet, founder of Magdalen college, Oxford. This foundation
foundation was particularly excepted in the act for the dilution of colleges and chantries, in the time of Edward VI. Its establishment, however, has been in some degree altered, and now consists of a provost, seven fellows, two schoolmasters, two conductors, seven clerks, seventy scholars, and ten choristers, besides inferior officers and servants. The annual election of scholars to King's college, Cambridge, founded also by Henry VI. takes place about the end of July, or the beginning of August, when twelve of the senior boys are put on the roll to succeed in this college as vacancies occur. The average number of vacancies is about nine in two years; at any ten years of age the scholars are superannuated. Eton college also sends two scholars to Merton college, Oxford, where they are denominated politmasters. It has a few exhibitions, of twenty-one guineas each, for its superannuated scholars, towards whose assistance Mr. Chamberlayne, a late fellow, has bequeathed an estate of 43l. per annum, after the death of his widow. The scholars elected to King's college succeed to fellowships at three years' standing. The independent scholars at Eton, commonly called Oppidians, are very numerous; the average number having been for several years past from 350 to 370: when Dr. Bernard was master, under whom the school particularly flourished, the number at one time exceeded 525. Among the many distinguished persons who received their education here we find the names of bishop Fleetwood, bishop Pearson, John Hales, Dr. Stanhope, Sir Robert Walpole, Horace Walpole, Oughtred the mathematician, Boyle the philosopher, Waller, Gray, Woff, the late earl Camden and Chatham, and the late learned Jacob Bryant; with many other eminent literary and public characters of the present day.

An ancient custom, appertaining to this college, called the "Montem," or "Ad montem," must not be passed unnoticed. This is a procession of all the scholars, &c., made every third year on Whit-Tuesday, to a tumulus, which has acquired the name of Salt Hill, by which also the neighbouring inns have been long known. The chief object of this ceremony is to collect money for funds, as the phrase is, from all persons present, even from passersby travelling the road. The scholars on Shore, called minstrels, and are dressed in rich silk habits. This ceremony has been frequently honoured with the presence of the king and royal family, whose liberal contributions, added to those of the nobility and gentry educated at Eton, who purposely attend this meeting, have so far augmented the collection, that it has been known to exceed 800l. The sum so collected is given to the senior scholar who is going to Cambridge for his support at the university. It would perhaps be a vain endeavour to trace the origin of all the circumstances of this singular custom, particularly that of collecting money for funds, which has been in use for time immemorial. The procession itself seems to have been coeval with the foundation of the college, and it has been confected, with much probability, that it was that of the bairn or boy bishop. It is so attested in a note among the MS. collections bequeathed to the British Museum by Mr. Cole, who was of Eton and King's college: but whence he procured this information, which, if correct, might be decisive, does not appear. The term held annually by the Eton fellows on Saturday in the election week, supposing to have been an ancient tenure, was abolished by the late provost, Dr. Cooke.

Eton college consists of two quadrangles; in the first are the school, the chapel, and lodgings for the masters and scholars. The other is occupied by the library, the provost's lodgings, and the apartments of the fellows. The chapel, as far as relates to its external appearance, is a very handsome structure; the inside has none of that ornamental architecture so much admired in King's college chapel at Cambridge, to which this has sometimes been compared, but is quite plain, and has been much disfigured by some injudicious alterations, made in the beginning of the last century, when several of the monuments were removed, and others concealed behind the window then placed at the east end. The whole length of the chapel is 175 feet, including the ante-chapel, which is 62 feet long. Among the eminent persons who are buried in this chapel, are Richard, lord Gray of Wilton, chancellor to king Henry VIII.; John Long-land, bishop of Lincoln, confessor to that monarch; Sir Henry Saville, the learned warden of Merton, and provost of this college, who founded the Savilian professorships of astronomy and geometry at Oxford; and Henry Wotton, an eminent ambassador and statesman, who was also provost of Eton; Francis Rawle, a distinguished writer among the puritans, and one of the lords of Cromwell's upper-house, who died while provost of Eton in 1675. Dr. Allotree, also provost, an eminent doctor, who built the new or upper school, with the cloisters beneath, at the expense of 1500 l., and died in 1680; and Nathaniel Ingelow, who died in 1683. The monuments of some of the above-mentioned persons are not now to be seen. Sir Henry Wotton's tomb has the following singular inscription:

"Hic jacet hujus sententiae primus uctor—
Dilapidandi proritas sit ecleifarem scabies"

"Nomen alias quare?"

In the ante-chapel is a statue of the founder, by Bacon, erected in 1786; the fun of 800 l. having been bequeathed for that purpose by the Rev. Edward Betham, fellow of the college, who died in 1783; and a monument of the young earl of Waldegrave, who was drowned when at Eton school, in 1791.

The college library contains a very large and valuable collection of books, having been from time to time enriched by munificent bequests. In 1452 the college had a charter for a market on Wednesdays, with considerable privileges; but it has been long disfranchised. Two fairs were granted by the charter of 1444; one for the three days following An Wednesdays, the other for six days next after the 15th of August. There is now only one fair, held on An Wednesdays. The parish church of Eton, called in ancient records Eton-Gildables, having been suffered to fall to decay, the inhabitants are permitted to attend divine service in the college chapel. The provost is always rector, and has archidiaconal jurisdiction within the parish. There is a chapel of ease in the village served by one of the rectors of the college; it was built for the use of the inhabitants by William Hetherington, who had been one of the fellows, and was a very liberal benefactor to the blind and to the poor of other descriptions.

Eton is situated on the northern banks of the Thames, opposite to Windsor, with which it is connected by a bridge. It is 22 miles distant from London; consists chiefly of one street; and contains 290 houses, and 2200 inhabitants. Lysons's Magna Britannia, vol. i. Beauties of England and Wales, vol. i.

ETOKOY, one of the Kurile or Kurile islands, lying 300 versts from Urup; and about 500 versts in extent. The whole island is covered with lofty mountains; one of which, at the northern extremity, emits a continual smoke, and occasionally flames. The summits of the mountains are bald, with steep cliffs and heaps of rubbish. Here are forests, containing of the same trees with those of the island.
Urup. In the southern half, near about the centre of the island, grew larch-trees, in the proximity of the sea, but farther, though farther inland, in the plains of the valleys, good timber trees, fit for the purposes of building. Here are likewise black bears, and in the forests fables and foxes are met with. Of rats there is no scarcity; fish-otters haunt the streams; and the brooks abound in fish. During the storms that happen here, whales and large dolphins are thrown ashore by the sea. The sea-ottter is not seen here, but sea-lions, though not of any great dimensions. The inhabitants are hairy Kuriis, who dwell together in villages. They are numbered in the capitation-tax at 92 perfons.

ETREPAGNY, or Estrapagny, a small town of France, in the department of the Eure, chief place of a canton in the dittrict of Les Andelys, with a population of 1201 individuals. It is situated 9 miles from les Andelys, and 9 miles W. of Gisors; its canton contains 10,442 inhabitants, diffperred in 25 communes, on a territorial extent of 140 kilometres.

ETRIGNY, a town of France, in the department of the Saone and Loirect, and district of Chalons-sur-Saone; 3 leagues S. of Chalons.

ETRIS, a town of Egypt; 18 miles N.W. of Cairo.

ETROUEN, a town of France, in the department of the North, and district of Avyes; 14 league S. of Avyon.

ETRURIA, in Ancient Geography, a country of Italy, separated on the west from Liguria by the river Macra; from Latium and Umbria on the east by the Tibet; on the north-east by a part of the Apennines from the country of the people called Boii and Senones; and on the south-west washed by a portion of the Mediterranean sea, called Mare Tuscanum, or Tyrrhenium, the Tyrrhenian sea. This country was once more extensive than the present Tuscany, as it reached as far as the Tiber. The inhabitants of Etruria, who for a long time possessed a great part of Italy, were denominated Tufci or Etruscii. (See ETRUSCI.) The principal rivers of this country were the Arno, the Umbro, the Clanis, and the Tiber. The chief lakes were the Lacs Trasimenus, and Volumnias. Among the most considerable cities we may reckon Luna, Pisa, Lucca, Pistoria, Florentia, Fieste, Portus Herculis, Labronisa, Volaterra, Sessa Julia, Arethusa, Cortona, Perusa, Clusium, Vetulario, &c. &c.

ETRURIA, in Geography, a country situated between the Mediterranean, the Tiber, and the Apennines; bounded on the east by the dominions of the pope, on the north and north-east by the kingdom of Italy, on the west by the republic of Lucca, and on the south-west by the Mediterranean; about 115 miles in length, and 80 in breadth. The face of this country is beautifully varied with hills and valleys, and the soil which is rich and fertile produces abundance of corn, and excellent fruit, oranges, lemons, olives and grapes. The air is in several parts rendered infalubrious by fens and moraines; the salt-pits are rich. Manna is gathered in the marsh-lands near the sea; and the mountainous parts are rich in mines and minerals. Several medicinal springs have been discovered besides those of Pisa. Arno is the principal river; and Florence is the capital. After several revolutions, Etruria became a republic, and deriving its name from its capital, was called Florence. And in the republic the Medici family obtained by commerce the wealth and rank of princes. It was also denominated Tuscanum, which fce; and in 1569, Cosmo I. was declared duke of Tuscany by pope Pius V., which title was ratified by the emperor Maximilian II. in the year 1575; on condition of his enjoying and holding it as a fief of the empire. By the fifth article of the quadruple alliance, made in 1718, it was stipulated that, with the consent of the Germanic body, the emperor should confer it as a fief on the king of Spain’s eldest son by the second marriage, and that it should devolve to his male descendants, and on their failure to the younger brother and his heirs. In 1737, the duchy of Tuscany became annexed to the house of Austria. By the fifth article of the treaty of Lunelville in 1801, the duchy of Tuscany was ceded to the duke of Parma, and erected into a kingdom, under the name of Etruria. It has since been annexed to the kingdom of Italy.

ETRUSCA TERRA, in the Materia Medica, a kind of bole of which there are two species, the white and the red; these are called by many authors the terra ffigillata alba et rubra magni ductis, as they are brought to us sealed with different impressions.

The white Tuscan earth is a dense and compact substance of a dull deadish white, which in drying acquires some degree of yellowness; it is of a smooth surface, and does not flay the fingers in handling. It is not easily broken, and, but slightly adheres to the tongue, and freely melts into a substance like butter in the mouth. It makes a light effervescence with acid menstrua.

The red Tuscan earth is a pure bole, very heavy, and of a compact texture, and of a dull brownish red colour. It is naturally of a smooth surface, breaks easily between the fingers, and does not flay the hands; it adheres strongly to the tongue, and melts freely in the mouth, and has a strong astringent taste, and leaves no sandy hardness between the teeth. It makes an effervescence with acid menstrua. This is made up of small flat cakes, and impressed with a shield bearing a ducaul coronet, &c. These are the characters by which both these earths may be known from others of the same colour; they are both dug in several parts of Italy, particularly in the neighbourhood of Florence; they are kept in the shops there, and preferred with feeces in fers of many kinds, and in diarrhce, dyntenties, and the like cafes.

ETRUSCI, Etruscans, in Ancient Geography, a people of Italy, who inhabited that part which is now called Tuscany; though it was formerly much more extensive under the name of Etruria. The Etruscans, in very ancient times, are supposed to have been masters of almost all Italy; for the whole region called Italy by the Latins was denominated by the more ancient Greeks Tyrrhenia, according to Dionysius Halicarnassensis (Antiq. Rom. lib.i); whence it is inferred, that it was formerly subject to the Tyrrhenians, or Etruscans, and from them received that denomination. Livy and Plutarch intimate, that the seas, which partly surround Italy, viz. the Tyrrhenian, Ionian, and Adriatic, were anciently denominated the Etruscan sea; and that the Etruscans possessed the whole large tract extending from the Alps to the Frians separating Italy from Sicily. They built twelve cities beyond the Tiber, which were afterwards the boundaries of Etruria Proper on one side; and they were the founders of Nola and Capua, and possessed twelve capital cities in the tract terminated by th Po and the Alps. Virgil and Silius Italicus rank Cefaia and Mantra among the cities of Etruscan extraction; and we learn from Livy, that this ancient nation in very early times occupied the whole tract between the Alps and the Apennines. According to Piny, Bononia, or Bologna, was anciently regarded as the principal city of Etruria; and we may observe, that many Etruscan relics and fragments of antiquity have been dug up in various provinces of the kingdom.
As each of the twelve tribes, or cantons, called in the Tuscan language "Lucumonim," was governed by its own prince, a king preceded over the whole; and whilst the lucumon assumed the administration of affairs in his own province, the king was consulted on all extraordinary occasions, and convened the general diet of the twelve nations on all pressing emergencies. This diet was held at the temple of Volturnus, which was a celebrated city of Etruria, seated on the spot which is occupied, according to Cleenius, by the present city of Viterbo; and in this temple measures were concerted for making war upon, or concluding peace with their neighbours. Although the power of each lucumon was limited, the Etruscan kings seem to have been seduced with a fort of absolute authority, conformant to the first oriental form of government.

Some of the principal Tuscan laws were as follows: 1. By the original constitution of Etruria, no single state, or lucumon, could enter upon a war, or conclude a peace, with any neighbouring power, without the participation of the whole Etruscan body. 2. The Etruscan, by a particular law (Athen. Deipn. l. i. p. 23.) admitted their women to all nocturnal entertainments; in which they were afterwards followed by the Romans. 3. They obliged themselves to treat all foreigners with the utmost humanity. 4. They gave all possible encouragement, as it should seem, by virtue of their constitution, to all polite arts and artificers. 5. In order to deter people from contracting larger debts than they were able to pay, the Tuscan lords, by way of ridicule, followed all insolvent debtors with an empty purse. 6. They must have had many good moral institutions, since from them the Romans received a supplement to their Twelve Tables. 7. The juridical science were first observed by the Etruscans. 8. The Etruscan polity, in general, seems to have been founded upon maxims of the most consummate wisdom, as may be collected from Aristotle, and Herodotus Ponticus in Athenaeus's Deipnous; to which the curious reader may be referred for further information.

The religion of the Etruscans was a gross and multifarious idolatry. In common with the ancient Greeks, and Phoenicians, they worshipped the Cabiri, or Dii magni majorum gentium. They were also initiated in the Samothracian or Cabirian mysteries.

Defies the Greek and Roman deities, they had a few peculiar to themselves; some of which were confined to particular towns or districts. The divine service and sacred mysteries of the old Etruscans agreed, in several points, with those of the Greeks, but in others differed from them, and these they communicated to the Romans long before that nation had any intercourse with the Greeks. The festivals, holy days, and stated times of public worship of the Romans and Etruscans, must also have agreed in several particulars, as the Romans, before they became acquainted with the Greeks, received every thing relating to religion, and even their calendar itself, from the Etruscans. The latter borrowed of the Egyptians, or rather the Phoenician Seminarians expelled Egypt, their public supplications, ceremonies, and solemn proceedings, which occurred at some of their principal festivals. The rites and ceremonies used by the haruspices, augurs, and pontifices at Rome, were derived from the Etruscans, who seem to have been the most celebrated nation in the Pagan world for skill in augury, and divination, as well as knowledge of the nature of sacrifices, to which all rites and ceremonies necessarily relate. This, however, was their character among the Romans, as Cicero and Livy have testified. Hence this branch of science was emphatically styled at Rome "Ars Etrusca," and "Disciplina Etrusca," so that Etruria was denominated by Ar.

4 B 2
nobilis the mother of superstition. It is observable, that neither the Etruscans nor the Romans had any magnificent temples in the earlier ages. The Etruscans had some peculiarities in their religion, which distinguished it from that of every other nation; but the ancient Egyptian and Phœnician modes of worship were the same with those, for many of the earliest ages, used in Etruria; nor can any material difference be found between the oldest oriental and Etruscan divinities. With regard to the theological notions of the Etruscans, they beheld one supreme Being, whom they called Jove, or Jove; they considered him as the great governor of the universe, as the principle of life and motion. They were firmly persuaded of the immortality of the soul, and therefore believed a future state of rewards and punishments; though in later times they seem to have followed the system of Pythagoras, and consequently to have adopted the metempsychosis of that philosopher. However, the generality of the Tuscans adhered to the Sabian superstition, in common with most of the inhabitants of the East.

The Etruscan language must have been the same, or nearly so, with the Hebrew and Phœnician. The first Pelasgic settlements in Etruria could not have taken place many centuries after the deluge, and very few after the dispersion; and at that time the languages, or rather dialects of the Egyptians, Affyrians, Babylonians, Celtes, Syrians, and Arabs, must have approached extremely near to the Hebrew and Phœnician, which the learned allow to have been almost the same. In short both sacred and profane history concur in shewing the Hebrew, Phœnician, and Etruscan tongues to have been, in the earlier ages, nearly the same. This also appears from the letters and manner of writing anciently used in Etruria. The letters are almost the same with those of the earliest Greeks, brought by Cadmus out of Phœnicia. The manner of writing is purely oriental, the letters being drawn from the right hand to the left, as in Etruria, the practice of the eastern nations. The former point is rendered indiscernible by the Eugubian tables, in conjunction with the Sigean inscription; and the latter by merely perusing the Etruscan inscriptions. The very remote antiquity of the first colonies that settled in Etruria, as well as of the Etruscan language and alphabet, may be easily inferred from these inscriptions; for as the Pelasgic alphabet, that prevailed in Greece before the age of Deucalion, consisted of sixteen letters, the Etruscan or Pelasgic alphabet, first brought into Italy, composed only of thirteen letters, must have preceded the reign of that prince. The high, and indeed the almost incredible antiquity of the Etruscan language and alphabet, has been clearly evinced in two dissertations, printed at Oxford in the year 1746. For other particulars relating to this subject, we refer to Dempffler's "Etruria regalis," Gori in his "Muuseum Etruscorum," published at Florence in 1737; M. Bourguet's "Dissertation" published in 1735, and Buonarotta's "Dissertation" of 1752; and Sawin's "Etruscan alphabet," published at Oxford; and for an abstract, Anc. Un. Hist. vol. xviii.

The Etruscans were extremely well versed in all the arts of war and peace, and from them the Romans derived those arts and sciences that paved the way to the empire of the world. In the best ages of Rome, the Romans imitated the Etruscans; nevertheless, in after-ages the Etruscans became thoroughly debauched both in principle and practice. Augury, and every kind of divination; all the principal religious institutions, temples, statues of gods and heroes, the manner of forming or building cities, fortifications, conflagrations, and nuptial rites were transmitted to the Romans by the Etruscans. Every thing also that bore any relation to civil government at Rome, such as ensigns of royalty, the distinction of nobles from plebeians, the sacres and efeles, the lictors, &c. was derived from the same source. Arms, instruments of military music, military acconctments and decorations, trophies, triumphs, chariots, crowns, &c. and in short every thing belonging to the art of war, or military exercises, that prevailed at Rome, were brought from Etruria. This was also the case with respect to money, locks and keys, lamps, candlesticks, glasses, cups, drinking vessels, together with the laws and customs relating to banquets and entertainments. Agriculture, planting of vines, all instruments requisite in husbandry, mills, architecture, music and a variety of musical instruments, many sorts of diversions, especially tragedies, various kinds of garments, and even the rudiments of physic, seem to have been introduced into Italy by the Etruscans, or indeed to any of the mathematical sciences. For military learning they were famous, and especially for the art of drawing up an army, and making dispositions for an engagement. Athenæus informs us, that the formation of the phalanx, and manner of fighting consequent upon it, was invented by the Etruscans, or at least borrowed from them by the Romans. To all the other branches of literature and science for which the Etruscans were distinguished, we may add that they excelled in the knowledge and composition of history.

The first person who fixed monarchical government in Etruria was Janus, supposed by some to be the Javan of scripture, or one of his posterity, and in subsequent ages deified by his subjects as a fangulus benefactor. The history of their succeeding kings is intermixed with much fable; and, of course, very obscure and uncertain. It appears, however, that they were a maritime power in the time of the Argonauts; and that they commanded respect as much as at least a generation before the Trojan war, and made a figure at sea before the Greeks. That the Etruscans were a powerful and polished nation, when Romulus founded or rather restored Rome, appears from some approved authors. This prince could not carry the deligit he had formed into execution, without the assistance of the Etruscans. From them he derived all his civil and religious institutions. Anc. Un. Hist. vol. xviii.

ETSED, in Geograph., a town of Hungary, 40 miles N.W. of Zatmar. N. lat. 43° 2', E. long. 21° 51'.

ETTENHEIM, a town of Germany, in the bishopric of Strasburg: 12 miles S.S.E. of Strasburg.

ETTENSTAT, a town of Germany, in the principality of Anspach; 5 miles N.E. of Weilburg.
ETTENSHAUSEN, a town of Germany, in the principality of Wurzburg; 3 miles N. of Volkach.

ETTLSTORFF, a town of the archdeaconry of Austria; 9 miles W. of Samesberg.

ETTRICK, a river of Scotland, which originates in the S.W. angle of the shire of Selkirk, and runs N.E. augmented by many small streams in its progress through a pleasant valley to the Tweed, into which it falls near Sunderland-hall, 11 miles below Selkirk. The banks of this river were formerly shaded with woods, whence the county obtained the name of Ettrick forest.

ETUEND, a mountain of Persia, in the province of Ira; 60 miles S.E. of Hamadan.

ETYMOLOGICON, is used for a book, containing the etymologies of many languages. See ETYMOLOGY.

ETYMOLOGY, (from the Greek etymon, true, and logos, a word,) means a true or real account of words; and as this true account is obtained by tracing them to their origin, etymology hence signifies that part of grammar which teaches the derivation of words.

Etymology is an essential and useful branch of philology; but from partial views, and an inattention to the principles which it implies, it is regarded by many as the fruitless study of words, in which neither knowledge nor certainty is attained. In order to limit, as much as possible, the province of etymology, and to remove the objections which have been made against it, we shall here briefly state the laws which direct, and the considerations which give it the precision and the fixed aids of a science.

1. Etymology implies a due attention to the structure of the vocal organs, or to the affinities of elementary sounds. All men have the same organs of speech, and the same letters are founded by a similar modification of those organs. Letters pronounced by the same organs, or the same parts of the mouth, approximate in sound to each other, and from this consideration become more easily corrupted and changed one for another. Thus all the vowels, whatever peculiarity in character and sound they present to a person familiar with them, have yet a closer affinity to each other than to other letters; and hence are even interchanged. The more modern art of printing, indeed, has contributed to fix the fluctuating sounds of the vowels, by uniformly presenting them to the eye under distinct characters; but still in an etymological view they are utterly to be disregarded, or to be regarded only as one capacious, ever fluctuating impulsion of the voice.

The justness of these observations will immediately appear to any one who considers those words in Latin, which are evidently derived from the Greek; or those in French and in Italian, which are derived from the Latin; or those in modern English, which are borrowed from the Gothic and Saxon tongues, and are still farther diversified in the Scotch, Frisian, and Welsh dialects.

While the vowels form, as it were, the ever corrupting flesh, or the ever varying complexion of language, the consonants are the sinews and bones which impart to it strength and firmness, and which alone render it a subject of philosophical investigation. But the consonants have a closer alliance to form than to other letters; and their affinity depends on the manner in which they are enunciated. Thus, b, d, t, p, s, z, m, and n in Greek, are kindred letters, being produced principally by the lips, and are therefore often changed one for another, as caprice or custom shall dictate. The same observation holds in regard to the letters f, s, z, r, l, which being produced by the tongue, impregnated in various degrees on the extremity of the upper teeth, are called dental; to those which are produced by the tongue and the roof of the mouth and the palate, such as g, j, v, ch, and finally to the gutturals, which, though they exist not in our tongue, form an important class of letters in most other languages. To this distribution of the consonants into labials, dentals, palatals, and gutturals, the scientific etymology will pay a strict attention, and observation will soon teach him that, however perfect any alphabet may be in regard to etymology, each class is but a variation of the same letter.

2. Etymology supposes a strict attention to be paid to analogy, that is, to those general principles by which any language is formed in regard to its internal structure, to the distinguishing terminations of its nouns and verbs, to its general mode of combining words, and to those changes which words usually undergo after they have been imported and naturalized, as it were, from any foreign tongue. In order to discover the nativity and parentage of any term, we must, as it were, strip it of the dews with which the custom of the country has clothed it, and we can trace it to its true origin, only when we view it separated from the termination by which it is disfigured: thus words, when imported into English, appears under the form of words, having dropped the peculiar termination; and when expressing that period of time which comprehends one revolution of the moon, it assumes the termination th, which the analogy of the language hath warranted month; while in Latin it exists in the shape of mensis. And here it is to be observed, that the general principles of analogy, as in natural philosophy, so in etymology, are to be collected by induction from inferences that are simple, unequivocal, and definite, and then applied to words that are not so. The propriety and justice of these remarks it will be necessary to illustrate by a few examples.

Suppose we were asked the derivation of met, wine, bo, or sels, wassers, to rule, in Greek; we should be able to ascertain this only by unfolding a general principle in the structure of that language. The oriental tongues, to which the Greek owes its origin, abound with gutturals, which by degrees have descended into an aspirate in many of those words derived from them; while in others they melted into simple vowels, or were replaced by a lispial, such as de, bi, aw, or ov. Thus am, bee, life, self, became bo; Nth, khan, a king, wassers, to rule, and yew, yew. In these derivations our conviction would be complete, because it is justified by a general principle that holds in a thousand other instances.

Suppose, farther, we were asked what were the origin of the Latin vicus, a village; videre, to see; vinum, wine; ovis, a sheep; or of wheel, year, wheel, in our own tongue: we answer that the substitution of a labial for an aspirate or a guttural, or a diphthong, forms a general principle which pervades the Latin tongue in its formation from the Greek. Hence vicus is from vus; vinum is from vum; ovus, ovis, from vus; videre is from vide. With respect to our own language a similar analogy obtains, which has converted a guttural into a labial; thus laugh is pronounced laff; enough, enuff; and most of those words which begin or end with y and w, whether derived from Hebrew, Greek, or Gothic, began or ended with a guttural. On this general principle the year may safely be said to be derived directly or indirectly from water, a circle, and means a period or revolution of time: wheel, from roll, to roll; well, from well, a fountain; and wheel from wheel, strength, which also has given birth to the words boil, and belib.

Moreover, if we were asked the origin of sperma, to disperse, we should say that it comes from spera, the heel, for the prefixing of the letter s to Greek words is a principle that pervades the Latin tongue; thus the primary sense of sperma, is
is to put the heel upon; on the same principle is *folio*, *infelix*, *influen*, taken from *ολιγος*, *ολυμποιος*. The French generally drop the gutturals either in the middle or at the end of words; hence we should be justified by an invariable analogy in saying, that *man, water,* is from *aqua,* and *seal* from *fusculus*. The Italians generally drop the liquid *I*; agreeable to this custom of the language, *fiume* is derived from *flumen*, *a stream*, and *piano* from *planus*, a plain. In German most of those words which have *e* in English are used with an *a*; as *eater, water;* *beater,* *better;* *et,* *it*; and the corruption of *w* into *f* or *v*, is a principle that runs through the Welsh tongue; thus, *we,* *war,* and *way,* are but the Latin words *me, mare,* and *major*.

3. Etymology, in order to claim its proper rank as a branch of science, requires a strict attention to the association of ideas, the great law which regulates the human mind. The opinions and customs of men, it is well known, greatly influence their language; and this influence is produced by the secret and unerring impulse of association; and the reason why this branch of philology has been so much abused or called in question, is, that little or no regard has been hitherto paid to its connection with that grand invariable principle which governs the human understanding. He who attempts at etymology in any language must know the philosophical, the religious, and the political notions of the people who use it; he must be acquainted even with the physical peculiarities of their country, and from an acquaintance with the laws of the human mind he should be able to trace the secret processes by which those circumstances influence their speech. We will give a few examples in illustration of these remarks.

In the early ages of the world, the principal idea under which the character of God presented itself was that of *superior power*; and, accordingly, the feelings which it awakened in the beholder were chiefly those of *fear*. And even the Jews, who had far more rational notions of the Deity than the Gentiles, apprehended that no one could see God and live. According to most of those names, which signify a god, are in Greek either immediately derived from a word which signifies *fear*, or both from a common origin; thus, from *Δια*, *both, the first principle of things*, are taken *διος*, *God*; and *φυς*, *fear*; *ταυρος*, *towards*, *terror*, owes its origin to the Chaldean *γιλα*, *Galeph*, a household god. παπας, the god Pan, is only the Hebrew *עון*, *pans*, *confirmation*: *διος* is the god of terror; and hence *διασκορεια*, *an invisible spirit*, which was an object of *fear*, and *νυσσαλος*, *fear* of the demons, *religion*. It was the common notion that those demons produced violent passions and disorders in the mind and body; hence came the verb *διαβαλο*, to be mad. It was thought, too, that they were the agents of God in precluding over men; hence *ισχυρος*, *one who had a good demon* for his guardian angel; and *νυσταλος*, *one who had an evil one*.

The introduction of evil into the creation could not be accounted for by the heathen philosophers, only by supposing the existence of two principles equal in power, and opposite in character and operation. The good principle they naturally affiliated to the *sun*, the most splendid body in nature, whilst the evil they called *darkness*: hence the saying *God is light*: *ς*, is pronounced by the Persians *заa*, by the Arabians *daleh*, *dilaa*, *light*; hence *ςα* from the former mode of pronunciation, and *ςα* from the latter. On this principle the Chaldean *ςις*, *αις*, to make hot, the action of the sun, gave birth to *ςος*, *to woship*, *to reverence*. The general opinion among the philosophers was that water is the first principle of things. Hence the Arabic *mao* came, in Persian, with little variation, to signify *fruit*, *wine*, and in Greek, *naos*, the *goddess* of birth, and in English the producing month, *May*. The same word in Hebrew, by assuming after the analogy of feminine nouns, is *םה*, *death*, which means *resolution into water*; hence the Egyptian *mot* (whence Moses is supposed to have been taken,) and *mud*, what is washed together by water, just as *luten, clay*, is the suface of *lawn* or *lure*, to *wosby*.

In eastern countries, where the heat of the sun is violent and long continued, rain is deemed the greatest blessing, and all the terms expressive, in most of the Asiatic tongues, of plenty, success, and joy, are generally borrowed from the names of water; hence the Hebrew *םָּרָּב*, *herb, to blest*; in Greek is *βρωμον*, *to rain*; in Latin *precipio*, to ask for *blessing*, *parce*, *to give blessing*; *spare*, and *sparge*, to shed as the dew, or *scatter as seed*. The same root *excita* in English in the form *brook*, the effect of rain.

4. Etymology, in the *absence of a rational study*, implies an extensive and an accurate acquaintance with languages. It is not sufficient to be acquainted with Latin *to know Greek*; nor to know Italian to be acquainted with Latin, nor to know English to be acquainted with the Saxon or Gothic; but to be a good etymologist in either of these, a man must comprehend them all. So manifold is the intercommunication between all languages, that no language *excita* derived from one and the same source. Words exist in English which exist also in most other tongues, under differences of character and termination; and they are derived not from each other, but from a common origin; and a scientific etymologist, instead of deriving them from each other, will trace them all till they meet in a few primitive terms. It would probably be wrong, or at least it would be very doubtful to say, that *hand* comes from the Latin *obloco bando, to catch with the hand,* or from *gams*, the parent of *handa*, but it would be right to say that there are *connate, or kindred terms,* *spring,* if not from each other, from some common root. In Hebrew, Persian, and Arabic *הס, to the hand*, the action of this is two-fold, as it *imparts,* or as it *receives*. In the former sense it gave birth to the Saxon or Gothic *giff,* and hence *jiff*; in the latter to capio. To take in hand is to begin a thing; hence the same word *excita* in the form of *Capio*; and passing into Greece it produced *καπές*, a *bundle*.

And here it is obvious to remark, that as the root, passing into different countries, produces as it were new branches; those branches will not continue long till they in their turn become the flemes of more numerous and diversified shoots; and as they thus multiply by accident, the progress of knowledge, the multiplication and distinction of ideas attendant thereon, seize, as it were, these wild and promiscuous offspring, and give them the function of custom, the supreme arbiter of speech, thus considering as genuine, words which at first were mere corruptions. Thus in our own tongue *gul* is wind; *gul* of *gul*, what confits of *wind*, *spire, oloph*, *gholp*, ghly, like a spece, and *gat*, an aeriform fluid, to deminated from gholt, first by *Van Helmont*. Thus also in Latin, from *καπές*, to join together, is *gans*, to *fallen, pack, to unite in concord, pacify*. To paint is to render adventitious colours on a thing; hence *pings*, and to give toolland the adventitious colours of truth is *frans*, to *seign*.

Again, from *may* is men's mind, force, effences, mems, to call to mind, menes, to put in mind; *manes*, force, or that organ in which the strength of the human body chiefly consits, *manes*, the souls or departed *spirits*, spirit being the effence of man; and *manoes, to excita*, the foul being that which excita after the destruction of the body.

Etymology, then, to be raised above the caprice of fruitless study, and to be claffed among the useful and solid

1 branches
branches of science, must be founded on a just regard to the affinities of letters, and to the structure of the organs of speech. It supposes an acquaintance with the philosophy of the human mind; with the analogies which form and distinguish each language; with the history of mankind, philosophical, religious, and political. From these, its qualifications, result its utility as a department of human knowledge. Etymology, it is evident, furnishes the reader with most effectual means to acquire the knowledge of language; and as language is but the dress of our ideas, it holds up a mirror to delineate and reflect the operations of the human mind. It helps to ascertain the positions of ancient places, to clear obscurities in the antiquities of nations and families. What is more, when confined within its proper limits, and purified to its full extent, it will throw much light and additional evidence on the truth of the Mosaic history, respecting the origin and propagation of mankind.

EU, or Eo, in Geography. See Eo.

Eu, a sea-port town of France, and chief place of a canton, in the department of the Lower Seine, and district of Dieppe, seated on the Bresle, near the coast of the English channel; 15 miles N. of Dieppe. The place contains 3,400 and the canton 12,910 inhabitants, on a territorial extent of 1924 square kilometres; and in 27 communies.

EVA, in Ancient Geography, a town of the Peloponnesus, in Arcadia.—Alfo, a hill of the Peloponnesus, in Laconia, near Sellinia. Polybius.

EVAQUANTS, in Medicin, are those remedies which operate by diminishing the quantity of fluids in the body. This effect may be produced either directly, by an artificial opening into the vesicles or cavities containing the fluid to be evacuated; as by blood-letting, by means of the lancet, or by cupping; or by tapping; &c. Or the evacuation may be accomplished indirectly, by exciting the action of the vesicles, which are naturally destined to throw off redundant fluids, on the one hand; or by producing inflammation, and a consequent discharge of fluids, from parts not naturally secreting them. Evacuants acting upon the natural emunctories, as the organs of excretion have been called, are of various quality and denomination, according to the parts upon which their action is exerted; thus, some stimulate the vesicles which open into the cavity of the intestines, and carry off the fluids by stool, and are called purgatives, laxatives, or Cathartics; others excite the vesicles of the kidneys to increased action, and are denominated Diuretics; others augment the peristalsis, and are termed Diaphoretics and sudorifics; others again stimulate the salivary glands, and produce a great discharge of saliva, whence they are called Salivagogues; and others excite an increased discharge of the mucus of the nostrils, and are termed Erhines. All these kinds of evacuant medicines are occasionally employed, with a view to relieve the constitution at large, or some part of the body, from an inflammatory or febrile condition; or to remove local congestions in particular organs, &c. See BLEEDING, CUPPING, and the words in capitals; under which heads the principles of the evacuation, thus variously effected, are explained.

EVACUATION, see the preceding article.

Evacuation, in a Military Sense, relates to the withdrawing of troops from any fortresses or posts, not besieged, but intended to be relinquished, or eventually to be dismantled. This term is sometimes erroneously used in capitulations, where it is expressed that the garrison shall evacuate within a certain number of hours. Now, as it is in almost every cafe, a filiputation on the part of the victors, that they shall be put in possession of certain gates, or defences, previous to the garrison marching out; thereby securing every advantage that may have been obtained; it stands to reason, that the term evacuation is incorrectly applied. We have, indeed, but rarely instances wherein it is properly introduced; one very recent case is however very prominent; namely, the evacuation of certain fortresses in Prussia by the French troops; far, if we are correctly informed, the Prussian forces did not, in some instances, attempt to enter until their friends had completely withdrawn.

It is sometimes made a condition, that particular approaches, lines, or posts, shall be evacuated; there we see the term appropriately used; because such approaches, and lines especially, are not considered as permanent works; therefore are intended to be dismantled as soon as those who erected them should retire.

Where a place is to be evacuated under the express condition of all damages being paid for, it becomes the duty of the future possessors to be very correct in causing an enquiry to be made into all depredations and grievances, before the forces about to retire quit the place. Commissioners on both sides are necessary; in order that every matter may be adjusted at the moment, so as to obviate future disagreements. This appears to have been attended to when the Portuguese territory was evacuated by Junot; though we have strong reason to apprehend that great evasion, and many highly nefarious acts, were practised by the French on that occasion.

EUŒMIA, or wē, well, and αἷμα, blood, is used by Tlemius and some other writers, to denote a good and healthy state of the mass of blood.

EUŒMON, in Ancient Geography, a town of Greece, placed by Steph. Byz. in the territory of the Orchomenians.

EVAGRIUS, in Biography, patriarch or bishop of Constantinople, who succeeded Eudoxius in 370, and whose election was much resented by the emperor Valens. From this event commenced a cruel persecution against the Catholics, which did not terminate till the accession of Gratian to the throne. Evagrius probably died in exile during this period.

Evagrius, bishop of Antioch, succeeded Paulinus in the year 385; in consequence of whole election, in opposition to Flavianus, the schism in the church of Antioch, that has been much lamented by the orthodox, was continued. However, by the influence of Siricius bishop of Rome, in the council of Capua, held in 390, Evagrius's election was approved. Two years afterwards Evagrius died; and the schism terminated. Evagrius was the friend and companion of St. Jerome, who represents him as a person of an active and ardent spirit, and as the author of various writings, which he had perused. None of these that deserve particular mention are now extant. Cave. Dupin.

Evagrius, surnamed Ponticus, and by St. Jerome Hyperboreus, on account of the situation of the place of his nativity near the Euxine sea, flourished near the close of the fourth century. Having been ordained deacon of Constantinople by St. Gregory Nazianzen, he was instructed by this bishop in hiblic learning, and advanced to the office of his archdeacon. His person and manners recommended him to the favour of the ladies; and being suspected of an improper intimacy with the wife of a man of consequence, he was obliged to retire from Constantinople in the year 385, and to remove to some distant place. At Jerusalem he embraced the monastic life, and passed 15 years at a monastery amidst the deserts of Nitria in Egypt. Whilst
ancient church to such as preached the Gospel up and down, without being attached to any particular church, being neither commissioned by the apostles to instruct the nations, nor of their own accord, abandoning every worldly attachment, consecrated themselves to the sacred office of preaching the Gospel.

In which sense some interpreters think it is that St. Philip, who was one of the seven deacons, is called the evangelist, in the twenty-third chapter of the Acts of the Apostles, ver. 4. Again, St. Paul writing to Timothy, Ep. iii. ver. 5, bids him do the work of an evangelist. The same apostle, Eph. iv. 11, ranks the evangelists after the apostles and prophets.

EVANGELISTS, in Geography, four small islands at the western extremity of the Straits of Magellan, near the coast of South America; three are low, and one, at some distance, appears like a hay-stack. S. lat. 52° 45'. W. long. 67° 16'.

EVANIA, in Etymology. See St. Mark.

EVANID, a name which some authors give to those colours which are transient, or not of long duration; as those in the rainbow, in clouds, before and after rain, &c.

Evanid colours are the same as those otherwise called fantatical and emphatical colours. Some authors also use the same term to express those flowers of plants whose petals fall off as soon as they are opened.

EVANS, John, in Biography, was born at Wyetham, Berkshire, in the year 1665. His father was one of the ejected ministers in 1662, who, on account of his non-conformity, being driven from the established church, became minister to an independent congregation at Wyetham. The son was educated with great care, and inducted to the different branches of literature necessary to qualify him for the office of the ministry, which he afterwards exercised in London, first as an assistant, and afterwards as successor to Dr. Daniel Williams. He died in the year 1730, in the fifty-fifth year of his age, highly esteemed by all who knew him. He had ever been eminent for piety, integrity, and public spirit; in his principles he was orthodox, but disposed to think well of, and to honour, those who differed from him, without any regard to the sentiments which they might hold. He received a diploma of doctor in divinity from the universities of Edinburgh and Aberdeen. His principal work as an author consisted of two volumes of sermons, entitled "Practical Discourses concerning the Christian Temper," which are still in considerable estimation. The celebrated Dr. Watts characterized them as "the most complete summary of those duties which make up the Christian life." Gen. Diog.

EVAN'S Island, in Geography, a small American island, near the coast of Main. N. lat. 44° 31'. W. long. 67° 3'.

EVANSHAM, a town of America, the capital of Wythe county, in Virginia, situated on the E. side of Reedy creek, which falls into the Great Kanawha, Woods or New River. It contains a court-house, gaol, and about 25 houses; 40 miles W. by S. from Chrittensburg.

EVANTES, in Antiquity, the priestesses of Bacchus, thus called, because in celebrating the orgia they ran about as if distracted, crying evan, evan, eie eie! The word is formed from eva, a title or appellation of Bacchus.

EUANTHI COLORES, in Petruion, a term used by the Greeks to express what the Romans call the floridi colores; there were such colours as had remarkable brightness in their works. The other diller and coarser colours the Romans called aulteri colores, and the Greeks barbari.
Of the first sort were cinnamar, lapis armenus, chrysocolla, zircon, indigo, and purpurilla, according to the Romans; but the Greeks, as we find by Dioscorides, made cinamar one of the auffere colours.

EUAPHION, (from ω, ota, and ων, the touch,) in Surgery, a medicine for the hemorrhoids, named from its gentleness. Galen.

EVAPORATION, in Natural Philosophy, is that process by which water and other liquids are converted into vapour or steam, an elastic fluid, and disseipated in the atmosphere. Certain solid bodies, too, are subject to a similar diffippation in air; this is usually denominated evaporation: but as the cause is no doubt the same in both cases, it may be properly considered under this head.

The spontaneous evaporation of water, or that which is constantly going on in a greater or less degree from all parts of the surface of the globe, has always been an interesting phenomenon to the speculative philosopher. Various hypotheses have been advanced to account for the ascent of water into the atmosphere in an invisible form, and for its subsequent descent in the form of rain; but the opinions of early writers on this subject are of little importance, as they were not acquainted with the principal facts and experiments which ought to guide us in the investigation. Aristotle seems to have ascribed the formation of vapour to the action of fire; and so far his notion was correct. Halley supposes small hollow spheres of water to be filled with a subtile elastic fluid, so as to make them specifically lighter than air; he also hints at a chemical affinity between air and water, similar to that between water and salts. Descartes, after having shown the insufficiency of former hypotheses, proposes a new one; he affirms that water is capable of being converted by heat into an elastic fluid much lighter than air, and that the steam engine is a proof of this; he shews, too, that a glass vessel filled with water, and inverted in another vessel of water, and then exposed to the heat of ebullition, has its water expelled, and steam, an elastic invisible fluid, takes its place. This steam, he shews, is again condensed into water as the vessel cools. He argues that steam is 156 times lighter than air, and that when formed at a low temperature must ascend in the atmosphere till it meets with air of the same density, and there it will stop; but when accumulated, the cold condenses a portion of it into drops of water: hence clouds and rain. This notion, which goes to identify vapour in the air, with the steam or vapour of water formed by heat in a vacuum, is ingenious and apparently original, but how the vapour should ascend till it arrives at air of the same density, is not very easily conceivable: for the vapour, in ascending, must expand as the pressure is diminished, according to the established laws of elastic fluids, and therefore never can obtain the same density as the air. The vapours might indeed ascend to the top of the atmosphere, and form a distinct stratum, as some have imagined with respect to hydrogen gas. The author has extravagantly under-rated the specific gravity of steam, or aqueous vapour, which is certainly at least one-half that of atmospheric air. Upon the whole, this hypothesis was more plausible than that adopted by Halley.

As the science of chemistry gradually expanded, the phenomena of evaporation began to be considered as most nearly allied to those of chemical solution. From the year 1743 to 1766 the essays of Nollet, Franklin, Roy, Hamilton and others, tended to establish the opinion that water is taken up into the air by chemical solution, in a similar way to that in which water and other liquids diffuse farts. In the 5th vol. of the Philosophical Transactions, there is an essay of Professor Hamilton on evaporation, in which he infers at large on the hypothesis of solution. Hot water, he observes, dissolves farts sooner and in greater quantities than cold water, and departs a part of the fume on cooling: so warm air takes up more water than cold air; but the water is deposited again when the air cools, or by the contact of a cold body, as a glass of cold water. Evaporation always produces cold; this is observed when any part of the human body is moistened with water, and the same suffered to evaporate, but still more remarkably when moistened with either other or other fluids more evaporable than water; in like manner, certain farts dissolved in water constantly produce cold. In short, the points of resemblance between evaporation and chemical solution are so numerous and striking, that the generality of philosophers seem to have adopted the idea that air possesses a chemical affinity for water, and attaches a portion of it to itself, which becomes incorporated with the elastic matter of the atmosphere, under the denomination of vapour, till cold, or some other cause, reduces it again to the state of water.

In the year 1783, Sauffure of Geneva published his celebrated essays on hygrometry, in which the subject of evaporation is discussed much more largely than had been previously done. This author does not claim the merit of any new theory; for, he says, "the conversion of water into elastic vapour has been known time immemorial; the diffusion of water in air was discovered by Rois, and the vehicles, which compose fogs and clouds, were discovered by Halley, and curiously demonstrated by Kratzenstein. But no philosopher has, I believe, clearly distinguished the different modifications of vapours: all the systematic authors have endeavoured to reduce all vapours to one and the same species, whilst in reality they exist under forms absolutely different. It had not been perceived that water, on being dissolved in the air, is converted into an elastic fluid; but I have shewn this to be the fact by the most exact experiments; and further, the specific effect which the solution of a given quantity of water in air has upon the specific gravity of the air. Finally, the laws according to which the humidity of the air varies in proportion to its condensation and rarefaction, form an entirely new subject, on which our ideas hitherto have been vague and erroneous. These, I believe, will be found to have received a satisfactory elucidation," Preface, page 10. Before we examine the conclusions of Sauffure, it may be proper to advert to the facts which are adduced to above. Having procured a large glass vessel, containing 42 cubic feet of air, Sauffure adapted it to a manometer or instrument to measure the force of elastic fluids; the balloon being filled with air of the natural humidity, the manometer, or thermometer, and a vessel containing alkaline alkali of a given weight, were all enclosed in the balloon, and confined from the action of the external air. The alkaline alkali absorbed the vapour in the balloon, and the manometer showed the diminution of elasticity consequent thereon; after the experiment was carried as far as was desired, the balloon was opened, and the increase of weight of the alkaline vessel was ascertained. Hence were derived data for calculating the influence of vapour on the elasticity of the air, and likewise the whole quantity of water in a flate of vapour in a given bulk of air. This might be called the analytic experiment; but the synthetic one was also made. By enclosing a piece of wet linen of a given weight in the balloon containing air as dry as possible, along with the other instruments, the moisture of the linen evaporating increased the elasticity of the confined air a quantity which could be observed; and at the close of the experiment the loss of weight of the linen indicated the quantity of water which had been evaporated.
EVAPORATION.

and had increased the elasticity. The two methods were thus found to corroborate each other remarkably well. The results were, that at the temperature of 64°, a quantity of extremely dry air acquires an increase of \( \Delta \) in elasticity in attaining extreme humidity; and *vice versâ:* that a cubic foot of air takes up 10 grains of water in passing from extreme dryness to extreme humidity; and that consequently it diminishes the specific gravity of the air, as if a volume of elastic fluid, equal in weight to 10 grains, and of \( \Delta \)ths the specific gravity of air were added to it. Of the general accuracy of these results there is no room for doubt. They form a valuable acquisition to this branch of science.

One important fact was full wanting; as air was supposed to diffuse water by virtue of an affinity, it was reasonable to expect that every species of air would have its peculiar affinity, or take up a certain portion of water peculiar to itself, agreeably to what is observed in other cases of chemical saturation. Saffurie ascertained this point clearly in regard to inflammable and fixed air, that is, hydrogen and carbonic acid. Both these gases were found in their pure state, and when mixed with any proportion of common air, to affect the hygrometer in the same way as common air, and to promote evaporation in the same degree. In short, there was not any appearance to indicate that they contained either less or more vapour than common air in like circumstances. Saffurie found that evaporation was accelerated in proportion to the rarefaction of the air; this circumstance he accounted for by observing that the pressure of the atmosphere retards evaporation; however, upon the principle of solution, it might have been expected that the greater quantity and density of the solvent would have compensated for the greater preasure. The condensation of air, on the contrary, uniformly tends to make it deposit moisture, and retard evaporation. This he explains by observing, that the solvent power of air does not increase so rapidly as its density; continued condensation therefore must fill saturate the air with moisture, and then make it deposit a portion. Saffurie found that warm and dense air required more vapour to saturate it than cold and rare air; he was led too hastily to ascribe the solvent power of the air partly to its temperature and partly to its density; but it has since been proved that temperature alone is concerned, and the density has no effect whatever. On the head of rarefaction and condensation, Saffurie adverts to a curious fact, known by every philosopher, but not satisfactorily explained by any one; namely, the abundant and instantaneous formation of a cloud or mist upon exhausting a receiver by the air-pump. As the rarefaction of air is found to promote evaporation, it appears astonishing at first sight that the air should exhibit signs of superaturation at the same instant. When the pump plate is covered with wet feathers the above appearance never fails; but the abbé Nollet found it to take place when water was totally excluded. Saffurie, however, denies this to be the fact; he thinks that water must not have been excluded with sufficient care in Nollet's experiments; and affirms that from his own experience no appearance of mist was found upon exhaustion, when the pump was carefully dried. The hygrometer at the time was 70°, extreme moisture being 130°. As the two authors here appear to be at issue as to the fact, the writer of this article, from his own experience, can venture to affirm that both of them may still be correct. When care is taken to exclude water from the pump and receiver, the mist is by no means so copious as otherwise; it is also more diminutive as the air is dry or far from extreme humidity; with both these circumstances and a large receiver, no mist will appear by a moderate rate of exhaustion; but it may always be produced by using a small receiver, and rapid exhaustion. Saffurie's explanation of the fact is very inadequate, and unworthy of repetition; he further notices the dew observed on the receiver of an air-pump after letting in the air, and very justly ascribes it to the condensation of the vapour raised up into the receiver after exhaustion; the air taking in with it nearly as much vapour as it is capable of holding. Upon liberating condensed air a great mist is observed in the receiver; Saffurie explains this in the same unsatisfactory manner as before, and that in one case only, namely, when the receiver contains water; but his explanation does not apply when the receiver is perfectly dry; yet the phenomenon of mist is equally apparent in that case. The true explanation is, that a great but momentary cold, of 50° or more, occasions the precipitation of vapour, both upon rarefying air and liberating condensed air. The fact has since been demonstrated by Mr. Dalton; but it was hinted at by Lambert, as quoted by Saffurie, page 331.

Though Saffurie does not affect to introduce any new theory on the subject of evaporation, he certainly advances some notions on the subject that were not previously held by others, especially by those who adopted the chemical solution of water in air. He says, "evaporation, properly speaking, is the refult or rather the effect of the intimate union of elementary fire with water; by this union the water and fire combined form an elastic fluid specifically lighter than air, and which is peculiarly distinguished by the name of vapour. This vapour being formed in a vacuum, or otherwise when the heat is sufficient to give it force superior to atmospheric pressure, so as to expel the air from any vessel in which it is formed, is called pure elastic vapour." Page 363. This representation is, in all probability, correct, and will be generally adopted without hesitation. He proceeds: "but when the vapour cannot entirely surround the pressure of the air, it penetrates it, mixes with it, undergoes a true solution, and may then be properly called diffused elastic vapour." Page 362. Certainly the advocates for the solution of water in air cannot adopt this language. Pure elastic vapour is first formed; then by means of such force as it happens to have, which is generally small, it penetrates and mixes with the air; afterwards it is diffused by the air; that is, the particles of air finding those compound particles of water and fire amongst them, attract them, and form triple compounds of air, water, and fire. Here the buffets for which solution is called in is performed before hand; for we must suppose it to be the affinity of air for water which enables the latter to rise at all against so superior a preasure. If the vapour can, by virtue of its elasticity, penetrate the air, why may it not continue there by virtue of the same elasticity? Saffurie proceeds; "when afterwards the air saturated lets fall the water which it contains, this water sometimes takes the form of vesicles or bubbles; these vesicles, filled and surrounded with a subtle elastic fluid, are supported in the air, and even sometimes rise in it, by their less specific gravity. These vesicles are essentially different from the air, as well as from the vapour above defined; but according to custom I have arranged them in the class of vapours, and distinguished them by the name of vesicular vapour. Finally, when the elastic vapour, or the vesicles themselves, condense into solid drops, which only differ from drops of rain by their extreme smallness, they are still very different from vapours properly speaking. Notwithstanding, as these small particles float in the air, and can even be supported in it for some time, by its agitation and viscosity, I have classed them also amongst vapours, and given them the name of concrete vapours."

Page
EVAPORATION.

Page 363. It may be proper to observe here, that the volatile vapour of Dr. Halley was supposed to be transparent, and therefore to correspond to the *diffused elastic vapour* of Sauffure. It was moreover hypothetical; but Kranzlein and Sauffure affirm that the small visible particles flying over fleamimg water, as well as those of certain fogs, are discernible by a microscope to be hollow or vesicular. These visible particles are the *vesicular vapour* of Sauffure. Though it is by no means improbable that the vapour issuing from warm water is enveloped in a film of water, just as we see it in ebullition, and that the same bubble of fleam on cooling may shrink into a vesicle, containing an atom of air, the original nucleus of the fleam; yet it is not equally probable that in the condensation of pure vapour a vesicle should be formed: still less likely is it that sometimes vesicles, and at other times solid drops, should be formed. Microscopic observations on atoms dancing about in the air are scarcely to be relied on. But whatever may be the fact as to the constitution of condensed vapour, that is, whether the particles are hollow or solid, there is not any sufficient reason for supposing them constituted of any other principles than water and atmospheric air. The only one that has been provided with such an hypothesis is, that without some subtle elastic fluid, internal or external, the watery particles constituting clouds must constantly descend; whereas clouds are seen to remain stationary and sometimes even to ascend, which, it is alleged, could not take place, were not the particles of less specific gravity than the air. Now the ascent of clouds is in all probability an optical deception. It is occasioned by the dissolusion or evaporation of the under surface of the cloud, and the subsequent new formation of a cloud. We have no sufficient reason for believing that the individual particles of clouds ascend; yet they frequently descend with a velocity almost imperceptible; this arises from the resistance the air makes to the motion of small bodies, which, it is well known, increases in proportion as their diameters decrease. The epithet *vapour*, which denotes an elastic fluid, cannot, with philosophical propriety, be applied to the visible particles of water constituting clouds.

Mr. Pictet of Geneva published an ingenious essay on fire, which was translated into English and published in 1791. This recent essay, profiting with the ideas of the powers of fire in every thing which relates to evaporation, is tempted to look upon it as the sole agent in this class of phenomena, and to renounce the idea that air acts in the manner of chemical dissolusions. He observes, *the very specious arguments of my learned colleague (Sauffure,) in his hygrometry in favour of that opinion, had long seduced me; but the charm of simplicity which the theory of evaporation would acquire if we could divest it of the agency of air; the possibility I perceive of reducing the whole to the action of fire; the probability which increases with the simplicity of every natural hypothesis, attract me, I confess, still more forcibly.* Page 222.

In the Phil. Transac. for 1792, there is an essay of De Luc on evaporation. This acute philosopher ably maintains that vapour in the air is precisely the same as vapour in vacuo, and in both cases is formed by the intimate union of fire with water; he denominates it *fleam,* and flew that fleam in air of any density, and fleam in vacuo, affect the hygrometer alike, and proved the fleam has the same temperature and elasticity, at least: within the ordinary range of atmospheric temperature. He strengthens his opinion of fleam in air, and in vacuo being the same from the fact that cold is produced, or heat absorbed, by evaporation in both cases. From the facts, as ascertained respecting fleam by Mr. Watt and others he justly infers, that there is a certain minimum distance of the particles of fleam for each temperature, at which they retain their elasticity; if they are to be used by the mechanical force within the limit of this distance, they lose their elasticity and become water; if not, they retain it, and act as any other permanently elastic fluid. In speaking of fleam in air, he observes, *that no mechanical cause can produce the decomposition (condensation) of that fluid, but by forcing its particles to become nearer each other than the actual temperature can admit, which cannot happen in the atmosphere, except by the accumulation of fleam itself in some part of it.* "He concludes that the product of evaporation is always of the same nature, namely, an expanisible fluid, which either alone, or mixed with air, affects the manometer by pressure, and the hygrometer by moisture, without any difference arising from the presence or absence of air, at least, without any perceived luster." In 1793, Mr. Dalton published a volume of meteorological essays, in which he gives a theory of vapour, very nearly allied to that of De Luc above-mentioned, and to the opinion of Pictet, though he seems to have been unacquainted with these circumstances. From the results of many experiments which he concludes, *that the vapour of water (and probably most other liquids) exists at all times in the atmosphere, and is capable of bearing any known degree of cold, without a total condensation, and that the vapour so existing is one and the same thing as fleam or vapour of 212° or upwards.* The idea, therefore, that vapour cannot exist in the open atmosphere under the temperature of 212°, unless chemically combined therewith, I consider as erroneous; it has taken its rise from a supposition that air pressing upon vapour condenes the vapour equally with vapour pressing upon vapour, a supposition we have no right to assume, and which, I apprehend, will plainly appear to be contradictory to reason and unwarried by facts; for, when a particle of vapour exists between two particles of air, let their equal and opposite pressures upon it be what they may, they cannot bring it nearer to another particle of vapour, without which no condensation can take place, all other circumstances being the same; and it has never been proved that the vapour in a receiver from which the air has been exhausted, is precipitated upon the admission of perfectly dry air. Hence the limit which till the contrary can be proved, that the condensation of vapour exposed to the common air does not in any manner depend upon the pressure of the air." Essays, p. 201.

In 1802, Mr. Dalton published, in the fifth vol. of the Manchester Memoirs, a series of interesting essays relative to evaporation; he found, 1st. The expansive force of pure fleam over water in vacuo at all temperatures from 32° to 212°; 2d. The expansive force of dry air for the same range of temperature; and, 3d. The expansive force of dry air in contact with water for the like range. From a comparison of these experiments it appeared that the observation of De Luc was universally true; namely, that fleam in vacuo and fleam in air are precisely of the same force at the same temperature. The law was found to apply equally to the fleam from ether and other liquids, and to other elastic fluids, as well as common air. Mr. Dalton considers these facts to be decisive as to the nature of the connection between fleam and air, and infers that fleam forms a mechanical mixture with air, and not a chemical compound, as some have supposed. This conclusion is confirmed by experiments upon the quantity of water evaporated at different temperatures; which was always at proportion to the elastic force of vapour at the temperature. For instance, water at 212°, or kept just boiling, evaporates twice as fast as water.
ter of 180°, and this twice as fast as water of 150°; and the forces of pure steam at those temperatures are 30, 15, and 7½ inches of mercury respectively. The rule, however, does not apply without a correction for low temperatures; because the steam already in the air prevents in degree the ascension of fresh steam; whereas in high temperatures, the small portion of steam commonly in the air is too trifling to have any ob servable effect. Mr. Dalton has given a table founded upon experience, and adapted to the above-mentioned law, by which not only the actual quantity of water evaporated in atmospheric temperatures may be ascertained, but also the quantity of vapour existing in the air may be found; provided the rate of evaporation is given. The following is an abstract of it.

The first column of the table expresses the temperature; the second, the corresponding force of vapour in vacuo, derived from experiment; the third column expresses the number of grains of water evaporated per minute, from a surface of 28 1/2 square inches, in a moderate current of air or nearly calm; the fourth is the like evaporation in a medium current; and the fifth is the evaporation when a strong breeze exists, or a rapid current of air sweeps over the evaporating surface. The air is supposed to be perfectly dry or free from vapour; otherwise every particular state of atmospheric vapour would require a table. The table is intended to be used when we want to find the quantity of water evaporated from a given surface by the flow and gradual operation of the atmospheric temperature, or what has been called spontaneous evaporation. But as it is adapted to air perfectly free from vapour, it cannot be of any practical utility without further data. The force of vapour actually existing in the atmosphere at the time must be first ascertained, by determining the temperature at which dew begins to be formed on a glass, &c. containing cold water or a cold mixture. Then the force due to that temperature must always be subtracted from the whole force due to the given temperature of the evaporating water.

Whole evaporating force, per table, for 60° = 2.70 grains.
Existent force of atmospheric vapour for 59° = 1.92 grains.
Remainder = .78 grains.

Hence a surface of 28½ inches would lose .788ths of a grain in each minute.

Again; suppose the atmospheric vapour to be at 20°, with a strong breeze, in one cafe, the air being 32°; and the atmospheric vapour to be at 50°, in another cafe, with calm air at 58°; query the rates of evaporation in those two cafes?

1st Cafe. Whole evaporating force per table, for 32° = 1.26 grains.
Existent force of atmos. vap. for 20° = .82 grains.
Remainder, or rate of evaporation = .44 grains.

2d Cafe. Whole evaporating force, per table, for 58° = 1.06 grains.
Existent force of atmos. vap. for 50° = 1.50 grains.
Remainder, or rate of evaporation = .46 grains.

Hence it appears that under the circumstances above-mentioned the evaporation would be nearly the same in both cafes.

### Problem 2

Having given the rate of evaporation, to find the quantity or force of atmospheric vapour.

Suppose the evaporation from a surface of 28½ inches is found to be one grain in a minute, with a medium breeze, the temperature being 70°; query the quantity and force of atmospheric vapour?

Whole evaporating force, per table, at 70° = 3.70 grains.
Observed evaporating force = 1.00 grains.
Remainder = existing atmospheric force = 2.70 grains, which corresponds to 60°, for the temperature at which the atmospheric vapour would be found to be condensed at the time.

Mr. Dalton contends that all the different gases constituting the atmosphere, namely, azotic, oxygenous, carbonic acid, and steam, are independant of each other; so that they prefer the surface of the earth and other bodies with their own weight only, when in a state of equilibribum. Whence he considers the quantity and force of steam in the atmosphere as synonymous terms. Thus in the above example, the force of steam of 60° being represented by .524 parts of an inch of mercury, the weight of the incumbent atmosphere of steam must be the same, or equal to 7 inches of water nearly. This notion, concerning the whole quantity of steam in the atmosphere incumbent upon any place, is entirely new; and, if correct, must be of the first importance in meteorology.

Though the reasons assigned by De Luc and Dalton for the non-condensation of steam, already existing in air, appear to be uncontroversible; yet from what has been said above, no sufficient reason has been given by either of them for the entrance of steam of low temperatures into the atmosphere. How does steam of 31st part of the force of the atmosphere at first penetrate it? Even Saufler speaks of the fact, and as if there were no difficulty attending it. De Luc does not attempt any explanation. Dalton seems to have been fully aware that the hypothesis of pure steam existing in air was not tenable without obviating this difficulty. Accordingly he conceived that the particles of steam are not repulsive to those of air, but only to other particles of steam; hence the new formed steam has a kind of vacuum, to enter in the pores or interstices of the air. But this, it is thought by many, is going into the other extreme, and
making the facility much too great; besides, there is no notion so general as probable, as the one that heat is the cause of evaporation; and if this notion be true, the particles of steam cannot be admitted to be repulsive of each other, and indifferent to those of air. Mr. Dalton, it seems, now considers the inequality in the size of the ultimate particles of different elastic fluids to be the cause why they constantly diffuse themselves through each other, and never obtain a proper equilibrium till their particles take the arrangement, which they would do in a vacuum; and the elevation of steam from the surface of water, he supposes, takes place, because certain particles of the surface are in a great measure exempt from the prelude of the atmosphere. See New System of Chemical Philosophy, p. 100.

From the experiments of Mr. Watt on steam, it appears that evaporation at high and low temperatures is much the same as to the expenditure of heat for a given weight of water.

The evaporation from ice of 32° does not differ materially from that of water, at the same temperature. Electricity is said to promote evaporation in some degree.

Evaporation in Meteorology.—With respect to the natural evaporation of water from the surface of the earth, the experiments of Mr. Hoyle and Mr. Dalton, of Manchester, are nearly the only ones that are sufficiently numerous from which to draw any conclusions. They took a cylindrical vessel of tinned iron, 10 inches in diameter, and three feet deep; there were two pipes folded into it, one at the bottom, the other at the top, for the water to run off into bottles. The vessel was filled with gravel, sand, and soil, and subsequently the foil was covered with grass and other living vegetables. It was nearly buried in the ground in an open situation, and provision made for placing bottles to the two pipes. In this manner it was exposed to receive the rain, and to suffer evaporation from the surface, the same as the surrounding green ground. A regular register was kept of the water which percolated through the soil and gravel into the bottles, and a rain gage of the same surface was kept close by, for the sake of comparison. The results are contained in the table below, together with the mean evaporation from a like surface of water, for the three succeeding years.

From this table it appears that the evaporation from a surface of water, is nearly twice as much as from green ground; also, that about eight or nine inches of rain are left for the supply of springs and rivers. This surplus of water must be evaporated from the sea, and return to it again by the rivers.

Evaporation in Chemistry.—When artificial heat is applied, the quantity evaporated will be nearly in geometrical progression to the excess of temperature, above that of the air. It is always nearly in proportion to the surface exposed. When the liquid is much below the margin of the vessel, the evaporation is greatly retarded.

Evaporation in the Arts. In certain arts, such as dyeing, printing, &c. quick evaporation is expedient. This is effected by exposing the wet pieces in a stove, which has commonly a fire and long flues from which the heat is dissipated into the room. The cold air should be admitted into the room as near the fire and flues as possible; and several small openings at the top of the stove should be made to suffer the vapoury air to escape.

See the articles Clouds, Dew, Distillation, Hydrography, Rain, Steam, &c.

Evaporation, in Pharmacy, Chemistry, &c. denotes an operation by which the more aqueous and volatile parts of fluids are spent, or driven away in steam, so as to leave the remaining part stronger, or of a higher confidence than before.

Evaporation is effected by setting a liquor over a gentle heat, to carry off the most fluid and volatile parts, without lessening the quantity of the other matters with which the liquor is impregnated.

The vessels used for this purpose are basons, tefts, or crucibles, which are made of glasses, metal, or earth, according to the nature of the bodies on which the operation is to be performed. They are flat, shallow, and wide, so that the body from which the evaporation is to be made may present a large surface to the air. In all evaporations the degree of heat ought to be proportioned to the volatility of the substance to be evaporated, and to the degree of fixity of the substance intended to be left, and of its adherence to the volatile parts. In some cases, as in obtaining oil from rectified spirit of wine and ether, the liquors ought to be evaporated upon the surface of water in open air, without any other heat than that of the atmosphere; in others, when the part to be evaporated is not very volatile, and when the remaining substance is very fixed, and does not adhere much to the volatile part, as in the purification of gold by antimony, a strong heat may be applied, and a current of air directed upon the surface of the body.

EVARCHUS, in Ancient Geography, a river of Asia, forming the boundary between Paphlagonia and Cappadocia. Valerius Flaccus alludes it to Scythia, and says it abounded with swans.

EVARISTUS, in Biography, bishop of Rome, was elected to that office about the year 100, in which he continued eight or nine years. Much has been said of him with regard to his decreets; his distribution of Rome into parishes, his presenting Adrian with a book concerning the excellence of the Christian religion, and his martyrdom under the reign of that emperor; but these and other facts collected by modern writers do not stand on sufficient authority, to obtain credit. Moreri.

EVASION, in Laws, is used for any sanguine; endeavour to set aside truth, or to escape the punishment of the law, which will not be endured. Thus, if a person says to another that he will not strike him, but will give
him a pot of ale to strike him first; and accordingly he strikes, the returning of it is punishable; and if the person first striking he killed, it is murder; for no man shall evade the infliction of the law by such a pretence to cover his malice.

A. Hawk. P. C. 81.

EUSAER, in Geography, a river of India, in the northern part of the mountain Paropamisus, which ran S.E. into the Indus.

EVAUS, a branch or division of the ancient Celtic philosophers, the Druids.

Strabo distributes the philosophers among the Britons and Gauls into three sorts: bards, poets, and Druids. He adds, that the Bards were poets and musicians; the Evates, priests and naturalists; and the Druids, moralists as well as naturalists. But Marcellinus, Sisyllus, and Hornius, reduce them all to two sorts, viz. Bards and Druids. Lastly, Caesar, lib. vi. comprehends them all under the name of Druids; which see.

The Evates or Vates of Strabo might probably be what other authors, and particularly Ammian. Marcellin. calls Eubages; but Mr. Bouche, in his Hist. de Provence, lib. ii. chap. 2. distinguishes between them. The Vates, he says, were such as took care of the sacrifices and other ceremonies of religion; and the Eubages, those who spent their time in the search and contemplation of the great mysteries of nature.

EVAUX, in Geography, a town of France, in the department of Creuse, and chief place of a canton, in the district of Aubusson; 26 miles E. of Gien. The number of inhabitants in the place is 2,691, and in the canton 8,036, and the territorial extent of 232 square kilometres includes 12 communes. Near it are a mineral spring and baths. N. lat. 46° 13', E. long. 3° 34'.

EVAZ, in Botany, Gen. v. 2. 393, see FILAGO.

EBAZA, in Ancient Geography, an episcopal see of Asia propria, under the metropolis of Ephesus; mentioned in the acts of the council of Ephesus.

EUBAGES, an order of priests or philosophers among the ancient Celts or Gauls. Chorier takes the Eubages to be the same with the Druids and Saronizde of Diodorus. Others will have the Eubages to be those whom Strabo, lib. iv. p. 197, calls Euvates, Evates, or Vates, on which principle there is room to conjecture, that the word should be written Euvates, it being easy to mistake a P for a T. See Druid.

EUBELSTADT, in Geography, a town of Germany, in the bishopric of Wurzburg, on the Maine; three miles S. of Wurzburg.

EUBEA, in Ancient Geography, one of the most considerable of the Greek islands, formerly joined to Boeotia, as Pliny informs us, by an isthmus, so narrow is the Euripus in some places, which separates it from the continent; and extending from north-east to south-west 132 miles, but where broadest being only 40 miles, and 20 where it is narrowest. In compass it is estimated at 365 miles. This isle was anciently denominated Chalcis, Eileia, Aonia, Abyantis or Abantia, Macris, Oche, Bomo, &c. Its appellation Eubea is said to be derived from a famous cave on the eastern coast of the island, called by the Greeks αίγος, or ox, or ox stall, and this name was probably deduced from its excellent pastures. Eubea had several remarkable promontories, which stretched far into the sea; of these Pliny and Mela mention three, viz. Geratius and Carphesus to the south, and Cenimum to the north; and Strabo mentions a fourth, which he calls Petalia, over-against Sunium. Cenimum, now Capo Litor, and Geratius, now Cape Rodo, are, according to Strabo, 1200 furlongs distant from each other, which measure exactly the length of the island, as it is set down by Pliny. The mountains of Eubea are high, and covered during a great part of the year with snow. The famous city of Chalcis was situated under one of them of the same name, and on another, called Dryphus, was a temple dedicated to Diana. The following rivers are mentioned by Strabo, viz. Collis, Budaerus, Criseus, and Neleus or Melas. The champagne country was exceedingly fertile, and yielded great plenty of corn, wine, oil, and all sorts of delicious fruits; but it was chiefly famous for its rich pastures. This island had in former times many cities of great note, which are mentioned by Strabo, Pliny, Ptolemy, and Mela. On the eastern coast flourished the cities of Geraus, which was a famous haven, Petalia, and Caryus, near which were the celebrated quarries of Carya- tian marble, so much valued by the Romans, and also of Amanthus or Arbatos. About five miles from Caryus was the village of Amaranthis, famous for a temple of Diana. On the same coast floated the cities of Eucrius and Chalcis, which see respectively. Between Chalcis and the promontory Cenimum, floated the cities of Edepluma and Oroseos; the former being famous for its hot-baths, and the latter one of the most powerful cities of Eubea during the Trojan war, and occupying the fourth part of the island, in the time of Julius, the father of Alexander. The name Oroseos was changed by the Athenians, when they became masters of the island by means of Pericles, into that of Ithaca, or Heltheia, which was the name of their tribe. On the north side of the island, opposite Thiffalia, and extending from Cenimum to Artemium, flood Dios, or Atheno Diades; and on the coast, washed by the Aegean sea, floats theAEgean sea. The island cities mentioned by Strabo, Pliny, Ptolemy, &c. were Ellopia, Nybae, Eubæa, Orabia, Rhamnus, Portimus, Alge, and Tamyna.

Eubea was probably one of the islands in which the first Oriental, who passed from the continent of Asia towards the coasts of Greece, made a settlement. It must have formed a very powerful state at an early period, since its king Elephoros conducted 30 ships to the war of Troy. Solinus affirms the commencement of this monarchy to the Titans. Others suppose Abas to have been the first sovereign of Eubea. The succession of its sovereigns is little known. In the time of Darius Hystaspis, the cities of Chalcis, Eretria, Caryus, and Oroseos, formed distinct republics, governed by the nobles, whom they called hippobates, or horsemen; none being received into the government who were not able to maintain a certain number of horses. This oligarchy was not of long duration; but it was succeeded by a democracy, composed of domestic tyrants, who feized all power to themselves, and ruled in their several cities without control. At length the Eubceans submitted to Philip of Macedon, and then to his son Alexander, on whose death they endeavoured to shake off the Macedonian yoke; but they were again brought under subjection by Antigonus. When the Romans first passed into Greece, the kings of Macedon held this island in subjection; but it was soon after declared free by the senate, in order to weaken the power of Philip in these parts. But not being supplied with forces, they were unable to maintain their liberty; and fell under the power of Antiochus the Great, and Mithradates king of Pontes. The Romans, however, prevailing in the East, restored the Eubceans to their former state of liberty. It was not long before Marc Antony subjected them to Athens; but Augustus, incensed against the Athenians for afflicting his rival, first gave freedom to the city of Eretria, and four years after the whole island, which remained in a flourishing condition, under its own laws, till
the reign of Vespasian, when it underwent the same fate as the other states of Greece.

Europa, the name of several towns in the island of Euboea, Corycia, and Lemnos.

Eubolides, in Biography, a native of Miletus, was a successor of Euclid in the Megarian school. He was a strong opponent of Aristotle, and seized every occasion of confuting his writings and calumniating his character. He introduced new difficulties into the art of disputation, several of which, though often mentioned as proofs of great ingenuity, deserve only to be remembered as examples of egregious trifling. They belong to that sophistical mode of reasoning, called by Aristotle eristic syllogism. A single specimen will be sufficient. It shall be of the sophism, called from the example, "the Lying: if, when you speak the truth, you say you lie, you lie; but you say you lie, when you speak the truth; therefore in speaking the truth, you lie. These silly inventions for perplexing plain truth were formerly in such high repute, that Chryllippus wrote six books upon the above mentioned sophism; and Philetas, a Cook, died of a consumption which he contracted by the close study he bestowed upon it. The inscription upon his tomb was Ο ἐκ μακράς, "The Deceived." Brucker's Hist. Phil. by Endfield, vol. i. p. 192.

Gen. Cl. Cal. Perianth superior, of one leaf, abrupt, entire, permanent, closed before impregnation with a convex or conical, entire, deciduous lid, which is sometimes, if not always, of two or three layers. Cor. none. Stam. Filaments numerous, thread-shaped, equal, inserted into the margin of the calyx within the lid, and not expanding till after it falls, anthers roundish, two-lobed, small. Fil. Germen inferior, ovate, firmly united with the base of the calyx, sometimes angular; style simple, columnar, as long as the full-grown flower; stigma simple, bluish. Peric. Capsule roundish, crowned with the rim of the calyx, of three or four cells, opening at the top. Seeds numerous, angular, small.

Eff. Cl. Calyx superior, permanent, truncated, covered before flowering with an entire lid, which soon falls off. Capsule of three or four cells, opening at the top. Seeds numerous.

This genus was founded by the late M. L'Heritier in his Scintum Anglicum, upon a single species, from Van Diemen's land, named by him obliqua, and figured in the 2nd plate of that work. Its description never appeared. The generic characters were by him communicated to the Hortus Kewenensis, and adopted, with some necessary corrections, in Dr. Smith's Botany of New Holland, where a second species is figured, E. rugosa, t. 13. This is called New Holland Mahogany, or Brown Gum Tree, and is one of the loftiest trees about Port Jackson, being often 100 feet high, and proportionably thick. The wood hard, heavy, strong, red and very refrinous. Leaves alternate, folded, ovate, entire, a little oblique and unequal. Flowers in dense simple umbels, of a tawny yellow, on simple or divided angular stalks, growing in a corolloyle manner about the ends of the branches. The lid in this species is conical, as long as the calyx and germen, with a frutice in the middle; that of the former is short and hemispherical, with a minute point. Four more species from New South Wales are described in the work just mentioned, and fix additional ones by the same author in the Trans. of the Linn. Soc. v. 3. p. 283—288. All these 12 are adopted by Willdenow in his Sp. Pl. A new one, E. marginata, was added to this list by Dr. Smith in Tr. of Linn. Soc. v. 6. 302, who has since figured and fully described one of the multi-important of the former, E. reclinata, the Red Gum Tree, in his Exotic Botany, v. 2. 49. t. 84. This bloomed in Lady De Clifford's greenhouse at Paddington. The flowers are green with white filaments. L'Heritier, vol. i. p. 425. He alludes, as long as the calyx and germen, consisting of three coasts, of which the outermost is formed of three ribs, with three flaps attached to the angles of the germen. The tree produces an affright plant of a fine deep red, whose probable uses in medicine or the arts merit inquiry. Many more species of this genus are said to abound in New Holland, all lofty trees, delitute of hairlets, with simple, lanceolate, or somewhat ovate, pointed, entire leaves, generally oblique, and often unequal, at the base; without stipules. They are commodiously divided into two sections, by their hemispherical or conical lids.

Eucauria, in Ancient Geography, a town of Asia, in Greater Phrygia, according to Porcelly and Strabo.

Eucera, in Entomology, a genus of Hymenoptera, proposed by Scopoli, and adopted by various late writers. Under this denomination are comprehended those of the Linnaean genus Apis (bee), which have the mandibles horned, incurvated, acute, and toothless; jaw elongated, and membranaceous at the tip; lip horny, five-clift; tongue inflected and five-clift; antenna cylindrical, those of the male very long, and often exceed the length of the body; the abdomen short and downy; tail of the female armed with a fling. The insects of this genus form cylindrical cavities in the earth, in which they deposit their eggs, each included in a separate cell, and furnished with a suitable provision of honey for the subsistence of the young when hatched. The winged state the Eucera fly with great rapidity, and like the bee, collect the farina and nectar of flowers with great industry and activity. The females commonly differ much in appearance from the males of the same species, independently of the length of the antenna.

Species.

Native of Europe. The female of this species is not distinctly ascertained. Mr. Kirby seems to entertain no doubt of its being the insect figured by Pauzer under the name of Andrena lugicola. Since his observations appeared, however, Latreille has written on the same subject, and though he does not refer to the remark of Mr. Kirby, he evidently alludes to it in the following passage, "Je doute que l'andrene, que Pauzer nomme lugicola, foit la femelle de cette espèce. Son abdomen est très-different par ses taches de celui de Eucera longicornis et cet insecte ne paroit qu'au milieu du pétale, tandis que le dernier ne se voit, qu'au printemps." The difference of the abdomen may perhaps be considered in this ambiguous race less definitive than the time of its appearance in the winged state; for if the first be conjointly found only in the middle of the summer, and the other in spring, we should admit them to be distinct. It further merits observation that Latreille describes an insect which he imagines to be the true female, "La femelle, &c." The female, or, at least, that which I regard as such, and of which I have-
have been an individual in the collection of the naturalist Baumhaaver, differs only in the frontlets of the antennae; the head entirely black, and the posterior feet very downy. The species inhabits Europe.

Atricornis. Antennae black, as long as the body, which is hairy and ferruginous. Fabr.

Native of Barbary.

Glaucus. Antennae ferruginous, as long as the body, the latter hairy and glaucous. Fabr. Sp. Inf. &c.

Inhabits the East; two first segments of the abdomen with a black band.

Linguaria. Antennae black, length of the abdomen; thorax cinereous; abdomen black. Fabr.

Native of Europe, on flowers.

Tumulum. Antennae length of the abdomen; body black; legs and jaws yellowish. Linn. Fz. Suec.

Eucera tumulorum, Fabr.

An European insect, also found on flowers.

Grisescens. Antennae black, as long as the body; the latter hairy and cinereous. Fabr.

Inhabits Barbary.

Antennata. Antennae as long as the body; abdomen black, with white hairs. Fabr.

A small insect, found in abundance in the environs of Paris in autumn, and also in other parts of Europe. The tip is marked with a trilobate spot of yellow; the head and thorax cinereous; abdomen glabrous; edges of the segments fringed with white, legs telfaceous.

Curvicornis. Blackish-grey; antennae convoluted, sub-elliptical; abdomen roundish; margin of the wings black. Scopoli. Native of Carniola.

Brevicornis. Ferruginous hairy; abdomen brassy; antennae short and black. Fabr. Suppl.

This is an inhabitant of Italy, and is described by Fabricius from the cabinet of Dr. Allioni. The head, thorax, and legs with ferruginous hairs.

Crasipes. Hairy cinereous; abdomen black, with the margin of the segments greenish; posterior thighs thick. Fabr. Suppl.

Native of Tranquebar in the cabinet of Lund. The antennae of this insect are short; the wings are dusted with ferruginous tip; legs yellowish; thighs of the posterior pair thick, dentated, and black; tarsus incurved, toothed, and yellow.

Whether this and the species immediately preceding ought strictly to be placed with the Eucera, (so named from the length of their antennae,) if they should be of the male kind, may be submitted with deference; the sex is not mentioned in either instance. Fabricius described them as Eucera, and they agree in every respect with that genus, except in the remarkable brevity of the antennae.

Eucharistia, The sacrament of the Supper, or a participation of the body and blood of Christ, under the species or figures of bread and wine. See Communion, Sacrament, Species, Transubstantiation, and Consubstantiation.

The word in its original Greek, Εὐχαρίστημον, literally imports thanksgiving, being formed of εὐ, well, and χαίρειν, gratia, thanks.

Euchendorf, in Geography, a town of Lower Bavaria, on the Vils; 14 miles W. of Vilzhofen.

Eucherius, in Biography, a bishop of Lyons in the fifth century, began his career in secular life, in the various offices of which he acquired wealth. He sustained the rank of senatore, and having married, had several children, among whom were two sons, whom he lived to see advanced to the episcopal dignity. Weared with the pursuits of the world, he embraced a monastic life, which he quitted for the bishopric of Lyons in the year 434. He attended the deliberations of the first council of Orleans in the year 441, and was distinguished for his learning and sagacity. He was a popular preacher, upon those principles of grace which were vindicated by St. Augustine. He died about the year 454. Among the various documents attributed to Eucherius, may be noted "Epistola de Laudibus Eremitarum et De Vita Solitaria," intended to extol the advantages of asectic life, written, for the times, with uncommon beauty and purity of language: "Epistola de Contemptu Mundi, et Sacrorum Philosophiae ad Valerium Cognatum suum," which was published by Eusipus, with annotations, at Basile in the year 1520, and pronounced to be one of the most elegant pieces of antiquity. To these may be added two treatises intended to illustrate difficult passages of Scripture, of less value than those mentioned above. These, and some others, attributed to Eucherius, were collected and published at Basile in 1531, at Rome in 1564, and are likewise to be found in the fifth volume of the "Bibliotheca Patrum." There was another Eucherius who was likewise a bishop of Lyons, and assisted at the second council of Orleans about the year 529. Moreri.

Euchites, a native of Egypt, in Ecclesiastical History, a sect of ancient heretics, who were first formed into a religious body towards the end of the fourth century, though their doctrine and discipline subsisted in Syria, Egypt, and other eastern countries before the birth of Christ; they were thus called because they prayed without ceasing, imagining that prayer alone was sufficient to save them.

Their great foundation was those words of St. Paul, Ep. Phil. i. to the Thessalonians, chap. v. ver. 17. pray without ceasing.

The word is formed of the Greek, ἐυχαρίστημον, prayer, whence εὐχαρίστησις, the fame with the Latin, precatorium, prayers. They were also called Euthyphrae and Μαθηταί, a term of Hebrew origio, denoting the fame as Euchites.

The Euchites were a sort of mystics who imagined, according to the oriental notion, that two souls refided in man, the one good and the other evil; and who were zealous in extolling the return of the good spirit of God, by contemplation, prayer, and singing of hymns. They also embraced the opinions nearly resembling the Manichean doctrine, and which they derived from the tenets of the oriental philo-

The name denomination was used in the twelfth century, to denote certain fanatics who infested the Greek and Eastern churches, and who were charged with believing a double Trinity, rejecting wedlock, abstaining from flesh, treating with contempt the sacraments of Baptism and the Lord's Supper, and the various branches of external worship, and placing the essence of religion solely in external prayer, and maintaining the efficacy of perpetual supplications to the Supreme Being for expelling an evil being or genius, which dwelt in the breast of every mortal. This sect is said to have been founded by a person called Lucope-

Euchites, whose chief disciple was named Tycheus. By degrees it became a general and invincible appellation for perfons of eminent piety and zeal for genuine Christianity, who opposed the vicious practices and infulent tyranny of the priesthood; much in the same manner as the Latins comprehended all the adveraries of the Roman pontiff under the general terms of Waldensian and Albigenses.
lazy, scandalous life. A cenuse likewise applicable to
monasteries in general.

EUCHOLOGIUM, Euchologe, a Greek term, signifying,
literally, a discourse on prayer. The word is formed of euch, prayer, and logos, discourse. The Euchologium is properly the Greek ritual, wherein are prescribed the order and manner of every thing relating to the order and administration of their ceremonies, sacraments, ordinations, 

The Ea. Guan has given us an edition of the Greek Euchologium in Greek and Latin, with notes, at Paris.

EUCHYRION, in Surgery, a plaster mentioned by
Scribonius Largus.

EUCHYMIA, from euch, good, and nyia, juice, in Medicines, a good temper of the blood, or other juices and fluids in an animal body.

EUCLABRIS, in Antiquity, a table whereon the slaughtercd victim was spread, in order to have its innfeines carefully inspected. It was from this table that the vessels used in sacrifices were called euclybra.

EUCLASE. The colour of this mineral is a very clear sea-green. It occurs only crystallized. Its primitive form is that of an oblique quadrilateral prism, but its fimmitis are generally so complicated by truncatures and bevelling as to render a mere verbal description of it wholly unintelligible: in this flat it resembles certain varieties of topaz, but may readily be distinguished by measuring the obtuse angles of the prism, which in this mineral are 135°, whereas in the topaz they are 124°; its lamelle also are not perpendicular to the axis of the prism. It has a brilliant vitreous luster. Its fracture in the direction of its axis and parallel to the small diagonal of its base is perfectly lamellar; but when parallel to the large diagonal is very imperfectly so. Its crofs fracture is somewhat conchoidal. It is transparent and has a double refraction. It is sufficiently hard to scratch quartz, but is remarkably brittle. Sp.gr. = 3.06.

When exposed to the blowpipe, it first loses its transparency, and then melts into a white enamel. It has been analysed by Vaquinin, with the following result:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
</table>
| Silex | 35 | 36
| Alumine | 18 | 19
| Glycine | 14 | 15
| Iron | 2 | 3
| LofS | 69 | 73
|     | 31 | 27
|     | 100 | 100

This mineral is so very rare that only a small portion could be afforded for analysis; of the lks, Vaquinin attributes the greatest part to water of crystallization, and the rest is probably alkali.

The euclyra was found in Peru by Dombey, and all the specimens in the cabinets of Europe were brought over by this naturalist.

LUCLEA, in Botany, is derived by Professor Martyn from eulea, glory, or celebrity, which seems to no respect applicable to this plant. We would rather explain it by eu, well, and klea, to sink up, because of the manifold coverings of the seeds, each of which is enclosed in an arillus, within the cell of a capsule, whose outside moreover is protected with a covering of pulp. To all this indeed L'Hertier first adverted, and not Linnaeus nor Thunberg, one of whom probably invented the name. Linn. Suppl. 67. Thub. Nov. Gen. 84. L'Hert. Sert. Angl. 31. Vol. XIII.

Gen. Ch. Cult. Perianth inferior, small, with five teeth, permanent. Cor. of one petal, larger than the calyx, is in five deep, oval, obtuse, equal, spreading segments. Stam. Filums about fifteen, short, inserted into the receptacle; anthers erect, square, scattered by downward than the corolla. Juss. German superior, oval, somewhat pyramidal; stylos two, the length of the stamens; fligmas simple. Peric. Capsule with a pulpy coat, roundish, with three horns, three cells, and three valves. Seeds solitary, roundish, enclosed in an arillus; one or two of them frequently proving abortive.

Old. L'Hertier, from whom the above characters are taken, remarks that some flowers have an abortive germin, but he never saw any that were entirely female without stamens. Thunberg describes dilisnt male and female flowers, and affords that the former are most frequently five-cleft, the latter four-cleft. Linnaeus does not advert to any such difference.

Thunberg defines three species, all natives of the Cape of Good Hope, in his Prodromus, p. 85.

1. E. lancea. "Leaves lanceolate, flat."
2. E. racemosa. "Leaves ovate, flat."—E. racemosa; Linn. Suppl. 428. L'Herit. Sert. Angl. 32. Ait. H. Kew v. 3. 411. (Pads foliis subrotundis, fructu race- moso; Burk. Afric. 243. t. 85. f. 1: and Euonymus foliis subrotundis integris, fructu coriiculato; ibid. 260. t. 97. f. 1. Africanus, foliis laurinins, fructu aculeato; Brey. l. c. 41. t. 22. f. 3.) A smooth branching shrub, with alternate, obovate, thick, somewhat roundish leaves, about an inch long, on short footstalks. Flowers eight or ten in each axillary drooping cluster, about as long as its corresponding leaf. Petals snow-white. Fruit red, the size of a pea.
3. E. undulata. "Leaves ovate, undulate."—Much like the last in general aspect. Its red fruit is eaten by the Hottentots, who call the plant Guarru-boches.

EUCLID, in Biography, a native of Megara, and founder of the Megarian or Eleatic sect, was distinguished by his subtle genius, and early application to the study of philosophy. Having acquired some knowledge of the art of disputations from the writings of Parmenides, he was induced by the fame of Socrates to remove from Megara to Athens, where he became the auditor and disciple of this eminent philosopher. Notwithstanding the terror of the decree which enacted, that any inhabitant of Megara who should be seen at Athens should forfeit his life, he frequently came to Athens by night, from the distance of about 20 miles, concealed in a long female cloak and veil, to visit his master. He also frequently engaged in the busines and disputations of the civil courts, by which proceeding he offended Socrates, who defiled forensic contests; and this circumstance seems to have occasioned a separation between them. Afterwards he delivered himself at the head of a school in Megara, where his chief employment was to teach the art of disputations. Although he was so much addicted to vehement debates, he professed to great command of temper, that in a quarrel with his brother, who said to him, "Let me persuade if I be not revenged upon you," Euclid replied, "And let me persif, if I do not subdue your resistance
sentment by forbearance, and make you love me as much as ever."

Averie from the analogical method of reasoning, Euclid was of opinion that legitimate argumentation consists in deducing fair conclusions from acknowledged premises. He held, that there is one supreme good, which is called by the different names of Intelligence, Providence, God; and that evil, considered as an opposite principle to the supreme good, has no physical existence. The supreme good he defined to be that which is always the same. Good he therefore considered abstractedly, as refiding in the Deity, and he seems to have maintained, that all things which exist are good by their participation of the first good, and that in the nature of things there is no real evil. When Euclid was asked his opinion concerning the gods, he replied, "I know nothing more of them than this; that they hate iniquitous perfons." Brucker's Hist. Phil. by Enf. v. i.

Euclid, known to every well educated youth by his "Elements," was, according to the testimony of Pappus and Proclus, a native of Alexandria, in Egypt, where he flourished and taught the mathematics in the reign of Ptolemy Lagus, about 300 years before Christ. His was the first mathematical school in that far famed city, where, till its conquest by the Saracens, most of the eminent mathematicians were either born, or studied. To Euclid, and to those immediately educated by him, the world has been indebted for Eratosthenes, Archimedes, Apollonius, Ptolemy, &c. "The Elements," to which we have already referred, are not to be wholly attributed to Euclid, many of the invaluable truths and demonstrations contained therein were discovered and invented by Thales, Pythagoras, Eudoxus, and others; but Euclid was the first who reduced them to a regular order, and who probably interwove many theorems of his own, to render the whole a complete and connected system of geometry. "The Elements" consist of fifteen books, but the last two are suspected to have been written 200 years after Euclid's death, by Hypsicles of Alexandria. The best edition published in this country is that printed at Oxford, in folio, in 1703; but the most common edition in our schools is that by the late learned Dr. Simson. Euclid is said to have been a person of agreeable and pleasing manners, and admitted to habits of friendship and familiarity with king Ptolemy, who once demanded of the mathematician if he could not direct him to some shorter and easier way of acquiring a knowledge of geometrical truths, than that which he had exhibited in his "Elements," to which Euclid replied, that "there was no royal road to geometry."

Euclid, as a writer on music, has ever been held in the highest estimation by all men of science who have treated of harmonics, or the philosophy of sound. As Pythagoras was allowed by the Greeks to have been the first who found out musical ratios, by the division of a monochord, or single string, a discovery which tradition only had preserved, Euclid was the first who wrote upon the subject, and reduced these divisions to mathematical demonstration. His "Elements" were first published at Baal, in Switzerland, 1533, by Simon Grynaeus, from two MSS. The one found at Venice, and the other at Paris. His "Introduction to Harmonics," ( المواطنين) in which some MSS. were attributed to Cleonidas, is in the Vatican copy given to Pappus; Meibomius, however, accounts for this, by supposing those copies to have been only two different MS. editions of Euclid's work, which had been revised, corrected, and refixed from the corruptions incident to frequent transcription by Cleonidas and Pappus, whose names were, on that account, prefixed. It first appeared in print

with a Latin version, in 1498, at Venice, under the title of "Cleoneiz Harmonicum Introductiorium," who Cleonidas was, neither the editor, George Vall, nor any one else pretends to know. It was John Pena, a mathematician in the service of the king of France, who first published this work at Paris, under the name of Euclid, in 1577. After this, it went through several editions with his other works.

His "Section of the Canon," (قانون) follows his "Introduction:" it went through the same hands and the same editions, and is mentioned by Porphyry, in his Commentary on Ptolemy, as the work of Euclid. This tract chiefly contains short and clear definitions of the several parts of Greek music, in which it is easy to see that mere melody was concerned; as he begins by telling us, that the science of harmonics considers the nature and use of melody, and consists of seven parts: sounds, intervals, genera, syllables, keys, mutations, and melopoeia; all which have been severally considered in the differentiation.

Of all the writings upon ancient music, that are come down to us, this seems to be the most correct and compressed: the first are generally loose and diffused; the authors either twill and distilling every thing to a favourite sytem, or filling their books with metaphysical jargon, with Pythagorean dreams, and Platonic fancies, wholly foreign to music. But Euclid, in this little treatise, is like himself, close and clear; yet so mathematically short and dry, that he bellows not a syllable more upon the subject than is absolutely necessary. His object seems to have been the compressing into a scientific and elementary abridgment, the more diffused and speculative treatises of Aristoxenus. He was the D'Alembert of that author, explaining his principles, and, at the same time, seeing and demonstrating his errors. The musical writings of Rameau were diffused, obscure, and indigested; but M. D'Alembert, extracting the essence of his confused ideas, methodized his system of a fundamental base, and compressed, into the compass of a pamphlet, the substance of many volumes. See Elements de Musique, ftiuans les Principes de Rameau.

According to Dr. Wallis, (Phil. Trans. No. 242, and Lowthorp's Abridged, v. i.) Euclid was the first who demonstrated that an octave is somewhat less than five whole tones; and this he does in the 14th theorem of his "Section of the Canon." In the 15th theorem he demonstrates that a fourth is less than two tones and a half; and a fifth less than three and a half; but though this proves the necessity of a temperament upon fixed instruments, where one found answers several purposes, yet he gives no rules for one, which seems to furnish a proof that such instruments were at least not generally known or used by the ancients.

What Aristoxenus called a half-tone, Euclid demonstrated to be a smaller interval, in the proportion of 5 to 243. This he denominated a limen, or resonant; because giving to the fourth, the extremes of which were called semi-fiddles, and were regarded as fixed and unalterable, the exact proportion of 4 to 3, and, taking from it two major tones 4/3, the limen was all that remained to complete the diatessaron. This division of the diatonic genus being thus, for the first time, establihed upon mathematical demonstration, continued in favour, says Dr. Wallis, for many ages. But this is further explained in other articles.

Gen. Ch. Cal. none. Cor. of one petal, inferior, bell-shaped, regular, permanent, in fix deep, equal, oblong, obtuse, spreading segments. *Stam. Filaments* fix, shorter than the corolla, awl-shaped, dilated at the base and united by that part into a concave nectary, attached to the bottom of the corolla; authors oval. *Pfjl.* German superior, ovate, with three funnels; yale awl-shaped; stigma simple. *Peric.* Capsule ovate, three-leaved, of three cells. *Seeds* numerous, small, ovate.

El/. Ch. Calyx none. Corolla inferior, in fix deep, spreading, permanent, equal segments. *Filaments* united at their base into a concave nectary, attached to the corolla.

It is kept in the greenhouse, and flowers in the spring, but is scarcely cultivated except for the sake of curiosity.

3. E. purpurea. (E. purpureocanalic.; Andr. Repof. t. 369.) Stalk club-shaped. Leaves numerous, obovate, obtuse, depressed. *Fertile bracteas* shorter than the flowers; *barren ones* linear-lanceolate. Drawn by Mr. Andrews in the garden of G. Hibbert, Esq. The broad, defpetoned, numerous *leaves*; thick, violet *flatt*; and numerous, narrow, purple-edged leaves of the crown, readily distinguish this species.

5. E. undulata. Ait. ibid. Curt. Mag. t. 1083. (E. regia; Redout. Liliac. v. 3. t. 175. Balsam; Lamarch f. t.) Stalk cylindrical. Leaves ovate-oblong, undulate, spreading. *Barren bracteas* almost as long as the *spike.* Introduced in 1760 by Mr. Miller, who, from its blooming in autumn, which is not invariable, named it *Fritillaria autumnalis.* Stalk taller than in the last. *Leaves* narrower and longer. Mr. Cawler observes that their undulations disappear as they decay.

6. E. panulata. I. Herit. Sert. Angl. t. 18. Curt. Mag. t. 913. (Basilica; Lamarch f. t.) Stalk cylindrical. *Leaves lanceolate, channelled, spreading. Spikes* many times longer than the *barren bracteas.* The *long narrow leaves, flakt* elegantly speckled with violet, and especially the great extent of the *spike*, which is about a foot in length, render this species very distinct. The *corolla* is of a very pale green. *German* violet. The bases of the *leaves* are externally spotted like the *flatt*. It flowers in June or July, and is rarely of cultivation.

**EUCRASY**, of *wu, well, and xapion, temperature, an agreeable, well-proportioned mixture of qualities, whereby a body is said to be in good order, and disposed for a good state of health.

Gen. Ch. Cal. Perianth, of five minute, ovate, permanent leaves. *Cor. Petals* five, large, obovato-lanceolate, spreading; covered before expansion with a deciduous veil, separating from the base into four segments. *Stam.* Filaments inserted into the receptacle, numerous, awl-shaped, shorter than the petals; anthers roundish, of two cells. *Pfjl.* German superior, ovate, filariated; *styles* about 12, shorter than the *flaments*; stigma simple. *Peric.* Capsule ovate, with a wooly furrowed bark, burbling at the top and bottom into as many cells as there are *styles*, each remaining attached by two fibres to the receptacle. *Seeds* several, obovate, imbricated, each terminated by a small membranous wing.

1. E. cordifolia. Cavan. Ic. v. 4. 39. t. 372.—A fine tree gathered in Chili, by Louis Nee, from the whole herbarium Cavanilles described it. *Wood* red. *Branches* downy when young. *Leaves* opposite, short, obovato-lanceolate, obtuse, undulate, and bluntly crenate, veiny, coriaceous; heart-shaped at the base; smooth above; downy and white beneath; scarcely two inches long. *Sinipula* none. *Flowers* axillary, foliar, each on a stalk about an inch long, with many scales at its base. *Petals* white, turning red in drying. *Vail* of the flower externally downy.—It is commonly called in the country *Roible di Chile*, or Chili Oak.

**EUDEMA**, in Ancient Geography, a small island of the Aegean sea, placed by Pliny in the Thermaic gulf.

**EUDEMUS, John Andrew, in Biography,** a learned Jesuit, was a native of Candidia, and went to Rome in pursuit of knowledge, where he entered himself a member of the society of Jesus. He was afterwards professor of philosophy, and then of theology in the university of Padua. He was honoured with the ecclesiastical and friendly letters of Pope Urban VII. who appointed him the chaplain to his own nephew Cardinal Barberini, when he was sent papal legate into France. He died at Rome in 1625, leaving behind him various publications many testimonies to his talents and learning. He was expected to be the author of a work entitled "Admonitio ad Regem Ludovicum XIII," which attacked the authority of the kings of France, in matters of an ecclesiastical nature. This treatise brought the society, of which Eudemus was a member, into great and general disrepute; it was likewise condemned by the faculty of the Sorbonne, and the assembly of the clergy at Paris, and condemned by the parliament. Morter.

**EUDEMUS, in Biography,** a name, it would appear, common to several physicians in different ages, of whom little is known with any degree of certainty or precision. One Eudemus is mentioned by Galen as contemporary with Herophilus, in the 37th age, and is compared with the latter in respect to his anatomical skill, especially relative to
the novice. Another Eudemus is said to have suffered death for his crimes, in the year 31 of the Christian era. And others of the same name, as Eudemus the taker of antidotes, Eudemus of Chio, are occasionally mentioned. See Eyl, Dict. Hist.—Le Clerc Hist. de la Medecine.

Eudemus of Rhodes was a pupil of Aristotle. The Ethics of Aristotle are referred to him, and some suppose them to have been written by him.

EUDES, duke of Aquitain, succeeded to his dukedom towards the close of the seventh century. When Pepin Heritil laid claim to the royal authority in France, Eudes declared himself independent, and feigned upon the remainder of Aquitain, and in a short time by force of arms made himself master of all the country lying between the Loire, the Ocean, the Pyrenees, Septimania, and the Rhone. In 721 he defeated Zama, lieutenant of the Saracen caliph, who had invaded Gaul, under the walls of Toulouse, but in a few years afterwards he found it necessary to make an alliance with Munuza, another Saracen general, to whom he gave his daughter in marriage. After this his country was completely over-run by the Saracens, over whom, by the aid of Charles Martel, he obtained, in 732, a complete victory, which delivered France from the Mahometan yoke. Eudes died in 735, leaving behind him three sons by his wife Valtrude, who was the near relation of Pepin. Moreri. Uniuer. Hist.

EUDES, John, born at Rye in Lower Normandy, in the year 1601, was brother of the celebrated historian Mezerai, and received his education at Caen, under the care of the Jesuits, where he was afterwards entrusted with the superiority of the house belonging to the congregation. In 1643 he quitted the duties of this institution, and undertook the establishment of another, of which he became the first superior as well as founder. This was denominated "The congregation of Jesus and Mary," and the principal objec of it was to provide a seminary for the instruction of young persons in piety and sacred knowledge, and to form a body of religious men, influenced by greater fervour and exaltation in their devotional feelings, than was encouraged by the regulations of the society of which he had been a member. He died in 1682, at the age of seventy-nine. He is described as having been an excellent and well meaning man, both intellectual and highly civilised. As a preacher and inductor of youth, he was very popular; but his writings evince little knowledge and less judgment, though they exhibit a devotional spirit, tinctured with large portions of superstitious credulity. The most remarkable of his pieces are (1) A treatise "On the Devotion and Office of the Heart of a Virgin; (2) "Man's contract with God;" and, (3) some particulars concerning a peasant in Normandy, whom he regarded as under divine inspiration, entitled "The life of Mary of the Vallies," Moreri.

EUDEIOMETRY. This term is applied to those processes which have been employed to ascertain the purity, or, in other words, the degree of oxygenation of any gaseous mixture, or especially of atmospheric air.

A considerable variety of methods have been used by chemists, all of which, though essentially different, agree in acting upon the oxygenous portion alone, the azot being in all cases left as the unchanged residue. The following are the several methods employed.

Of nitrous gas as an eudimeter.—This was the first eudimeter used by D. Priestley in his original experiments on air, which immediately followed the discovery of oxygen by this illustrious philosopher. If nitrous gas be mixed with oxygen gas, in a glass jar over water, in the proportions in which they saturate each other, to form nitric acid, the gases will totally disappear, a ruddy flame is seen at the moment of mixture, and the water will rise to the top of the jar, leaving unabsorbed only the unavoidable impurities of the gases. If, on the other hand, nitrous gas be mixed with atmospheric air, or any other admixture of oxygen and azot, the former alone of the two will be condensed by and with the nitrous gas, and the azot will remain unaltered. Hence by measuring the respective quantities of the gases employed, and the quantity absorbed, the purity of the atmospheric air may be ascertained, (supposing it known by previous experiment what are the exact proportions in which nitrous gas and oxygen saturate each other, and become totally absorbable by water.) Thus, for example, if 100 measures of nitrous gas be added to the same quantity of common air, and the two completely mixed, the bulk after such mixture will not be 200 measures, but only about 108, and consequently 92 measures will have been absorbed: which last, therefore, confers all of the oxygen of the air, with so much of the nitrous gas as has been employed to saturate it. This result Dr. Priestley was in habit of denoting, for brevity sake, by the expression that the air was of the purity of 108, by which he always meant that when 100 of nitrous gas, and 100 of the air to be examined were mixed, the residue after the mutual action of the airs was over, was of the number specified. The quantity of the two airs absorbed being known, the portion which is estimated to belong to the oxygen must therefore depend on the proportion in which nitrous and oxygen gases saturate each other, which requires another elementary experiment. Thus in the influence before us, if three parts of nitrous gas saturate one part of oxygen, the 92 parts which have disappeared are composed of 69 of the former gas, and 23 of the latter, and hence the composition of the 100 parts of atmospheric air examined, will be 23 of oxygen, and the remainder unabsorbed residue chiefly azotic.

A number of valuable experiments by Fontana, Ingenhouz, and especially by Mr. Cavendish, made on this subject, have shown that different portions of the very same mixture of nitrous gas and oxygen will experience a prodigious difference of absorption according to the width of the tube in which they are mixed, the order of mixture, the time of standing together, the degree of agitation used, and other manipulations. Thus Mr. Cavendish observed, that if one measure of nitrous gas and as much common air be rapidly mixed, and immediately shaken, the absorption will be nearly half the entire contents, but if the airs are suffered to remain in contact for about a fourth of a minute before they are shaken, the absorption will be no more than about 8. The nature of the water also in which the experiment is made is found very materially to influence the result. By attending to every circumstance of the kind, Mr. Cavendish, with that admirable accuracy which distinguishes all the researches of this eminent philosopher, was enabled to obtain very satisfactory results as to the uniform nature of atmospheric air.

Still, however, the difficulties of employing this mode of analysis with sufficient precision in all admixtures of oxygen and azot have been found so great, and the apparent anomalies so numerous, that it has been long nearly abandoned by chemists, till of late the subject has been revived by Mr. Dalton, who has added some important observations, which require some notice in this place. (See the Manchester Transact. New series.)

Mr. Dalton gives the following experiments:

If 100 measures of common air be thrown up to 35 measures of nitrous gas in a tube only 3-1/2ths of an inch wide,
EUDIOMETRY.

Wide, and 5 inches long, and no agitation be used, in a few minutes the whole will be reduced to 75 or 80 measures, and exhibit no signs of either oxygen or nitrous gas, but will consist entirely of azot.

If on the other hand 100 measures of common air be thrown up to 72 of nitrous gas, in a wide vessel over water, such as to form a thin film of water, and an immediate agitation be used, both the oxygen and the nitrous gas will, as before, totally disappear, and the residue, as before, will also be 75 or 80 measures of azot.

If in the last experiment less than 72 measures of nitrous gas be used, there will be a residuum containing some oxygen; if more, the residue will contain nitrous gas.

From these elementary experiments Mr. Dalton infers that the oxygen, contained in 100 parts of common air, may unite totally either with 56 parts of nitrous gas, or with 72, double that quantity, but with no intermediate portion. To infuse the former effect, the gases must be mixed in a narrow vessel without agitation; to infuse the latter the vessel must be large, and the points of contact between the ingredients must be increased by agitation. But in the ordinary circumstances of the experiment, Mr. D. supposes that both these effects partially take place, so that one part of the oxygen unites with the nitrous gas in the smaller proportion, and another in the larger; and hence he accounts in a very ingenious and satisfactory manner for the greater part of the apparent anomalies which have been observed in the employment of nitrous gas in eudiometry. Therefore, he observes, to use nitrous gas for the purpose of eudiometry, we must attempt to form one or other of these combinations wholly, and he prefers that with the smallest proportion of nitrous gas, in the following way:

Take a narrow tube of the dimensions above given, add 100 parts of common air to about 36 of nitrous gas, and when the diminution is complete, without agitation, transfer the residue to another tube and measure it; then 75-1/2ths of the loss will be due to the oxygen present.

But a stronger objection arises against the employment of nitrous gas in its present state, owing to the difficulty of obtaining this gas of uniform purity. From a very elaborate series of experiments on this subject, undertaken by Humboldt and Vauquelin (Ann. Chem. tom. 28.) it appears that when nitric acid of any strength is poured upon copper wire (which is the usual mode of obtaining nitrous gas,) an effervescence more or less vehement takes place, and a gas is discharged, consisting of nitrous gas, but always mixed with more or less of azotic gas, and sometimes nitrous oxid, and it is this varying portion of azot which constitutes the chief difficulty and trouble in the employment of nitrous gas in eudiometry. The quantity of azot is found to depend largely on the strength of the acid being from about one-tenth to one-half the entire gas. According to Humboldt, the degree of strength of acid which produces the purest nitrous gas, is that in which the specific gravity is about 1.05 to 1.17, or from 17 to 21 of Beaune's electrometer. Mr. Dalton finds that nitric acid diluted with an equal bulk of water poured on copper and mercury, without any artificial heat being used, gives a nitrous gas nearly pure, or with only from two to three per cent. of azot.

The proportion of azotic impurity in any mixture of this with nitrous gas, is most conveniently ascertained by agitating the gas with a solution of green sulphat of iron, which absorbs the nitrous gas without materially affecting the other. This experiment was first made by Dr. Priestley, who found that the solution of iron acquired thereby a reddish or olive brown colour, and a very acid tincture.

Other chemists have also found a certain quantity of ammonia in the solution.

To obviate the objections brought against the use of nitrous gas, in the gaseous form, as an eudiometer, Mr. Davy has ingeniously applied to this purpose the solution of sulphat or muriat of iron, saturated with nitrous gas as above-mentioned, and this, with a few precautions, is found to answer with great precision, and to be applicable with little trouble to all cases of the analysis of gases where oxygen is one of the sublimates sought for. The mode of use in ordinary cases is as simple as possible. The gas is put into a graduated eudiometer tube, some of the solution is poured in, and by very gentle agitation for about a minute, the whole of the oxygen is absorbed. The chief precautions required are, not to use the same solution twice, to keep it in a well-stopped bottle, and particularly to remove it from the gas under analysis as soon as the utmost degree of absorption is produced, as after this time a small increase of bulk is again observable in the residue, owing probably to some evolution of gas from the solution. It is also found that if the solution be very highly impregnated with the nitrous gas, and much daily agitation be used, a little of the nitrous gas escapes in the gaseous form into the eudiometer tube, which may be removed by the application of a little sulphur or muriat of iron. One cubic inch of the impregnated solution of moderate strength will absorb about five or six cubic inches of oxygen gas.

Of the sulphures as eudiometers.—The eudiometer first employed by the illustrious Scheele, in his original experiments on the constitution of the atmosphere, so early as the year 1779, was a mixture of iron filings and flowers of sulphur, moistened with a little water. By confining a cup of this mixture under a jar of common air over water, this excellent chemist observed an absorption soon to begin, the water gradually rising in the jar for about eight hours, after which no further diminution took place, and the refractory gas confined chiefly of azot.

This valuable elementary experiment has been employed in eudiometry with great advantage, but modified considerably, and a few precautions must be taken to avoid inaccuracies. In the first place it is to be observed that this mixture of iron filings and sulphur is slow in its operation, and moreover, a quantity of hydrogen gas is given out towards the end, which mixes with the refractory azotic gas. To lessen the duration of the experiment the liquid alkaline or earthy sulphures have been substituted to the mixture of iron filings and sulphur, with great advantage. When atmospheric air, confined in a tube, is shaken for a few minutes with a little of the liquid sulphuret of lime, potash, or soda, the whole of the oxygen is absorbed in a few minutes.

Guyton has proposed to hasten the absorption by heating the solution, but it has been found that in this case there is some danger of expelling from it a portion of sulphurated hydrogen gas, which would impair the accuracy of the experiment.

A more important source of error has been mentioned by Marti, (Journal de Physique, tom. 52.) which must be avoided. It appears from his experiments that liquid sulphuret of lime, (and probably the other liquid sulphures,) when recently made, is capable of absorbing a portion of azot as well as oxygen, which, though small, is sufficient to affect materially the result of a delicate experiment. Marti found that when one measure of common air was shaken with 20 measures of the liquid sulphuret of lime, the entire absorption amounted to as much as 26 per cent. of the air. But of these it is known that only about 21 can be-
be oxygen, and consequently about 5 of azot must have been absorbed. The experiment being repeated with the same solution, only 21 per cent. were now absorbed, so that the solution had been saturated with azot by the previous experiment. The same solution was then shaken with pure azot, but no absorption took place, which confirmed the fact of the previous saturation of the sulphuret with azot. On the other hand, when a perfectly fresh solution was used, which immediately after being prepared, had been allowed to cool in a well-closed bottle, and only a twentieth of its bulk of common air was confined with it, the latter in a few minutes had diminished full one-half.

It is easy to avoid errors from this circumstance. All that is necessary is, previously to using the liquid sulphuret as an eudiometer, to shake it for a few minutes in a bottle of common air, and it is never necessary to use more than about two measures of the sulphuret to one of common air. With these precautions, the sulphuret proves a very useful and accurate eudiometer.

Of hydrogen as an eudiometer.—This ingenious method was proposed and employed with great success by the celebrated Volta. It consists in mixing known proportions of pure hydrogen gas with the air to be examined; in a very strong glass tube, through which a metallic communication is made, and detonating the contents by the electric spark. After the shock, a sudden diminution takes place, owing to the production of water by the detonation of the hydrogen with the oxygen contained in the air examined. The exact saturating proportion between the two gases has been variously given, but an excess of hydrogen should be used. One hundred parts of oxygen require at the highest exhaustion somewhat less than 200 of hydrogen for saturation; so that when equal bulbs of hydrogen and atmospheric air are used, there is an abundant allowance of hydrogen. Mr. Davy finds 60 of the latter sufficient for 100 of common air, and the diminution is very uniformly 60 parts with the above proportions; and hence, if common air contains 21 per cent. of oxygen, the saturating proportions of oxygen and hydrogen are 21 of the former to 39 of the latter.

The chief objection to the universal use of Volta’s eudiometer is, that it requires an apparatus to give the electric spark, which cannot be always procured; and in all experiments of this kind it is particularly desirable to employ one uniform mode of experimenting where general results are to be established.

Of phosphorus as an eudiometer.—Phosphorus has two different modes of combustion in common air, according to the temperature to which it is raised. One of these is rapid, and attended with the evolution of a prodigious quantity of heat and light, and it occurs when phosphorus is heated a little above its melting point, or in common language is set fire to. The other takes place in a temperature not exceeding from 90° to 100° at the utmost, and is that in which the phosphorus emits copious fumes, white in the day-time but highly luminous in the dark, and without any sensible emission of heat. In either case the phosphorus is consumed, or oxygenated; but it is the slow combustion without sensible heat that is alone employed in eudiometry. The whole apparatus required for the purpose is simple and convenient of application. Nothing more is necessary than to fix a fimb of phosphorus in a portion of glass tube run through a cork, which loosely fits the open end of the small jar which is to contain the air to be analyzed, and confine it by water. If the temperature is very cold, the process may be assisted by the warmth of the hand. The phosphorus is immediately surrounded by the white luminous fume, which slowly falls down to the surface of the water, during which time the oxygen of the air is gradually absorbed by the vaporized phosphorus, and in consequence the bulk of the contained air is diminished. The absorption of oxygen is complete when the contained gas is no longer luminous, which, in a small jar with a fimb of phosphorus that travels nearly its whole length, requires about half an hour at the heat of from 70° to 85°. The process succeeds equally well at a lower temperature, though a longer time is required. The heat cannot be safely raised more than about 85° or 90°, without danger of kindling the phosphorus, which may be avoided by observing that it melts and becomes glibly just before it catches fire.

The exact operation of the slow combustion of phosphorus used in this experiment has been very happily explained by Goettling and Berthollet. When phosphorus is exposed to air at any temperature below that of rapid combustion, the first effect seems to be a solution of the surface in the azot of the surrounding air, and this phosphorized azot instantly unites with the oxygen, becomes thereby luminous, and the phosphorus acid absorbable by water is generated. Hence it is (strictly speaking) only that portion of phosphorus which becomes dissolved in the azot which is the eudiometrical substance; and in confirmation of this it may be added that phosphorus inclosed in pure oxygen gas is not in any degree luminous, but remains perfectly inactive till the heat is raised to the point of strong combustion. On the other hand, if the purest possible azot is passed into a jar full of water, and containing a fimb of phosphorus, the gas only becomes luminous for a very short time, after which this appearance ceases, but the azot continues to saturate itself with phosphorus. If now a bubble of common air or oxygen is let up into this phosphorized azot, the luminous appearance immediately returns, and continues till all the oxygen is exhausted. Phosphorus, therefore, furnishes also an useful test of the purity of azot, by not becoming luminous in it, but by enabling it to become luminous as soon as a particle of oxygen is added.

One circumstance of importance should be added, which is, that azotic gas in saturating itself with phosphorus is found to expand about 1-40th of its bulk, which accounts for the apparent difference in the composition of common air as determined by phosphorus or by other eudiometrical substan ces. After all absorption has ceased, when phosphorus is used, the apparent loss is not more than from 20 to 21 per cent. of the atmospheric air employed, whereas with all the other eudiometrical processes the loss is from 21 to 22 per cent., but this difference may be chiefly accounted for by the expansion of the residual azot from its saturation with phosphorus. It is therefore more accurate to diminish the bulk of the residuum by 1-40th, and this diminution must be thrown into the side of the oxygen absorbed. In analyzing an air much more oxygenous than the atmosphere, in proportion as the azotic ingredient diminishes, the operation of the phosphorus in removing the oxygen becomes less rapid and powerful, and hence either a dilution with pure azot is advisable, or some other eudiometrical test should be preferred.

The general results of all the operations of atmospheric air have established it as an incontestible truth, that scarcely any difference exists in the proportion of oxygen, whatever be the height, season of the year, climate, and temperature at which the experiment is made, and even where the greatest changes would be expected from vitiation of air by the respiration of crowded assemblies of people, and the like, the loss of oxygen is much less than would have been generally expected. Hence the utility of eudiometry as a measure of the purity of the atmosphere has much diminished since this
Several kinds of apparatus are used in eudiometrical experiments, some of which may be here described.

Dr. Boyle's eudiometer is the following. (Plate X. Chemistry, fig. 1.) It consists of two parts, the lower of which is a short thick glass tube, with an upper and a side opening; the latter closed by a glass stopper, and the other receiving a graduated tube closed at the top, and accurately fitted by grinding. To use it, take off the tube, and fill it quite full of the gas to be examined, and also fill the bottle with liquid sulphuret of lime, and, without shaking, fix it in water, and then immerse the open end of the graduated tube in the same water, and slide it upon the bottle and thrust it in. Then take out the bottle and tube, and shake them, to bring the sulphur to a particle in the contained gas, and immerse the bottle from time to time in water, opening the side stopper to allow the water to rush in, and finally the vacuum made by the absorption of oxygen. This will indeed somewhat dilute the eudiometrical liquor, but not so much as to prevent it from acting. When all absorption is over, the quantity of residual gas is found by inspection of the scale of the graduated jar.

The apparatus for detonating oxygen and hydrogen, which forms Volta's eudiometer, consists of a very thick graduated glass tube, open at bottom, and towards the top are two sealed holes, admitting the wires by which the electric spark is taken. A very useful improvement in this apparatus has been introduced by Mr. Pepys, to prevent the violence of the shock, either from breaking the glass (with moderate quantities) or from throwing out any of the mercury when confined by this fluid. In this improved apparatus, the thick graduated jar is fixed to a heavy iron stand, which has a strong spring near the foot, that draws out in the manner of the fire-iron, when the concussicn is given, and thus takes off the recoil. Fig. 2.

An improved and very useful apparatus for nice eudiometrical experiments, is given by Mr. Pepys in the Phil. Trans. for 1807, to which we shall refer our readers for a full description. It consists of a graduated tube, an elastic gum-bottle, furnished with a perforated glass stopper, closely fitting to the end of the tube, and another very small tube with a surrounding jar for the purpose of measuring quantities less than the smallest subdivisions of the larger graduated tube. The eudiometrical liquor is put into the elastic gum-bottle, and by pressure is injected strongly up into the larger tube, by which means the action is facilitated, and none of the liquor is spilled or wasted.

EUDOCIA, in Biography, a Roman empress, wife of Theodosius the younger, was daughter of Leontius, an Athenian philosopher. She was educated in the sciences and religion of ancient Greece, and so great were her mental acquirements and personal beauty, that Leontius divided his property between his sons, conceiving the child to need of nothing to recommend her to a proper husband. About the year 421 she was married to Theodosius, when she denounced the errors of paganism, and received the baptismal name of Eudocia, having previously been called Athenasia. She was reconciled to her brothers; and, having invited them to court, conferred upon them offices of rank and power. Upon the throne, as in a more humble station, she cultivated the learned, and employed her talents in the service of the religion to which she was a convert. She put into verse several of the books of the Old Testament, and wrote paraphrases on some of the Jewish prophets. She lived for a considerable time in harmony with her comfort; and after the marriage of her daughter to the emperor Valentinian III., she was permitted to pay her vows in a splendid pilgrimage to Jerusalem; and at Antioch she pronounced an oration to the senate from a throne of gold. After her return, suspicions were excited of her fidelity in the death of her husband by his sister Pulcheria, who had been the means of bringing them together by marriage. The object of these suspicions was Valentinian, a handsome and accomplished man, who held high offices at court, and who was put to death on the occasion. Eudocia was reduced to a private condition, and allowed to seek a retreat in the Holy Land, where she had formerly obtained a high degree of credit by the magnificence of her presents. Here she devoted herself to religious and devotional studies, and died in 460, at the age of 67. In her last illness, she affected the most solemn manner her innocence of the crime for which she had been dethroned and sufferers banishment. Moretti. Gibbon's Hist.

EUDOCRIS, in Ancient Geography, an episcopal town of Asia, in Pamphylia.—Alfo, an episcopal town of Asia, in the second Galatia.

EUDON, a river of Asia, in Caria.

EUDOXIANS, a party or sect of heretics in the fourth century, so denominated from their leader Eudoxius, a native of Arabissus in Armenia Minor, and patriarch of Antioch, to which he was advanced in 356, and Constantinople, to which he was promoted in 359, and which he retained till his death, in 370. He was a great defender of the Arian doctrine, though represented as somewhat fluctuating and unsteady in his principles. He was charged with being a bitter persecutor of the Catholics. Of his works, no remains are extant, except some fragments of a treatise "De Incarnatione Dei verbi," to which Cave (Hist. Lit.) has referred.

The Eudoxians adhered to the errors of the Arians and Eunomians, maintaining that the Son was created out of nothing; that he had a will distinct and different from that of the Father, &c.

EUDOXIOPOLIS, in Ancient Geography, an episcopal town of Asia, in Paphlagonia.

EUDOXUS, the Cnidian, in Biography, was celebrated as an astronomer, a geometer, a physician, and legislator, but was most particularly distinguished in the first of these characters. His first preceptor was Archytas, by whom he was instructed in the principles of geometry and philosophy; about the age of 25 he came to Athens. His knowledge of medicine is said to have been obtained in this way. A physician, named Theomedonous, observing the ardent defire which he manifested for study, notwithstanding his extreme poverty, prefulned that he possessed talents which deserved cultivation, and therefore took him to his house, and afforded him every means of accomplishing his wishes, enabling him, as his own patrimony was small, to attend the schools of the philosophers, particularly that of Plato. Eudoxus afterwards went into Egypt, accompanied by a pupil, named Chryphonus, and here he was introduced by Agesilas to king Nectanebus II., and by him to the Egyptian priests. He is highly celebrated by the ancients for his skill in astronomy; but none of his writings on this or any other subject are extant. Aratus, who has described the celestial phenomena in verse, is said to have followed Eudoxus; to whom is attributed the honour of bringing the celestial sphere and the regular astronomy from Egypt into Greece. Having left Egypt he taught astronomy and philosophy with great applause at Cyzicus, on the Propontis; and he afterwards removed to Athens, where he opened a school, and gained so high a degree of reputation.
reputation, that he was consulted on subjects of policy as well as sciences, by deputies from all parts of Greece. His death is generally referred to the first year of the 107th olympiad, 352 years before Christ. See Le Clerc. Hist. de la Med. Eloy.

Eudoxus is said by Fabricius (Bibl. Graec. lib. iii. c. 5.) to have written upon mufic, and he gathers from Theon of Smyrna, p. 94, that Eudoxus was the first who expressed the ratios of concords by numbers, and who discovered that grave and acute founds depend on the flow or quick vibrations of the founding body.

EUDRACINUM, in *Ancient Geography*, a town placed by the Itinerary of Antonine on the Alps, between Summus Penninus and Augustia Papatia.

EUDRAPA, EVA, or EDIR, a town of Asia, situated in Mesopotamia, W.S.W. from the town of Carmanda.

EUDROME, in the *Ancient Muses*, the name of an air played by lautohos at the Athenian games, instituted at Argos in honour of Jupiter. Hicorax the Argian was the inventor of this air.

EVE, the 'first woman,' and mother of the human race. The history of her formation and other particulars is recorded in the Hebrew Scriptures (Gen. ii. iii. iv.); and it is needless to recite from Bayle and others the absurd fables invented concerning her by the Jewish rabbis.

Eve. See *Vigil*.

EVEA, or EVA, in *Ancient Geography*, the ancient name of Byblos, a town of Phoenicia.

EVECTION, in *Astronomy*, the most considerable of the lunar irregularities, and the first that was known to the ancient astronomers. It was discovered by Ptolemy. Its general and constant effect is to diminish the equation of the centre in the fyzzygies, and to increase it in the quadratures. If this diminution and augmentation were always the same, the evection would depend alone on the angular distance of the moon from the fun; but the absolute value of the evection depends likewise on the distance of the moon from the perigee of her orbit. After a number of trials and observations, it was found that this inequality could be represented very exactly by supposing it proportional to the sine of double the angular distance of the moon from the fun, minus the mean anomaly of the moon. The coefficient to this proportion is 1° 26' 30".

The period of the evection differs but little from the periodic revolution of the moon: it is 27.178533 days. The evection is caused by the action of the fun upon the moon, and may be explained by supposing a change to take place in the excentricity of the moon's orbit, and at the same time a motion in the apogee.

Ptolemy supposed the epicycle of the moon to be carried along in an excentric circle, and that it was nearer to us in the quadratures than in the conjunctions and oppositions; so that to explain this inequality at the same time with the equation of the centre, he imagined an excentric and an epicycle. It is curious to trace the progress of these discoveries, and the history of the first observations of the evection has been transmitted in the words of Ptolemy himself. (Almagest. lib v. cap. 1.)

In observing, says he, with care, the order of this inequality, we took notice that there was no other than the first and simple inequality in the conjunctions and oppositions, and even in the quadratures when the moon was in apogee or perigee, (meaning by the Simple inequality the equation of the centre); but we may be assured that this is not sufficient to calculate the particular motion of the moon in other aspects. The second inequality, (i.e. the evection,) is connected with the distance of the moon from the sun, and is re-established and disappears in the conjunctions and oppositions, and is greatest in certain quadratures. We discovered this inequality by the observations transmitted by Hipparchus, and by those which we have made by means of an instrument constructed for the express purpose of measuring the difference of longitude on the zodiac between the moon and the sun.

Ptolemy found that there was a difference of 2° between the observed and the calculated place (when the first inequality or equation of the centre was only used) when the moon in quadrature was three times from the apogee. (Almagest. v. 3.) Thes the fun being in the apogee or perigee of the moon, the inequality, which should have been 5°, was found to be 1° 26' 30" to explain which he supposed the epicycle as above-mentioned.

Copernicus, to explain the evection, employed two epicycles. The small epicycle is supposed to describe the circumference of the great one in the space of an amnathlic revolution, and contrary to the order of the signs; while the moon describes the small epicycle contrary to the order of the signs in 14° 18', or in the space of half a synodical revolution.

It was in this manner that the second inequality of the moon, called now the evection, was explained till the time of Tycho. It was called by Ptolemy "epyzoeex, epicychi qutam annunntum," by Copernicus "proplapherein leunci vel minoris epicychi," by Tycho "proplapherein excentricitatis," and by Bouillaud "evection," which name it still retains.

The evection was explained in a different manner by Horrox about the year 1649; but his theory was not made known till 1673, when Flamstead calculated his new tables of the moon, upon the principles and numbers given him by Horrox. These tables were published in the posthumous works of Horrox in 1673. This hypothesis is the same with that of Arzachel, an astronomer who flourished in Spain in 1680, when that country was possessed by the Arabians, and who applied it to the motion of the fun.

Let T be the centre of the earth (Plate XII. *Astronomy*, fig. 107); C the mean place of the centre of the orbit which a planet is supposed to describe; so that TCA may be the line of the apicides, and T0C the excentricity of the planet. If the centre of the orbit, instead of being fixed in C, be supposed to describe the circumference of a small circle ABC, there will result a double effect: 1. The line of apicides T A will change its position, and instead of remaining constantly in the direction TCA, it will pass, for example, into the position T G, and will make with the first position an angle AT G. 2. The excentricity, instead of being equal to the original quantity T C, will become T G, T B, &c. This hypothesis was invented by Arzachel to explain a supposed diminution of the excentricity of the fun's orbit, which he had inferred from some defective observations, and has not only been adopted by Horrox to deduce this inequality of the moon, but by Flamstead, Halley, and Newton, for the same purpose.

Kepler had already announced that he employed an excentricity of the lunar orbit which varied every year; but Horrox was led likewise to this hypothesis by observations of the diameter of the moon; for about this time the application of micrometers to telescopes enabled astronomers to determine the apogee and perigee of the moon much more exactly than formerly. From these observations he perceived that the apogee of the moon was about 25 more advanced when the distance from the sun to the apogee of
of the moon was 45° or 225°, than when it was 135° or 315°; hence the motion of the apogee, instead of being uniform, seemed to have an annual libration of more than 12°. This variation in the motion of the apogee being once known, its connection with a change of excentricity was not difficult to be discovered. Both Halley and Newton employed the above hypothesis. According to the method of Newton the centre A of the orbit of the moon (fig. 108.) describes a circle A C B, the earth being at T. Thus T C expresses the mean excentricity of the moon; T A the least and T B the least; T C being to C B as the mean excentricity is to its difference from the least, or as the total line is to the line of 12°18', which is the greatest equation of the apogee. It is likewise supposed that if the angle A C G be taken equal to double the annual argument, or the distance between the fun and the mean apogee of the moon for a given time, the angle C T G will be the equation of the apogee, and T G the excentricity for the same time. Then in the triangle T C G, the two sides and included angle being given, we have the fun of T C, and C G is to their difference as the tangent of half A C G, (or the annual argument, whose double is A C G,) is to the tangent of half the difference of the unknown angles. This is reduced to a conflant logarithm, which added to that of the tangent of the mean annual argument, gives the annual argument corrected; and this, added to the place of the sun, gives the true place of the apogee of the moon. This is the form which Halley employed in his lunar tables.

It cleared the observation of Flamsteed, Halley, and Newton, that this equation might be calculated without supposing a variable excentricity and libration of the apogee. Enter employed this method, of which the following is the demonstration.

Let L (fig. 109.) be the moon, T the earth, C the mean centre of the lunar orbit, G the centre for a given moment; C T the mean excentricity of the moon, C L T the half of the mean equation of the orbit, because it is the double excentricity which produces the whole equation; G L T the half of the excentricity for the time given, and represented in Newton's method by an augmentation of excentricity; C L G is the difference of these two equations, or the effect which the change of excentricity, and the libration of the apogee, produce upon the half equation. To find by a simple operation this angle C L G, which is the half of the excentricity, it must be remembered that when this angle is the greatest, or when L C is perpendicular to C G, the angle C L G is 45°, that is, the conflant relation between C L and C G is such, that the value of L can only be 45° when it is the greatest, or 135° for the whole excentricity. When the angle L C G is oblique, the angle C L G will diminish, and that in the ratio of the perpendicular G D to the line C G, or as the line D C G to radius. Hence the excentricity will be 80° fin. D C G; but the angle D C G = A C L - A C G is the mean anomaly of the moon, minus twice the distance of the fun from the moon's apogee, or what is the same, twice the distance of the moon from the sun, minus the mean anomaly of the moon, which forms the argument of excentricity.

The half excentricity, or angle G L C, is equal 45° sin.
(2 diff. C - m. anomal.) This is the form in which it is usually found in the lunar tables.

When we come to treat of the theory of the moon, and the lunar inequalities, we shall have occasion to resume this subject, and to shew how correctly this equation is derived from the law of universal gravitation; we shall confine ourselves at present to a very general explanation of the physical cause of this phenomenon.

Vol. XIII.
for example, if we name the number of days elapsed since a given epoch as that of the tables t. The angle 2 dil. \( \theta \) •

or simply 1° 20' 28" fin. m. t. making \( m = \frac{360}{27.178533} \).

EVEILLON, James, in Biography, was born at Angers in the year 1542; he was distinguished at a very early age for his literary acquirements, and obtained considerable ecclesiastical preferment, in the year of his birth, till at length he was made grand-vicar to the bishop. Eveillon was locked up to for his superior knowledge of the rights and usages of the church; and of every subject connected with the crown, the fathers, and the canon law. He was not unfrequently employed in matters relating to church discipline, the reformation of abuses, rituals, and monastic institutions. His principal works were entitled "De Precellimoniis Ecclesiasticis, in quo eorum Institution, Signification, Ordo, et Kitus explicatur."—"De recta Philosophia," and "A Treatise on Monitions and Excommunications," which has borne a high character in the Catholic communion. Eveillon died at the age of 79, in the year 1621. He was a man of extensive benevolence, having obtained the title of father to the friendless, and the poor, to whose relief he devoted the whole of a liberal income, excepting what was absolutely necessary for his own support. Moteri.

EUELPIDIUM, a kind of fluid colloryum.

EUELPISTI, a plaster described by Scribonius Largus.

EVELYN, John, in Biography, the son of Richard Evelyn, esq., was born at Wotton, in Surrey, in 1620. He received the early part of his education at Lewes, from thence he went to Christ church, Oxford. During the civil wars he spent his time on the continent, particularly in France and Italy. He married in the year 1647 the only daughter of Sir Richard Browne, the king's minister at Paris, and returned to England about the year 1651, where he employed himself in literary occupations, chiefly in translating from the French and Latin. He was much inclined to a life of learned leisure; and in his zeal to forward a similar plan for others he formed a scheme for the erection of a college, where persons might live together for the erection of a college, where persons might live together for the erection of a college.

In 1657 he published a favourable account of the king's character, with a view of preparing his countrymen for the restoration of monarchy, and on the return of the exiled Charles, he was graciously received, and introduced into public life, though without abandoning his literary pursuits. In 1662 he published a curious and learned work, containing much useful and important information, entitled "Sculptura, or the Hiftory and Art of Chalceography, or Engraving on Copper." This piece was reprinted in 1755, with additions. Mr. Evelyn practised the art himself, and is introduced by Mr. Walpole into his catalogue of English engravers. On the institution of the Royal Society, he was nominated among the first fellows and members of the council, and he ever after continued a zealous and truly active member of that learned body. At some of the early meetings of the society was read his discourse on forest trees, which was the basis of the treatise entitled "Sylva, or a Discourse of Forest Trees, and the propagation of Timber in his Majesty's Dominions, to which is annexed Pomona, or an Appendix concerning Fruit Trees, in relation to Cyder, &c." As a sequel to this work, he afterwards published his "Terra, a Philosophical Discourse of Earth, relating to the Culture and Improvement of it for Vegetation, and the Propagation of Plants." Both these works have been reprinted several times. The edition of the Sylva by Dr. Andrew Hunter, of York, is with plates of all the trees, in the parts of that system are accurately displayed according to the Linnaean system.

Mr. Evelyn was appointed, at the desire of the king, in 1664, one of the commissioners of the sick and wounded seamen, and like wise a commissioner for rebuilding St. Paul's cathedral. How well fitted he was for the latter office was shown by a work which he published, entitled "A Parallel of the Ancient Architecture with the Modern," translated from the French of Roland Freart, sieur de Chambray; with additions from Alberti and others. He resided at this period at his house of Sayes-court, near Deptford, which he had in right of his wife; here he cultivated a garden, and was regarded as a great improver of the art of horticulture, and celebrated for the pains which he took in the introduction of exotics into this country. During the reign of Charles, a board of trade was formed, and Mr. Evelyn was appointed one of its members. On this occasion he drew up a small treatise on the origin and progress of navigation and commerce, with an insertion of the king's title to the dominion of the seas.

Among the papers which he communicated to the Royal Society is a curious letter, given at length in the Biographia Britannica, describing the mischief's done to his garden by the severe winter of 1683-4. This letter will be read with interest, as affording information of the perennials at that time chiefly cultivated in England, and as stating the dire effects of rigorous frost. We shall give the concluding paragraph:

"The vines have escaped, and of the equitable plants and fallads, molt, except artichokes, which are universally loft; and what I prefer before any fallad whatever, eaten raw when young, my sampler is all rosted to the very root. The arborecent and other fedefus, aloes, &c. though houled, perish'd with me, but the yucca and opuntia escaped. Tulips, mame are loft, and to the Conflantine purniculfs, and fuch tubeflores as were not kept in the chimney corner, where was a continual fire. Some anemones appear, but I believe many are rosted. My tortofiche, which by his conftant burying himfelf in the earth at the approach of winter, I look'd upon as a kind of plant animal, happen'd to be obftructed by a vine-root from mining to the depth he was ually wont to inter, is found fkrk dead, after having many years escaped the feverest winter. Of fish I have loft a few, and the nightingales, which for being a fhort winged bird, and fo exceedingly fat at the time of the year, we commonly fuppofe them to change the climate, whereas indeed they are then hardly able to fly an hundred yards, are as brisk and frolic as ever; nor do I think they alter their summer rations whatever may become of them, all the winter."
much elegance, was intended to procure, if possible, a public establishment for the Royal Society. Mr. Evelyn died in Feb. 1706 in his 86th year, having passed his days in useful and elegant pursuits, and distinguished by benevolence, piety, and integrity. Bioi. Brit.

Evelyn, John, son to the former, was born Jan. 14, 1654, at his father's house at Deptford. He was at a very early age admired for his rapid progres in knowledge, so that in the year 1666 he was sent to Oxford under the special care of Dr. Bathurst, till he could be admitted a gentleman-commoner, which was in the Easter term, 1668. It does not appear that he took his degrees there, but returned to his father's house, where he prosecuted his studies with much diligence and success. During his residence in Trinity college, he is supposed to have written the elegant Greek poem which is prefixed to the second edition of the Sylva. He became deeply learned in the ancient and modern languages, and cultivated poetry, of which there is evidence by a translation "Of Gardens, first written in Latin by Renatus Rapius." This was published when the translator was a youth of nineteen years of age only. He afterwards translated Plutarch's Life of Alexander the Great from the Greek; and from the French he gave a translation of "The History of the Grand Viziers, Mahomet, and Achmet Coprogli." He was likewise author of several poems, two of which have been chiefly admired, the one "On Virtue," and the other entitled "The Remedy of Love," and have been inferior in Dryden's Miscellanies. Mr. Evelyn was a man of business as well as a cultivator of literature, and was appointed one of the commissioners of the revenue of Ireland. He died in the prime of life, in London, March 24, 1698, in the forty-fifth year of his age, leaving behind him two sons and three daughters. Bioi. Brit.

EVERMOLOS, (from w. well, w. in, and Balka, to eat,) a person skilful in setting bones.

EVER FOOT, in Poetry. See Foot.

Even number, is that which may be divided into two equal parts or moieties. See Number.

EVERELADS, in Geography, a river of England, in the county of Oxford, which runs into the Isis, about 5 miles W. of Oxford.

EVEREUS, a town of Norway, 18 miles N. of Drammen.

EVENING STAR, in Astronomy. See Vesper.

Evening island, in Geography, a small island in the Pacific ocean. N. lat. 2° 46'. W. long. 133° 1'.

EVENLY even number, is that which is exactly divisible by an even number taken an even number of times; such is 32, since it is divisible by 8, taken four times.

EVENLY odd number, is that which an even number measures by an odd one; as 30, which is measured by 6, taken five times.

EVERUS, in Ancient Geography, a river of Aisa Minor, according to Pliny, who says that the towns of Lynneia and Miletus were built upon its banks. The inhabitants of Adamittium drew water from this river by means of canals. Strabo.

EVERUS, Fidari, a river of Greece, in Attica, which took its rise towards the north-east in Mount Pindus, on the frontiers of Thessaly, and passing through the territories of the Ionians, Ophecians, and Apodoti, watered Calydon, and discharged itself into the sea; to the west is the town called Chalcis. It was on the banks of the Evenus that Hercules, according to the fable, flew the centaur Nessus.

EVERARD'S sliding rule. See Sliding.

EVERBODE, in Geography, a town of France, in the department of the Dyle; 5 miles N. of Diefl.

EVERDINGEN, Caesar Van, in Biography, a painter of histories, portraits, and landscapes, born at Alkmaer in 1621. The writer under whom he studied, Van Bronckhorst, of whom he learned and encouraged his superior talents from among the rest of his disciples. He had a lively invention, and painted with freedom and firmness, and a good force of colouring.

Many of his pictures are spoken of in terms of praise; but the one selected as his principal performance is the representation of the victory of David over Goliath. It was painted on the folding doors of the organ in the great church at Alkmaer; and the sketch of it was preferred in the council chamber of that city; it was painted in 1643. He died in 1679, aged 73.

EVERDINGEN, Aldret Van, a landscape painter, whose merit was very considerable. He was the nephew of Caesar Van Everdingen, and was born in the same city, Alkmaer, in 1621. Having first attended to the instructions of Roland Savery, he afterwards greatly improved by those of Peter Melyn; whom at last he surpassed in skill. He delighted most in the grand scenes of nature, or rather in the most romantic features, such as rocks, torrents, and cathedrals, which he executed with great freedom and variety of touch. In his time he had no superior, but Jacob Ruisdau followed him immediately, was indeed perfectly contemporary with him, and in his own stile left him far behind in the brilliancy and force of his colours and execution, and the choice of his forms. However, Everdingen is highly deserving of great praise for the care which he took to make himself acquainted with the effects of nature, and the truth with which he marked them. He made a voyage up the Baltic, and was much gratified by and made much use of the scenery, which the romantic coasts of that sea, and of Norway, (which he also visited) afforded him. He died in 1679, and left behind him a great number of drawings, both of real views and compositions, which are very freely wrought. He was thought not to succeed so well in large works as in smaller ones, tho' coming more within the management of the men of pencilling, which characterizes his stile of execution. The latter are very highly and very deservedly valued in Flanders and Holland.

EVERDINGEN, in Geography, a town of Holland, in Guelders; three miles W. of Culemburg.

EVERET'S BRIDGE, a place of Nansemond county, in Virginia; where is a post-office; 266 miles from Washington.

EVERGEM, a town of France, in the department of the E Louis, and chief place of a canton in the district of Gann. The place contains 6878, and the canton 13,176 inhabitants, on a territory of 6741 kilometres and four communes.

EVERGETAE, in Ancient Geography, a people of Asia, placed by Strabo in the vicinity of Dara.

EVERGETES, Evergetes, a Greek term, signifying benefactor, being formed of w. bene, well, and pote, work. It is still retained in our language by way of addition or epithet, given to two princes or kings of Syria and Egypt, who succeeded Alexander. Thus we say Ptolemy Evergetes, king of Egypt, Antiochus Evergetes, king of Syria.

EVERGREEN THORN, in Gardening. See Mespilus Pericaucina.

EVERGREEN Trees, are such trees, whether of tall or shrubby growth, as constantly retain their leaves during the whole year. There is a great number of this sort of plants,
plants, which will be particularly described under their proper genera.

These kinds of trees, shrubs, etc. are increased in different modes, according to their particular nature, as by seeds, layers, cuttings, suckers, &c., which is fully shown under the culture of the different sorts, but principally in the spring season, though occasionally in the summer, and frequently in the early autumn.

The proper seasons for planting them out are the early autumn or latter spring months, according to the nature of the soil. Where the soils are of the more stiff, retentive, moist kind, the more advanced spring months are the best; but where they are of the light, dry, loose description, the beginning of the autumn is the most proper period; as in the former case the plants will be in no danger of being injured by flagrant moisture in the winter, and in the latter there will be no risk of their being destroyed by the heat and dryness of the summer, before they become perfectly established in the ground.

In the planting of evergreen trees, it is seldom necessary to dig them into any great depth, as they are very liable to be injured by deep planting. There is likewise another circumstance that ought to be regarded, which is that of having the mould in which they are to be set sufficiently fine, and the roots well bedded in it, without being too much cut in or retrenched. In all cases the loose mould should be well trodden in about them; and the more tall growing kinds well supported with strong stakes, so as to keep them properly ready in their situations.

Trees of this kind, as well as other sorts, are destroyed for want of attention in this respect, as when once they get loose they soon die by the motion which takes place. The pruning or cutting in of this sort of trees, where it is necessary, should be performed either in the more advanced spring season, or the latter part of the summer, but never in the winter season, as they are liable to much injury from cold. This is equally necessary to be regarded in the chipping of hedges constituted of plants of this sort.

Many of these sorts of trees and shrubs are sufficiently hardy to admit of being planted in most sorts of soils and situations. The tall-growing kinds are well adapted for affording ornament and variety in mixture with those of the deciduous class in extensive plantations, and such as are of a shrubbry growth in the borders, clumps, and other parts of ornamented grounds. In these situations they should be suffered as much as possible to take their natural growth, especially the fir kinds, and in the others only very little cut in, and the dead wood removed from them.

In the forming of hedges various plants of this sort are employed; but the best are those of the holy, yew, evergreen privet, and box kind; though the common laurel and laurus might be the most advisable, where they are required to be lofty. These are likewise capable of being trained so as to cover naked walls, palings, or other unpleasant objects. Hedges formed of these plants should be clipped once or twice during the summer season, so as to keep them in perfect next order.

Various ornamental devices were formerly made with these and other sorts of evergreens in gardens; but these are at present little in use, as a better and less troublesome taste prevails.

It has been remarked by the author of "The Philosophy of Gardening," that in these sorts of trees and shrubs the buds rise in the bofoms of the leaves, which, as they are not shed in the autumn, continue to oxygenate the juice of the plants, and supply nutriment to the buds during the fine days in the winter and spring seasons, surviving till nearly the middle of the summer, when the new buds have expanded leaves of their own. It is hence conjectured, that evergreens provide no store of nourishment in their roots, or alluvium in the summer for the support of their enfuing annual buds, and of course have probably no bleeding lea, as is the case with those of the deciduous kind.

And there is another circumstance which has been stated by Dr. Milne, in his botanical dictionary, to take place in respect to evergreen trees, which is, that when they are engrafted on those of the deciduous sort, it determines the latter to retain their leaves. This is asserted to be confirmed by repeated experience, in grafting the hawthorn, (luteo-croftes) an evergreen, on the common cherry, (cerata), and the (hucer), an evergreen oak, on the common oak. And it is probable that many other facts of the same kind may exist, though they have not been noticed by common gardeners.

**EVERLASTING.** See GNAECIUM.

**EVERLASTING FEN.** See LATHYRUS.

**EVERLASTING FEN, in Agriculture,** is the common name of a perennial plant of the vetch kind, which grows naturally in fome situations in this country, and is capable of being cultivated with great care and advantage as a green food for cattle or other flock, where the soils are inclined to be of the more heavy loamy kinds; as it affords a large produce of the most nutritious kind of fodder. Where it is suffered to lie the grass is fed, it has been found in the few trials that have been made with it to pollute a highly fattening property when consumed by animals.

**EVERRAIOR.** Derived from cys and verris, is an evergreen, in Antiquity, an officer who was obliged in a solemn manner to cleanse such houses as were defiled by dead bodies, called domus funeris.

**EVERRICKULUM, from cys and verris, to sweep away,** a kind of instrument, in Surgery, resembling a spoon, and used for taking away any small fragments of the stone, which may remain behind in the bladder, in the operation of lithotomy.

**EVERS, in Rural Economy,** a term sometimes provincially applied to those fields which open; in which case the top rail has a bolt of iron driven through it at one end, the other falling into a notch in the opposite post, by which contrivance an opening can occasionally be readily made.

**EVERSBERG, in Geography,** a town of Germany, in the kingdom of Württemberg; 54 miles N. of Cologn.

**EVERY YEAR'S LAND,** in Agriculture, is a term applied to such lands as have been cropped with what are termed brown and white crops, or pulse and grain crops, in alternation or succession for a very great length of time, without the intervention of any sort of fallow. Mr. Marshall has remarked that extensive common fields in Gloucestershire have been conducted under this fort of management for "perhaps centuries:" and the same is the case in some other countries.

**EVES-DRORERS, in Law.** See EAVES-DROPPERS.

**EVERSHAM, or ESHEAM, in Geography,** is a borough and market town, pleasantly situated upon a rising ground, above the banks of a navigable river, named the Warwickshire Avon, in the hundred of Blakenhurst, and county of Worcester, distant from London ninety-six miles. This place claims high antiquity, and is not less notable for its subsequent celebrity. The first notice of it upon record, like the origin of most towns referable to the Saxon period, is the account of Ewas, bishop of Worcester, having founded a monastery here in the year 709; and amply endowed it by the assistance of Kenred, son of Wulphere, king of Mercia. This was one of the mitred abbeys; its abbot
Evesham.

Sit in the house of peers as a baron of the realm; its privileges were numerous and extensive, and the revenues on the dissolution were valued at the annual sum of £1837. Of the building, which from records appears to have been immense, few vestiges remain. The large elliptical arch, decorated with rich but mutilated imagery, is still standing; and the tower noticed by Leland. "Clement Lichfield the last abbot of Evesham gave one, did very much coll in buildings of the abbey and other places longing to it.—He made a right sumptuous and high square tower of stone in the cemetery of Evesham. This tower had a great bell in it, and a goodly clock, and was as a gateway to one piece of the abbey." Itinerary, vol. iv. p. 108. This tower is a regular and beautiful structure, twenty-two feet by twenty-two, and one hundred and seventeen in height; and is generally considered the last monastic building erected under papal influence in England. Though the churches have towers, this still continues the flattening for the clock and bells.

In that part of the town called Bengworth, which may be viewed as a suburb on the eastern side of the river, over which the communication is formed by a landstone bridge of seven arches, float an ancient castle, probably erected soon after the Norman conquest. For in the year 1152, abbot William de Audville gained this fortress from lord William de Beauchamp, who held it for king Stephen, razed it level with the ground, and converted the site into a place of internment.

Evesham is a very ancient borough, enjoying numerous privileges, both by prescription and charter. It was one of the towns fossumed by writ to send members to parliament, in the twenty-third year of king Edward the First's reign, when he barely pretended to restore the Saxon constitution; and was one of the eight boroughs which had their elective franchise restored in the time of James the First. That monarch at the same time granted a charter to the town to be governed by a mayor, seven aldermen, twelve burgesses, and twenty-four affidants, recorder, chamberlain, who are also of the common council, and other subordinate officers. The mayor and four senior aldermen are judges of the peace, form a quorum, and have power to hold a sessions of oyer and terminer, and gaol delivery, to punish all crimes, except high treason, and execute felons within their liberty.

The town is much altered since Leland visited it: the houses, which then were what are called half timbered, that is, timber frames, having the open parts filled up with wattle and dab, are mostly well built with brick, the streets are wide and spacious, and the nobility of the air, with the beauty of the situation, induce many genteel families to take up their residence here. In the town are three parish churches, two in the part usually called Evesham, and one in Bengworth; a well endowed free grammar school, charity school, and alms house. The market, held on Mondays, is well supplied, and four annual fairs are held February the second, the first Monday after Easter, Whit Monday, and the twenty-fifth of September. From the latter returns to government under the population act, the number of houses appear to be 016, and of inhabitants 2837. The richness of the soil in the vicinity has been long an inducement to turn many of the fields into garden ground, and the peculiar fineness of the vegetable productions of this place has rendered Evesham gardens proverbial for unrivalled skill. They not only supply the neighbourhood, but also the city of Worcester, fourteen miles distant; Birmingham, thirty; and during the asparagus season Bath and Bristol, more than fifty.

Tindal's History and Antiquities of Evesham.

Evesham, Vale of. The fine tract of land comprised under this denomination, unrivalled in fame or fertility, is situated on the eastern and western banks of the river Avon, extending for several miles in various directions into Warwickshire, where it is bounded by the high land of the Ridgeway, and into Gloucestershire, where the Cotswold hills form a terminating barrier; and the south is washed by the river Severn.

It is described in Monastic history as having derived the name, which it gives to the town already described, from Eves, a Saxon, swine-herd to Egwin bishop of Worcester, in the latter end of the seventh century; this ham having been Egwin's property till he was dethroned by the pope, and his estates confiscated. Previously to this it was called Heth-holme, or Heath-field.

To those who wish to see what "fun and soil," unassailed by art, can do, parts of this district will furnish striking specimens. And to the admirers of agriculture other portions will evidence what wonders may be effected from aiding the efforts of nature by the application of art. The soil is principally a deep heavy loam, or rich loamy clay, of inexhaustible depth, equally calculated for corn, or pasture. And whether it be placed under an arable, or a grazing system, the produce and the profits alike exceed analogous belief. The vale of Evesham, says Leland, "is, as it were, for such an angle, the horreum of Worcestershire, it is so plentiful of corn," and justly has he characterized this productive spot. For the abundance of herbage is not equalled by the famous Tiley forest in the hundred of Marshland and county of Norfolk; nor can the crops of corn be surpassed, except by those described in Brydone's Tour as produced in the vales of Sicily. The rent of lands in the farms of this district is equal to that of accommodation lands in most other parts of the kingdom; yet persons who have occupied estates in some others, at an exceeding low rate on a comparison of the net proceeds from both, do not hesitate in deciding in favour of the higher rental. In this vale, about a mile distant from the town of Evesham, was fought the most memorable battle recorded in the annals of English history, between Simon de Montfort, the powerful earl of Leicester, and prince Edward, afterward king Edward the First; in which the earl was completely defeated, and the refractory barons, with most of their adherents, taken or slain. He has been not unaptly compared to the Roman conspirator Catiline, for, like him, he verified in his conduct the remark of Tiberius, recorded in Tacitus Ann. i. iv. c. 18. "Beneficiae et latitude latam, dum videntur exsolvi polet. ""Favours are only so long properly bestowed as they appear a probability, or at least a capability of return." After king Henry the Third had conferred upon him an accumulation of honours and emoluments, and even permitted him to marry the princes, his sister; he experienced from the earl the most ungrateful requital. He pursued the monarch with the most inveterate hatred; and by inflammatory speeches, and other overt acts, excited the most perplexing commotions, and disturbing intestine warfare, the kingdom ever experienced; under a pretence of restraining the predatory, reforming the government, and avertting and securing the liberties of the subject. The contest, however, was productive of good, intended by neither of the parties. The prince, when he had ascended the throne, determined to fill further curtail the enormous power of the barons; and by his writs summoned together, as his advisers, representatives from numerous cities and boroughs, as well as counties; the battle of Evesham therefore may be considered "as the origin of our present house of commons."
EUGENE

New Jersey, situated between the forks of Moore's creek, which runs north-westly to Delaware river; 16 miles E. of Philadelphia.

EUESTÚRIS, in Ancient Geography, a people of Africa, in the maritime part of Libya, to the west of the Anulites; whole country, according to Herodotus, was singularly fertile; whence it has been supposed that the famous garden of the Heliceides was found in their territory. This name, in its grammatical acceptation, signifies Occidental.

EUESTURIS, a town on the coast of Africa, which afterwards took the name of Berenice.

EVENT, in Geography, a river of Ruffia, which runs into the Dwina, near Kreutzburg.

EUETIA, from e, well, and etih, in Medicine, a good found habit of body.

EUETIA, St., in Geography, a town of Naples, in the province of Otranto, two miles N.E. of Alessano. Alco, a town of Naples, in Calabria Ultra, situated on a bay of the Mediterranean, to which it gives name. N. lat. 36° 21'. E. long. 16° 39'.

EUFTRA, a town of South Finland; 12 miles N.E. of Abo.

EUGALEUS, SEVERUS, in Biography, a physician of Doccum, in Friesland, known chiefly as the author of a treatise on the febrity, which once maintained a considerable character, and passed through many editions. Its title is "De Scorbuto Liber, cum Observationibus quibusdam, brevico et facilitate quinque curationes indications, 1604." But the treatise of Dr. Lind, on the same subject, in which the absurdities and ignorance of Eugaleus are pointed out, has superceded it. Elyot. Mangeti Bibl. Script. Med.

EUGANEI, in Ancient Geography, a people of Italy, towards the Alps.

EUGANO, in Geography, a mountain of Italy, in the west part of the Padoan, bordering on the Vicentin.

EUGENE, FRANCIS, of Savoy, in Biography, generally denominated prince Eugene, grandson of Charles Emanuel, duke of Savoy, was born at Paris in 1663, and ordained for the church. His mother, on account of her ill-conduct, was obliged to leave Paris. She retired to Bruffels, and young Eugene being deprived of her support, and having been disappointed in his expectations of preferment, went as volunteer to serve in Germany against the Turks. He, with other French volunteers, was recalled on pain, in case of disobedience, of perpetual banishment. He left the order at defiance, and so much distinguished himself in his first campaign that the emperor gave him a regiment. After the siege of Vienna was raised, he served in Hungary under the command of the duke of Lorraine and the elector of Bavaria. From this time his reputation increased, with every action in which he engaged, till, in the year 1697, he was appointed to the command of the imperial army. In the autumn of this year he entirely defeated the Turks at the battle of Zenta, in which the grand vizier and more than 20,000 men were left on the field, and the grand signior was obliged to make a precipitate retreat with the broken relics of his army. Eugene had hazarded this engagement contrary to the express orders of the imperial court; but in completely justified his conduct, that Leopold gave him a written authority to act thereupon according to his own judgment. He was now opposed by all the great French generals, but in every battle his exertions and prowess were crowned with success, and on returning to Vienna the emperor created him president of the council of war, and entrusted the military chief to him; but that chief was frequently ill supplied, which occasioned him more trouble than the most vigorous opposition in the field. He was frequently united with the duke of Marlborough, and by their talents and concert they obtained a decisive superiority over the French in Germany. At the celebrated battle of Blenheim, Eugene commanded the imperial part of the army, and had no small share in the success. In 1705, he was defeated in Italy, but in the following campaign he regained his reputation by marching across Lombardy in the face of the French army, and attacking the French in their intrenchments at Turin, over whom he obtained a complete victory, which secured the duke of Savoy and reformed all the Milanese to the emperor. In 1707, he invaded France, but without obtaining any decisive advantage, and in 1708 he was with the duke of Marlborough at the battle of Oudenard, and the capture of Lille. He commanded the centre at the bloody battle of Malplaquet, where he was grievously wounded, but refused to retire from the field, saying, "Of what use will it be if we are to die here; — if we are to survive it will be time enough in the evening to be drest." When the politics of England took a turn and peace was determined on, Eugene carried on the war alone, till it was concluded by the peace of Ratisbon in 1714. Shortly after this he was called on to contend against the Turks, whom he finally defeated in the year 1716. In the following year he undertook the siege of Belgrade, when the Turks came to its relief, and invested him in his camp. He suffered them to approach very near; and then suddenly quitting his lines fell upon them with so much vigour, that he killed 20,000 men, and possessed himself of their cannon and camp equipage. Belgrade immediately surrendered, and an advantageous peace was the result of this important victory. Eugene now retired to Vienna covered with glory, and justly considered as the favourite of the empire, and the greatest benefactor to the house of Austria. He was great in retirement, as he had been heroic and magnanimous in war. In the year 1733 he attempted new exploits, in consequence of the disputed election to the Polish crown; but he was no longer the great, the enterprising Eugene. He died in 1736 at Vienna, aged seventy-three. As a man he was cold and reserved in his manners, and serious in his aspect: as a friend he was liberal, free from pride, faithful to his promises, and ever ready to do a kind action. As a general he was regarded by those under him in the character of a father and protector; in his military capacity he was enterprising, full of resources, and though he sometimes committed faults, he rarely failed to redeem his credit by new and brilliant successes. Moretti. Modern Universal Hist. Hist. of England. See also the article CHURCHILL in this Dictionary.

fligma simple; *Peric.* Berry roundish or angular, crowned with the calyx, of one cell. *Seed* solitary, roundish, smooth and even.

Eff. Ch. Calyx superior, in four deep segments. Petals four. Berry of one cell, with one seed.

Obf. The number of petals, and segments of the calyx, is frequently five, in one infloence eight. The germens has, in some species at least, two cells, though one of them becomes obliterated as the fruit ripens.

This is an extensive genus, chiefly from the East and West Indies, whose species are as difficult to define as the roses in our European gardens. Their habit is akin to the myrtle, but often more stout and arborescent. Leaves simple, opposite, ovate or elliptical, entire, without stipulas, most frequently smooth, paler beneath, evergreen. Flowers either terminal or axillary, white or red. *Fruit* not unwholesome, but scarcely very grateful to the palate; in some cases highly fragrant. Willdenow has 30 species, a number far short of what are known, and yet two of them (*neutangula* and *racemosa*), are scarcely true Eugenia. There is also some confusion between this genus and *Plinia*, the original *E. uniflora*. Linn. Sp. Pl. 672; being not only *Myrtus brasiliensis*, ibid. 674, but also *Plinia rubra*, Linn. Mant. 428; as well as *P. pedunculata*, Linn. Suppl. 253; under which last name it is figured in Curt. Mag. t. 472, with a wrong quotation of Linn. Mant. Whatever the *Plinia* of Phimier may be, this plant is the original *Eugenia* of Michelian's figure, and is well known in the Brazil and West Indies, its fruit resembling an indifferen cherry in size, taste, and colour, though different in being externally furrowed. This fruit sometimes ripens in June in England, but the plant is no general favourite, being a meagre representative of the common myrtle.

E. Jambor. Linn. Sp. Pl. 672. (Malacca Schambu; Rheede Hort. Mal. v. t. 1. 17.), is much celebrated for the fragrance of its fruit, which reembles that of a rose, or rather rose-water. It is also of an extremely fine yellowish colour with a rosy tinct, and though not pleasant to the taste, is frequently brought to table in the Indies, for the sake of its perfume.

E. malaeeotis. Linn. Sp. Pl. 672. Sm. Exot. Bot. t. 61, a beautiful East Indian species, is esteemed for the elegance of its red clutched flowers, as well as the flavour and cooling quality of its fruit.

**EUGENIUS I.** In Biography, pope, was born at Rome, and raised to the highest dignity in the church in the year 634, on the deposition of pope Martin. He owed his elevation to the choice of the Roman people and clergy, and their choice was confirmed by the emperor Constatn. At this period the western and eastern churches were furiously contending with each other upon the question whether Christ professed one will or two. Eugenius, after his promotion, took pains to quiet the minds of the disputants. A compromise was entered into between the parties, but it was not of that nature to command general approbation: it was unsatisfactory to the Roman people and clergy, who opposed the admission of the patriarch Peter's consecration of faith. Peter had taken the other side of the question, and in his consecration he took no notice of the will and operations in Christ. So vehement was this party that they refused to permit the pope to perform divine service in the church of St. Mary, until he had publicly declared his condemnation of it. We have no other particulars relating to this pope, who died in the year 657, but he was commended by his contemporaries and successors for piety, mildness, humanity, and generosity. Moreri. Bower.

**EUGENIUS II.** pope, was a Roman by birth, and from being archpriest of St. Sabina, was made bishop of Rome in the year 824. This election was opposed by the people, who made choice of a different person for pope. The double election excited considerable disturbances at Rome, which occasioned the interference of Lewis the Debonnaire, who decided for Eugeniius, and confirmed him in his high office. The monarch took this opportunity of reviving several ancient customs and laws, declaratory of the dependence of the bishops of Rome on the imperial power, and determining the limits of the submission and obedience which were paid to them. Eugenius, to secure his own power, took the oath of fidelity to Lewis and his son Lotharian, in which he included his solemn engagement that no future pope should be consecrated with their consent, but in the presence of the emperor's deputy, and after the exactation of a similar oath to what was at that time administered. During the pontificate of Eugenius, a council was assembled in France of the bishops of Lewis and the Greek emperors Michael and his son Theophilius, to examine the doctrine of the Greek church, in relation to images. This was in the year 825, and at the conclusion of the council the bishops wrote a letter to Lewis, giving sentence against both parties, viz. the churches of Constantinople and Rome; the former for breaking images, whereas they were denominated "Iconoclasts," and the latter for worshipping them, whereas they obtained the title of "Iconolatry," declaring at the same time that it was a far greater crime to worship than to break images. The emperor was also exhorted by the council to interfere with the pope, and to intreat him to abolish the superstitious worship of images, which was the cause of much offence to all good men. Lewis wrote to the pope, and deputed two bishops to reason with him on the subject, but at little or no purpose; he continued not only to promote, but to justify the practice of image worship. In the following year Eugenius held a council at Rome, in which a number of decrees were passed, intended to reform the flate of ecclesiastical discipline, and to encourage the progress of literature both sacred and profane, but he died in the year 827, before he could carry his plans into effect. He was highly spoken of by Catholic writers, and applauded for his humility, his beneficence, and the humane policy of his government. He is represented as excelling in mental and corporeal endowments. As a writer, two of his epistles, and eleven of his decrees, are extant in the seventh volume of the "Collectio Conciliorum." It has been reported, and not greatly to the credit of Eugenius, that he was the incultrator of the ordal by cold water. See Ordeal. Moreri. Bower.

**EUGENIUS III.** pope, so called upon his elevation to the popedom, from his usual name Bernard, was a native of Pifa, and a disciple of St. Bernard. On the death of Lucius II. in the year 1145, Bernard was unanimously fixed on by the cardinals as the new pope, and was enthroned with the usual ceremony under the title of Eugenius III. The people, who had been long struggling to wrest from the popes the sovereignty which they had acquired over them in temporal matters, would not suffer Eugenius to be consecrated, unless he resigned all pretensions to dominion, otherwise than as connected with his spiritual rank, and would be contented with the revenue to be derived from tithes, and the voluntary contributions of the faithful. Unwilling to make these concessions, he privately withdrew to the Benedictine monastery of Farfa in Sabina, whither he was followed by the cardinals, and consecrated. Not daring to return to Rome, he removed from Farfa to Viterbo, where he continued for some months. During his absode there embassadors arrived from the Cufaders in the East, to im-
EUGENIUS.

The neutrality that His bull, Immediately Rome, the perfon legate death man and contemner His difobedient temporal pontiff the plunge in powered heretics: the this council, was bound to afford them his support. Eugenius was immovable, and the council were determined to fet his power at defiance. After confirming the decrees of the council of Conftance, which declared the papal power to be subordinate to that of a general council, and bound by its statutes and mandates they voted that no power on earth could diflodge them without their confent, and that none should withdraw from them without their leave; and they went so far as to summon the pope to appear in perfon before them within a limited time, or to fend legates with full authority to act in his name. The firmness of the council, after much altercation, brought the pope to submission, and in the year 1435 he issued a bull, declaring null and void whatever had been done by him, or in his name, in derogation of the council-general of Bafil. In the fame year Eugenius received the emperor Sigifmond at Rome with great magnificence, and crowned him there. Shortly after this he was attacked by Philip duke of Milan, who laid waste the territory of Rome, and when the inhabitants laid their complaints before the pope, he referred them to the cardinal his nephew, who, regardless of every thing that did not contribute to his own ease and pleasure, treated their sufferings with neglect and contempt. Enraged at this behaviour they took up arms, and produced a temporary revolution at Rome. It was with the utmost difficulty that Eugenius escaped from their fury, and took refuge at Florence; a reconciliation was effected, which was farther confirmed through the mediation of the council of Bafil, who dispatched some of their body to offer friendly advice on the occasion. In 1437 fresh difputes arose between the council and the pope, which terminated in their final rupture, and a new council was appointed to meet at Ferrara, whose firft act was to declare the congregation of Basil an unlawful assembly, and themselves the only occumenal council lawfully assembled, and they ordered all bishops who had retained at Basil to withdraw from that city within thirty days, on pain of excommunication, and the forfeiture of their dignities and benefices. The council of Bafil, on the other hand, passed a decree or sentence of suspension against Eugenius from papal jurisdiction, forbidding all ecclefiastics, on pain of excommunication, to obey him. Early in the year 1439, a contagious disorder breaking out at Ferrara, the pope translated the council to Florence, where a pretended union was effected between the Greek and Latin churches, which, being violently opposed at Constanlinsple, was rendered null and void. In the mean time the council of Basil, after declaring the superiority of councils over the pope to be an article of the Catholic faith, proceeded to depose Eugenius from the papacy, as disobedient to the commands of the church, a contaminer of the canons, a disturber of the unity of the church, and an obdurate heretic; and they dispatched nuncios to the different courts of the Christian princes to acquaint them with the measures which had been adopted. Eugenius thundered out his excommunications against the fathers at Basil, but they held his decrees in derision, and raised to the papal throne Amadous, duke of Savoy, who assumed the name of Felix V. The rival popes and rival councils anathematized each other, laying claim to the true apostolic powers. Eugenius was supported by France, Italy, Spain, Portugal, Hungary and England, but Felix was defended by the people of Savoy, by the Swiss, and by the dukes of Bavaria and Ausfria. The German princes chose to prefer a neutrality till the year 1447, when they declared for Eugenius, determining that he was the only true vicar of Christ upon earth. In the midst of the public rejoicings on this occasion, he died in
his sixty-fourth year. His character as a pope is easily gathered from what has been said: he was ambitious, intriguing, and a decided enemy to reform. In his last illness he is said to have been painfully affected with reflections on his past life; "Oh Gabriel," exclaimed the dying pontiff, "how much better had it been for thy soul's safety, hadst thou never been promoted to the dignity of cardinal or pope!" He was a patron of literature and learned men, though he had no pretensions to learning himself; his epistles and bulls are to be found in volumes xii. and xiii. of the "Collectio Conciliorum." He was a handlie man, of a venerable aspect, and always looked downwards when he appeared in public. He was frugal and temperate in his own person, but was liberal and hospitable; and at his table there was a princely magnificence. In this reign the cardinals began to indulge in the sports of the field, and to abandon themselves to all kinds of luxury. Bayle. Morei. Bower.

EUGENIUS, Catholic bishop of Carthage, was raised to that situation in the year 481, at the request of the emperor Zeno, who had entered into a treaty of peace with Hunneric, at that time the reigning monarch. In the year 483, he was summoned, with the other Catholic bishops, by the king, to Carthage, to maintain a public debate in defence of their principles against the Arian bishops, whom he patronized. Eugenius undertook to draw up a treatise, explanatory of the Catholic faith, which was approved by all the bishops of his party, and presented to Hunneric, and he offered to defend the principles contained in it by an appeal to the sacred writings, as well as to the sentiments of the fathers. He also delivered a petition to that prince, in the form of an apology, the design of which was, to obtain peace for the Catholics. It was, however, of no avail; the bishops of that party were all sentenced to banishment; and Eugenius was sent into exile, amidst the dreary deserts of Tripoli. In the following year Hunneric died, and Eugenius was permitted to return to Carthage, but was again banished, on the accession of Thraxamund, and sent into Gaul. He died at Albi, in the year 505. His principal works are, "Expositio fidei Catholicae," "Apologeticus pro fide," "Alternatio cum Arianis," and a letter to his people, exhorting them to constancy in the orthodox faith. Morei. Moreri.

EUGENIUS, bishop of Toledo, in the seventh century, was attached to the monastic life, but compelled, by order of the prince, to accept of the episcopal dignity in the year 614. He filled that see several years, and made a figure at the councils of Toledo, which were held in the years 653, 655, 656. He was author of a treatise "On the Trinity," and two books on miscellaneous subjects. He revised and improved Dracontius's work on the creation of the world, which was published at Paris, together with his "Optica," in the year 1619. Moreri.

EUGHTGUR, in Geography, a town of Hindostan, in the circar of Kutchward; 15 miles E. of Ouunin.

EUGIA, in Ancient Geography, a small country of the Pelorphenus, in Arcadia.

EUGMO, in Geography, a small island on the east side of the gulf of Elba. N. lat. 63° 49'. W. long. 22° 42'.

EUGUBIO. See GUBBIO.

EUYHRYDIN, in Ancient Geography, a town of Greece, in Thessaly, according to Livy.

FIVIAN, in Geography, a town of France, in the department of the Leman, on the coast of the lake of Geneva, containing two parishes and two convents. The place includes 1502, and the canton 12,911 inhabitants, on a territory of 280 square miles, and in 19 communes.

Near Favian are some mineral waters, which render it in summer a place of resort. It is situated 23 miles N. E. from Geneva. N. lat. 46° 25'. E. long. 6° 24'.

EVICTION, from evinco, I overthrow, in Law, signifies a recovery of lands or tenements by law.

EVIDENCE, a quality in things whereby they become visible and apparent to the eyes, either of the body or the mind.

The schoolmen distinguish evidence into formal and objective. The former is the act of the intellect, considered as clear and distinct; the latter consists in the clearness and distinctness of the object; or it is the object itself so constituted as that it may be clearly and distinctly known.

Others divide evidence into moral, physical, and metaphysical. A thing is said to be morally evident, so far as we have a distinct notion or knowledge thereof, by exceptionable witnesses; physically, so far as natural sense and reason, pointing out any thing, convince us thereof; metaphysically, when we enter fully and clearly into the essence of any thing.

Evidence is the essential and infallible character or criterion of truth, and is that in effect which with us constitutes truth.

If evidence should be found in propositions that are false, we should be compelled into error, since the affent we give to evidence is necessary: whence would follow this impious position, that God who made us is the author of our errors, as he has constituted us so as to put us under a necessity of falling into them.

It may be added that as we necessarily love truth and hate error, it seems inconsistent with the nature of a beneficent being to form us with a love of what we could not obtain, or not know whether we did obtain it or not; besides, that if we should err in things that are evident, as well as in those that are not so, we should sometimes find contradictions in evident propositions, as we commonly do in things that are obscure.

Evidence therefore must be allowed the mark of truth; and those things must be allowed true which carry with them such a degree of evidence as obliges us to assent to them. Whatever we see evidently agreeable to things whereof we speak, that we must acknowledge to be true.

The Epicureans allow of no other evidence but that of sense, or that arising from sense, it being a fundamental principle with them, that sense is the first and primary criterion of all truth. By evidence of sense, they mean that specious or image exhibited by the sense or phantasy which, when all impediments to a just judging, as distance, motion, medium, &c. are removed, cannot be contradicted or gain Said; wherefore, the question being put, whether or not a thing be such as it appears; the answer is not to be given, till it has been tried and examined in all the ways, and by all the senses, of which it can be an object. See Error.

There are certainly other superior and less fallible sources or grounds of evidence than sense: such is that inward consciousness by which we learn what belongs to the mind, or that which Mr. Locke calls reflection; of which such are intelligence, intuition, and common sense, principally relating to those abstracted, or other propositions that carry their own evidence with them, and admit no doubt about them; whence we derive our assent to propositions called axioms and maxims: such is also reasoning, whereby we infer one truth from others by natural and just methods of argument, wherein rests science: such is likewise the testimony of others, on which we found the evidence of Faith (see also Testament): to which we may also add
EVIDENCE.

Inspiration, or that impression made on the mind by God himself, which gives a convincing and indubitable evidence of the truth of any proposition, and attested to others, either by prophecy or miracles. Watts's Logic, part ii. chap. ii. § 9.

By thus considering the various sources whence our perception and belief of any truth are derived, we may be led to distinguish evidence into affirmative and corroborative, and that founded on testimony. Intuitive evidence comprehends that of pure intellect, of consciousness, and of common sense, under the bias of which that of memory is included. (See Intuitive.) Deductive evidence is divided into scientific and moral; the latter of which includes those kinds of evidence that are deduced from experience, argument, and testimony, to which may be added a mixed species, derived from the calculation of chances. (See Deductive.) See also each of the above-mentioned subjects. See Campbell's Phil. of Rhet. book i. chap. 5.

The evidences of the Christian religion are distinguished into two kinds, the direct and collateral: the direct evidences are external and internal; the external are miracles and prophecy; the internal evidence is deduced from its excellence, considered in reference to the main and principal end of Christianity. Whatever does not either belong to its excellence considered in this light, or fall under the head of miracles wrought on purpose to attest it, or of prophecies fulfilled, and yet affords a proof or any real presumption of its truth and divinity, is a collateral evidence for it. All the collateral evidences of the truth of Christianity are in one sense internal evidences, because they all arise from some particulars in the nature of this religion, from some circumstances which have attended its reception, or sprung from it, or from some remarkable facts connected with it, and related in the gospel history. Of this kind is the argument deduced from its great efficacy at its first appearance, in banishing polytheism, idolatry, superstition, and the arts of magic; in softening the rigour of despotism, introducing moderation into government, excluding many inconvenient civil laws once generally prevalent, giving rise to others of a very happy tendency, refilling the laws of war, humanizing the manners, and improving the customs of nations, and reforming the temper and conduct of those who embraced it.

Another class of collateral arguments for the truth of the Christian religion, arises from particulars in its nature or effects produced by it, or from facts in the Gospel history, which cannot be at all accounted for but on the supposition of a Divine original; or which are, at least, most naturally explicable on that supposition. To this class may be referred those presumptive arguments deduced from the character of Jesus, so exalted, and yet so uniformly supported; the nature of his last discourse with his disciples; the character of some of his apostles; that of Judas the traitor; the controversies among Christians in the apostolic age; and the method used by Christ and his apostles, of referring their claims to the impartial inquiries of men. Other collateral arguments have an affinity to the external evidences of Christianity: such are those derived from the miraculous conversion of the apostle Paul and his subsequent conduct; from the character of the man of sin foretold by Paul; from the quick and extensive propagation of the Gospel; from the continuance and present state of the nation of the Jews. Some of these arguments have an immediate relation to the proof of Christianity from prophecies; others are related to the proof from miracles. Other arguments have an equal relation to the internal and external evidence of Christianity; such as is that deduced from the manner in which Christ and his apostles propounded the evidences of their mission, and the advantage they have gained in consequence of the opposition and scrutiny of unbelievers. See on this subject Lord Lyttelton's Observations on the Conversion and Apostleship of St. Paul, Dugdale's Prefcriptive Arguments for the Truth of the Christian Religion, and Garrard's Diflertation on the Genius and Evidences of Christianity.

Evidence, in Law, is any proof, whether by testimony of men on oath, or by writings and records; the former called parol evidence, that is, by word of mouth, and the latter written evidence. (See Evidence.) See also each of the above-mentioned subjects. See Campbell's Phil. of Rhet. book i. chap. 5.

With regard to parol evidence, or witnesses, we may observe in general, that all witnesses, whatever be their religion or country, that have the use of their reason, are to be received and examined, except such as are infamous, or such as are interred in the event of the cause. All others are competent witnesses; though the jury from other circumstances will judge of their credibility. Infamous persons are such as may be challenged as jurors, proper delictum; and, therefore, never shall be admitted to give evidence to inform that jury, with whom they were too scandalous to associate. Interested witnesses may be examined upon nc voir dire, if suspected to be secretly concerned in the event; or their interest may be proved in court. A party interested in a suit, or a wife for or against her husband, a husband against his wife, except in cases of treason, an alien infidel, persons non jure commune, those that are attached to a conspiracy, or in a preamble upon flat. 5 Eliz. cap. 1. populi recusant convict on flat. 3 Jac. l. cap. 5. (See contra 1 Hawk. P. C. c. 12. § 6.) persons convicted of felony, perjury, &c. those who have judgment have been on the pillory, or been whipped, whilst the judgment is in force, are disbarred from giving evidence: but kinmen, those of a good neighbour, near, tenants, servants, matters, attorneys for their clients, but not against them, because they are obliged to keep their secrets, one of the jurors upon trial, and all others that are not infamous, who want not understanding, or are no parties in interest, may give evidence in a cause, though the credit of servants is left to the jury. (2 Rol. Abr. 685. 1 Vent. 243.) If after a man hath been in the pillory, &c. he be pardoned, he may be an evidence; and though judgment of the pillory infers infamy at common law, by the civil and canon law it imports no infamy, unless the cause for which the person was convicted was infamous; and, therefore, such may be a good witness to a will, if not convicted of any infamous act. (2 Lev. 426. 427.) It has been held, that it is not standing in the pillory which disables a person for giving evidence; but standing there upon a judgment for an infamous crime, as forgery, &c. If for a libel, a man may be a witness. (5 Mod. 743 Nell. Abr. 557.) Persons excommunicated cannot be witnesses, but persons outlawed may be witnesses, because the outlawry has no influence on their credibility. (Bull. N. P. 292. 3.) A man convicted of felony, and afterwards pardoned, may be a good evidence. (Raym. 359.) Burning in the hand is laid to restore a person to his credit. (Ibid. 350.) A person condemned to be hanged for burglary, but having a pardon for transportation, hath been allowed to be a good evidence. (5 Mod. 108.) One outlawed for treason and pardoned may be an evidence. (State Trials, vol. iii. 515.) Persons acquitted, or guilty of the same
EVIDENCE.

fame crime, while they remain unconvicted, may be evidence against their fellows. (Kel. 17.) Although no evidence ought to be given of what an accomplice hath laid, who is not in the same indictment; (State Trials, vol. ii. 414.) an informer may be a witnes, though it is to have part of the forfeiture, where no other witneses can be had. (Wood's Inlif. 598.) If an action is brought against many persons for taking of goods, one of them may be admitted as an evidence against the rest. (Comberb. 367. 1 Mod. 282.) In criminal cases, as of robbery on the high way, in action against the hundred; in rapes of women, or where a woman is married by force, &c. a man or a woman may be his own evidence. (1 Vent. 243.) And in private enormous thefts, a person may give evi- dence in his own cause, where nobody else can be a witnes of the circumstances of the fact but he that suffers. (1 Salk. 286.) Upon an information on the statute against affury, he that borrows the money, after he hath paid it, may be an evidence, but not before. (Raym. 190.) Although an alien informer may not be an evidence, a few may, and be sworn on the Old Testament. (1 Inl. 6.) A quarker shall not be an evidence in any criminal cause unless he will take an oath; though on other occasions his affirmation shall be accepted instead of an oath. Stat. 7 and 8 W. III. c. 34. See Quaker.

The oath of a Gentoo, sworn according to the circum- stances of his religion, has been admitted in a civil matter. (1 Atk. 21.) And by Wilt C. J. an infidel in general is an admissible witnes, for the term does not imply that he is an atheist; but whenever it appears that a witnes hath no idea of a God or religion, he shall not be permitted to give his testimony. (1 Atk. 40. 45.) When persons that are competent witneses are forced with wrong and unfair means to act as such, they may be entitled to come to the trial on pain of being forfeited to the king, to which the Stat. 5 Eliz. cap. 9. has added a penalty of 50l. to the party aggrieved, and damages equivalent to the loss sustained by want of their evidence: but no witnes, unless his reasonable expenses be tendered him, is bound to appear at all; nor if he appears, is he bound to give evidence till such charges are actually paid him, except he refises within the bills of mortality, and is summoned to give evidence within the same. In a criminal cause, if a witnes refuse to appear, and give evidence, being served with process, the court will put off the trial, and grant attacment against him; and as refusing to give evidence is a great contempt, the party may be committed and fined. (1 Salk. 278.) Preventing evidence to be given against a criminal is punish- able by fine and imprisonment; and persons diffusing a witnes from giving evidence, &c. and jurors or others, dicing or giving evidence, are likewise offences punished in the same manner. (2 Hawk. P. C. c. 22.) Members of either house of parliament may be witneses on impeachment. (State Trials, vol. ii. 612.) A person who hath a legacy in a will, is not a good witnes to prove the will; but if he release his legacy, he may be a good evidence. (Sken. 704.) Thus also, a person who claims any benefit by a deed, may not be an evidence to prove that deed; and a person concerned in the fame title of land in question will not be admitted as evidence. (Ibid. 705.) If a legatee is permitted to be sworn and examined, the counsel cannot afterwards except against his evidence. (1 Lord Raym. 736.) To obviate all difficulties, it is enacted by Stat. 25 Geo. III. c. 6. that any devise to a person being witnes to any will or codicil shall be void, and such person shall be admitted as a witnes; and that any creditor attesting a will or codicil, by which his debt is charged upon land, shall be admitted as a witnes to the execution, notwithstanding such charge; the credit of every such witnes being left to the considera- tion of the court and jury. The son of a legatee is no witnes to a will in the spiritual court: but it is held he may be a good evidence to prove a nuncupative will, within the intent of the statute of frauds. (1 Lord Raym. 85.) See Will.

One credible witnes is sufficient evidence to a jury of any single fact in all civil actions, though the concurrence of two or more corroborates the proof; but in cases of high- treason, petit-treason, and misprision of treason, by statutes 1 Edw. VI. cap. 12. 5 and 6 Edw. VI. cap. 11. and 2 Ph. and Mar. cap. 10. two lawful witneses are required to convict a prisoner except in cases of coining and counterfeiting the seals, or unfils the party shall willingly and without violence confess the same: and by Stat. 7 W. III. cap. 3. the confession of the prisoner must be in open court; and both witneses must be to the same overt-act of treason, or one to one overt-act, and the other to another overt-act of the same species of treason. Baron Montefique, indeed, lays it down for a rule, Spirit of Laws, book xii. chap. 3. that those laws which condemn a man to death in any case, on the deposition of a single witnes, are fatal to liberty.

All evidence is to be given in open court, in the presence of the parties, their attorneys, the counsel and all by-bidders, and before the judge and jury: many advantages attend this way of giving testimony, or tenes, a method familiar among the ancient Romans, as may be collected from Quintillian, Inlif. Orat. lib. v. cap. 7. and it was continued as low as the time of Adrian; but the civil law, as it is now modelled, rejects all public examination of witneses.

An accused person must give any answer by which he confesses or acquits himslef of the crime. The end of all criminal cases is to examine the witneses, and not the prisoner or pro- fectors. A witnes shall not be permitted to read his evidence, but he may look at his notes to refresh his memory. A witnes may not recite his evidence to the jury, after having gone from the bar, and he hath given his evidence in court; if he does, the verdict may be set aside. (Cro. Eliz. 159.) One that is to be an evidence at a trial, ought not to be examined before the trial, but by the consent of both parties, and a rule of court for that purpose.

No evidence ought to be produced against a man, in a trial for his life, but what is given in his presence. State Trials.

Positive proof is always required whenever the nature of the case pohtibly admits of it.

Sometimes violent presumption will be admitted for evidence without witneses; as when a person is run through the body in a horse, and one is seen to come out of the horse with a bloody sword, &c. but on this the court ought not to judge hastily, 1 Stat. 6. 673. and though presumptive evidence on a circumstantial evidence may be sufficient in felony, it is not so in treason. State Trials.

Though all presumptive evidence of felony should be admitted cautiously, for the law holds that it is better that ten guilty persons escape, than that one innocent suffer. (See Presumption.) Sir Matthew Hale lays down two rules, most prudent and necessary to be observed. 1. Never to convict a man for stealing the goods of a person unknown, merely because he will give no account how he came by them, unless an actual felony of such goods be proved: and, 2. Never to convict any person of murder or manslaughter, till at least the body be found dead; on account of two in- stances, which he mentions, where persons were executed for the murder of others, who were then alive, but missing. 2 Hal. P. C. 200.
Evidence by writings and records, is where acts of parliament, statutes, judgments, fines, and recoveries, proceedings of court, and deeds, &c. are admitted as evidence. The printed statute-book is good evidence upon a general act of parliament, which need not be pleaded; but in the case of a private act, it is otherwise; for there it must be pleaded and examined by the records of parliament before it can be admitted in evidence. Records and enrolments prove themselves; and a copy of a record or enrolment, sworn to, may be given as an evidence. (Co. Litt. 119. 262.) A record of an inferior court has been rejected in evidence; and the proceedings in county-courts, courts-baron, &c. may be used by a jury. But court-rolls of a court-baron, when shown, are good evidence; and, in many cases, copies of the court-rolls are allowed as evidence. An ancient deed of thirty years' standing proves itself; but modern deeds, and other writings, must be attested and verified by parol evidence of witnesses. The counterpart of a deed is no evidence, when the original is in being, and can be procured; though it may be, when the original cannot be procured. (Co. Litt. 225. 10 Rep. 92.) The counterpart of an ancient deed hath been admitted as evidence. (Mod. Cal. 225.) In case of a fine, a counterpart is good evidence of itself. (1 Salk. 287.) Although a witness sweare to the hand and contents of a letter, if he never saw the party write, it will not be good evidence. If all the witnesses to a deed be dead, continual and quiet possession is presumptive evidence of the truth of it; yet it may receive farther credit by comparison of hands and seals. (Wood's Init. 599.) When witnesses to deeds are dead, their hand-writing must be proved. (2 Init. 118.) If one of several witnesses be dead, his hand must be produced; yet in living witnesses, and strict inquiry made after him, and affidavit made that he cannot be found, before the hand-writing of the deceased witnesses is to be proved. (1 Litt. 536.) And a shop-book may not be given in evidence for goods sold, &c. by 7 Jac. I. c. 12, after one year, before the action brought, except there be a bill, &c. for the debt; unless between merchant and merchant in the usual intercourse of trade. In order to make books evidences, if the servant who was accustomed to make entries in it be dead, his hand must be proved; and this, when accompanied with other collateral proofs of fairnames and regularity, is the best evidence that can then be produced. In debt, a reliefe may be given in evidence; so may any matters of fact, tampering with witnesses, or fraud.

In order to prove a lease for years, nothing shall be admitted, but the very deed of lease itself, if in being; but if that be positively proved to be burnt or destroyed, then an attested copy may be produced, or parol evidence given of its contents. No evidence of a discourse with another will be admitted, but the man himself must be produced; yet in some cases, as in proof of any general customs or matters of common tradition or repute, the courts admit of hearsay evidence, or an account of what deceased persons have declared in their life time; but such evidence will not be received of any particular facts. The probate of a will, when it concerns merely personal estate, may be given in evidence; but where title of lands is claimed under a will, the original will must be shewn, not the probate, though if the will be proved in the Chancery, copies of the proceedings there will be evidence. (2 Rol. Abr. 687. Trials per pais, 234, 1 Salk. 286. Raym. 335.) In some cases the ledger-book of the ecclesiastical court in which the will is entered is sufficient evidence, being a roll or record of the court. (Bull. N. P. 245. 6.) Depositions of witnesses in Chancery between the same parties may be given as evidence at law, if the witnesses are dead, and the bill and answer proved. Depositions before a coroner are admitted as evidence, the witnesses being dead, or gone beyond sea. (1 Lev. 18. 2 Nell. Abr. 760.) The confession of a prisoner before a magistrate, &c. may be given in evidence against him. (See 2 Hawk. P. C. c. 46.) See Baron Gilbert's Treatise of Evidence, or the Introduction to the Law of Nisi Prius, 4to. 1767.

From this treatise the following rules of evidence are extracted. 1. In general, the best evidence must be given that the nature of the thing will admit of. 2. No person interested in the question can be a witness. To this rule there are some exceptions; as 1. A party interested may be admitted as a witness where he is made a party by the will of the court. 2. He may be admitted for the fake of trade in the common usage of businessmen, as partners, apprentices, &c. 3. Where no other evidence is reasonably to be expected. 4. Where he acquires his interest by his own act, after the party who calls him as a witness has a right to his evidence. 5. Where the possibility of interest is very remote. 3. The third general rule is that hearsay is no evidence. 4. In all cases where a general character or behaviour is put in issue, evidence of particular facts may be admitted; but not where it comes in collatorally. 5. In every issue the affirmative is to be proved. 6. No evidence need be given of what is agreed by the pleadings, &c. &c. See Pleading.

Evidence, demurrer to. See Demurrer.
Evidence, exception to. See Exception.
EVIL, Malum, in Ebie, a privation or absence of some proper or necessary good, or of some measure or degree thereof.
Evil is either natural or moral; between which there is this relation, that moral evil produces natural.
EVIL, moral, is defined a deviation from right reason; a discernment of right from wrong, being given us as a guide of our actions; or it is the disagreement between the actions of a moral agent and the rule of those actions, whatsoever it is derived, and whatsoever made known; and no action can be morally evil unless the agent be properly such, intelligent and free, and capable of distinguishing, choosing, and acting for himself. This the philosophers call indoctrum, and turpe, as tainting the image of God, and fulfilling our original beauty; likewise malum culpe.

Evil, natural, is a want of something necessary to the bene esse, or perfection of a thing, or to its answering all its parts; such are defects of the body, blindness, lameness, hunger, disease, death. This species is denominated triste, injudicium, maxim, and malum pase.

Good and evil, says a learned writer, are opposites, and arise from the relations which things have to each other: for since there are some things which profit, and others which prejudice one another; and since some things agree, and others disagree; we call the former good and the latter evil. Whatever, therefore, is incommodeous or inconvenient to itself or any thing else; however becomes troublesome or frustrates any appetite implanted by God; whatever forces any person to do or suffer what he would not, that is evil. These inconveniences appear to be of three kinds: those of imperfection; those that are natural; and those that are moral. By the evil of imperfection we may understand the absence of those perfections or advantages which exist elsewhere, or in other beings; by natural evil, pains and uneasiness, inconveniences and disappointments of appetites arising from natural motions; and by moral evil, vicious elections, that is, such as are hurtful to ourselves,
or others. This opinion is otherwise stated in the following manner: all evil is inconvenience, but some inconveniences arise from the series of natural causes without our consent, and sometimes our knowledge; these we call natural evils: but others happen from the abuse of actions, when an undue choice occasions them; and in this case, besides the natural evil that arises from them, there is likewise an obligation on the person that makes the choice to answer for the hurt he has done by it. Now these choices that bring inconveniences are called moral evils; and the difference between natural evil and moral evil is not their both bringing inconveniences and injury to ourselves or others, for this constitutes the nature of their evil, but that the ill effects of the one proceed from the choice, those of the other from natural causes; and hence the author of that choice is answerable for the one, but nobody for the other. Moral evil, therefore, is natural evil, with choice superadded. See architect King's "Essay on the origin of Evil," by Law, vol. i. and ii. Sherlock, also, in his "Treatise on Judgment," p. 20, &c. distinguishes in a similar manner between moral and natural good and evil; the only difference between them, he says, is this, "that moral good and evil is in the will and choice, natural good and evil is in the nature of things; that which is good or hurtful to ourselves or others is naturally good or evil; to love, to choose, to do that which is good or hurtful to ourselves or others, is morally good or evil, or is the good or evil of our choice or actions. If you will but recollect yourselves, you will find that you have no other notion of good or evil but this: when you say such a man has done a very good or very evil action, what do you mean by it? Do you not mean that he has done something very good or very hurtful to himself or others? When you hear that any man has done good or evil, is not the next question, what good or what hurt has he done? And do not you mean by this, natural good or evil? which is a plain evidence that you judge of the moral good or evil of actions by the natural good or evil which they do.

The ingenious author of the "Enquiry into the Origin of our Ideas of Beauty and Virtue," give the following statement of the nature of moral good and evil, and of the difference between these and natural good and evil. Moral evil, according to this philosopher, denotes our idea of a quality apprehended in actions which excites aversion and dislike towards the actor, even from persons who receive no disadvantage thereby; as moral good signifies our idea of a contrary quality which procures approbation and love towards the actor, even in persons unconcerned in its natural tendency. This notion supposes an universally acknowledged difference of moral good and evil from natural. Moral good, we all know, procures love towards those we apprehend possessed of it; whereas natural good does not. How differently, for instance, are we affected towards those we suppose possessed of honesty, faith, generosity, &c. when we expect no benefit from those qualities, and those possessed of the natural goods, as houses, lands, gardens, health, strength, &c. So whatever quality we apprehend morally evil, raises our hatred towards the person in whom we observe it; as treachery, cruelty, ingratitude, &c. whereas we love and pity many exposed to natural evils, as pain, hunger, sickness, &c.

The origin of these different ideas of actions has greatly puzzled the moralists: some make self-interest, or self-love, the source of them all; we approve the virtue of others as it has some small tendency to our happiness, either from its own nature, or from this general consideration, that a conformity to nature and reason is in the general advantage of the whole, and to us in particular; and on the contrary, disapprove the vice of others, as tending at the long run to our particular detriment.

Others suppose an immediate natural evil in the actions called vices, that is, that we are determined to perceive some deformity or displeasure in such actions, without reflecting on any disadvantage that may arise from the action; and that we have a secret sense of pleasure accompanying such of our own actions as are called virtues, and that we expect no farther advantage from them; but then they add, that we are excited to perform those actions, even as we purse or purchase pictures, statues, landscapes, &c. from self-interest, to obtain the pleasure which accompanies the action.

But the author just mentioned maintains that some actions have to men an immediate goodness, and others an immediate evil, i.e., we perceive pleasure in some and pain in others, and are determined to love or hate the doers, without any view of natural advantage, without any view to future rewards or punishments, or even without any intention to obtain the sensible pleasure of the good, but from a very different principle, viz. an internal moral sense, or a natural determination of the mind to receive amiable or disagreeable ideas of actions, when they shall occur to our observation, antecedently to any opinion of advantage or loss to redound to ourselves from them, even as we are pleased with a regular form or a harmonious composition, without any knowledge of the mathematics, or seeing any advantage in that form or composition different from the immediate pleasure. But according to this account of Dr. Hutcheson, however plausible, moral good and evil signify nothing in the objects themselves, to which they are applied, any more than agreeable or disagreeable to us; and virtue is a mere affair of taste, whereas it seems to be much more just to conclude, that right and wrong, good and evil, are real qualities of actions, and not merely of our minds; and that the power whereby we perceive these qualities is not any arbitrary sense but the understanding: or to suppose with another excellent writer, that moral good, considered as synonymous with virtue, denotes the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness, and moral evil or vice, the contrary. Price's Original of our Ideas, &c. p. 13, and p. 59, &c. Paley's Principles of Moral and Political Philosophy, vol. i. p. 41. See farther under Deformity, Sense, Good, Virtue, and Vice.

The question concerning the origin of evil has very much perplexed philosophers and divines, both ancient and modern. Plato, for the solution of this question, maintained, that matter, from its nature, pollutes a blind and refractory force, from which arises in it a propensity to disorder and deformity; and that this is the cause of all the imperfections which appear in the works of God, and the origin of evil. Matter, he conceives, refits the will of the supreme artificer, so that he cannot possibly execute his designs; and this is the cause of the mixture of good and evil, which is found in the material world. "It cannot be," says he, (Theat. t. i. p. 176.) "that evil should be destroyed, for there must always be something contrary to good," and again, "God wills, as far as it is possible, every thing good, and nothing evil." What is that property of matter which opposes the wise and benevolent intentions of the first intelligence? Plato has not clearly explained, but he speaks of it as "Navetes fuccipus," an innate propensity to disorder, (Phileb.) and says, "that before nature was adorned with its present beautiful forms, it was inclined to confusion and deformity, and that from this habitu
bitude arises all the evil which happens in the world." Pintarch supposes the Platonic notion to be, that there is in matter an unconscious irrational soul; and this supposition has been adopted by several modern writers. But the writings of Plato afford no evidence, that he conceived the imperfection of matter to arise from any cause distinct from its nature. Such a notion is inconsistent with Plato's general system, and it is contrary to the doctrine of the Pythagorean school, to which he was probably indebted for his notions on this subject; for the philosophers of that sect held, that motion is the effect of a power essential to matter. Some of the Stoics adopted the notion of the Platonists concerning the origin of evil, and ascribed it to the defect of nature of matter, which it is not in the power of the great architect to change; asserting, that imperfections appear in the world, not through any defect of skill in its author, but because matter will not admit of the accomplishment of his designs. But it was perceived by others, that this hypothesis was inconsistent with the fundamental doctrine of the Stoics concerning nature. For if, according to this system, matter itself receives all its qualities from God, if its defects be the cause of evil, these defects must be ultimately ascribed to him. No other way of relieving this difficulty remained, but to have recourse to fate, and say, that evil was the necessary consequence of that eternal necessity, to which the great whole, comprehending both God and matter, is subject. Thus, when Chrysippus was asked, whether diseases were to be ascribed to divine Providence, he replied, that it was not the intention of nature that these things should happen; nor were they conformable to the will of the author of nature and parent of all good things; but that, in framing the world, for the innumerable defects and inefficacy concurring, to his wise and useful plan. To others the question concerning the origin of evil appeared to intrigue and difficult, that finding themselves unequal to the solution of it, they denied either that there is any God at all, or, at least, any author or governor of the world. The Epicureans belonged to this class; nor does Lucretius allege any other reason for denying the system of the world to be the production of a deity besides its being so very faulty. Others again judged it to be more rational to ascribe a double cause of visible effects than to assign no cause at all; as nothing, indeed, can be more absurd than to admit actions and effects without any agent and cause. These persons, perceiving a mixture of good and evil, and being persuaded that so many incompatibilities and disorders could not proceed from a good being, supposed the existence of a malevolent principle, or God, directly contrary to the good one; hence they derived corruption and death, diseases, griefs, mischiefs, frauds and villainies, whilst from the good being they deduced nothing but good. This opinion was held by many of the ancient philosophers by the Perian magi, Minoichaeus, Palaicaius, &c. &c. See these articles, and also Zoroaster. Absurd as this hypothesis was, it very long and generally prevailed, not only in the Heathen but in the Christian world; nor have the light and influence of Christiinity yet availed to its total extermination, so that no trace or remnant of it remains. Those who wish to find a satisfactory refutation of it, may consult "King's Origin of Evil," vol. i. and the annexed notes of the editor.

The excellent Dr. Clarke, in his "Demonstration of the Being and Attributes of God," deduces from the possibility and real existence of human liberty an answer to the question, what is the cause and original of evil? "For liberty," he says, "implies a natural power of doing evil, as well as good; and the imperfect nature of finite beings, making it possible for them to abuse this their liberty to an actual commission of evil; and it being necessary to the order and beauty of the whole, and for displaying the infinite wisdom of the Creator, that there should be different and various degrees of creatures, whereof, consequently, some must be left perfect than others; hence there necessarily arises a possibility of evil, notwithstanding that the Creator is infinitely good. In short thus: all that we call evil, is either an evil of imperfection, as the want of certain faculties and excellencies which other creatures have; or natural evil, as pain, death, and the like; or moral evil, as all kinds of vice;" the first of these is not properly an evil. For every power, faculty, or perfection, which any creature enjoys, being the free gift of God, which he was no more obliged to bestow, than he was to confer being or existence itself; 'tis plain the want of any certain faculty or perfection in any kind of creatures, which never belonged to their nature, is no more an evil to them, than their never having been created or brought into being at all, could properly have been called an evil. The second kind of evil, which we call natural evil, is either a necessary consequence of the former; as death, to a creature on whole nature immortality was never conferred; and then 'tis no more properly an evil than the former; or else 'tis counterpoised, in the whole, with as great or greater good; as the afflictions and sufferings of good men; and then also it is not properly an evil; or else, finally, 'tis a punishment; and then 'tis a necessary consequence of the third and last fort of evil, viz. moral evil. And this arises wholly from the abuse of liberty, which God gave to his creatures for other purposes, and which 'twas reasonable and fit to give them for the perfection and order of the whole creation: only they, contrary to God's intention and command, have abused what was necessary for the perfection of the whole, to the corruption and deprivation of themselves. And thus all sorts of evils have entered into the world, without any diminution to the infinite goodness of the Creator and Governor thereof.

Evil, or King's Evil, the appellation formerly given to leprosula, in consequence of the supposed power possessed by the kings of England and France of curing this disease by touching the sick.

The origin and first exercise of this royal faculty are not agreed upon by historians; those of France are disposed to maintain, that it was originally inherent in their kings, some ascribing to St. Louis, others that king Robert, was the first who was thus gifted; but by most other writers it is assigned as an earlier prerogative of the English crown. Edward the Confessor is generally mentioned as the first possessor of this miraculous power; and it was disputed in the days of Mahnbur, who lived not long after his reign, whether this faculty were a peculiar reward from heaven for that king's sanctity, or hereditarily resident in the English crown. Polydore Virgili has noticed this gift to Saint Edward, and its continuance in the line of his successors; and Dr. Harpsfield, in his Ecclesiastical History of England, after describing the miracles of the Confessor, observes, "quam strumosos famuli admirabilis dote in poëteros fuos Anglorum reges, ad nobis uque tempora transsubiine reperuisset, merito credimus." The practice was long continued, and seems to have reached its greatest height in the reign of Charles II. to whom multitudes flocked to receive the benefits of the royal touch; insomuch, that after his restoration, he is said to have laid his hands upon more than six thousand persons in one year. His majesty was therefore obliged to make some restrictions with regard to the times of healing, and the number of patients. All persons were obliged to go to the king's surgeon, whose duty it was to

Examine
EVIL.

examine their certificates from the minister and churchwardens of their parish, to determine whether they were proper objects, to give them tickets of admission to the royal presence, and to introduce every one to the king's faeced hand to be touched. The king usually gave public notice of the day of healing; in the winter the ceremony was always held at Whitehall; in the summer sometimes at Whitehall, and sometimes at Windsor.

The following curious paragraphs were made public in 1660:

"The kingdom having been for a long time troubled with the evil, by reason of his majesty's absence, great numbers have lately hocked for cure. His faeced majesty, on Monday last, touched 250 in the Banqueting house; among whom, when his majesty was delivering the gold, one shuffled himself in, out of an hope of profit, which had not been stroked, but his majesty quickly discovered him, saying, this man hath not yet been touched. His majesty hath for the future appointed every Friday for the cure, at which 200, and no more, are to be presented to him, who are first to repair to Mr. Knight, the king's surgeon, 8c. Parliamentary Journal, July 2-9, 1660.

"Saturday being appointed by his majesty to touch such as were troubled with the evil, a great company of poor afflicted creatures were met together, many brought in chairs and flalletts; and being appointed by his majesty to repair to the Banqueting-houle, his majesty sat in a chair of state, where he stroked all that were brought to him, and put a silver medal about each of their necks a white ribbon, with an angel of gold on it. In this manner his majesty stroked above six hundred; and such was his princely patience and tenderness to the poor afflicted creatures, that though it took up a very long time, his majesty, who is never weary of well-doing, was pleased to make inquiry whether there were any more that had not yet been touched. After prayers were ended, the duke of Buckingham brought a towel, and the earl of Pembroke a bonfon and ever, who, after they had made obeisance to his majesty, knelt down till his majesty had washed." Mercureus Politicus, June 21-28, 1660.

An exact register was at that time kept of the number of cases that came for relief, and the whole amount is very great. From 1660 to 1664 inclusive, a period of five years, 23,601 persons were touched by Charles II.; and from May 1667 to May 1668, the number of persons touched amounted to 63,564, making all together 92,127. For the intervening years, 1665 and 1666, no register was made, the king having removed from the metropolis on account of the plague.

This superstitious practice was dropped by the present royal family, "who observed (says Hume) that it would no longer give amazement, even to the populace, and was attended with ridicule in the eyes of all men of understanding." Rapin indeed remarks, that "the late king William III. of glorious memory, was so persuaded he should do no injury to persons afflicted with this distemper, by not touching them, that he refrained from it all his reign." The practice continued in vogue in the reign of queen Anne; it is recorded of Dr. Johnson, that he was touched by that prince, but without effect.

It is extraordinary that this belief in the efficacy of the royal touch in the cure of this severe disease was by no means confined to the vulgar, nor to persons unacquainted with the nature and cure of diseases. Dr. Johnson's mother is said to have been infallible by the advice of a celebrated physician, for John Floyer, to bring her son to London for the purpose of receiving the remedy. And Wifeman and Browne, eminent surgeons of their day, and surgeons to the king (Charles II.) have given their strongest testimony in favour of the superiority of the royal remedy, over any which their art possessed. "I must needs profess," says Wifeman, "that what I write will do little more than shew the weakness of our ability, when compared with his majesty's, who cures more in any one year, than all the chirurgeons of London have done in an age. However, that this attempt may not seem to want precedent, give me leave to tell you, that it is no more than the French kings' chirurgeons have done before me, and whose old Mr. Closo did in queen Elizabeth's days, and all other general writers in chirurgery have done more or less." And he affirms that he had been "a frequent eye-witness of many cures performed by his majesty's touch alone, without any assistance of chirurgery; and those many of them such as had tired out the endeavours of able chirurgeons before they came thither." The other surgeon royal just mentioned has left us the most circumstantial account of this royal healing, in a publication, entitled "Aderno-chirugaleologia; or, an Anatomick-Chirurgical Tretise of Glandules and Strumex, or King's-evil-swelling, together with the Royal Gift of Healing, or Cure thereof, by Contact or Impafion of Hands, performed for above 640 years by our kings of England; continued with their admirable effects and miraculous events; and concluded with many wonderful examples of Cures by their faeced touch. All of which are ineffectively described by John Browne, one of his Majesties Chirurgeons in Ordinary, and Chirurgeon of his Majesties Hospital, London, 1663." His office evinces that the author was a man of character, and his book is approved, as was the custom of his time, by the president and several fellows of the College of Physicians. Like Wifeman, he seems to have been a staunch loyalist, and a vehement defender of the divine right of kings; he detected all diffenters, and confidently afferts that the usurper, Cromwell, tried in vain to exercise this royal prerogative, "he having no more right to the healing power, than he had to the regal jurisdiction." The third part of the treatise of Browne, which is devoted to the history and nature of the royal gift, is entitled Charisina Bassia. Besides an historical view of this prerogative, it contains rules for the meanest capacity to find out the disease, which were deemed expedient to prevent poor people from unnecessary journeys; and sixty admirable cures, performed with or without gold, are circumstantially detailed, as well as several cases of scrofulous tumours and sores, which disappeared on being touched with handkerchiefs dipped in the blood of Charles I.

Some shrewd sulpicides had, indeed, been thrown out, that the piece of gold, given by the king on the occasion, was the most efficacious remedy employed; and the above mentioned writers are anxious to refute such a slander on the royal qualifications. The author of a late treatise tells the following story, which may, in some degree, account for the numbers registered at Whitehall. "An old man, who was witness in a cause, had by his evidence fixed the time of a fact, by queen Anne having been at Oxford, and touched him while a child, for the cure of the evil. When he had finished his evidence, the relator had an opportunity of asking him whether he was really cured. Upon which he answered, with a significant smile, that he believed himself never to have had a complaint, that deferred to be considered as the evil; but that his parents were poor, and had no objection to the bit of gold!" See Wifeman's Chirurgical Treatises, book iv. chap. 1. Browne above cited. Edin. Med. and Surg. Journal, vol. iii. p. 185.
EUL

With respect to the nature of the disease, vulgarly called
King's Evil, and the practice now adopted for its cure, see
Scofoula.

Evil, falling, in Horae. See Falling-evil.

Evil, hungry. See Hungry and Bulimy.

Eviratau, in Geography, a town of Brasil, on
the river of the Amazons, 36 miles W. of Fort Rio Negro.
S. lat. 2° 50'.

Evit's Creek, a river of America, in Maryland,
which runs into the Potomack. N. lat. 39° 38'. W. long.
73° 44'.

Euksinah, a town of Asiatic Turkey, in Natoia;
10 miles N. E. of Eregrl.

Euleus, in Ancient Geography. See Choaspes.

Eulebach, or Eulenebch, in Geography, a town
of Germany, in the county of Erbach; 3 miles N. E. of
Erbach.

Eule, a town of Bohemia, in the circle of Kauzim;
12 miles S. of Prague. N. lat. 49° 55'. E. long. 14° 31'.

Eulenberch, a town of Moravia, in the circle of
Olmutz; 14 miles N. of Olmutz.

Eullenburg, a town of Saxony, in the circle of
Leipfic, situated on an island in the Mulda, and
containing three churches. Beer is the principal article of trade. It
is 12 miles N. E. of Leipfic. N. lat. 51° 27'. E. long.
12° 58'.

Eulepa, in Ancient Geography, a town of Cappa-
docia. Tit. Anton.

Euler, Leonard, in Biography, a great mathema-
tician, was born at Bafi on the year 1707, where he was
educated. He performed his academical tasks with so
much rapidity, that he had a good portion of time left at
his own command, which he confected to the study of
the mathematics. In the pursuit of this kind of know-
ledge, he was assisted by John Bernouilli, who was regarded
as one of the chief mathematicians of Europe, and whose
distinguished attention and esteem he obtained, by his early
proficiency and unwearied application. In 1723, M. Euler
was admitted to the degree of M. A. on which occasion
he obtained great applause by delivering a Latin discourse,
wherein he drew a comparison between the philosophy of
Newton and the Cartesian system. In compliance with his
father's desire, he applied himself to theology and oriental
literature, in which he made no inconsiderable progress, but
his predominant bias still leading him to the mathematics,
his father allowed him to follow the bent of his inclination.
In the course of his studies under Bernouilli, he contracted
an intimate friendship with his two sons, Nicholas and
Daniel, which proved to be of the highest advantage to
him in after life. Those two celebrated mathematicians
having been invited to Petcrsburgh, in the year 1725, by
Catharine I. for carrying into execution the project of
Peter the Great, for the establishment of an academy of
science, proposed Euler to use every endeavor to find
him a situation in that city. By their advice he applied
himself diligently to the study of natural knowledge, and
attended the lectures of all the eminent professors of Bafi.
While engaged in these pursuits he composed a disputation
"On the nature and propagation of Sound;" and also an
answer to a prize question, "Concerning the sailing of
Ships," which obtained the second prize. By this circum-
stance his attention was early drawn to the curious and
important studies of naval architecture and navigation,
which he contributed greatly to enrich in the sublimate
periods of his life. He now joined his friends the Bel-
nouillis at Petcrsburgh, and was appointed with them a
joint professor in the university of that city. In this situ-
Euler.

he was active in the pursuit of science, and in the course of seven years transmitted to the academy of Peterburgh seventy dedicated memoirs, and left behind him two hundred more, which were afterwards revised and completed. In the beginning of September, 1785, he was seized with several attacks of a vertigo; these, however, did not prevent his calculating the motion of air-balloons, which then began to engage the attention of the philosophical world; but on the 7th of the same month, while he was amusing himself with his grand-children, an apoplectic fit terminated his illustrious career, at the age of 76. Besides being foreign member of the Royal Academy of Sciences at Paris, M. Euler was member of the Imperial Academy of Peterburgh, ancient director of the Royal Academy of Berlin, and fellow of the Royal Society of London. His works were very numerous; his knowledge was not confined to his favourite studies of the mathematics and astronomy, of which he has secured to himself an imperishable fame. He had made much progress in medical, botanical, and chemical science. He also possessed, in a high degree, what is generally called erudition. He had read with attention and taste the most eminent Latin classicks, and was familiarly acquainted with the civil and literary history of all ancient and modern nations. His uncommon memory seemed to retain every idea that was conveyed to it either from reading or from meditation. The Aeneid of Virgil he could repeat from the beginning to the end, and point out to his hearers the first and last line of every page in the edition which he used. He enjoyed a vigorous constitution, and a surprising share of health, considering the intensity and arduous of his application. His manners were unaffected and pleasing, his temper lively and cheerful, and his conversation both instructive and entertaining. The evening of his days was calm and serene, sweetened in no small degree by the fame that follows genius, the universal esteem and respect that were due to his exemplary virtues, and the satisfaction which he received from the kind offices of friendship, and the endearments of domestic felicity.

This great mathematician had bestowed much meditation, early in life, on harmonics, or the philosophy of sound; for in 1730, at the age of 32, he published at Peterburgh, in Latin, a work in 4to. under the title of "Theoria Museorum ac Algorismi Harmoniae principis dilucidatio explicata, auctore Leonardo Euleri." This work, being written in Latin, and requiring in the reader, besides that language, a knowledge in geometry, algebra, and fluxions, was little noticed by the public at large on its first appearance, and still few understood by musicians, for whose use it must have been chiefly intended. It, however, set mathematicians and men of science to work, and started many curious subjects of meditation to such as interested themselves in the study of harmonics.

But we do not very well see how the author could with propriety call his treatise an attempt at a new theory of music. The ratios were all known ever since the time of Euclid. Indeed he has followed the proportions which Zarlino tried to establish in his "Institutiones," which had been adopted by Des Cartes, Rameau, Tartini, &c.; and Des Cartes, and others after him, had accounted for the pleasure which we receive from concords, by the simplicity of the ratios between the sounds which form them. There is a plate, p. 35, representing, we think, in a new and ingenious manner to the eye, the pulsations of two strings; the one fixed to a given tone, and the other moved progressively to all the consonant intervals, which clearly shows the coincidences of vibration, upon the frequency of which the degree of sweetness and perfection in concords depends.

We believe, however, that this was done in the 17th century, but in a less elegant manner, by our countryman lord keeper North, in a quarto pamphlet of only twenty-two pages, intituled, "A Philosophical Essay of Music directed to a Friend," London, 1677.

In this little tract the vibrations of each concourse are represented to the eye, and the coincidences with the fixed tone, its base or principal, in the same manner as in the work of the great mathematician Euler, who has published ratios as far as our perception and appreciation can go, extending the whole compass of our musical system to eight octaves. See Compass.

The degrees of felicity in concords from the simplicity of ratios and frequency of coincidence, had, we believe, been felt before the year 1739, when this treatise was published.

The following is a translation of the titles of the several chapters of this work. After a preface of twenty pages, Chap. I. treats of found, and the auditory sense.

1. Of the sweetness and principles of harmony.
2. Of music in general.
3. Of concords.
4. Of concords in succession.
5. Of a series of concords.
6. Of intervals, and their names.
7. Of the genera of music.
8. Of the diatonic-chromatic genus.
9. Of other more compounded genera.
10. Of the concords in the diatonic-chromatic genus.
11. Of the modes or keys and systems in the diatonic-chromatic genus.
12. Of the ratio of composition in a given mode and kyth.
13. Of the modes and kythems in transposed keys.
14. Of the laws of composition, and the possible combinations in any given mode, key, or kyth.

Among these combinations every note in the scale, seemingly at once, which would be extremely offensive if heard together. The author probably means, that all these sounds may be heard successively in melody, provided they are in tune, and have a fundamental base.

Upon the whole, Euler seems not to have invented much in this treatise, and to have done little more than arrange and methodize former discoveries in a scientific and geometric manner. He may, indeed, not have known that antecedent writers had discovered before; and though not the first, yet to have imagined himself an inventor.

Euler's Logarithms, or Binary Logarithms, are a species of artificial numbers contrived by M. Euler, to facilitate the calculation and comparaison of musical intervals, which they do, by representing each interval in decinal parts of the octave, which is 1 in this notation, the successive octaves or powers of 2 being represented by 2, 3, 4, &c. as in the following table, for the first 10 numbers, viz.

<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>4</td>
<td>8</td>
<td>16</td>
</tr>
</tbody>
</table>

By the help of the primes which compose musical ratios, and their binary logarithms in this table, Euler's logarithm may be found, which answers to any interval: as the names of the several intervals occur, we shall give their binary logarithms.

4 G

EULISIA,
EULISIA, in Ancient Geography, a country of Scythia, towards the Pulsus Maeotis.

EÜLOGIUS, in Biography, patriarch of Alexandria, was, at first, presbyter of the church of Antion, and distinguished himself by his zeal for the Catholic doctrines in a letter which he wrote to Eutychius, patriarch of Constantinople, containing an exposition of the true faith. He was elevated to the see of Alexandria in the year 581, and became very active in rooting out heresy, not only by the allowable and fair weapons of reason and argument, but by expelling from their situation all ecclesiastics who were advocates for the doctrine of one nature in Christ. He lived in habits of intimacy with Gregory the Great, whose sentiments and dispositions were congenial to his own. He died in 618. Of his works only fragments are remaining. Morei.

EÜLOGIIUS, called archbishop of Toledo in the ninth century, was born at Cordova about the year 890. He was educated for the priesthood, and discharged the duties of that office with zeal and activity till the year 842, when he was driven into exile by the Saracens for his boldness in maintaining the principles of the Catholic faith. After much suffering he ventured to return to Cordova, where, in the year 850, he was thrown into prison on account of his religion. In the dungeon he employed himself in writing animating exhortations to the Christians, to support and console them under their persecution, for conscience sake, and to encourage them to undergo the severest trials rather than disgrace themselves by apostacy. He was afterwards liberated, and by his personal labours, as well as writings, perverted in fortifying his fellow Catholics against the arts and terrors of their enemies. As a reward for his exertions in this hazardous employment, he was chosen to fill the vacant see of Toledo; but he was put to death before he could receive the episcopal consecration. The accusation against him was the having converted a young Mahometan female to the Christian faith; he was beheaded in 859. He was author of "Memorials Sanctorum, five Libri III. de Martyris Cordobensibus!" "Apelogetis pro Martyribus, &c." "Exhortation ad Martyrium," and some moral epistles. These were collected and printed with notes by Ambrosius Moralis in 1554, and again in a more correct form by Poncius Leo in 1574. Moreri.

EÜLOGY, EULOGIA, in Church History. When the Greeks have cut a loaf, or piece of bread, to consecrate it, they break the roll into little bits, and distribute it among the persons who have not yet communicated, or fend it to persons that are absent; and these pieces of bread are what they call eulogies.

The word is Greek, εὐλογία, formed of εὖ, well, and λόγος, dice, I say, speak; q. d. benedictum, blessed.

The Latin church has had something like eulogies for a great many ages; and thence arose the use of their holy bread.

The name eulogy was likewise given to loaves or cakes brought to church by the faithful to have them blessed.

Lastly, the use of the term passed hence to mere presents made a person, without any benediction. See the Jefuit Gretlier, in his Traite de Benedictiones & Maledictiones, lib. ii. cap. 22. 24. &c. where he treats of eulogies thoroughly.

From a passage in Bollandus, on the Life of S. Melaine, cap. 4. it appears, that eulogies were not only of bread, but any kind of meat blessed and hallowed for that purpose. And that almost every body blessed and distributed eulogies; not only bishops and priests, but even hermits, though laymen, made a practice of it. Women also would sometimes send eulogies.

The wine used as a present was also held an eulogy. Bollandus remarks farther, that the eucharist itself was also called eulogy.

EULOGY, likewise, means an encomium on any perfon, on account of some virtue or good quality.

EUMARIDES, of apoqo, toj, among the Ancients, a kind of shoes common to men and women.

The eumarides were used for protection, and painted with various colours.

EUME, in Geography, a river of Spain, which runs into the sea near Corunna.

EUMENIDES, in the Writings of the Ancient Naturalists, the name of a stone which Pliny tells us resembled a flint, and was found in Bactria; the ancients had an idle opinion that, if laid under the head, it occasioned true and prophectic dreams, foretelling to the person the more remarkable future events of his life. Hist. Nat. lib. xxxvii. cap. 10.

EUMENES, in Biography, a captain under Alexander the Great, a native of Cordiebus, in the Thracian Cheronee. His father was of a low station, but one in a condition to have entertained at his house Philip king of Macedon, who became the patron of his son. So well did the youth approve himself as secretary to the monarch, that his son Alexander continued him in the same office, and gave him a command in the cavalry. According to Plutarch, Eumenes took every advantage that his station afforded him of accumulating money, for his tent being set on fire by the private orders of his sovereign, to whom he had refused the loan of three hundred talents, there was found to the value of more than one thousand talents in melted gold and silver. After the death of Alexander, when the provinces were divided among the principal commanders, the government of Cappadocia, Paphlagonia, and the country bordering on the Euxine sea, as far as Trapezus, which as yet were un conquered, were assigned to Eumenes. Eumenes attached himself to Perdiccas, who made him his chief minister, and gave directions to Antigonus and Leonatus to put him in possession of his government. Antigonus paid no attention to the order, but Leonatus, pretending to comply, marched an army seemingly for the purpose, which Eumenes joined. His design was, however, to feize the kingdom of Macedon for himself; but upon making it known, Eumenes deferted him by night; after feizing his treaures, and repaired to Perdiccas. In reward for his fidelity, Perdiccas himself made an expedition in Cappadocia, and after defeatings and killing the king Arrhebus, left Eumenes master of the country. He was next appointed prefect of Asia, between mount Taurus and the Hellespont, and was enstituted with the care of opposing the army expected to march against him out of Greece under Antipater and Craterus. On the approach of these great commanders, Eumenes concealed from his army that they were about to contend with Craterus, for whom they entertained the most profound respect and veneration, and giving battle to him and Neoptolomeus, he slew the latter with his own hand, while Craterus was mortally wounded, fighting at the head of his phalanx. Eumenes, who felt for him emotions of the sincerest friendship, griped his hand as he was expiring, wept over his remains, and honoured him with a magnificent funeral. After the murder of Perdiccas by his own army, Eumenes was declared a public enemy, and Antigonus was sent to conduct the war against him. Eumenes was routed, but able to retire to the impregnable castle of Nora, which he defended with great ability. He was abundantly supplied with corn, and though without...
out any other kind of provision, he kept his men in good
honour, by his affable and cheerful demeanour. Another
scene opened itself for the ambition of Antigonus, and
Eumenes was set at liberty. He instantly began to levy
troops, and in a short time was declared general of
Asia, and there was assigned to him a guard of Argryphides,
or silver shields. To inspire his troops with a sort of
religious enthusiasm in the cause, he pretended to have
